Seven teachers (4 female and 3 male) cooperated in the development of the multimedia materials. The author invited four teachers after they had presented aspects of their work with computers at a local professional development activity. When their schools were approached for permission to film, one of the principals suggested two additional teachers from his school. Finally a recent graduate who was known to be commencing an Internet project with a class was invited to participate.

Their teaching experience ranged from beginning teacher to as many as 20 years. The class levels being taught at the time of the interviews varied from Years 1 to Year 7 and the arrangements for computer access varied from laboratories to one or more computers in the classroom. For the purposes of the materials, the teachers were identified by pseudonyms and these are used in the following brief biographical notes.

Carla was a secondary teacher who was working part-time as a specialist computing teacher with children in Years 3 to 7. She took groups of children for weekly classes in a ten-seat computer laboratory and had some responsibility for assisting other teachers to develop skills and adapt curriculum to integrate computers.
was commencing her first teaching appointment and had arranged for her Year 4 class to participate in an Internet Travel Buddy project with a class in New York State. She had access to a single computer in her classroom. Karen was an experienced teacher who had been using the Internet with her class for several years. Her Year 6 class shared a mini-laboratory of five computers with the class in the room next door. Ken had more than 16 years teaching experience and was active in his local computer using teachers group. He had a single computer in his Year 4 classroom. Matt had 15 years teaching experience and a strong local reputation for innovative uses of computers in his teaching. He had two computers in his Year 7 classroom. Neil had twenty years of teaching experience but was a relative newcomer to using computers in his teaching. His Year 4 class in one end of a double teaching space shared five computers with the other class in the space. Robyn had been teaching for 4 years and was studying a masters degree majoring in educational computing. She regularly took her Years 1 and 2 class to a 15-seat computer laboratory, which she managed for the school.

There is no suggestion that these teachers are necessarily typical of computer-using teachers, nor that they are a representative or random sample. They were invited to participate in the project because they were known to use computers or were suggested by a peer or principal. They present a sufficiently varied group to avoid any suggestion that there is a preferred stereotype of the computer-using teacher. The interviews were conducted in the teachers' classrooms using a common schedule of questions (Table 1) with supplementary questions or prompts used to clarify meaning where necessary. The teachers' responses were videotaped and later transcribed. The digitized video and transcripts were included in the multimedia materials.

### Emerging Themes

Analysis of the responses was undertaken manually using a constant comparative method. Although the responses were directed to the questions, common themes were identified across responses to different questions. Six major themes, each with several sub-themes, emerged (Table 2).

Table 2: Major categories emerging from interview analysis

<table>
<thead>
<tr>
<th>Category</th>
<th>Description</th>

<tr>
<td>Impact</td>
<td>Statements about the ways in which using computers has affected the teacher or children</td>
</tr>
<tr>
<td>Issues</td>
<td>Statements about problems or challenges associated with using computers for teaching</td>
</tr>
<tr>
<td>Internet</td>
<td>Statements which offer a view of the Internet and its significance for education</td>
</tr>
</tbody>
</table>

### Purpose

Although all seven teachers were dealing with children who were at least 4 to 5 years from entering the workforce, all but one made statements which related the importance of computers in education to future
employment. Almost half of the statements about purpose related to future employment or study. Julie suggested that the skills she would teach her nine-year olds were “the same skills that they’ll learn when they’re in high school, when they want to write reports for university, or in the work force.” Karen thought that her twelve-year olds “could use some of the things they have done, for instance, if they were looking for a job”, although she added that looking for a job was unlikely at their age.

Five of the teachers appeared to regard technological advance as inevitable but ascribed no particular educational value. Neil said, “Technology is a thing of the future. Kids need to have a basic idea of computers because they’re going to be everybody’s going to be using in the future.” Ken chose to use ICT because “it’s available and, if we don’t we’re certainly behind the eight ball and it’s just the way of the future.”

Even when they referred to the educational potential of computers it was often undefined as in Carla’s suggestion that computers provide “such wide scope for the children” or Julie’s choosing to use technology “because it was something different”. Only Matt was able to articulate the value of ICTs as “a way of enhancing the curriculum” and supporting other aspects of his work with his class. Nevertheless, as is evident in the statements coded under other themes, these teachers were strongly committed to a variety of educational applications of computers.

**Development**

Issues associated with learning how to use computers in teaching or obtaining support for their use loomed large in the minds of the teachers. More statements were coded under the theme denoted by development than in any other, indicating the importance these teachers accorded to ongoing learning. That theme also had the greatest number of identified sub-themes, suggesting an openness to a variety of sources of learning.

The most mentioned source of professional development was a variety of activities that the analysis grouped into a sub-theme labeled as networking. Ken said, “I talk to other people. I steal ideas from other people and they steal ideas from me”, although he was probably using “steal” in a metaphorical sense. Robyn spoke of building a network of friends, locally and through the Internet, for mutual support and commented that the “increased interaction with other teachers is very beneficial”.

A second major source of development was tagged as experience. Julie referred to her learning to use computers as a “learn as you go sort of thing” and Ken spoke of how he “played around with them on Christmas holiday” and of “trial and error”. Karen “just kept using it and teaching (her)self and using it with the children, and learning with them which was very good.”

Children are often described as developing confidence with ICTs more quickly than adults. Julie and Ken noted this and Julie referred to teachers “not wanting to try to use the computer in their classroom because they just don’t think they have the knowledge.” In Karen’s class “there were quite a few very good computer children and they taught (her) what (she) needed to know.” Robyn was open to learning with or from children:

> Don’t expect to know everything. Or to always be the person who knows the most. There will always be children in the class who know more than you. Use them. Make them a part of the team. They’ll love showing their skills off and you’ll love learning from them. You build a really good relationship.

**Method**

Key ideas grouped within this theme included teaching with rather than about computers, integrating ICTs into the curriculum, and managing the complexities of matching among children, computers and curriculum. Despite the challenges, these teachers managed to maintain a focus on the educational value of the activities rather than on using ICTs for their own sake or as a “filler” when students completed other activities.
Matt said, “I don’t think it’s appropriate that you build your curriculum around technology, but that the technology fits in with the curriculum.” He described how he had equipment “set up in the classroom in such a way that (he could) monitor what the kids are doing.” Robyn described her management strategy as being to always have open ended projects so that children: the brighter ones, the faster ones can always just do that little bit extra on their work. You don’t ever want to have the children finish and that’s it. Or go too far ahead of the rest of the class. So it’s best to have open-ended projects and they can work on it.

Impact

The most commonly cited impact of ICTs was enhanced motivation of teachers and children. Ken described his reaction after he had purchased a home computer: “I kept coming to school and saying ‘Look what I can do, look what I can do, look what I can do!’” His enthusiasm spilled over to his class, resulting in “a lot of keen kids who enjoy being on the computer in non-school time and doing school tasks in the school time.” Julie found that her Internet project impacted motivation in her class:

Andrew yesterday was writing this report and he didn’t want to do it and I said this has to go to the class in New York and his face lit up and he was saying “Oh, it has to be my best hand writing and my best spelling” and then he had his best handwriting and everything and he was so proud of it then because it was going to someone else and he had a real audience.

Ken found that his new skills increased his efficiency so that where he “used to spend a lot of weekends making charts”, he could “go to the computer at home, whip up a very professional chart, blow it up to A3 and it’s done.” Robyn found that the computer allowed her to “get to children that normally won’t click onto the idea.” Both Robyn and Karen noted improvements in the quality of work done by children.

Another frequently mentioned impact was professional growth. Matt described how using ICTs had allowed him to “learn a lot of bits and pieces about teaching”. Robyn spoke of moving away from “chalk and talk” but the major impact for her was enhanced professional interaction:

I feel like I’ve enjoyed meeting and getting to know many more teachers than I probably, ordinarily, would have because teachers who are interested in technology tend to talk about it more. They get excited about what they’re doing and they start asking things like “Have you tried this?” ... So there’s a lot more interaction, a lot more talking and teachers tend to build up a network of friends around the area.

Issues

Very few of the statements coded for the issues theme related to technical aspects of computer use. The most frequently mentioned issues were concerned with the acquisition and management of physical resources and time. Matt cited placement of computers as a key issue and Julie described some factors she had considered in deciding where to place her computer in the classroom.

Managing access when there were many more children than computers was typically resolved through the careful allocation of time using timetables or rotation of groups. Robyn and Neil both referred to using parent volunteers to facilitate their own time with children. As a beginning teacher, Julie was struggling with the balance between group and whole class activities:

I’m finding it hard at the moment when to decide when its OK for them to be on the computer and not being in the lesson and when they have to be in the lesson. Like sometimes I might send them over and a few seconds later I realize that they needed to hear that.
Internet

Most of the statements about the Internet referred to it primarily as a means of communication. However, the object of that communication was often access to information. Julie had explicitly described the Internet to her class as a community in which they were participating. Robyn compared the Internet to a

global village. The children get to know other children around the world through e-mail or through live chats. And it doesn't become a case of “us and them” any more. They relate to these children and understand that they're just children like themselves.

Carla viewed the Internet more as a source of information and suggested that, as a result, “encyclopedias are now out of date.” Matt referred to both communication with children elsewhere and to the capacity of the Internet to provide his class with a “taste of the world” although the existence of “good and bad points” required him to “manage the bad points a little bit.”

User Response

The multimedia materials were tested in use with a group of 22 pre-service teachers studying an elective subject related to the application of ICTs to teaching. As in the earlier study with the prototype (Albion & Gibson 1998), a majority of users (15 of 22) identified the video interviews as their favorite element of the materials. Data gathered using journals kept by users revealed that some users had spent a large proportion of their time with the materials (mean = 6 h) reviewing the video materials.

Several of the users indicated that the materials had exposed them to ways of thinking like a teacher about computer use. One pre-service teacher commented on the access to experiences that had not been available during time spent in schools. Other comments recorded changed ways of thinking about computer use away from seeing it as applicable only in mathematics classes, as a weekly skill lesson or as a filler activity when students had “spare time”. These users reported changing their views to see the potential of computers as being capable of almost constant use across a variety of curriculum activities.

Participants in the study valued the insights offered by different teachers. One student noted the inclusion of “alternate responses to the same questions – different doesn’t mean wrong.” Another wrote in a journal about the first scenario, “The interview with Julie was great – helpful to have an actual insight on the use of technology.” In an interview at the end of the trial a student commented on how the video interviews had given him “a bit of enthusiasm, a bit of excitement to see computing technology can be used in a real and practical way.”

Discussion

Taken as a whole, the ideas expressed by the teachers in their interviews were consistent with the research about computer using teachers. Studies of exemplary computer-using teachers have found that they tend to de-emphasize teacher-centered activity in their classrooms in favor of more student-centered approaches consistent with constructivist theories of education (Becker 1994; Hadley & Sheingold 1993; Honey & Moeller 1990; Sandholz, Ringstaff, & Dwyer 1994; Sherwood 1993). Teachers' use of computers and the Internet have been found to be related to their learning from or with students, orchestrating multiple simultaneous activities in class, assigning long and complex projects and giving students greater choice in tasks and resources (Dexter, Anderson, & Becker 1999).

The teachers in this study appear to have moved beyond a view of “teaching as telling” and to have accepted that one of their roles as teachers is to model the processes of lifelong learning. This is evident in their commitment to professional development and their willingness to learn from the children in their classes. There was an emphasis on teaching with, rather than about, ICTs. Ken spoke about how the use of computers had increased the enthusiasm of children for their work. Julie, Matt, Neil and Robyn spoke about the integration of ICTs to support the curriculum rather than as either an addendum or a central focus and described student-centered activities.
involving multiple simultaneous activities in the classroom. Matt set up equipment so that he could monitor the work of multiple groups. Robyn advised the use of open-ended projects to enable children to extend an activity.

The pre-service teachers who participated in the trial found the video of the interviews engaging because of the clear connection to the reality of classroom teaching. They were able to recall ideas from the videos and to articulate developments in their thinking about computers as a result of working with the materials. The interviews included in the CD-ROM appear to be an effective means of providing pre-service teachers with appropriate messages about the use of ICTs in teaching.

GIS (Geographic Information Systems) in Teacher Education

Marsha Alibrandi, Shannon White, Rita Hagevik
College of Education
North Carolina State University, USA
Marsha_alibrandi@ncsu.edu, shwhite@bellsouth.net, rhagevik@prodigy.net

Abstract: This paper introduces Geographic Information Systems (GIS) technology as a useful addition to other technologies being introduced in K-12 classrooms in the context of an experimental teacher education course. In the iterative course design, graduate students (classroom teachers) provided email feedback and input to inform instruction. An in-service teacher and two graduate student teaching assistants were part of the instructional team, as was a middle school student. Students in the process of learning GIS mastered many other related technological applications. From a wide range of backgrounds entering the course, all students were able to design original GIS projects, importing data from a variety of sources for integration with existing map projections. The projects relate to Social Studies and Science curriculum frameworks, and lesson plans accompany the map products. Qualitative data from email, quizzes and evaluations is presented along with student products and preliminary findings. The course runs again in Spring 2001.

Introduction

Geographic Information Systems (GIS) are used in virtually all industries and government agencies that require spatial planning and/or problem-solving. Emergency 911, TV weather reporting, satellite imagery and communications using GPS (Global Positioning Systems), transportation and distribution routing, infrastructure and community planning all require spatial analysis and design flexibility. GIS combines data from data-based information with coordinates in a spatial layout or map. When the data are coordinated with a geo-coded field to locations in the digital map, the data can be instantly located in the spatial layout. Once located spatially, the data can be analyzed in different ways depending upon what other data is related to it. For example, if data from a town water distribution system can be geocoded using street addresses, the fire hydrants all across town can be made to appear instantly on a computer screen in a GIS. Now, to analyze the locations of hydrants needing routine inspection, a field can be created in the database to record the inspection and conditions of the hydrant. Those in need of repair can now be shown on a map in a contrasting color to indicate where workers will route their repair work for the coming month.

How and why would GIS be used in schools? Why introduce a teacher education course in GIS? Once introduced, what kinds of problems will teachers find intriguing enough to answer using a GIS project? How will teachers learn and teach with GIS? These are the questions that guided the course and our inquiries with student participants.

Theoretical perspectives on GIS in Education

As billions of dollars are spent to infuse technology into US classrooms, the values of particular technologies will become more apparent. Because GIS is ubiquitous in industry and government, students with these skills are in high demand (Alibrandi, 1998). Beyond employability, the rationale for GIS in schools is potentially more transformative. GIS analysis represents an opportunity for students and schools to provide real research-based service to their communities. Attendant with this potential is also an important responsibility to apply the technology ethically and responsibly. This implies an ability to take a critical perspective on the technology, on the nature of representation and its attendant biases, and to be able to describe those limitations and biases while presenting information in a GIS format. We have
written about the need to ground virtual applications in actual experience, to apply a critical perspective on
the technology in order to ethically apply the technology to community problems.

Based on Pickles' (1995) Ground Truth; Social Implications of Geographic Information Systems,
several students selected projects in which they analyzed race and ethnicity data from the Bureau of the
Census. One advanced student developed a voter precinct problem that became more relevant in light of
the 2000 presidential election. By framing the learning of GIS in a critical perspective, the students (pre-
and in-service teachers) became interested in addressing social issues using GIS.

Notes from the Field

Data for this preliminary case study derive from emails sent by students. Students taking the
course for graduate credit were asked to reflect upon their learning processes through weekly questions
posed on an email list that was an important means of communication for the class. Students shared their
thoughts with us as instructors, and also often did so with their peers. As mastery improved over the
semester, students used email to announce newfound resources or strategies to one another. This became
an important source that informed course design. In GIS departments, the new landscapes of distributed
cognition and expertise is common. We responded to student mastery by including it in the instructional
design. As students discovered new ways to overcome problems, we asked them to share these strategies
with the class. In this way, we modeled teaching with technology in a more democratic, collective and co-
constructive environment. We experienced the discomfort of having to problem-solve on the fly with
students; we couldn't always provide the answers to their problems, but we respected all who found
solutions and immediately incorporated their learning to be shared with the whole group.

This model of teaching is not familiar to students and at times the cognitive dissonance over not
always having an answer created frustration and productivity gaps. The gaps were places in which other
students' strategies and findings could be inserted into this highly experiential and problem-based
approach. As students shared their projects, problems and solutions, unanticipated dynamics and new levels
of technical expertise were achieved that surpassed the instructors' expectations and in some areas, our
abilities. This also is an artifact of teaching with technology that becomes useful when incorporated into
the instructional design.

Preliminary Findings and new directions for research

As we review the gaps, we see opportunities for designing to address them. Where simple
repetition is needed to routinize procedural operations of GIS software and its many related applications
such as hotlinks, graphing, integrating data from various sources such as the Internet, GPS, video and still
imagery, we see opportunities for process and product design. Identifying gaps will be important in the
upcoming iteration of the course, collaborative group problems will move to the foreground, emphasizing
actual experience will become a more grounded starting point, and a continuing inquiry into the learning
processes of teachers as students will continue to inform our design and research. Finally, as we build
upon the projects of our students, a bank of GIS projects for teachers will become available to other
teachers through web-served versions of GIS projects. Once established, teacher access to GIS projects on
a website in a limited version can serve to other teachers and communities to begin to manipulate GIS and
see its potential for integration into existing curricula as well as to demonstrate applied GIS.

Digital Cameras in Education

Dr. Valerie Amber
National University
School of Education
vamber@earthlink.net
USA

Sharon T. Thies
Shandin Hills Middle School
USA
sthies_shms@yahoo.com

Abstract: Intended for convenience, digital cameras are an inexpensive learning technology schools may easily benefit from. Once captured, digital photographs are already in a universal format that makes them exceedingly uncomplicated to distribute and use with PC or MAC computers. There versatile usage makes including visual images in word processing documents, e-mail, class projects or on web sites effortless. Digital camera technology brings about a totally new innovative and motivational approach to teaching and learning.

Designed for quick and easy operation, digital cameras are one of the most inexpensive learning technology purchases a school can make. Though only a few years old it is already finding wide acceptance in many areas where images are needed to enhance projects. (See Figure 1).

Figure 1. Student projects

Digital cameras and traditional cameras are very much alike in many respects. The biggest difference is the way images are captured. With traditional films, they are captured on silver-based film. With digital cameras, they are captured on solid state devices called image sensors.

Once captured, digital photographs are already in a universal JPEG format that makes them exceedingly easy to distribute and use with PC or MAC computers. For example, you can insert digital photographs into multimedia projects, word processing documents, send them by e-mail to colleagues, or post them on a Web site, just to mention a few ways. With many cameras you can immediately see your images on a small LCD screen on the back of the camera, or you can connect the camera to a TV and show them much like a slide show.

Editing is simplified because once transferred, the images can be manipulated, digitally edited on-line, and then copied back to a variety of other software programs. Not only is it easy, there is no loss of image quality comparable to scanned photos. Once on the computer, you can also easily add audio, change the texture, change
the size or add frames. Images in digital form may also can be pieced together and pasted into other images. These composite images can be routine or funny. In fact, composting is done so often on television and in print advertisement that we're growing used to it. Digital is the universal format.

A convenient feature of digital cameras is that images are ready to post as soon as they are taken. The images don't have to be first processed and then scanned, as film has to be. This saves both time and money. Since most screens display only low-resolution images, the low-resolution of some cameras is no drawback. In fact, higher resolution images would be too big to post on most Web sites and would have to be reduced anyway.

Figure 2  Earthlink DISCPRO Digital Still Camera

The Arc soft photo base software available with this camera automates image transfer with a personal computer. It automatically starts image uploading whenever you connect the camera to your computer using a special USB cable. Uploaded images are stored in folders named according to the dates images are recorded. Images can be viewed on your computer using a standard Web browser, either as a group or individually.

Figure 3  Sony Mavica Digital Still Camera

The Sony Mavica Digital Still Camera (See Figure 3) stores picture images on a standard 3.5" HD floppy disk, therefore, no extra software is necessary. Each floppy disk holds approximately 40-50 pictures depending on the complexity of the picture image. The Sony camera has a playback menu option to view or delete any or all photo images without removing the disk from the camera. The floppy disk can be removed at any time and reinserted back into the camera without any problem. When the disk is full or you're finished with the desired pictures remove disk from camera and insert it into a computer. All picture images are stored by number of the order in which pictures were taken. Pictures can be viewed by opening each folder and used in a variety of ways. When finished with the picture images on the disks they may be deleted and the disk may be reused.

Point and shoot cameras as in the Earthlink DISCPRO, are generally small and inexpensive (at least in relative terms). They are fully automatic and usually don't provide a lot of overrides that give you creative control - that's why they are called "point and shoots." At the low end of this category are cameras with lower resolution whose images are limited to about 4 x 6 inches or so. Despite this small size, the images are ideal for Web pages and e-mail attachments.

Positioned between the inexpensive point and shoot cameras and the very expensive professional cameras discussed next is a family of cameras based somewhat on the 35mm SLR model but designed exclusively for digital photography. This is the Sony Mavica camera. It is sometimes called a presume camera. It has 2-megapixels or more. Generally, the higher resolution is combined with more advanced features such as through-the-lens (TTL) focusing, various exposure modes, and manual overrides of otherwise
automatic controls such as focus and white balance. This is one of the fastest growing categories because these cameras appeal to serious amateur photographers and professionals who want creative control of their camera settings and prints up to about 8 x 10 in size.

The following projects used digital photos taken with either the Earthlink or the Sony digital still cameras.

**Projects**

**Project 1:** This is a web site for a preservice graduate education class at National University in Los Angeles, California called CLD 605 The Diverse Classroom. On the web site there is a power point presentation or media gallery, which have a collection of images. There are writing assignments and class discussions designed around the images.

**Project 2:** Open House Fall 2000: This is a video developed for an open house presentation for students and their parents. Video consists of a collection of digital camera photographs of students engaged in class activities throughout the school year. The original work was developed on power point and then transferred to video.

**Project 3:** After school computer class: Students at Shandin Hills Middle School in San Bernardino, California completed this collection of presentations. Presentations will consist of student power point and digital camera projects.

**Project 4:** Gifted Students art project: Web site illustrating the art projects from a fifth grade class at Belvedere Elementary School in Los Angeles, California.

Digital cameras have many uses in the schools. Here are just a few of the most common uses in the average school.

1) school newspaper / newsletter - 
2) year book - 
3) open house / staff training presentations - 
4) student projects / reports - 
5) individual teacher and / or school web sites - 
6) school dances / activities / sports - 
7) field trips / class parties -

Tools of the Trade:
Integrating Technology in Research & Methods Courses for Preservice Teachers

Valerie Amber
School of Education
National University
USA
vamber@nu.edu

Abstract: This paper examines and describes one approach of integrating technology into research and methodology courses for teacher education. Each course is complimented with a web site that serves as a virtual office and learning resource center. The instructor used the resources at Blackboard.com to build the framework for each site. They were designed upon the premise that it is acceptable to not undergo a total systematic change in delivery but a hybrid where technology supports the learning environment is preferable. The courses have produced students that are competent and knowledgeable about the subject matter and technology, its use and instruction integration.

The true power and potential of computer based technologies lies not in the machine itself but in the prudent and appropriate use of software applications to gather, process and communicate information. Teachers; integration of these tools into the educational experience of students, including those with special needs, is crucial to preparing them for lives of personal, academic, and professional growth and achievement.

California Commission on Teacher Credentialing 1999.

It is this philosophy all teacher credential programs in California have been required to address in their approach of the implementation of new computer standards. With a multitude of skill levels & technology limitations, increasing how we implement technology in teacher education programs may first seem monumental. This paper explores one approach toward this task.

The three classes discussed in this paper are; Research in Education, Foundations of Education and Cross Cultural and Multicultural Teaching Methods. They are established in a teacher credential program where students are completing a credential or working toward a master’s degree in education.

There are several common denominators found in each group of students that enter the program. Each campus where the classes are held has a computer lab and all students automatically receive an email account upon enrollment. The students come to the program with a variety of skills in technology. The courses are taught in the standard face-to-face tradition where students are expected to attend each class meeting to receive general information and to have round table topic discussions. It is an accelerated pace with each class meeting twice a week for one month. Lastly, upon the first class meeting the students are introduced to the technology tools available to them in that particular class. When presenting class projects / presentations students are strongly encouraged to utilize technology in creative ways.
Each course is complemented with a web site that serves as a virtual office and learning resource center. The instructor used the resources at Blackboard.com to build the framework for each site. Courses on Blackboard.com have a unified appearance beginning with the same page layout starting each course. The first page of each course greets the user with icons on one section of the page that lead to various pages of documents, communication tools and video capabilities. The course sites make use of access to information on the Internet, synchronous and asynchronous communication. There are several other free, user-friendly resources educators may use to develop web sites. They all have similar features and are geared to accommodate a variety of skill levels. Blackboard.com was selected because of the ease for the novice computer literate student to utilize the supplemental information without having to surf the web. Everything is available at the student’s fingertips.

Guiding Philosophy

The integration of technology is not an all or nothing approach. It is acceptable to not undergo a total systematic change in delivery but a hybrid where technology supports the learning environment is preferable and comfortable to utilize appropriately (Bothel & Enfinger, 1999).

Knowledge is acquired through involvement with content instead of imitation or repetition. This allows for the horizontal transfer of skills, from the university classroom to the K-12 classroom. As content and technology share the goal of competence, technology should be taught in context, not in isolated tasks. It is important for the teacher education faculty to model the technology with proper usage. If we do not model effective uses than we are inhibiting the development of our students repertoire of teaching skills.

Key Features of Course Web Sites

Research Methods: The communication tool where students and teachers send documents is essential. The research classes are taught in a one-month format where much of the class time is based on individual meetings with the students. By using the web site, students may send the instructor drafts to review or submit at any time. This allows for the instructor to have more time with the students to discuss their drafts. The site also allows for external links where the instructor may post links to web sites which host quality research. Not only does this give students suggestions of where to begin their own research but it provides a base for them to use in evaluating quality information found on the Internet.

Cross Cultural and Multicultural Teaching Methods: Discussion of the required reading is continued well beyond the classroom. Students are required to respond to questions about the material in the threaded discussion feature of the web site. Threaded discussions are a common feature of online classes with asynchronous communication. The participants have the opportunity to process or reflect on material before responding. This assignment can be extended where groups of students are responsible for summarizing and synthesizing the threaded discussion each week and distributing the results through email. Each course site has a quiz and test feature that may be incorporated in the class. This course uses this feature as a test your knowledge exercise. The non-graded quizzes on material are used to help students grasp major concepts presented in the course.

Foundations of Education: This is often the first class in the program. The classes are comprised of new students balancing classes and full time employment. Students in this course have appreciated the synchronous communication tools that allow for them to work on group projects outside of classes. The students agree on a meeting time online in the course web site meeting area. For their convenience, they may be at any computer, i.e. home, school, or library and proceed to discuss their work. This class also features a media gallery with the case study assignments. Student may view a collection of pictures presented in a slide show. This collection of images gives the students a visual stimulus that is more favorable for visual learners.

Each of the courses described in this paper was designed with the desire to provide students with deeper learning, better use of time, and the possibility of additional cycles of observations and analysis of content materials. The courses have produced students that are competent and knowledgeable about the subject matter and technology, it’s use and instruction integration.

CECI: A Computer-Assisted Co-educational and Transdisciplinary Experience

Rocio Anguita, Cesar Osuna, Alejandra Martinez, Yannis Dimitriadis

Universidad de Valladolid, Spain.
Universidad Autónoma de Guadalajara, Mexico
cosuna@cu.gdl.uag.mx

Abstract: This paper describes a CSCL application named CECI (Co-Edición de Cuentos en Inglés. Co-Edition of Tales in English), which assists would-be teachers in the development of multimedia educational resources aimed at learning the English language. These resources are used by students with a basic or elementary level and are accessed through a computer net. Those would-be teachers write a children's tale and then add a methodology and collaborative activities that describe the prospective use of that tale in the classroom.

Introduction

One of the biggest challenges that is actually taking place in educational practice is teaching skills for the use and exploitation of Information and Communication Technology (ICT) to would-be teachers. However, despite all these efforts, we can still appreciate the would-be teachers' lack of initiative to promote the development of new technology for the classroom. From our point of view, apart from the lack of technological skills, there are also other aspects that affect this situation, namely the absence of a methodology that enables the creation of teaching materials and the difficulty entailed by the interdisciplinary teacher-technological developer relationship. This has led us to reflect on the need to treat teaching problems from the perspective of the skills but without forgetting the rest of the aspects listed above.

On the other hand, we can also observe the recent and increasingly usual emergence of applications oriented to the use of the technology through which students both interact and learn; this is known as CSCL (Computer Supported Collaborative Learning). There are applications that have been developed to learn different types of skills: scientific, social, reading-writing and teaching skills to name but a few. Among these technological applications, we can find some which are oriented towards language learning—especially English— but their main focus is learning how to use the language rather than how to teach it. These aspects are treated in a new CSCL application called CECI, which is based on the asynchronous authoring of documents by means of the Internet. To be more precise, the student is placed in a learning situation in which he/she has to create tales in English in a collaborative way; these tales are then represented as teaching material that will be used in the classroom; this aspect is fulfilled by means of technological tools and computer networks that enable the publishing side (Alario & Anguita, 1998).

The CECI Application

Taking into account the CECI goals, we can easily appreciate that the teaching-learning process covers features from different disciplines and this makes it even more complex. Not only do we expect to create an application for "the edition of material", but we also want it to allow the student to practice and work with the English language, to have a methodology assisting him/her and to produce materials that are adequate to be used with future learners of the language. In order to develop the application, a work group including teachers belonging to two different areas was created; on the one hand, Foreign Languages and New Technologies teachers, both subjects being taught in the Faculty of Education at the University of Valladolid; on the other hand, Telecommunication Engineers from the School of Telecommunication at the same university, took the role of technology developers. The group used the methodology called DELFOS (A Description of teleEducational Layer Framework Oriented to learning Situation) (Osuna, 2000). This framework provides a series of attributes that enable the analysis of the requirements needed to create a collaborative learning scenario. It also requires that both teachers and application developers play an active role in a transdisciplinary working environment in which dialogue and commitment are crucial for the development of the applications.

After an in-depth collaborative analysis, we decided to form groups of would-be teachers; they should jointly create multimedia materials that would be used to teach English to primary school students. Besides
creating the material, this would-be teachers had to propose a methodology for its subsequent use in the classroom. This is how we decided to develop an application that enabled the asynchronous edition of the material: each student edits the document individually and then it is published in an Internet server so that another student from the same group can edit it again. Fig. 1 shows the interface developed for the application. We can see that there is an editor that includes general HTML editing operations such as headings and bolds, and also special operations in order to publish (send to the server), collaborate (add comments, suggestions) and visualize (see "preliminary views" as you go along). Moreover, the application also includes an interaction analysis tool that enables the reconstruction of the tale taking as a basis the different identified events, as if we were in front of video sequences. The teacher and the student can add commentaries about the process and, at the same time, they can get information about any of the versions, know how is their group and subgroup acting, see what is the role of the teacher and check general information about the editing process. Lastly, the application presents an evaluation instrument that continually evaluates each of the new versions.

![Fig. 1 Interface of CECI](image)

CECI was used by would-be teachers during a whole academic year. Our aim by using this application was not focusing on technological architecture, but observing the progressive application acceptance process by would-be teachers and measuring how this process is related to technology and uses technology at the same time. In order to measure this, we have used the methodology proposed by DELFOS which is supported a set of ethnographic instruments such as interviews, questionnaires, classroom observation, etc.

**Conclusions**

The development of activities based on transdisciplinary orientation techniques is a valid strategy to ensure the educational process; this is especially so when we are dealing with technology learning because it enables a constant dialogue between the problems in both disciplines. Joining two different subjects in the same project helped the would-be teacher in two aspects: visualizing a problem from a twofold perspective and using technology adequately to solve educational aspects.

We should highlight that the students developed their technological skills progressively and as they went along and the need to use them emerged. Besides, they stopped viewing technology as a hardware and software set and started to see it as a potential tool to be used during classroom activities in the future. This situation made their former lack of initiative to develop new educational technology decrease.

Integrating Technology into Courses for Pre-Service Teachers

Dr. Elizabeth Balser, Chair of the Education Department
Saint Vincent College, USA
bbalser@stvincent.edu

Abstract: Collaborations of college faculty, pre-service teachers, and in-service teachers proved to be a successful combination in developing expertise in using technology in K-16 classrooms. Pre-service and in-service teachers developed units, lesson plans, and other activities that were implemented in the in-service teachers' classrooms. The students were able to see their work applied in real life situations. The college faculty employed the skills they learned through the collaborations to integrate the teaching of specifically designed technology skills in the pedagogy courses and content area courses that pre-service teachers must take from their first semester through student teaching. In this way, students apply learned skills immediately, and as the skills become progressively more advanced, pre-service teachers build on past activities and successes.

Introduction

Using technology has become a way of life for many children in today's K-12 schools. It is the youngsters who know better than their parents or teachers how to program a VCR, manipulate all the controls on a Play Station, and find really "cool" graphics on the Internet. These same children are entertained in a fast-paced simulated world that comes to them via the television set, the movie screen, and the computer monitor. In a classroom devoid of high tech approaches and applications, students become disinterested bystanders on the road to relevant education.

With the majority of K-12 teachers and college faculty nearing retirement age, they obviously did not grow up with computer technology and thus are, in some cases, intimidated by the seeming intricacies and complexities of the URLs and hypertext. Most can understand the advantages of using computer technology in their classrooms; they just don't have the means, or sometimes the patience, to learn how most effectively to employ this wizard technology.

What about today's college students who are the pre-service teachers preparing to enter the workforce as K-12 teachers? Their level of expertise might fall between that of the K-12 students and their teachers. The college students have Play Stations at home, use e-mail to keep in touch with all their friends attending other colleges, shop via eBay, and word process all of their college essays and research papers. Where they lack expertise is in the use of appropriate computer technology to create, deliver, and assess meaningful, relevant lessons in their content areas.

Link-to-Learn Program

To address the appropriate use of technology in the K-16 classrooms, Saint Vincent College in Latrobe, Pennsylvania sponsored a "Teaching and Learning with Technology" workshop that spanned two summers (1999 and 2000) and one school year (1999-2000). This program was funded by the Pennsylvania Governor's Link-to-Learn Initiative, designed to bring technology to the pre-service and in-service teachers of Pennsylvania.

Saint Vincent College is a four-year liberal arts college with an enrollment of approximately 1100 students; 15% of them are enrolled in the teacher certification program. All students at Saint Vincent College, including those in a teacher certification program, must major in a content area. Students must also include a very heavy concentration of core curriculum classes into their academic programs. The requirements of the major and the core leave students with little time to take the required courses needed for certification. Therefore, it becomes
necessary to incorporate important pedagogical and technological skills into all Education courses and into many of the content area and core courses, as well.

In order to include rigorous instruction in using appropriate technology for teaching and learning, the Education Department and six content area departments with teacher certification programs (biology, English, history, mathematics, physics, and psychology) adapted courses already being offered in the departments to be "technology designated" courses, all of which incorporated specific skills, competencies, and products in using technology for classroom instruction. Within these courses, pre-service teachers develop skills to incorporate technology successfully into their model lessons, units, demonstrations, lab experiments, and other learning activities.

The vehicle for developing the "technology designated" courses was the Saint Vincent Link-to-Learn workshop "Teaching and Learning with Technology." The workshop brought together teams of participants—one college faculty member, one pre-service teacher, and one K-12 teacher on each team. The teams collaborated in curriculum development and lesson planning based on educational objectives, state and national standards, the International Society for Technology in Education (ISTE) standards, and technology resources as they apply across the K-12 grade levels and the undergraduate college curriculum.

Participants

- 18 college faculty in chemistry, education, English, history, physics, mathematics, and psychology
- 18 pre-service teachers (college students) enrolled in elementary, early childhood or secondary (biology, chemistry, English, and mathematics, physics, and social studies) teacher certification programs
- 18 teachers from three area school districts

Because most of the in-service teachers served as cooperating teachers for the pre-service teachers, the collaborative lesson plans and other learning activities were implemented in the teachers' classrooms, with both the in-service and pre-service teachers having an integral part.

Goals

The Link-to-Learn Program sought to make people into educators who could use technology to enhance and improve instruction; thus the program concentrated on the following goals:

- Emphasize teaching with technology, not about technology.
- Provide adequate technical support for all participants to reduce frustration and burn out.
- Promote relationships among pre-service and in-service teachers and college faculty so that they can develop authentic curriculum materials that incorporate appropriate technology.
- Incorporate both technology standards and approved and emerging national and state academic standards.
- Design new course syllabi or lesson plans--or revise existing ones--to reflect academic and technology standards.

Equipment

All participants had access to state-of-the-art equipment. Acquisition of necessary hardware and software was supported by funds from the Link-to-Learn Initiative. All participants received IBM laptop computers. The college faculty and K-12 teachers retain use of their laptops until they leave their place of employment or until the laptop needs to be replaced. The college students keep their laptops through the end of their student teaching internship.

All workshop sessions were held in the new Saint Vincent College Instructional Technology Resource Center, which is equipped with the following:
Three "smart classrooms" each equipped with a Softboard, LCD projection device, document camera, laser disk, DVD, and videocassette
Multimedia laboratory with computer workstations, scanners, digitizers, plotters, printers, and audio-video resources
Academic Lounge which contains collaborative networking access pods with ports for laptop access by as many as 16 students and faculty

The classrooms in the Education Department were upgraded through the addition of three desktop computers, an ink-jet printer, a scanner, a document camera, and an LCD projector with a laptop computer per classroom. All classrooms have Internet connections. Students use this equipment during classes in simulations and in micro teaching demonstrations. When the rooms are not being used for class, students can use rooms as small computer labs.

Topics covered during the workshops included:

- Locating, reviewing, evaluating, and using software
- Trouble shooting problems
- Using imaging devices (scanner, digital cameras)
- Using productivity tools for word processing, database management, and spreadsheet applications
- Making multimedia presentations
- Using telecommunications to access information and enhance personal and professional productivity
- Demonstrating knowledge of equity, ethics, legal, and human issues concerning use of computer and technology
- Identifying computer and related technology resources for facilitating lifelong learning and emerging roles of the learner and the educator

By the end of the summer workshops, the K-12 teachers and the pre-service teachers had created products that they can use in the classrooms and had developed technology skills that enable them to incorporate appropriate technology into their teaching. See the Link-to-Learn Home Page to view the projects: http://facweb.stvincent.edu/L2L/projects.html.

The college faculty, likewise, developed expertise in using technology as part of their instructional repertoire. Their new goal was to teach the students in their classes how to use specific technology applications and how to incorporate them into lesson plans, learning activities, demonstrations, and labs. Fourteen courses became "technology designated," and specific skills and competencies were assigned to each course.

Below are courses or groups of courses taught at the college. Following each course is a list of competencies that students develop through instruction in the course or courses. Material in parenthesis refers to ISTE Foundation Standards (ISTE, 2000).

**Foundations of Education (required of all certification candidates):**

- Demonstrate knowledge of equity, ethics, legal and human issues concerning use of computer and technology. (1.2.6)
- Use productivity tools for word processing; submit all work in word-processed format. (1.2.1)
- Establish e-mail accounts; learn features including send, reply, forward; create contact lists, set up group lists, send attachments; maintain contact with course instructor and submit and receive assignments via e-mail
- Describe current instructional principles, research, and appropriate assessment practices as related to the use of computers and technology resources in the curriculum. (1.3.3)
- Research and compose a paper on the use of technology resources to facilitate lifelong learning. (1.2.7)
Develop a home page that will include resume, philosophy of education, service activities, work with students, annotated bibliography of interesting books and articles, list of educationally valuable web sites. This web page will be expanded throughout all subsequent courses.

**Observation and Interaction Laboratory (required of all certification candidates):**

(Students will use resources available at field placement sites and at the college in preparing these activities.)

- Develop a list of television, videotape, videodisc, and CD-ROM resources suitable to pre-service teacher's grade level and content area.
- Use digital camera and insert pictures into course work. (1.1.4)
- Develop scenarios of using classroom computers or computer labs for student learning.
- Use record-keeping software for creating gradebooks/rosters/progress reports for parents. (1.2.4)
- Add to homepage: photos of field experiences, lists and scenarios developed, sample gradebook page or roster.

**Strategies and Techniques of Instruction (required of all certification candidates):**

- Operate multimedia computer systems with related peripheral devices to successfully install and use a variety of software packages. (1.1.1)
- Use terminology related to computer and technology appropriately in written and oral communications. (1.1.2)
- Locate, review, evaluate, and select instructional software appropriate to pre-service teacher's grade level and content area. (1.3.1)
- Prepare a lesson that includes a selected software program suitable to pre-service teacher's grade level and content area; install and demonstrate software. (1.3.3)
- Use video camera to tape a classmate teaching a lesson. Review one's own videotaped lesson for self-evaluation.
- Add to home page: evaluations of instructional software, lesson plan with software application, video clip of teaching demonstration.

**Education Psychology (required of all certification candidates):**

- Perform Internet functions of search, retrieve, copy to file, and evaluate. Research a topic including use of original sources, artifacts, and reports to be used in lesson or unit plan. (1.2.3)
- Use software and other diagnostic tools to assess different learning styles among children. (1.3.3)
- Add to home page: research paper prepared with sources from the Internet as well as more traditional sources.

**Education and Psychology of the Exceptional Student (required of all certification candidates):**

- Demonstrate awareness of resources for adaptive/assistive devices for students with special needs. (1.2.5)
- Describe use of adaptive technologies such as text-to-speech, special keyboards, Braille printers, touch screens, closed caption, digitizers, large screens. (1.2.5)
- Use technology to adapt lesson plans for special needs students, incorporating strategies such as simulations, peer tutoring, dialog journal, and use of problem-solving videos.
- Add to web site essay on the use of assistive technologies, adapted lesson plan.

**Child and Adolescent Development (required of all certification candidates):**

- Develop an annotated listing of URLs that are useful resources for understanding child and adolescent psychology.
Add this list to home page.

Secondary Reading Instruction (required of all secondary education certificate candidates)
Children's Literature (required of all elementary education certification candidates)

- Use multimedia and other forms of technology to develop alternative activities for special needs students, ESL students, and culturally, racially, or ethnically diverse students. (1.1.1)

All Content Specific Methods Classes

- Evaluate software packages for their appropriateness in pre-service teacher's content area and grade level. (1.3.1)
- Develop an annotated listing of URLs appropriate to pre-service teacher's grade level and content area.
- Use appropriate resources for classroom instruction including databases, CD encyclopedia, atlases, dictionaries, spreadsheets, and Internet. (1.3.1)
- Use imaging devices such as scanners, digital cameras, and/or video cameras with computer systems and software in development of lesson plans or units. (1.1.4)
- Create multi-media presentations using a combination of computer, projection device, document camera, overhead projector, VCR, videodisc, CD-ROM. (1.1.1, 1.1.4)
- Add to home page: software evaluation, annotated list of URLs, multimedia lesson plan(s) that feature the above-mentioned resources, imaging devices, and equipment.

English (secondary) Reading and Language Arts (elementary)

- Use e-mail to communicate with children in local schools for tutoring and mentoring on reading and writing projects. (1.3.3)
- Use multimedia to create interactive learning environments in which technology can be used to show the relationships between literature and other subject areas such as music and art. (1.1.1)
- Develop criteria for evaluating Internet resources for accuracy, logic, use of propaganda, author's purpose, and tone. (1.3.1)
- Research effective oral reading presentations on laser disks, videodisc, CD-ROMs, or other electronic sources for use in developing listening skills and vocabulary. (1.3.3)
- Use computerized literature databases such as ERIC.
- Add to home page: criteria for evaluating Internet resources, lesson plan show integration of reading with other subjects, citations of useful auditory resources, a bibliography taken from ERIC or another literature database.

Mathematics

- Create electronic spreadsheet activities. (1.2.1)
- Use geometry supposition software to demonstrate electronic conjecturing and proof. (1.2.1)
- Use graphing software to visualize and print algebraic and trigonometric relations and functions. (1.2.1)
- Use materials generation software to customize worksheets/posters/banners for the classroom. (1.2.1)
- Establish math tutorial program with a middle or high school student through e-mail correspondence.
- Add to home page: a sample spreadsheet activity, samples showing use of geometry supposition, graphing and generation software packages.

Social Studies/Geography

- Develop criteria for evaluating Internet resources for accuracy, logic, use of propaganda, author's purpose, and tone. (1.3.1)
v Use computers to support problem solving, data collection, and information management. (1.2.4)
v Use computer software for site-location analyses, diffusion modeling, and simulation.
v Use spreadsheets to present results of regional geographic studies. (1.2.1)
v Produce data banks for regional study projects. (1.2.4)
v Produce CD-ROM programs of flora and fauna of bioregions.

Science

v Use computers to support problem solving, data collection, and information management. (1.2.4)
v Use appropriate content-specific technology tools such as probe ware, midi devices, graphing calculators, data plotters, video microscopes. (1.2.4)
v Use data acquisition and analysis software to design and build spreadsheets. (1.2.1)
v Use simulation software, computer-aided laboratory devices, and data reduction software to develop and test hypotheses regarding various physical phenomena. (1.2.4)
v Use instruments and systems such as CBLs for automated data collection/develop lesson plans that utilize this technology.
v Use analytical probes connected to graphing calculators to collect a variety of data.
v Analyze the data through calculator-based mathematical analysis or graphing. (1.2.4)
v Establish math tutorial program with a middle or high school student through e-mail correspondence.
v Add to home page: criteria for evaluating Internet sites, evidence of using laboratory equipment and software specified above.

Pre-Student Teaching Seminar

v Use computers to communicate information to parents, students, colleagues, teachers, and professors. (1.2.3)
v Prepare a lesson that teaches your students how to create a technology-based project.
v Produce informational pieces such as brochures, newsletter, flyers, sign, school newspaper, and letters using desktop publishing software or resources. (1.2.1)
v Use "grade book" or other record keeping software to record and track student progress. (1.2.1)
v Add to home page examples of electronic correspondence with parents or teachers, an instructional technology lesson, your brochure or flyer.

Conclusion

By the time the students are ready for their 15-week student teaching internship, they will have had experience in creating a number of units, lessons, activities, demonstrations, and labs that incorporate appropriate technology applications. They gain these skills and competencies through observing them being used in an instructional setting and then through applying them within the classroom to create materials required as part of the course.

Integrating technology into already existing courses for pre-service teachers was done out of necessity. The Education Department did not wish to add another course to the students' already heavy academic loads. With the success we have seen with this approach, we recommend the integrated approach even for schools that have the "luxury" of being able to add one or more instructional technology courses. The key, of course, is to make sure faculty are well trained in the use of technology before undertaking a department-wide integration endeavor.

References

Abstract: The Eureka Science Academy is in year 2 of a 3-year grant. This is a report on the Academy and 2 groups of preservice teachers that have taught in the program and how they integrated reading, writing, science, and technology in the project. Team leaders and interns spent one week in training prior to the arrival of the Eureka students. Their training, provided by the program directors, consisted of team building activities, writing team mission statements, developing effective literacy strategies, performing science activities, and reviewing books and computer software. Time was also spent reflecting on the focus of the Academy - meeting the needs of students through an integrated program of reading, writing, science, and technology.

Introduction

In August of 1998, with the aid of a Lilly Planning Grant, discussions with area teachers and principals from both public and parochial schools were initiated. While the needs of students experiencing substantial academic difficulty are addressed through special services and those high-achieving students typically have access to special classes, children of average achievement (40th-60th percentile in various standardized tests) often have few programs directed to their needs. These are the students who can gain the most from more encouragement and additional preparation, becoming enthusiastic and successful learners.

A 3-year Lilly Grant enabled the development of the Saint Mary's College/Students/Teachers/Parents Science Project, hereafter identified as CoSTEP. CoSTEP is a comprehensive science education outreach composed of three key activities which bring together students from South Bend area schools grades 4-12, their teachers, their parents, and Saint Mary's College faculty to encourage active inquiry-based science that engages the hands and minds of all participants. The project sought to help students, teachers, and parents achieve success in teaching and learning science; to increase the use of technology of students; and to nurture habits of discipline, scientific inquiry, critical thinking and communication that will help students succeed in school. An ancillary goal was the increased preparation of the Saint Mary's College elementary education majors prior to their student teaching.

Students attending the Eureka Science Academy, one part of the CoSTEP project, were given intensive instruction in reading and writing, exploring environmental science, and technology. Essential to the program were twenty interns: Saint Mary's College elementary education majors who completed their junior year of studies including courses in developmental and corrective reading, the science and language arts methods courses, a technology course, and at least 70 hours of field study in area schools. Each intern was responsible for developing and carrying out the daily lessons with three or more students and for keeping records on the students' progress. The interaction between the students and the interns gave the intern an opportunity to expand her teaching repertoire. A weeklong training program before the start of the Academy completed the intern's preparation for this important role.

According to Woodrow (1998) Technology-enhanced instruction (TEI) is not a new heady concept. It is just another step on the learning highway that permits disciplined organized, meaningful pursuit of understanding- whatever the subject. TEI is a pedagogical device, which does not smother creativity; it empowers access and choices to vast realms of information, an access that enriches thought,
and thus, creativity, a peculiar form of imagination. Somehow trainers of teachers must communicate this
message substantively throughout the educational community; they must become leaders in the
implementation of technology-enhanced instruction. Technology is not a master. It is a product of the
most essential forms of human creativity. A cycle has been completed from stone to silicone, the
toolmakers continue to extend their reach, to improve their grasp.

Five of the interns were chosen as team leaders. The team leaders worked with four interns each
and were responsible for team activities. Interns facilitated the program in a 3:1 or 4:1 student: intern ratio.
This ratio was a key element of the Eureka Academy because it provided for individualized instruction,
dialogue between the intern and students, and immediate feedback during discussions.

During the first year, fifty-three students from grades 4-6 representing four public and three
Catholic schools, arrived at Saint Mary’s College to begin their Eureka Science Academy experience.
During the second year 56 students from grades 4-6 representing 4 public and 6 private schools began their
Eureka Science experience. The overall science theme was the environment, and all the reading, writing,
technology, and science activities revolved around this central theme.

The Program

Planning for the first Eureka Science Academy summer session began in January 1999. A
brochure and an application form were designed and local schools were contacted about the program.
Classroom teachers identified students according to the criteria specified for the Eureka Science Academy.
Parents interested in having their children participate in the Academy, submitted application materials and
were notified of their status in a timely manner. Simultaneously, the application process for team leader and
intern positions began. Once selected, the team leaders began their initial training with the program
directors.

Team leaders and interns spent one week in training prior to the arrival of the Eureka students.
Their training, provided by the program directors, consisted of team building activities, writing team
mission statements, developing effective literacy strategies, performing science activities, and reviewing
books and computer software. Time was also spent reflecting on the focus of the Academy - meeting the
needs of students through an integrated program of reading, writing, science, and technology.

Woodrow (1998) reports if public education is to continue serving learner needs, then teachers
must be trained in the use and application of available technology. Except in very special circumstances,
little is achieved by loading up a school with technology and saying, “Get to it.” Be it rather fast,
technological application still must evolve to suit known learning needs in the classroom. Playing on the
Internet does not constitute advanced technological application to learning needs: the curriculum is still the
curriculum; methods of learning, together with the grammar of disciplines and the understanding of the
principles of the relationships among parts, must be learned. First however, a generation of preservice (and
inservice) teachers must learn to understand and be completely comfortable with computer/multimedia
technology as essential learning tools.

At the end of the preparation week for the preservice teachers, a parent orientation evening was
held. During this event, the Eureka students were introduced to their team leaders and interns and were
given an opportunity to get acquainted with their team members. All Academy students had their
photographs taken and displayed on their team boards. They also received T-shirts and hats with the
Eureka Science Academy logo on them. The evening ended as families toured the campus, giving
everyone the opportunity to visit classrooms, the computer lab, library, and dining hall. The goal was to
make everyone comfortable on the very first day.

Environmental science was chosen as the central theme of the Academy because it brings together
chemistry, physics, and biology. Each of the three weeks had a specific focus - the living environment
(Indiana plants and animals), the physical environment (air, water, energy, and matter), and the interactions
that occur between the living and the physical environments (food chains, weather, water cycle). Reading,
writing, technology, and science activities all revolved around this central theme. Favorite science
activities included dissecting owl pellets, germinating seeds, using microscopes, and working with the
weather station. The use of software such as Tom Snyder Science Court CDs with accompanying hands on
science kits - Water Cycle, Soil, Living Things, and Seasons were used to strengthen the students' process
skills.

One intern wrote in the Academy daily diary “We then went into the Regina MAC lab and did the
Owl Pellet CD-ROM on the presentation stand to allow the kids to better understand how the lab they were
to take part in would work. They thought the presentation board/computer was really neat. We then talked about the lab a bit and told the children what they could and could not do.”

As the focus of each week was planned, related literature was identified and writing experiences were designed. Each day a story was read aloud and discussed. According to Anderson et al (1985), reading aloud to children is the single most important activity for developing a sense of story structure, promoting vocabulary growth, and teaching higher level thinking skills which are ultimately reflected in the student’s writing. Tompkins (2001) points out that when teachers read aloud, they model what good readers do and how good reader’s use reading strategies. An example of a picture storybook read during the study of the living environment was Two Bad Ants written by Chris Van Allsburg. The story presents life - adventures, dangers, decisions, values - from the ants’ perspectives. Discussion of this book has focused on making choices, related consequences, and discovering what is truly important, as well as seeing the world from the ants’ perspectives. Writing response choices included writing a poem from one of the ant’s point of view, observing ants or other insects and writing their version of the story, and researching information about ants on the Web. Because the Academy was able to acquire many books, including multiple copies of paperback chapter books, students were also able to work in small literature response groups, read a common book as a team, and take books home for independent reading. Some favorites have included Poppy, Stone Fox, Song of the Trees. A word processing program AppleWorks was used to help students sharpen their writing and presentation skills.

A typical day at the Eureka Science Academy began with the 8:30 arrival of students, mostly on buses. Following breakfast, students and their team leaders/interns went to their classrooms for literature, writing, and science experiences. Teams often began with editing a sentence or paragraph related to the environment. Grammar, capitalization, punctuation, and spelling were emphasized. At least one read aloud was included each day - either a picture storybook or a chapter book - followed by discussion and a response activity along with vocabulary additions to the word wall. Another intern wrote “After the flower activity, our group worked on a project for The Well. Our project was to write a script about a scene in the book and then act it out in front of the camera. At first my group did not want to do this, but then they got into the idea. We then finished our script and went back into the classroom to regroup as a team to go to lunch.”

A science activity would often be the focus of a morning or afternoon or sometimes the entire day. Using a microscope to view commercially prepared slides as well as self-prepared slides, dissecting owl pellets, and building seed germinators were extensive projects, while checking and graphing the weather was an ongoing activity that involved a short period of time each day. An intern wrote, “When lunch was over, all of us returned to the classroom for two activities. One of the activities was to make paper. The other activity was for the students to identify a leaf, find a picture of the tree that it came from, and write a paragraph about the tree with just the Internet. Our group went about doing these activities by having two of the leaders work with one group of students on making paper and the other leader working with the other two groups in the computer lab. I feel that this worked well because the papermaking was very time consuming.”

Students also had the opportunity to go to the computer lab to search the Internet or use other aspects of the technology available. A intern reported in the daily diary, “They (the students) all logged on and I guided them to www.yahoo.com. I had them search for web sites on their favorite animal. Then I taught them how to copy their picture onto an AppleWorks document in order to save paper. They then gathered some Internet information so they can make a poster with the pictures and information they gathered.” Each student compiled a portfolio. Photographs with accompanying written commentary were included for projects too large to fit into a portfolio. Photographic entries were included of field excursions as well. Some days the students took photographs and cataloged them or digitized them and saved them to their personal file on the college server. Another intern commented “Right after breakfast, we split the team into two groups. We took those who were finished choosing articles for their portfolios to the computer lab, and those who needed more time choosing stayed in the classroom. In the computer lab, I showed the students how to write a table of contents using the Harvard outlining system. I decided to use the presentation station to show them how to make the table of contents since there was so many of them and only one of me (plus Jenny). So while I demonstrated on the overhead, Jenny went around helping and answering questions. This system seemed to work pretty well. The kids did really well and all of their tables looked unique and nice. Meanwhile, back in the classroom, the rest of the kids worked diligently at putting their portfolios together. Some kids opted to hand write and decorate their tables of contents. After the students were finished in the computer lab, they joined those in the classroom ad put their finishing
A family open house was held during the last week of the summer session. Although many parents work outside the home and their attendance at an afternoon event was questionable, an opportunity to view the products of their children's success seemed important. Every child but two had parents in attendance. The students enjoyed being able to present their science and literature projects as well as reviewing the activities that would be done at the site. One intern delineated her group's activities: "My small group is reading Tracker. We discussed some of what they have read so far. Then we went to the computer lab. They checked their e-mail. (They enjoy it but there must be a time limit). I had my students research leaves and then go to www.pbs.org/Kratts. They worked on a "Mad Lib" type activity and will go in their portfolios. They enjoyed the web site-it was a good one! They also went to Fernwood's website to get ready for Friday's field trip." Each venue provided students with the opportunity to listen to docents present information and explore the environs with their guidance. As students participated in field trips, they wrote observations, gathered specific information, and drew and photographed the environment. On-campus field trips included the Saint Mary's nature trails and a tour of the Science Hall. When students were asked what they noticed about the teaching space in the Saint Mary's College Science Hall compared with their schools, they noted that nearly every room was a laboratory. Professors facilitating the tour explained that most of the science learning at Saint Mary's takes place in the laboratory. Hands on excursions both on and off campus provided the students with exciting experiences that extended their understanding of science concepts.

A parent's e-mail to the program director said, "I had reservations about sending my child to an academic day camp during the summer months. I thought this was going to burn her out before school started. I was so wrong! My daughter is so excited when she comes home. She talks constantly about the camp activities and can't wait for tomorrow. [The student intern] has ignited a fire. My daughter wants to be an SMC girl like her. Thank you for providing my daughter with a good role model." On the parent survey sent home at the conclusion of the three-week Academy, one parent wrote, "We have never seen
[our daughter] more positive about a learning experience. So far her enthusiasm is being carried over into school. She wants to do science homework first. Thank you all!” Others mentioned how wonderful it was to see their children reading and writing over the summer because of their time at Eureka.

During a parent open house, a father was overheard telling his daughter that sure, she could attend Saint Mary's for college even though they had never thought about it before, and that it just might be a good place for her. Whether the child had thought about attending college prior to her experiences at Saint Mary's we can not say. The positive signal here is that the time spent on campus during the Academy stirred a desire in this child to ask her father about going to college at a place that she felt comfortable.

Most Eureka students will begin their school year with a greater interest in science and enhanced reading, writing, and technology skills. The hope is that the progress made during the Academy will not only continue into the school year but will make a difference throughout the academic lives of the Eureka students.

Abstract: This presentation will describe preservice teachers' experiences during their internship year in an elementary magnet technology school. This program is part of a grant designed to better prepare preservice teachers to work in urban settings.

Introduction

This study is part of a larger research project designed to investigate the effectiveness of training and support for pre-service teachers and the extent to which various technology tools and applications are used in their assigned schools and classrooms. It is our expectation that this insight will improve teacher preparation at the University of Tennessee and reduce the growing exit of educators leaving urban settings. The current study is based on a series of focus groups that examine the perceptions of a group of students enrolled in a five-year teacher preparation program in the College of Education.

Participating interns have chosen to serve one year in the Knoxville urban school setting working full time under the tutelage of a mentor teacher. Even though interns do not receive an income, their experience is a part of the training towards a Master's credential. The primary assignment for interns participating in this study is an urban public school (K-5) with a concentration in science, mathematics, and technology. This school, located in one of the poorest areas in the city, reflects many of the academic challenges known to urban education. Nonetheless, it is uniquely rich in technology resources with state-of-the-art equipment due to a variety of special funding sources.

Two focus groups were conducted over two consecutive weeks with 15 students for approximately 90 minutes. Through our conversations with the interns, we were able to gain a sense of their perspectives about teaching, technology, and the integration of both areas in a technology-rich school environment. In addition, we were able to increase our understanding of their perceptions of their mentor teachers' uses of technology in the classroom. Future studies in this project will include interviews with the mentor teachers, administration, and parents to gain their own perspectives. The ultimate goal is to understand the broader context of the roles, relationships, and support needed to maximize learning opportunities for students and teachers to succeed in a changing, technological world.

Teacher Preparation

Technology can be a powerful tool to help teachers in all aspects of their jobs, however many new teachers report being unable to use technology in their classrooms (OTA, 1995). With the increased attention to the level of technology in schools, certain obstacles preventing the effective use of these resources must be addressed. Of these, providing teachers with adequate preparation in the use of technology in their teaching is a major concern.
Teaching isolated skills is not as effective as grounding it within a context of relevance to preservice teachers. Typically, the response to preparing teachers to use technology has resulted in "add-on" courses that teach technical skills and topics in isolation from the rest of the teacher education program. Even if students use technology within their methods classes, many comment that they do not use technology during their student teaching experience because of a lack of adequate resources in the school.

Though interns were required to take an introductory computer course prior to their internship, findings from the focus groups revealed the following insights with respect to their technology experiences:

- Student knowledge and background experiences reflected a range of skill and comfort levels creating the need for differentiated instruction to build on existing skills and knowledge
- Comfort levels with software were varied and dependent on the frequency with which the software was used
- Computer preparation experiences within the College of Education did not provide consistent content or requirements, and sometimes led to repetition of topics and concepts
- Classroom management issues related to teaching and teaching with technology in a K-12 classroom were not adequately emphasized
- Course experiences prepared some students to use technology as a personal productivity tool but not necessarily as a teaching tool for instruction
- Software selection and use did not always reflect developmentally appropriate practices
- Students did not grasp underlying principles and concepts that would give them the flexibility to transfer their knowledge to different computer programs (e.g. Excel vs. AppleWorks spreadsheet)

**Instructional and Professional Technology Use**

Preservice teachers observed different trends in the use of technology in the classroom. Among these, interns reported that teachers used technology as a whole class presentation tool, as a center for small group activities, as a remediation activity, and as a drill-and-practice application for practicing basic skills. There seems to be a relationship between mentor teacher’s use, or support of technology use in the classroom, that impacts the degree to which interns themselves support or use technology. Technology resources differ within the school depending on the source of funding attached to different programs operating within the school. For example, some teachers submitted applications and received funding through the State to become a 21st Century classroom. The focus group findings revealed the following trends:

- Mentor teachers use of technology varied – classroom applications may not be consistent
- Mentors use (or non-use) of technology had an impact on interns use of technology in both positive and negative ways
- Interns with more experienced technology-using teachers felt more comfortable taking the initiative to explore the use of technology in the classroom. Teachers who used the technology often modeled various teaching strategies, applications and integrated uses of technology
- Greater coordination could contribute to more effective collaboration between teachers and the support and technical staff

**Conclusion**

We have learned through the voices of interns that school and classrooms contexts are complex. Funding resource streams differ. For example, in a given school, classroom resources may vary depending on the funding source. Emerging findings from interns' reports suggest that teachers' values, beliefs, and attitudes differ and may be associated with such factors as age, training, and experience. Student needs vary, particularly in this context where poverty and equity issues often emerge. It is a context where technology can be used to ease some of the challenges on the teacher, especially when technology is integrated and not introduced in isolation. The leadership and excitement of being at a magnet school has set a positive tone and generated a lot of discussion and buy-in about the possibilities and expectations of a more coordinated and integrated practice.
Unique Collaborations in Teacher Education Programs

Abstract: The critical need for teachers coupled with the need for quality teacher preparation has led to a unique collaboration of a public school district, community college and the education department of a university. This collaboration has developed a teacher certification program that targets the non-traditional student with a strong emphasis in technology integration, authentic projects and quality fieldwork experiences.

The CCACC Initiative

In the past few years, a critical teacher shortage of has developed in the United States. The U.S. Department of Education predicts that the nation will need more than a million new teachers by 2010. (Kantrowitz and Wingert, 2000) In Arizona, the state which provides the context for this unique partnership, the media reports a demand for 27,000 new teachers throughout the next 10 years, a rate of growth currently ranking third in the nation. These new positions are intended to keep pace with the additional 200,000 students that will be relocating to Arizona over the next decade, and do not include additional positions to be vacated through attrition and retirements.

Coupled with a high demand for certified teachers is a renewed public scrutiny regarding teacher preparation. Concerns with current practices include a disconnect between universities and schools, limited field experiences, and weak links between education units and liberal arts departments (Burstein, Kretschmer, Smith, & Gudoski, 1999).

Although the needs are readily identified across the teacher education literature, few systemic or substantive changes have been made beyond superficial modifications to existing programs. This may be due in part to administrative or social barriers, including structures within higher education that support isolation, independence, and competition (Miller & Stayton, 1999).
Faculty members who want to improve the quality of teacher preparation often do so out of their own
hide, without the support of the institutional environment.

The prevailing thought in current education reform focuses on collaboration and the potential
for change to occur as individuals work in cooperative ways. As noted by Miller and Stayton (1999),
"collaboration and innovation in teacher education are essential ingredients for preparing teachers for
increasingly diverse and challenging school populations" (p. 290). Despite their potential, however,
collaborative enterprises are also fraught with challenges. Often noted in the literature is the clash of
cultures between schools and universities, resulting from a lack of shared vision or sense of larger
issues through which the two cultures can be brought together. Superficial relationships between
teachers and university-based faculty can also limit program impact (Bullough et al., 1999).

Three partners -- a university education program, a public school system, and a community
college have developed a successful collaborative that is attempting to meet the dual demands of
teacher shortages and quality preparation. The “Chandler Unified School District, Chandler-Gilbert
Community College, Arizona State University East Certification Collaborative” (CCACC) was
developed at the request of the Chandler (Arizona) School District, which is anticipating that its
population of 20,000 pupils will double by 2012. The district requested a “grow your own” program
that would allow its current instructional aides and paraprofessionals to earn credits towards
certification while continuing their employment in the district. The community college would offer
lower division courses, leading directly to admission at the university for a two-year teacher
preparation block that would fulfill the requirements for a Bachelor’s degree.

The CCACC initiative has the potential of addressing the current teacher shortage crisis while
reforming teacher preparation through rigorous standards, innovative teaching, and intensive field
experiences. Miller and Stayton (1999) purport that “creating professional communities designed for
innovation is a complex social challenge, one that will require the actors to act with courage, integrity,
and a willingness to create the structures we need for real reform” (pp. 301-302).

The CCACC partnership includes several distinctive features, including a focus on district and
state standards in the development of a joint university/community college curriculum. The standards
identified and aligned with each course serve as the framework for performance-based measures to
trace the success of teacher candidates. For example, as students participate in intensive field
experiences, their performances are mapped through observational rubrics and individualized
professional portfolios. Quality is also enhanced through an emphasis on technology, and its
effective adaptation to classroom instruction.

In addressing demands placed on the profession to accelerate the certification process, the
CCACC collaborative optimizes conditions for current district employees to participate in the program.
Courses are offered entirely on-site, and are primarily taught by the district’s master teachers who
consistently model best practices and standards integration in their own classrooms. The program
also revolves around the district’s calendar, facilitating the participation of employees while providing
concrete experiences based around a complete school year. Critical to the collaborative nature of the
initiative is the Site Coordinator, a university adjunct professor assigned to the district to assist in
developing syllabi, advising, supervising, and mentoring the master teachers. These unique
programmatic features, offered in the context of a university/district/community college collaborative,
will provide the venue for the session's interactive exchange.

"Grow Your Own" Certification

The Chandler Unified School District, in the Phoenix, AZ metro area, serves a diversified
population of over 21,000 students in grades PreK-12. Due to a booming city population and open
enrollment laws, Chandler Unified is one of the fastest-growing districts in the state. The district has
opened 8 schools in the last 10 years and now consists of 17 elementary schools, three junior highs
and two high schools. In the next 15 years, the district will build a new high school (scheduled for
2004), a new junior high (scheduled for 2003) and at least 10 elementary schools. Additionally, in the
last 5 years, the district has hired over 700 teachers. This number is half of the current 1200 certified
staff members. In the last 3 years the district has hired 220 plus teachers per year.

As the school district reviewed the number of teachers retiring, the pool of new teaching
candidates, and the number of prospective teaching positions, it was decided that a proactive stance
needed to be taken. The district decided it was time to “grow our own.” They were determined to find
quality individuals who were interested in entering the teaching profession. Many of these individuals
are the employee pool of support staff. With the partnership of Chandler Gilbert Community College and Arizona State University - EAST campus, the district has been able to offer a program. Students who have completed their required courses at Chandler Gilbert or elsewhere will take their methods courses in the Chandler district and participate in valuable learning experiences with master Chandler teachers. Additionally, this program is available to students with a degree in another area, wishing to pursue a post baccalaureate degree. Opportunities for participants to work for Chandler Schools as an instructional paraprofessional are available for those participants interested.

The Role of the Community College

It is approximated that at least 40% of prospective teachers meet at least a portion of their general studies requirements at two-year institutions (Haver & Watson, 1997), and that community colleges enroll 43% of all U.S. undergraduates (Anglin, Mooradian, & Hamilton, 1993). These institutions are therefore, prime venues for recruiting prospective teachers and, in particular, present a virtually untapped resource pool for minority teachers.

The role of the community college is to provide general education classes at times that are convenient for the working student or full time student. In addition, advisors meet individually with each student to develop a program of study. When cohorts are large enough, classes can be offered on site at the school district. Students can choose education classes as well as general education classes that meet the requirements of the first two years of college, and they can attend either full time or part time. Upon completion of the community college courses, they can transfer to the university program or one of the on-site collaborations as a junior.

The community college education program at the Williams Campus is geared for full-time students, many of who are already admitted to the university through the Partnership in Baccalaureate Education program (http://www.east.asu.edu/programs/pbac/index.html). A 4-semester block of classes has been developed. Learning communities and a structured set of courses have been planned.

During the first semester, students are involved in a learning community which includes First Year English, Introduction to Education, and the Internet. This 7-9 credit hour block of classes is taught for 4-hours, twice a week. The three courses are fully integrated so the papers that the students will write for English 101 will be based on topics discussed in the Introduction to Education course. The Internet class will include development of computer literacy skills, research skills and web page design skills.

During the second semester, the learning community courses will be the second semester of First Year English, Contemporary Multicultural Film and Literature, and presentation graphics (PowerPoint). The Contemporary Multicultural Film and Literature will help students meet a humanities requirement, cultural diversity awareness, or a literacy requirement while serving as the theme around which students will write their research papers for the English composition course. Eventually, students will be sharing their research through the use of PowerPoint presentations, skills which will be developed in the presentation graphics computer course. Students will be asked to research, write and present around the theme of “Teaching and Learning in a Multicultural Classroom.”

During the third semester, a 3-credit computer course will be linked with Children’s Literature and Math. The students will learn more about computer terms and concepts using word processing, database, and presentation graphics to do various assignments with the children’s literature class. They will use spreadsheets within the math class.

While the fourth semester is still in the planning stages, the students will be completing foundation courses in their major and certification requirements.

The students will proceed through the four semesters by taking some general education courses and some courses in education, specific to their major. In each semester they are completing important core requirements, gaining exposure to life as a teacher, and developing technology skills. A very important element of the program is that during each semester, the students will be involved in service learning experiences that include direct interface with school-aged children. They will serve teachers and children in a variety of K-8 school settings: working with children living in a nearby transitional housing program which provides shelter for formerly homeless families; serve at a branch of the Boys and Girls Club; and work at a YMCA early childhood program.
The faculty at the community college and the university are working in a collaborative manner to establish common goals for the students with items such as portfolios and course expectations.

**Teacher Preparation Curriculum**

The Elementary Education Program at ASU East is an extension from the program of the main campus at Arizona State University. ASU has entered into a partnership with the city of Mesa and the Chandler-Gilbert Community College to utilize the former U.S. Air Force Base -- Williams Field. The program began 2 1/2 years ago with 14 students.

In the course of development, the ASUE program began to no longer "mimic" the ASU Main program. Fieldwork became a more integral aspect of the ASU East program required each semester of the education program. Methods classes were taught at partnership elementary schools in the area. As the program began to grow, it became more obvious that major revisions were necessary in the curriculum.

Collaboration of the faculty lead to the development of a curriculum with a strong literacy base. The literacy methods courses follow the timeline of child development beginning with "Emerging Literacy". In each semester, there is an integrated learning experience, which emphasizes the application of the content of the methods courses, classroom management and portfolio development. The study of technology has been strengthened from a 1 credit course to 3 credit course with more emphasis on the integration of technology into instruction. The faculty has collaborated to develop cross-curricular assignments requiring the authentic use of content and technology in field experience. The faculty has also made a commitment to "model" the integration of technology into their instruction with the use of an Internet portal, multimedia presentations, and other forms of assistive technology.

**Technology Integration**

A 1997 report by the President's Committee of Advisors on Science and Technology stated that preservice teachers are not getting the training that they need to integrated technology into instruction. Preservice teachers do not routinely use technology in field experiences and do not work with mentor teachers who can demonstrate and advise on technology integration. (Moursund and Bielefeldt, 1999).

The Education Program for ASU East is fortunate to be based at the site for the university's computer and technology program. Classrooms on the campus are equipped with instructor stations (computer, VCR, projector) and the instructional support is very strong. With this support, it is a natural progression to integrate technology use into the education classes.

As part of a PT3 grant, the education faculty worked with classroom teachers to incorporate technology based projects in methods classes. These projects utilized skills developed during the required technology course and periodic workshops. At the expiration of the grant, the faculty made a commitment to continue with a strong technology integration model. Faculty has collaborated to develop assignments that are cross-curricular. The use of Internet resources is required in the research for these assignments and all work must be "word-processed" or produced using technology -- for example, video and digital cameras. The faculty also is endeavoring to model the use of technology in their own instruction. All instructors are required to provide instructional support through the use of the university Internet portal software. Students have 24/7 access to syllabus and other course documents, posted grades and discussion group. All notices and announcements are posted on the department's "community" site and are sent to the students via e-mail.

The administrators of the public school recognize the need for teachers to receive a solid foundation in technology training. In a recent survey, a vast majority of principals indicated that they would give more consideration to hiring a teacher with demonstrated technology training. (Heng-yu and Hopper, 2000). ASU East offers students the opportunity to earn a technology credential through additional coursework, workshops and an applied project.

It is a natural progression to continue the strong technology integration model of ASU East to the CCACC program. Chandler is home for the Intel Corporation and the company has strong ties with the school district. Intel and the CUSD are in the process of developing "the classroom of the future" where teachers will be trained in the latest educational applications -- including the use of PDA's as a teacher and student learning tool. The preservice teachers enrolled in CCACC will have the opportunity to train in the "classroom of the future" and develop projects to use in their fieldwork.
Field Experience

One of the strengths of the education program at ASU East has been the required field experience. Preservice teachers complete 6 hours weekly each semester working with a mentor teacher. To coordinate with the child development focus of the literacy curriculum, the fieldwork assignments are coordinated with that particular semester's study -- i.e., during Emerging Literacy, preservice teachers are assigned to K-2 classrooms as interns. Assignments in methods classes are developed to utilize the fieldwork.

To accommodate the non-traditional students of the CCACC program (working adults), modifications have been made in the fieldwork requirement. Fieldwork is still a strong component and valuable asset of the teacher education program. The number of required hours has been reduced while the district administration has screened and trained mentor teachers to make sure that the fieldwork hours are all "quality" hours. Those students who are employed as paraprofessionals in the district will use their work experience as fulfillment of the fieldwork credit. This may require "visiting" other classrooms in order to complete an assignment. Those students who work as substitutes in the district can count their substitute experiences for half of the fieldwork hours. Other students have made arrangements with employers for flexible hours to free time for fieldwork. The school district has also asked for interns to work in "Saturday" school -- a remedial study program.

Conclusion

The collaboration for providing training for future teachers is continuous and reciprocal. Each party has approached the discussion with the goal of providing the best possible scenario for training teachers. Although, we have not endeavored to "reinvent the wheel", we have made an effort to look at pedagogy with new eyes and not be caught in the trap of how it has always been done. There is much give and take, but never a compromise on quality of the program. The discussions will continue throughout the program as we analyze what works.

Technology and Pedagogy: The Evolution of A Curriculum

Dr. Margaret Brown and Dr. Gregory MacKinnon
School of Education, Acadia University
Wolfville, NS Canada

Abstract

Acadia University was the first laptop university in Canada. Being first has had its challenges. This paper discusses how between 1996 and 2000 a School of Education has adapted to the new technologies and made efforts to incorporate them pedagogically in their two-year after-degree teacher education program. Data gathered from review of equipment and facility inventories, demographic and curriculum documents, and surveys of students and faculty regarding background computer knowledge, attitudes, skill development, application, and innovations have formed the basis for this analysis. An examination of the first four years since initial implementation of laptop technology infusion into the teacher education program demonstrates an interesting evolution of curriculum and its impact on education students and faculty. The conference presentation graphically illustrates various survey results, and raises discussion questions about the technology/pedagogy/curriculum linkages.

Technology and Pedagogy: The Evolution of A Curriculum

Introduction

In 1996 Acadia University embarked on an IBM-sponsored laptop project, the first of its kind in Canada. By the fall of 2000, full implementation of this initiative, coined the Acadia Advantage, put Pentium laptop computers in the hands of some 3420 full-time students and 357 full- and part-time faculty. A complete rewiring of the campus has allowed for virtually unlimited network and internet access. The campus-wide project has had profound implications for the School of Education teacher education programs. Computer technology was an immediate concern, and remains so, as Education faculty seek to develop, to use, and to model the use of, pedagogically appropriate classroom strategies. This paper follows the evolution of curriculum between 1996 and 2000 as technology has taken a more prominent role in our teacher education programs.

The Setting: Acadia University

Founded in 1838 and one of the oldest universities in North America, Acadia University is located on a 250 acre campus in a rural farming community. The student population of approximately 3420 is attracted from over 30 countries around the world. The university offers 200 degree combinations, primarily undergraduate degrees, although a limited number of Master degree programs are available in most faculties. Research funding from Canadian granting agencies alone reaches approximately $2 million dollars annually. Class sizes vary of course, but average teacher:student ratio of 1:15.

Acadia University is recognized as an educational institution worthy of considerable praise. In each of the past three years, Maclean's magazine conducted a national survey
and ranked Acadia as the "best overall", "most innovative", and "highest quality" primarily undergraduate university in Canada. In 1999, the Acadia Advantage initiative was inducted into the Smithsonian Institute.

All teacher education programs in Nova Scotia are legislated as two-year pre-service professional education following a first degree (arts, science, etc.). Acadia University School of Education takes in approximately 130 students each year for a total enrolment of 260. School of Education faculty includes 18 full-time and 7 part-time professors.

The Process
For this study, data gathered from a review of equipment and facility inventories, demographic and curriculum documents, and surveys of students and faculty regarding background computer knowledge, attitudes, skill development, application, and innovations have formed the basis for this analysis. The purpose of examining the first five years of initial implementation of laptop technology infusion into the teacher education program, was to describe the pedagogical and curriculum changes that became necessary as students and faculty grew into their new roles as teachers/learners in a fully-wired and technologically-enhanced learning environment at Acadia University.

Technology Infrastructure
For the campus: Acadia University campus has 5200 data connections spread over dormitories, student meeting areas, classrooms and teaching laboratories. Laptop computers are leased by students as part of their $5000.00 tuition fee. The same model laptop computers are provided for each faculty member.

Computers Used by Students and Faculty 1996-2001

For the School of Education: Acadia University School of Education has 286 network connections and 10 wired classrooms. Equipment available includes digital projectors, opaque projectors/overheads, sound systems, VCRs, analog/digital video production, digital cameras, and scanners in teaching labs plus one in each faculty office.

Technology Support
AITT: Acadia Institute for Teaching and Technology (AITT), or more commonly known as the Sandbox, provides support for instructional design and teaching innovations for faculty. AITT has a full-time staff of eight, including one seconded member of faculty, and a part-time staff of up to 20 students. Typically to access support, a faculty member starts with an idea of how technology might improve the manner in which a particular course component

could be taught, and then works with AITT staff to develop the necessary technical design and application.

ACME: Acadia Courseware Management Environment is an on-line framework for each instructor to post contact information, course outline, course text information and materials, course notes, questions, on-line discussion groups, and tests. Staff includes 1 programmer and 3 academic computing specialists.

USC: User Support Centre has 13 full-time and 11 part-time staff. This service is used extensively by students and faculty particularly early in the academic year. For example, between August 16th and September 28th, 1999 (43 days), USC responded to 9446 calls for support.

CSS: Computing Services provides system support with a total of 16 full-time staff including 1 director, 2 managers (network services; information systems), 1 senior network analyst, 3 system analysts, 1 junior systems operator, 2 unix operator/systems administrators, 3 programmer analysts, and 3 technicians.
Evolution of Curriculum in Teacher Education Programs

1995: The School of Education computer lab was equipped with 10 IBM clones 386/486 attached to a campus computer network and a single network printer for students to access. Five Macintosh computers in a LAN were equipped with such specialized inclusive education peripherals as Touch Window, Intellikeys, Braillers, etc. Three Macintosh computers were connected to the campus network. Fifteen students enrolled in each of two sections of an elective introductory computer applications course. The curriculum was comprised of 80% skills and 20% applications. Each student's background was assessed and an appropriate skill development stream implemented.

1996: The computer lab remained the same. Introduction to Computers in Education became a required course for all B.Ed. students; four sections with 25-30 students in each. Computers were shared by three students. The curriculum again was comprised of 80% skills and 20% applications. Group tutorials addressing general areas of growth were required.

1997: AA Initiative (Acadia Advantage) sponsored by IBM began. A new small classroom with 25 network drops was provided for the now required Introduction to Computers in Education course. Network support for Macintosh was no longer available and therefore could only run Mac's in LAN or stand-alone. The curriculum was comprised of 70% skills and 30% applications. File management and email became obsolete areas of the curriculum. Workshops at beginning of the semester were introduced to ensure that all students had a beginning base of computer skills to bring to the course. Some exposure of students to the Macintosh platform was maintained.

1998: Large classrooms became available with 60 network drops. Class sizes increased to 30-35 students. Some exposure to Macintosh platform was maintained. The curriculum was comprised of 60% skills and 40% applications. Students' backgrounds in all areas seemed to have improved to an extent that much less time was spent in skill areas: word-processing, spreadsheets, databases, internet use and file management. Student attitude about computers had changed significantly in a positive direction. A new elective course in Computer Multimedia was offered in response to student demand for more applications. Although this was not a required course, two sections had to be capped at 15 students each, based on resources available.

1999-2000: Large classrooms became fully equipped with data projectors and opaque projectors, VCRs and sound systems. The curriculum continued to be comprised of 60% skills and 40% applications. However, students now had a much more positive attitude and seemed to need much less ongoing support. Professors increasingly used more technology in their teaching. Students were exposed to a wide variety of applications in the context of other subject areas. Students became very adept at using the technology in the presentation of their own work in their on-campus classes, and in their teaching for those fortunate enough to have an internship in a technology supported school.
Summary:
An examination of the first five years since initial implementation of laptop technology infusion into the teacher education program demonstrated an interesting evolution of curriculum and its impact on education students and faculty. The influence of the technology on pedagogy and on curriculum might have at first seemed linear, but it became increasingly clear that technology, pedagogy, and curriculum are inextricably linked in a continuous ascending growth spiral. A change in any one element, created new opportunities for change in one or the other of the remaining two elements, which then precipitated a change in the third, and so on. New curriculum developments can stimulate a drive to create a new application of the technology. A new way of thinking about the pedagogy can stimulate a new aspect of curriculum development and a new application of technology.

Understanding the strength and importance of such linkages has significant relevance for teacher education programs. The increasing speed with which new developments in technology occur will likely provide ongoing challenges for teacher educators. If our efforts are successful in helping pre-service teachers understand and exploit these vital linkages between pedagogy, curriculum, and technology, then we might expect the diversity of young learners in today’s classrooms to readily engage in learning activities created by teachers that address their various learning styles and capture their interest.
Multiple-Delivery Systems—A New Approach to Education Courses

Henri Sue Bynum and Raymond H. Considine
Indian River Community College
hbynum@ircc.cc.fl.us
rconsidi@ircc.cc.fl.us

Abstract: Multiple-delivery Systems: A New Approach to Education Courses at Indian River Community College (IRCC) addresses the needs of non-traditional pre-service education students through multimedia Internet-based courses in education. These courses are learner-centered and combine the synchronous format required to develop social interaction skills with the asynchronous access to information and to assignments. The course addresses multiple learning styles and promotes active student learning, while facilitating student success by providing web-based college support services online. An example, "Introduction to Education," features instructional lesson summaries and lectures using streaming video and graphics, graphic support materials, e-mail, chat rooms, message boards, and multimedia technology to address auditory, visual, and kinesthetic learning styles. A description of the web-based course and an introduction to the student support services available to students is presented. Also, this paper presents the rationale for the course components along with a description of the additional courses engendered by this prototype.

How do you develop an on-line course that uses state-of-the-art technology to address student learning styles and that uses a virtual campus to meet Southern Association of Colleges and Schools (SACS) criteria? Distance Learning challenges faculty to capture the atmosphere of a traditional classroom and to communicate that atmosphere in an asynchronous manner. An additional challenge arises when the course serves the dual purpose of providing prospective teachers with a pre-requisite knowledge base for entry into a teacher education program and of showcasing the skills that characterize effective teaching.

All too often Internet classes are little more than high tech correspondence courses that offer communication only in a half-duplex mode. In other words, the instructor poses a set of exercises and of assignments. At a later time the student completes the work and sends it to the instructor only to be forced to wait again for results. This delay yields a sporadic stimulus-response system that is mutually unsettling. The impersonality of the experience invariably results in high attrition rates.

These negatives, however, can be reversed so that the Internet experience can be rewarding both to the instructor and to the student. McArthur and Lewis point out that "information technologies can improve the efficiency of learning and teaching" (1998). The Internet-based "Introduction to Education" course from Indian River Community College (IRCC) features multi-media streaming, video, and Internet resources to promote efficient learning. Moreover, as Frayer and West (1997) suggest, students are more actively engaged in the learning process, practice more, and receive useful feedback when learning styles are matched to the learner. This course uses state-of-the-art technology to address auditory, visual, and kinesthetic learning styles, while providing synchronous and asynchronous active student learning, educational resources, and extensive support services. "Introduction to Education" uses Internet-based instructional lesson summaries and lectures, streaming video and graphics, graphic support materials, e-mail, chat rooms, and message boards to create a successful learning experience. The student is able to see and hear the instructor and take part in class discussions. Students learn various teaching methods as they engage in the activities thus improving their personal teaching skills (Collins, Brown & Newman, 1989). There is less isolation for the student, and a feeling of camaraderie frequently develops among fellow students. The intimidation of communicating that might exist in a classroom setting disappears, and the frequency and intimacy of communication among students and between students and instructor increase (Chickering & Ehrmann, 1997).
As this course was conceived and designed, the student's needs took priority. Among the design principles are those enumerated by Kozma and Johnston (1991): using multiple modalities to engage students in drills, simulations, critical thinking, collaboration, scholarship, and construction of knowledge. Subject matter, concepts, and skills were presented using various modalities and in varied format. A student who needs to utilize a visual method of learning receives visual reinforcement. The student who needs to apply a more tactile approach is accommodated as well. The clarity of the streaming audio and video replicates the classroom situation to the extent that students have reported that "it was like having the instructor in the living room." Insofar as that was the case, the design was successful. The successful completion rate for this class is among the highest for the college, whether Internet, Interactive Television, Telecourse, or the traditional classroom.

During the development phase, the quality of the streaming media was a major focus. The course must be delivered so that the quality remains consistent whether the student has a state-of-the-art computer setup or a rather marginal one with a less than 56K modem. An initial welcoming video serves to introduce the instructor to the class. Using Real Media, the quality of the video is excellent and free from the distracting jerkiness of some web-based video. Lectures for each chapter in the course text were written by the instructor and recorded in the Distance Learning studio. The recordings were carefully edited to remove extended pauses, incomprehensible phrasing, and extraneous noise. Using Sound Forge, the finished product, 9 lectures in all, was loaded into RealMedia and matched with a set of PowerPoint slides that highlighted key points in the lectures. These slides may be printed for study purposes.

The separate yet integrative components of this course include a set of video tapes provided by the textbook publisher. These videos are keyed to individual chapters in the text. Each is remarkable in that it generates fervent discussion among students. These discussions take place on the message board and in the chat room. With the instructor as facilitator, these discussions allow a personal level of involvement for everyone.

Written assignments for this course include reflections on journal articles as well as in-depth research on various cultures. Assignments are e-mailed to the instructor who grades them online and resends them to the student. Immediate feedback is crucial in distance learning. The rapid turnaround of assignments offers the distance learning student immediate reinforcement.

Student progress in the course is measured by a series of online tests. There are two testing formats available for each test, either multiple choice or essay. The student chooses the format preferred. The test is available to students during a specified number of days. Students are allowed only one attempt and receive their score upon finishing the test. A time limit is imposed for each test. The final examination is proctored and must be taken at a campus site.

The last piece of the process is the support provided by the college itself. The IRCC web site replicates campus support services through a virtual campus. Students can read the IRCC Catalog, can obtain financial aid information and applications, can check up-to-date class offerings, can register, can buy textbooks and supplies, can access educational support materials and resources, and can use library resources on-line.

The course is mounted on the Internet using Web-CT. This relatively user-friendly course presentation software offers the flexibility required for the various course components. IRCC faculty interested in developing courses for the Internet receive intensive training in the use of Web-CT and the Distance Learning technical staff are available at all times to assist, to offer advice, and to provide video and sound editing. Successful creation of these materials depends on the communication between the educational faculty and the distance learning support team. Through teamwork, technical knowledge and course content are fused to design and to develop a successful distance learning course offering. Realizing that any such endeavor will always be a work in progress, adjustments, refinements, and additional resources can be added as needed. In a sense, then, the course does not become stale. Just as the classroom can become rigid and tiresome, any web course must receive regular and critical evaluation. Student evaluations, peer review, and experiential data supply the information used to update the course.
The success of this education course, both from the instructor and the student perspective, has given rise to the development of similar courses in Mathematics, Earth Science, and Ecology. Taking full advantage of new technology, virtual field trips, real-time interactive and asynchronous classroom visits, and web-based resources all become the delivery method and the substance of the student's learning experience, transcending the limits of a typical virtual classroom.

A Holocaust Web Site: Effects on Pre-service Teachers' Factual Knowledge and Attitudes Toward Traditionally Marginalized Groups

Brendan Calandra
John Fitzpatrick
Ann E. Barron
University of South Florida
United States
bcalandr@luna.cas.usf.edu

Abstract: The Holocaust remains one of the most effective and extensively documented subjects for an examination of basic humanitarian issues. Knowledge is the key to an intelligent understanding of such a tragic passage in human history, the key to a wisdom that will never let it happen again. To address the need for quality, accessible information about the Holocaust, the Florida Center for Instructional Technology developed an extensive website titled The Teacher's Guide to the Holocaust. This study was designed to investigate the effectiveness of the website. Specifically, data were collected via pre and posttest measures to determine if access to The Teacher's Guide to the Holocaust significantly impacted the knowledge level or attitudes of pre-service teachers.

Introduction

In response to a bill passed by the Florida Legislature in 1994 (Florida Statute 233.061 requiring public school instruction of the history of the Holocaust), graduate students and staff at a major Florida university created a web-based instructional program for Holocaust education. This award-winning site, The Teacher's Guide to the Holocaust, is now an amalgam of over 6,000 files in a variety of media ranging from virtual reality tours, videos, survivor testimonies, and photos, to thought provoking teacher-resource and student-activity sections (http://fcit.coedu.usf.edu/holocaust). The site is meant to be a resource for certified and pre-service teachers, many of whom have had little or no training for teaching such sensitive material.

The instructional goal of the website is to provide a single starting point for Holocaust education with relevant background information and links to instructional resources. The content of The Teacher's Guide to the Holocaust is presented from three perspectives: Timeline, People, and The Arts. An introduction to the Teacher's Guide reads: "Holocaust study is a very sensitive subject, and the appropriateness of material is dependent upon individuals. All materials should be reviewed before use in class." In designing the site, it was hoped that, through the study of the Holocaust, students and teachers alike would be able to develop an understanding of the ramifications of prejudice and racism, and help to ensure that an event such as the Holocaust will not happen again (Barron, 1998).

The purpose of this study was to investigate whether or not pre-service teachers' factual knowledge and attitudes toward traditionally marginalized groups would be significantly changed through interaction with the Teacher's Guide to the Holocaust website. Second, the study was meant to examine the state of pre-service teachers' knowledge on the Holocaust. Third, any correlation between subjects' knowledge and attitudes was analyzed.

The Study

Participants in the study were pre-service teachers enrolled in an undergraduate course – EME 2040: Introduction to Computers in Education. All students enrolled during the spring semester, 2000, were invited to participate. Of 143 participants who began the study, 115 completed both the pretest and posttest.

Two types of instruments were developed for this research: an objective test of Holocaust factual knowledge and two scales to assess attitudes toward diversity and perceptions of traditionally marginalized groups.
On the day of the pretest, each student received a packet containing a knowledge test, one version of the attitude instrument, a lesson plan assignment sheet, and a CD containing a website. Students were encouraged to answer the questions as honestly as possible. Following administration of the instruments, graduate assistants for the class collected the test forms.

Students were required to develop a lesson plan based on the CD included in their packets. Students assigned to the experimental group were required to complete an assignment using *The Teacher's Guide to the Holocaust* website, while students in the control group developed a lesson plan based on the 4th Grade *FCAT* website. These assignments were designed so that the student needed to review and investigate the particular resource they were assigned. The Holocaust activity incorporated a question that built upon a section of the guide titled *Timeline* and required the student to read and synthesize material from each of the sections. The students were given one week to complete the assignment. Posttest data were collected during the class session in which the assignments were turned in.

**Results**

Data were analyzed using both analysis of variance and correlational methods. Group difference in changes from pretest to posttest on knowledge and attitude scores were assessed using analysis of covariance. In addition, two factor ANOVAs, (treatment condition by occasion of testing) were used to examine changes in perceptual bias toward specific marginalized groups, and correlations between knowledge and attitude scores were evaluated. Finally, individual item difficulty indices were used to guide a content analysis of participants’ performance on the knowledge test.

The results indicate that exposure to the *Teacher's Guide to the Holocaust* did not have a significant impact on either the factual knowledge or the attitudes of the subjects. The findings suggest that the limited amount of engagement required of the subjects (they had to write a lesson plan related to the material) was not sufficient to impact a change in either knowledge or attitudes. Perhaps a more thorough, directive approach to the material would be more beneficial.

Abstract: This paper examines how web-based educational environments were used to foster collegial conversations in three case studies conducted in the Graduate School of Education at Portland State University. The cases describe instructors' and graduate students' experiences with interactive, online discussions. Two cases center on interactions in cohorts (groups) of preservice teachers, while the third case highlights the course-based exchanges of inservice and preservice teachers. Reactions to online interactions are analyzed. Several important considerations are shared about how to cultivate peer collaboration and encounter success when teaching and learning with web-based environments.

Introduction

Teacher educators know that discussion is vital to learning. Now, teacher educators are exploring whether telecommunications can broaden the discussion by taking it beyond the walls of the classroom. This paper describes the instructors' and graduate students' involvement with interactive web-based learning environments, examines their reactions to this type of interaction, and provides suggestions for implementation.

Given today's busy lifestyles, electronic discussions seem an efficient way to nurture such interactions without concern for geographical boundaries or time constraints (Johnson, 1997). Use of web-based educational environments may extend learning and teaching beyond our classrooms through electronic dialoguing (Norton & Johnson, 1997). An online dialogue helps to enhance our students' conceptual understandings of issues related to preservice and inservice teacher education.

Background

Web-based educational environments are rapidly establishing a presence on university and college campuses. These user-friendly resources allow instructors to create a unique online learning forum for their students. Today, most web-based educational programs require minimal expertise on the part of the student or instructor. Teacher educators are discovering that web-based tools such as e-mail and listservs facilitate communication among instructors and students (Van Gorp, 1998). Using web-based resources is a straightforward way to supplement course content and to increase communication among students and instructors.
Instructors use the controlled environment feature of web-based technology to promote discussion and collaboration. Since user IDs and passwords limit access to the web-based environment, online conversations remain cohort-wide as opposed to worldwide. As students connect with one another in this safe and limited space, their unique personalities and feelings are revealed (Wepner & Mobley, 1998). Similarly, this forum creates a safe learning environment for students to display their work among a smaller, known audience. Features that cultivate collegial interactions include electronic bulletin board tools for communication and cohort forums; course and calendar tools for posting assignments and important dates; and student project pages for sharing ideas and displaying products. These options allow instructors to create a purposeful and learner-centered network. Web-based educational environments are more than sites to access information; they create a place for interactive communication and the construction of knowledge (Van Gorp, 1998). These online environments have the potential to facilitate learning processes as well as peer collaboration throughout the teacher preparation and continuing education programs. Importantly, students and instructors are afforded with continual opportunities for interaction and reflection across both university and field settings.

Implementation

The following three cases reveal how instructors implemented web-based environments with their graduate students. The first case explores the interactions of preservice teachers in a graduate teacher education program. The next case examines the growth of preservice teachers in the special education program. In the final case, the collegial dialogue among inservice and preservice educators evolves.

Case Study: Beginning the Conversation

Yearlong access to the bulletin board and specific features of the web-based system was established for three successive field-based cohorts (groups) in Graduate Teacher Education Program (GTEP) at Portland State University. GTEP is an intensive, one-year teacher preparation program comprised of academic work and field experiences that leads to licensure. GTEP students complete the program requirements in cohorts. During the past three years, the field-based cohorts have had 28-29 members. Though students in these field-based cohorts took course work together, their student teaching placements were spread across several school districts. As a result, students were afforded the opportunity to use an online environment to maintain a professional conversation with members of their cohort. The web-based environment provided a means for students to stay connected across the academic year and began to shape a collegial network. Beginning in the fall term, students were introduced to the electronic bulletin board in the Classroom Instruction and Technology course. During the winter term, students routinely used the bulletin board feature to support the academic and field components of the teacher preparation program. When engaged in full-time student teaching in the spring, students were able to continue and deepen their collegial discussions. Students' encounters with the web-based environment expanded each year as the instructor drew upon prior experience from the previous cohort's interactions. Through this online forum, expectations were communicated effectively, information was exchanged efficiently, and meaningful dialogue flowed effortlessly.

Communication among students and instructors improved with the inclusion of an electronic bulletin board. More positive and productive interactions emerged. After sharing learning objectives, one student provided this supportive feedback, “Your objective was clear and precise. I understood exactly what you wanted the students to do. You not only stated what you want students to be able to do, but also what and how they were going to accomplish the objective.” Students responded to posted topics and posed questions about their field experiences. When prompted to report effective teaching behaviors that they had observed, an aspiring science teacher posted, “My teacher, through modeling and thinking aloud, helps the students learn how to organize the given information and develop a “plan of attack” to solve the problem.” A foreign language student teacher initiated a dialogue about modeling. “Modeling is a constant in the foreign language classroom. There seems to be much controversy about error correction in the classroom. Should the student be corrected on the spot when he/she mispronounces or uses the wrong word?” Other students sought feedback on their performance. “I just want to make sure that I have completed all of the required assignments that have been posted and that I am on track.” Students and instructors alike used the bulletin board to convey personal sentiments. Midway through the program, one student offered his thoughts to the cohort, which generated a flurry of heartfelt responses.

I know that I have not shared with all of you what an honor it is to be associated with this cohort. Throughout the three months that we have been together, I have witnessed genuine
caring and concern for the members of our group. It bodes well for the teaching profession that tomorrow's teachers exhibit this nurturing behavior, as it was often mentioned in our discussions of effective teachers. I thank all of you for continuing to make this one of the most memorable experiences of my life.

One instructor expressed her genuine and positive regard in this way: “I really appreciate your demeanor and sensitivity when you interact with us” and “Thank you for the contribution you have made to our cohort”. Overall, students communicated more frequently and openly, were more cognizant of course and program expectations, and reflected openly on their teaching experiences.

Case Study: Preparing Preservice Teachers To Be Online Teacher Collaborators

Being “connected” with colleagues is of vital importance for special education teachers as they learn their craft. Due to the nature of their jobs, they are often physically isolated from other special educators who can potentially offer valuable support and mentorship. It is with this in mind that Portland State University’s Special Educator Program began to integrate electronic discussion into preservice experiences. Across the span of an academic school year, a cohort of full-time graduate students learned how to participate in online discussions within the context of coursework and field experiences. This case study describes how graduate students preparing to be special education teachers learned to use electronic discussion methods as a means to maintain professional connections.

The first stage of the study required students to participate in asynchronous electronic discussion available through a course environment designed for the Collaboration 1 course offered during fall term. Students learned the technical aspects of online discussion by: a) participating in practice sessions that explicitly modeled the skills of composing new messages and replying to received messages; b) being mentored by other students in the cohort and; c) using web-based tutorials. For many students, this was the first time they had participated in web-based discussion outside of traditional e-mail applications. A weekly routine was established where students purposefully participated in electronic discussions as they reflected upon the assigned course readings and web links. The goals for this term were for students to get comfortable with using web-based technology, to learn to actively troubleshoot unexpected technical problems and to begin to connect with others by participating in threaded discussions. These expectations were surpassed as students successfully posted a total of 165 messages with 68% of those messages connected to short threaded discussions (most commonly consisting of 2-3 messages each). It became clear that students were learning to interact purposefully online as they exchanged opinions and ideas.

During the second term, the same group of students participated in electronic discussions as a requirement for the Collaboration 2 course. Students were expected to build upon the accomplishments of the previous term by increasing their interactivity and deepening the conversational nature of discussion forum activities. The total number of messages posted across the term (n = 328) increased substantially from the previous term suggesting that students were becoming more adept at using the electronic bulletin board. In addition, an evolution in the quality of the discussions began to occur as threaded discussions became driven by “hot topics” with more students asserting their perspectives. There were still threaded discussions with 2-3 messages but now, deeper electronic conversation threads with 7-10 messages were regularly occurring. In an effort to generalize online discussion skills outside of the course discussion board, students were also required to subscribe to a listserv or discussion group of their choice.

During the final term of the program, students actively contributed to the electronic discussion board as they immersed themselves into a full-time student teaching experience. The culmination of their online discussion experience created a rich dialogue among student teachers and university faculty inspired by the ongoing epiphanies and quandaries of each student teacher. Student teachers began to expand their electronic conversations into the reality of day-to-day teaching responsibilities. In the process of reviewing hundreds of messages posted during the 10-week student teaching period, six recurring themes emerged from the discussion threads including: 1) requesting help; 2) sharing common experiences; 3) expressing opinions; 4) broadcasting useful information; 5) sharing ideas for innovation; and; 6) offering support to others. In one instance, a student teacher that felt empowered by her online experience created a listserv for student teachers and first year special educators. Overall, the explicit teaching and guided practice of electronic discussion skills prior to student teaching transformed the discussion group from being “technologically inexperienced” to a cohort of savvy collaborators.
For the past three years, students have had the opportunity to take an elective course titled Applications of the World Wide Web for Teaching and Learning in PSU's Graduate School of Education. Over the years, the course format has evolved into a flexible format approach that combines face-to-face and online class sessions. About 20-25 students have enrolled in this 10-week course each year. Although a majority of the students have been inservice teachers, undergraduates and preservice teachers have participated in the course each year (approximately 30%). Because the content of the course focused on web-based learning, it also seemed appropriate to have the course serve as a model of web-based teaching.

During the first year, students met face-to-face each week for the first three weeks of the course. Class activities included locating and evaluating web resources and learning to use the email, bulletin board, and chat tools included in the online course environment. The fourth week of the course was held online, to test the bulletin board sharing and email assignments with chat discussion format to see how it would work. While the email and bulletin board discussions were successful, the chat sessions were not. Due to equipment or access challenges, almost 50% of the students failed to access one of the chat sessions. Those who did access the chat session found the challenge of typing messages and tracking the conversation awkward. During the next face-to-face session, students brainstormed and established criteria for improving the chat session format: 1) sessions were scheduled for various days and times to allow access and keep the number of participants to about 4-6 students; 2) students who did not have adequate access at home or work were encouraged to use campus labs; 3) during the chat sessions, students included the name of the person they were responding to when appropriate (chat etiquette). Three online sessions that applied these formatting changes followed, with better use of the chat function.

The course was redesigned for the second year with three of the ten class sessions held on campus: the first, mid-term, and final class sessions. This allowed time to learn how to use the course tools, begin to create a community, and set expectations for weekly online sessions. During the online weeks students were expected to: 1) send email to the instructor sharing progress on course assignments; 2) participate in bulletin board discussions of readings focused on issues such as equity, ethics, copyright, and child safety; 3) participate in a chat session discussing the work they were doing for course assignments. By applying the lessons learned from the previous years chat session's attendance improved, and conversations were more coherent. Yet, the quality of the discussions was still primarily chat (e.g., How are you? What movies have you seen lately? Were your kids out of control today?). While this did help us maintain a feeling of community, any significant dialog related to course issues was minimal, and most sessions lasted only 15-20 minutes.

Changes to this course during the third year focused on the need to initiate and sustain a more professional dialog during chat sessions. Course readings, bulletin board postings, and chat assignments were modified to establish the students themselves as both teachers and learners. Each session focused on an issue of the week, with students taking turns being the expert or sharing their experiences with a given issue. The resulting discussions were rich in content and quality, and frequently lasted longer than the scheduled thirty minutes. By centering each week around a specific subject with students as experts during chat and bulletin board discussions, and observing appropriate chat etiquette, chat sessions have evolved from simple conversations to professional discussions centered around issues related to web-based teaching and learning. As a result, this course now serves as both a useful learning experience, and an appropriate model of web-based learning.

Discussion

Teaching with web-based technology requires planning, implementation, and revision. Several important lessons were gleaned from teaching with web-based environments. 1) Start small and expand its use routinely. Instructors need to introduce their students to a limited number of features of the web-based system before adding additional components. 2) Create scenarios that foster student success with technology. Initial instruction that guides students to access and respond to messages on an electronic bulletin board works well in face-to-face sessions. 3) Engage students with meaningful work that naturally draws upon technology resources. Electronic discussions need to center on authentic, educational issues that resonate with students. 4) Ensure equity of access to technology resources. Instructors need to become knowledgeable about what resources are available to students and actively support their access to those resources. 5) Find ways to incorporate technology seamlessly into both the academic and field components of preservice programs. 6) Model technology's use for students, and problem-solve technology problems as quickly as possible.
Instructors need to focus students' attention on learning to use the available technology in order stay connected to their developing collegial network. 7) Reflect upon the experiences and outcomes of using web-based resources when planning its continuation.

Finally, student response rates and evaluative comments attest to the positive impact of their web-based interactions. Online environments appeal to a range of audiences as evidenced by numerous university courses and multiple student groups tapping web-based systems. Overall, web-based educational environments provide a forum for discussion among colleagues and expand the opportunities for learning.

Abstract: Over the past several years, I have attempted to raise both the computer knowledge level and the computer comfort level of preservice teachers by: 1) integrating technology into my own teaching, 2) using technology to foster preservice teacher inquiry and high level thinking, and 3) using technology to encourage preservice teachers to become educational leaders. This report describes several of the activities such as threaded discussion, publication of lesson plans on the Internet, access to lesson plans and further readings, and use of e-mail based class discussion and their impact on preservice teachers' perceptions of the role, use and purpose of technology in the classroom. Analysis of preservice teacher feedback following courses that require the use of technology in many different learning activities demonstrates that although undergraduate preservice teachers enter the program with slightly more developed computer skills than graduate preservice teachers, it is the graduate preservice teachers who are able to articulate how technology might be integrated into their own teaching.

Keywords: Integration of technology, Technology and teacher preparation, Technological literacy

Introduction

Like many teacher preparation faculty across the nation, I have decided not only to talk the talk but to walk the walk with respect to technology by transforming my literacy courses so that preservice teachers experience information technologies in support of learning and teaching (Quettsch, 1997; Zellner, Denton & Zellner, 1999; Gipe & Lamare, 1997; Rossiter & Bagdon, 1999). Multiple national and state reports such as Transforming Learning: Technology Integration Across the Teacher Education Curriculum (1999), Resources for 21st Century Teachers (1999), and Technology Competencies for Connecticut Educators (1997) and research (Vagle, 1995; Quettsch, 1997) state that in order for preservice teachers to become comfortable and capable with information technology, teacher preparation faculty must model innovative teaching that is facilitated and mediated by information technologies. In keeping with these recommendations, I have redesigned my literacy courses to make use of the Internet and other digital resources. I regularly use technology in my teaching and students are required to use a variety of technological tools in order to complete and submit assignments (Powers, 1998; Vagle, 1995; Northrup & Little, 1996).

Transformation of Courses and Teaching

Educational use of technology has been integrated into all of my undergraduate and graduate preservice teacher education literacy development courses. All courses can be accessed at the following address: URL: http://www.sje.edu. All course syllabi are on the Internet with direct links to scholarly and consistently available web sites for literacy information, research data, lesson plans, assessment information, national issues in teaching and assessing English Language Arts (Rossiter & Bagdon, 1999). In addition, research (Gipe & Lamare, 1997; Vagel, 1995) has shown that use of e-mail, e-journals and the Internet have been found effective instructional tools; therefore, all online syllabi contain links to all assignment, evaluation rubrics, required method of submission of assignments including email and the process for accessing course threaded discussions or e-journals.
Data Gathering: Preservice Teacher Technology Skills Self-Assessment

At the beginning of each semester, students complete a technology skills self-assessment which requires them to appraise their knowledge and expertise in the use of the Internet and email as having extensive experience, moderate experience or needing help. In addition, students were asked to respond to the following open-ended prompt:

When I (you) think of the role, use, and purpose of technology (the Internet and email) in the classroom, I think (I am concerned) that.

At the end of the semester, students are asked to discuss how the class affected their knowledge and expertise of educational technology, the role, use, and purpose of technology (the Internet and email) in our class, use of email to submit and receive assignments and updates from the professor and the use of Internet for further readings, the threaded discussion, accessing and submitting lesson plans. In addition, students are asked to respond to the same open-ended prompt as at the beginning of the semester:

When I (you) think of the role, use, and purpose of technology (the Internet and email) in the classroom, I think (I am concerned) that.

Data Analysis

Preservice Teacher Technology Skills and Attitudes, Beginning of Semester

The results for one semester in Table 1 show that for the most part approximately 88% of graduate and approximately 91% of undergraduate students rate themselves as having extensive or moderate experience with computers. My students have computers at home. Some have several email accounts and can design web pages, use email to communicate socially with colleagues and friends, use the internet to complete class assignments, gather news information, look up personally relevant sites such as a child’s school web page, order books, research topics of interest to family and friends, and use support group networks. (Cuban, 1999)

This project, also, involves the analysis of unstructured data including response to an open-ended statement about the innovation (integration of technology into courses) in order to develop an analysis or understanding of the feedback from students at the beginning of the semester and at the end of the semester. The structure for the data analysis is the Concerns-Based Adoption Model (CBAM): A Model for Change in Individuals (Table 2).

### Typical Expressions of Concern about an Innovation

Table 2: Adapted from Taking Charge of Change by Shirley M. Hord, William L. Rutherford, Leslie Huling-Austin, and Gene E. Hall, 1987. Published by the Association for Supervision and Curriculum Development.

Although my students are relatively proficient and successful technology users, the data analysis using the Concerns-Based Adoption Model (CBAM): A Model for Change in Individuals shows that at the beginning of the semester both undergraduate and graduate students are most concerned with the consequences or negative impact of technology on students and with how the use of technology in the classroom will affect them personally (Table 3). Many students are concerned that technology will be misused by adults preying on children, make children too dependent on it, or that children will not have sufficient access to technological training, or be hurt in many other ways such as,
"I am concerned students will rely on the Internet a great deal during research - rejecting books and articles."

"I think they need to be closely supervised by their teacher or some other adult because there are a lot of thing on the Internet that they shouldn't be looking at."

"The Internet is a wonderful aid and (but it) does not replace imagination, creativity and time spent working hard for the student."

"I am concerned that children spend too much time at home on the Internet using it for a social tool."

"I see a danger using computer time as a reward of lack of as punishment because it doesn’t give kids the right motivation for learning."

With respect to the personal concerns as indicated in Table 3, at the beginning of the semester undergraduate and graduate preservice teachers are concerned with how educational technology will impact them directly rather than just its impact on students. Many undergraduate and graduate preservice teachers said, I am concerned that

"My fear and limited knowledge about the Internet is my greatest fear about becoming a teacher. It is something that I really need to work on. I don't know enough about the Internet to properly assist the students."

"I am a bit concerned that computers at some point will replace teachers and I think the human contact is just as important."

In addition, graduate students expressed management concerns such as

"I am concerned about sifting through all that is out there to find information that is appropriate to the lessons I'll be teaching."

"There is so much out there and it is so time consuming."

Finally, neither undergraduate nor graduate students seemed to posses much information about the application of educational technology to their own future teaching. Although graduate students did speculate about possible uses of email and the Internet as indicated by the following statements,

"Email can be used effectively in the classroom when students need to do research, and to connect them with other classrooms on over the world and of emailing pen pals in other states, cities, etc."

"Hyperstudio and downloading of worthwhile links from the Internet can be used effectively in any classroom to extend and enrich specific units of study at a very low cost."

"Using the Internet for research for the older students and to go along with themes in the classroom for elementary students."

Data Analysis: Preservice Teacher Technology Skills and Attitudes, End of Semester

Focus on Instructional Use of Technology

Although I am always grateful that course evaluations are done at the end of the semester not at the beginning, Table 4 shows that student feedback with respect to the use of technology in my literacy classes is extremely positive. Students say,

"I think the technology is certainly enhancing the learning. This is good in that it is making the class aware of the information to which we have access. Technology is affecting our learning in a positive way."

"Technology aspects are refreshing. Many of my profs hate e-mail, are afraid of attachments, and so on. I feel that technology has extended the classroom to my home and increased my educational opportunities. I love it."

"Technology is having a tremendously beneficial effect. At first I was uncomfortable using the computer, but now I am at ease. I find it enjoyable and relaxing. I also think it's really cool to be able to post ideas on the discussion forums and respond to others ideas. I wish more professors would use the email and Internet to make their course materials and themselves more accessible to students."

"The technology certainly enhances the learning process and I am forced to stretch to learn...to become computer literate. this can only make me a better teacher."

It is interesting to note that almost half of the graduate students who tend to be older than undergraduate students refer to the use of technology in terms of enjoyment and discuss a delight in learning something new. I would speculate that this might be due to the fact that the undergraduate students have been surrounded by the technology and view it in very ordinary terms. Whereas, the more mature graduate students may still be able to recall typing papers on a typewriter and are appreciative of the wonders of a simple word processor. And, although some graduate students stated that the use of email unnecessarily complicated assignments and caused stress, over 60% of them appreciated its timesaving and efficient nature and the immediacy of communication with peers and the professor.

Table 4: Use of email to submit and receive assignments and receive updates from professor

Submitting lesson plans for publication on the World Wide Web proved to be the most exciting technological innovation for graduate students.

"Well, I did it successfully and was published! I guess that just about says it all for the impact!"
"Lots of satisfaction knowing I'll see it posted. When grandma surfs the web in Michigan, she'll see it!"

"It was fun to have my lesson plan accepted by ERIC. I can't wait to see it posted."

"Creating a lesson plan with the thought of submitting helped to motivate me. I could see adapting this as a motivating technique for my students."

On the other hand, the attitude of undergraduate students toward this activity may be summarized in the words of the following student,

"I think it was unnecessary. I think it should be an option for you if you want to do it but you shouldn't have to do it."

However, a few students find that the integration of technology is having a negative impact on their learning and would prefer a stand-alone computer course to this instructional method. For example,

"I feel it is inhibiting my learning. Some of the things we uncover are interesting and informative but after a while it just becomes time consuming and monotonous."

"Sometimes I feel a little bit overwhelmed with the amount of time I spend on the Internet."

**Conclusion: Focus on Implications for Future Application of Education Technology by Preservice Teachers**

At the end of the semester, some of my students demonstrated some dramatic changes as shown in Table 3. Although educational consequences and personal concerns are still the main concerns about the role, use and purpose of technology, these concerns are of a different nature. The concerns about perceived possible negative effects of the technology diminish greatly for both graduate and undergraduate preservice teachers. What does emerge in terms of education consequences are concerns about the impact of limited access to computers for some segments of our populations. These preservice teachers are giving voice to their social consciences as evidenced in the following words,

"I'm afraid many of the urban schools will be robbed of the possibilities and activities offered."

"How do I level the playing field for those students who have no access to computers or no desire to become computer literate?"

And, graduate students' personal concerns increase greatly in that they are concerned about being able to keep up with the rapid pace of technological innovation. As one student stated,

"I assume that by the time I am teaching (2 years) technology will continue to advance at an alarming rate."

Finally, as indicated in Table 3, graduate students seem to be able to articulate many specific ways that they foresee being able to use technology in their future classrooms. For example,

"Most definitely I will implement an email system in my classroom or an informal communication similar to it. I plan to include the Internet in some long-term projects that include research. I bought the print shop and will create motivational banners and certificates. I want to create a website with my class. I think that would give them a sense of pride and foster a cooperative community."

"I have already begun to collect educational software to be used for grades 1-3 which is where I hope to teach. I plan on providing TECHNOLOGY TIME for my students each day. I will allow 2-3 students to work on a computer and explore the wonders of technology. I'd also love to have students begin to learn proper ways to type. I'd like to offer a typing tutor program to 2nd and 3rd graders."

"I will use technology in my classroom through computer software such as Bailey's Bookhouse."

Unfortunately, this was not the case with undergraduate students who did not seem to make this intellectual leap. Undergraduate students tended to view educational technology in very general terms such as,

"Email and the Internet are very good tools for learning and gaining current information."
"It is good to have as an addition to traditional ways of research and teaching."

It would seem that undergraduate students need a somewhat different preservice experience with technology before they can speculate on how they might be able to apply it to their own teaching in the future. This experience has provided a direction for future research and has great implications for my efforts to use the integration of technology into my teaching as a vehicle for developing educational technology skills of future teachers.

Abstract: This paper examines three years' experience of collaborative teaching and learning of ICT on a PGCE course leading to qualified Teacher Status. Groups of students intending to teach ICT as their subject specialism have worked with groups training to teach Modern Foreign Languages to develop MFL teaching and learning materials that make effective use of ICT. They have then worked together in local secondary schools, using the materials to teach pupils from across the secondary age range (11 – 19).

This paper examines how these experiences change the attitudes to ICT of Modern Foreign Language students and how it affects their subsequent use of ICT to deliver MFL teaching and learning in the secondary school classroom.

Introduction

At Sheffield Hallam University we are in the third year of a project in which a group of student teachers with ICT as their specialist subject, work with the Modern Foreign Languages (MFL) group to support their ICT development. This includes the development of suitable teaching materials within the university and visits to local secondary schools to support the MFL students’ use of ICT in teaching French, German and Spanish. The initial results, reported during the first year (Chatterton, J & Willan, C, 1998), were very encouraging and the project is very much "on-going". The work has been developed and extended in each of the last two years and this paper discusses the student experiences to date and their changing perceptions of the possible role of ICT in their teaching.

In 1998 (DfEE 1998) it became compulsory for all students in initial teacher training to achieve a range of competences in using ICT, both to support teaching and learning in their specialist subject area and for their own professional development. In September 2000, a new National Curriculum for England and Wales (DfEE, 2000) came into force that made it compulsory for all pupils to be “given opportunities to apply and develop their ICT capability through the use of ICT tools to support their learning in all subjects”. The modern foreign languages document goes on to say that:

“Pupils should be given opportunities to support their work by being taught to:

(a) find things out from a variety of sources, selecting and synthesising the information to meet their needs and developing an ability to question its accuracy, bias and plausibility
(b) develop their ideas using ICT tools to amend and refine their work and enhance its quality and accuracy
(c) exchange and share information, both directly and through electronic media

1763
(d) review, modify and evaluate their work, reflecting critically on its quality, as it progresses. 

All those involved in initial teacher training must ask, how are we to ensure that our trainees develop their own skills and the necessary professional judgement to know how, when and where to make effective use of ICT in their teaching?

ICT and Modern Foreign Languages

It is important that ICT is used genuinely to support and develop MFL skills and is not merely a token gesture. Many examples of the latter have been seen where, for instance, pupils spend 30 minutes drawing a picture, then use only a few words or a single sentence of French to describe it. Pachler and Field say that it is important “… for the MFL student teacher to ensure that pupils using information obtained particularly via CD-ROM and/or the internet have actually understood the material and developed and/or consolidated linguistic skills, knowledge and understanding in the process of using this technology.” (Pachler, N. & Field, K. 1997)

In fact, there are many opportunities for pupils to make good use of ICT in supporting their learning of MFL. A non-exhaustive list of examples might include:

- The World Wide Web provides easy access to a range of authentic original sources (though there are issues about which sites are appropriate and usable at different levels).
- E-mail allows pupils to have direct and authentic contact with native speakers, allowing both the development of language skills and increasing cultural knowledge and awareness.
- Multimedia packages provide great help in catering for differentiation needs.
- Text manipulation packages help pupils to develop reading skills by text prediction and to develop memory skills through having to fill in gaps in a text having viewed the complete version for a time etc.
- Word-processing allows pupils of all abilities to redraft written work with relative ease (without going through the “red pen stage”!) and to produce a well presented finished article.

Cajkler and Addelman, however, make the point that “… many teachers may be wary of the computer and lack the skills and confidence to make full use of it in their teaching.” (Cajkler and Addelman, 2000)

A recent report of an inquiry by the prestigious Nuffield Foundation deals at some length with the issue of technology and the importance of its role in language learning, making a number of recommendations for enhancing its use in a variety of ways. It says that “ICT has immense potential to enhance language learning … it moves the focus from teaching to learning …” However, it goes on to say that “The full potential of ICT has yet to be realised in languages. Levels of use of ICT in language learning vary dramatically from sector to sector and from one institution to another.” and that “In schools there is evidence that logistical problems still make it difficult to provide levels of pupil access needed for success.” (The Nuffield Foundation, 2000)

It is in this context of compulsion from the government, resistance from some teachers and insufficient facilities in schools that our students have to demonstrate their ability to use ICT in all aspects of their professional development.

Development of the Project

The co-operative teaching and learning project is now in its third year. In the first year of the project we took a decision to concentrate on information handling skills. This had a number of advantages for both groups of students:

- information handling skills are easily applied to real-life and rôle play situations
- they can play a valuable part in encouraging target language use in MFL teaching and learning;
- the teaching of information handling skills forms a central part of the ICT school curriculum
- the MFL students were almost universally lacking in experience of using ICT to deal with information
- ICT-based information handling skills are currently under used in schools.

The sessions were entirely based within the university and it was left to the students to make use of the skills within their school placements.

In the second year of the project, the scope was widened to include using word-processing, art packages and html to prepare good quality teaching materials, including a small web-site. While students reported relatively high levels of WP skills on entry to the course, their view of what a word processor could do was limited: it became apparent that they had not considered the use of such things as call-outs, text boxes, flowing text around graphics etc. Work by the ICT students helped the MFL students to gain experience with such techniques within the target language. The MFL students, supported in the classroom by the ICT students, then used the materials to teach a number of sessions in a local secondary school. This year, the scope of the university-based sessions is effectively the same, but the school-based sessions will be extended to include a much larger group of pupils.

The Shared Sessions

It was clearly important, for both groups of students, that they developed the skills and attitudes that would enable them to match the government's requirements for the award of Qualified Teacher Status. The IT students were asked to plan and deliver the sessions, to create any necessary materials and to evaluate the effectiveness of the teaching and learning. In doing so, the sessions would meet very many of the standards laid down in DfEE circular 4/98, although this might be regarded as fortuitous as the original sessions were actually planned before we had sight of the document.

From an ICT viewpoint, the sessions covered a wide range of topics from basic computer skills, through text and image manipulation to data-base and web-site creation and manipulation. However, these were presented in a format that focussed on the types of activities normally found in a modern languages classroom – creating worksheets and games, setting up rôle play activities, searching for and organising information sources in the target languages etc. This sort of activity matches closely the expectations that schools have of ICT teachers: they not only teach the pupils, but also have a part to play, formally or informally, in developing the ICT capabilities of their colleagues in other departments.

For the linguists, the sessions would tackle directly their weaknesses in ICT, as revealed in the IT skills assessment done at entry to the course. The sessions would also give them some insight into how a relatively low level of ICT expertise could be used prepare good resources and to provide a good teaching and learning experience. They would also enable the students to practise their new ICT skills in the classroom, while being supported by ICT specialists.

Two example databases have been jointly developed by the students: in the first year students created a very simple “Hotel Room Booking” database; last year the new students created their own version of this and then went on to create a tourist “Campsite” database with links to on-line, commercial databases. These were intended for use as a stimulus for pupil rôle play activities across a wide age-range. For example, within the classroom one pupil would have a cue card / rôle play card telling him/her to request, from a tourist office, a campsite with various specified facilities. The other pupil would use the database to find a campsite appropriate to the needs of the “customer”. The national curriculum document states, in programme of study (PoS) part 1 that: “Pupils should be given opportunities to take part in activities in the target language that, where appropriate, combine two or more of the four language skills....” The rôle play activity fulfils the need in that both pupils are using speaking and listening skills within the context of a two way conversation and the “tourist office employee” is also using reading skills as s/he searches the database. The “Hotel Room” database would, of course, operate in much the same way, although with different vocabulary. With older children, the on-line elements allows them to interrogate live databases for details of campsites and to add the information to their own database, perhaps targeting the language for younger pupils to use. Thus they meet all four aspect of the language curriculum – listening, speaking, reading and writing – as well as many of the ICT aspects.
Gains — Skills and Attitudes

At the start of the one-year, postgraduate training course all students are asked to complete a self-assessment sheet in ICT: this is repeated towards the end of the year. The returns have been examined to look for changes in perceptions of ICT skills by the MFL students and to compare the MFL students with those from other groups who had not had input from the IT student group. It was decided to compare the MFL group with the English student group, as both tended to have non-technical backgrounds and, on entry, similar knowledge/attitudes to IT.

Over the three years, the initial assessment of ICT skills has shown no significant difference ($p = 0.5$) between the PGCE English and MFL and the course planning documents showed a similar level of expected ICT input, except for the joint IT/MFL sessions. Comparisons of the figures on the exit assessment with those at entry has shown that, while both groups gained in ICT skills, the improvement has been much more significant for the MFL group ($p < 0.0001$) than for the English group ($p = 0.025$). A direct comparison of the two groups at exit showed also that the MFL group’s perceptions of their own ICT skills was significantly higher than the English group’s ($p = 0.024$).

In the second year of the programme, the ICT and MFL groups worked together in language classrooms in a local school, with a number of different year-groups (grades). These sessions produced a marked enthusiasm from the pupils, apparent gains in language practice and a very positive attitude by the teaching staff involved. Indeed, the school staff retained the materials for their own use and they have been keen to be involved in further sessions. Methods of teaching which support or encourage pupil participation are important and, again, the effect has been noted elsewhere. “Many teenagers, particularly boys, who may be reluctant to engage in classroom interaction and are not inspired by conventional language teaching materials, have a keen interest in computers as well as excellent screen and keyboard skills.” (The Nuffield Foundation, 2000) The ICT and MFL students, too, were very positive about university and school-based sessions, both in terms of “enjoyment” and in perceived gains.

Exit figures for this year’s students are not yet available, of course, but initial survey data shows considerable positive feedback from the early sessions. After some 30 days in school, of which half was actual whole class teaching time, the Modern Foreign Languages students were asked to complete a questionnaire relating to their experiences, attitudes and use of ICT in a teaching context. Replies were received from 20 out of 22 students.

Considerably more than half reported that they were using computers frequently to make worksheets and flashcards for their teaching and all of the others were making at least occasional use in this context. Many also made overhead transparencies, language games or used ICT to present language in other ways.

In terms of ‘monitoring, assessing and recording’, one of the required competences, the pattern was rather more patchy. Few had, as yet, taken on ICT use for this purpose, although two were making frequent use in other administrative contexts.

About half of the trainees had used ICT with pupils to meet teaching and learning objectives, mostly on only one or two occasions thus far, though one student was working every week in the ICT Lab with a MFL group. Pupils had been involved in such activities as:

- designing birthday cards, using the internet to search for information;
- presenting statistics gathered from a class survey conducted in the foreign language;
- word-processing a description previously done for homework;
- playing language games found on an internet site;
- writing coursework assignments;
- creating a database from a survey of class pastimes;
- moving text boxes (in text matching exercises); and
- writing the class timetable in the foreign language.
All trainees, with one exception, intended to use ICT with classes as they continued through their placement but some expressed their uncertainty about how possible it would be in view of logistical difficulties – in particular access to computers. This fits with observation in a number of other contexts, such as quoted from the Nuffield report (ibid.) or by Cajkler & Addelman “Many schools are unable to offer full access to the computer to language teachers.” (Cajkler and Addelman, 2000)

Some two thirds of the trainees said they had continued to develop their personal ICT skills during their time in school. This was done variously by independent practice, by working with the school IT co-ordinator, by working with their mentor or by working with other students. Two students had bought their own computers to further enhance their skills. More than half of the trainees reported that their skills had been considerably enhanced and/or they had learnt new skills in the joint sessions at the University while all the others except two felt that their skills had been extended to some extent. Of the two others, one reported that s/he already had very high level skills and the other felt s/he was “treading water”. About two thirds of the students felt more confident and/or more enthusiastic because of the sessions and, of those who felt that this was not so, it was because their enthusiasm and/or confidence was already at a high level.

The Modern Foreign Languages departments in which the trainees were placed showed a wide range of involvement in the use of ICT to achieve learning and teaching objectives in MFL. The departments were almost exactly evenly split between those using ICT frequently, those making occasional use of ICT and those never doing so. Some students felt that they had themselves contributed to developing their department’s ICT use. Current evidence for this is rather thin, as, at the time of writing, this year’s trainees have only completed a short period of time in their schools. However, examples of contributions to the work of the departments that has already been done includes:

- providing print-outs of materials from German websites for departmental use;
- sharing ideas with the new Head of Department in the school; and
- storing copies of electronically created worksheets on the school’s computer for other department members to use.

Conclusion

The students’ immediate, enthusiastic response to the sessions initially encouraged us to continue to develop and extend the work. However, it is not just enthusiasm: a number of measures have all indicated that the students make good progress in their ICT skills and confidence and that they are able to demonstrate this new confidence in the stressful setting of their first teaching placement. Comparisons with other, apparently similar, students show to good effect the benefits of co-operative teaching and learning. In what might be seen as a constructivist setting, students are able to build on their existing skills in an open and supportive environment and to transfer these gains successfully to a variety of settings.

It remains relatively unusual for training sessions to be so universally well received by the different groups involved – our students, teachers in school and the school pupils themselves. This is due, in no small part, to the level of co-operation and mutual support achieved within the students groups themselves. It is also noteworthy that, for the first two years of the project, a relatively small time commitment within the university has produced a clearly demonstrable effect on students’ attitudes and skills several months and a long teaching placement later.

The use of ICT is now effectively a requirement in teaching and, in many schools, the ratio of pupils to computers is in single figures. As computers in the classroom, and at home, become increasingly the norm, motivational effects due to the novelty of using a computer will fall away. It will be interesting to see, then, how the upward trend in our students’ skills and attitudes to the use of ICT in their own classrooms continues this year, particularly as the three populations involved become ever more used to having computers around.

Abstract This paper presents findings of a study designed to analyze student performance from two unique perspectives: the technological perspective and the pedagogical content perspective. The student population consisted of three separate cohort groups enrolled in a computer literacy course (CS 1105) and a bilingual instructional reading course (READ 3303) concurrently. Students were enrolled in the courses during the fall 1999, spring 2000, or summer 2000 semesters. All students were preservice teachers in the bilingual education program at the University of Houston-Downtown's Department of Urban Education. During the semester enrolled, the students were required to complete several major assignments integrating technological content knowledge with pedagogical content knowledge. Assignments included the creation of an instructional lesson plan, a World Wide Web search for information to be used instructionally, and the production of a graphic organizer to present educational information. For each assignment, students were to show their mastery of the technological tool while also showing competence in a pedagogical content area. All student assignments were evaluated by both the technology professor and the bilingual reading professor. This study collected information on the similarities and differences between the grades received and comments noted by the two professors, each from a different perspective.

Introduction

The mission of the Department of Urban Education is to prepare future teachers for the urban classroom who will enhance the chances of academic success for at-risk children and adolescents in inner-city schools. Its teacher education program is a state approved Center for Professional Development and Technology. The center trains new elementary, secondary, and bilingual teachers and also provides staff development and technology support for public schools.

During the school year 1999-2000, there were approximately 432 students in total who registered in the three successive Blocks of professional development courses (91 in secondary education, 101 in bilingual education, and 239 in elementary education). To help them gain the knowledge and experiences needed to be a teacher of at-risk students, the department requires undergraduate and post baccalaureate students who have been admitted to the teacher education program and who do not currently teach on a permit in a public school classroom to successfully complete three interdisciplinary blocks in urban public schools in the Houston area. Following the model developed by Haberman (1991), the UHD-CPDT enables projective urban teachers to participate during their junior and senior years in a 27 semester-hour field-based professional development sequence in the format of blocks. The district-wide demographic line graph (see Figure 1) indicates that in the year 2000, students of Hispanic origin (approximately 120,000 students) make up over 50 percent of the student population in Houston Independent School District. This is a district that is currently a UHD partner for which UHD graduates will most likely serve. African
American students (approximately 70,000) are second, followed by Anglo students (approximately 23,000) and students categorized as Other (approximately 5,000) (http://www.houstonisd.org/ab/imnes2/enroeth.gif).

The 1990-98 Migration Scenario (see Figure 2) provided by Texas State Data Center at Texas A&M University shows rates consistent with 1990-98 patterns of total net migration and the 1980-90 patterns of ethnic distribution of migrants. This scenario predicts larger rates of Hispanic and Other population growth and smaller rates of Anglo and African American population growth in the Houston area as well as for the state of Texas as a whole. Under this assumption, the growth of students of Hispanic origin will continue to be strong in the next few decades (http://txsdc.tamu.edu/cgi-bin/prjctn2000.cgi).

Source: Texas State Data Center

Figure 2: The projected population 1996-2030 in Houston area
Bilingual education teachers are in one of the critical shortage areas in Houston. The Bilingual Education program at UHD has recently been awarded a 5-year grant by the Department of Education in the amount of $3.1 million to prepare new teachers and current teachers to better serve Limited English Proficient students. The new grant from DOE and the Gordon & Mary Cain Future Teacher Scholarship are expected to attract more applicants to the program in Bilingual Education. It is the department's urgent need to lay out the infrastructure to better support the incoming pre-service teachers. The improvement of prerequisite courses for the teacher education program and pedagogy and methodology courses are under discussion.

In order to provide its students with experience in using technology to enhance instruction and professional development in Bilingual Education classrooms, the department is blueprinting its way to integrate the educational computing component into its existing interdisciplinary block structure.

Since its conception in 1995, the department has a technology component combined with its "block" structure. The technology training is a one-hour credit course, which is held in the on-campus computer lab. The course CS1105 is described by Chen in "The Way to Go: Integrating Instructional Technology Initiatives into a Teacher Education Program." As described in the syllabus for the course, the five technology sessions are integrated into the first block for the pre-service teachers at the Department of Urban Education (http://www.dt.uh.edu/degree/urbaned/home1.htm). The course is offered in the format of five workshops of three hours each, which are spread throughout the whole semester. This paper presents findings of a study designed to analyze student performance from two unique perspectives: the technological perspective and the pedagogical content perspective.

**General course framework for CS1105**

The titles and brief descriptions of the five workshops (3 hours each) currently offered have been discussed by Bhattacharjee and Chen (2000) and are briefly summarized as follows:

**Workshop I: E-mail & Internet Discussion**
The instructor begins with an introduction to the use of different professional teachers' forums over the WWW by showing pre-service teachers how to follow the threads, respond to interesting topics, and start their own subjects. The instructor also assists students in creating accounts with a web-based e-mail program such as Hotmail and Yahoo. The instructor then demonstrates the ways to check in-coming mail, compose out-going mail, send documents as attachments, forward and respond to mail, set up distribution lists to send to multiple recipients, set up automatic signature files, and organize read e-mails into different folders.

**Workshop II: WWW & Web Search**
The instructor begins by showcasing the CS1105 class web site created just for them (http://www.dt.uh.edu/~chen/cs1105.html). The web site consists of different applications and examples of WWW uses in K-12 classrooms. Examples might include a demonstration for the bilingual education groups which emphasize Mexican culture and Spanish language arts. Students also learn how to download texts and graphics from the Internet while sharpening their web search and web research skills at the same time.

**Workshop III: Desktop Publishing & Graphic Organizers**
The instructor guides the students with the creation of a simple flyer and a newsletter while allowing them the flexibility of applying clip art, word art, colors, and content to enhance their ownership of the product. After this, the instructor explains the different looks and uses of graphic organizers and demonstrates the creation of a thematic unit with the fundamental building blocks of graphic organizers such as text, circles, lines, and colors.

**Workshop IV: PowerPoint Presentation**

---

1771
The instructor leads the students in creating two simple slides with headings, text, graphics, and charts by following an activity guide. The workshop ends with the showing of the more advanced functions of PowerPoint such as animation, sound, and transitions.

Workshop V: Software Evaluations
The software evaluation session starts with software demonstrations including Story Book Weaver, Body Works, Amazon Trails, Just Grandma and Me, and Encarta. Students are then informed about various criteria used in software evaluation. The workshop concludes with the students filling out software evaluation rubrics so that they will become comfortable judging educational software.

Analysis of Observations
During the semester enrolled, the students were required to complete several major assignments integrating technological content knowledge with pedagogical content knowledge. Assignments included the creation of an instructional lesson plan, a World Wide Web search for information to be used instructionally, and the production of a graphic organizer to present educational information. For each assignment, students were to show their mastery of the technological tool while also showing competence in a pedagogical content area. All student assignments were evaluated by both the technology professor and the bilingual reading professor. The following analysis study collected information on the similarities and differences between the grades received and comments noted by the two professors, each from a different perspective.

The following observations are based on student population that consisted of three separate cohort groups enrolled in a computer literacy course (CS 1105) and a bilingual instructional reading course (READ 3303) concurrently. Students were enrolled in the courses during the fall 1999, spring 2000, or summer 2000 semesters. All students were preservice teachers in the bilingual education program at the University of Houston-Downtown's Department of Urban Education.

From the Technological Perspective
When delivering the workshops, the technology instructor has tried to customize the activities to meet the special needs of Bilingual Education preservice teachers. For example, during Workshop II: WWW & Web Search, more culture and language related sites were demonstrated and discussed. Online resources such as Investigating Mexico (http://www.infinet.com/~baugust/mexico.html) and lesson plan archives just for Bilingual Education teachers are introduced. During Workshop V: Software Evaluations, the technology instructor demonstrated both the applications of the English version and the Spanish version of Just Grandma and Me by the Living Book, conducting student collaborative writing in Spanish with Story Book Weaver by MECC, and reviewing other tutorial/drill/practice for language learning with a critical mind to detect cultural or gender bias.

From the homework, the technology instructor can detect the different angles or perspectives taken by preservice teachers in regular Elementary Education preservice teachers and Bilingual Education preservice teachers. Teachers today face a challenge in ensuring students are given the opportunity to master basic skills. The preservice teachers are aware of the fact that some of the students in Bilingual Education classrooms do not have parent to read with them, either because the parent are too busy or do not have the reading skills. For example, in lesson plans intended to incorporate the Exploring Yellowstone CD-ROM by MECC in early childhood classrooms, regular Elementary Education preservice teachers more commonly emphasize on the knowledge parts while Bilingual Education preservice teachers have one more mission in mind, which is to enrich their students' vocabulary. Lesson Plan One (see Appendix A) and Lesson Plan Two (see Appendix B) are two original lesson plans designed by two Bilingual Education preservice teachers.

The technology instructor observed that reading/writing is by far the most popular subject when it came to picking content, whether the homework is for newsletter, lesson plans, PowerPoint, or graphic organizer. The author of Lesson Plan One sounds adept and comfortable with the content and therefore the quality of the technology integration is excellent. However, for the rare ones that take science or math
as the subject, the technology instructor can perceive that the preservice teachers are trying out a new field and are inept in doing so.

Take Lesson Plan One for example, the preservice teacher is focused, and can write an effective lesson plan with a clear goal in mind. However, the author of Lesson Plan Two has used many words but is still ineffective in grasping on a certain aspect of science. The instructor senses the need to find a balance among the subjects and better prepare the preservice teachers for the science/math subjects for them to feel more comfortable.

The technology instructor has also observed that the software mentioned in students’ work are the cartoon/game type of software that are most commonly found in the market such as Blue’s ABC Time Activities, First Grade Reader Rabbit Program, Colorful Letters and Numbers, Daily Doo, you can too!!! Alphabet. The Jump Start program series seems to be the software that has most frequently been incorporated into the lesson plans turned in by many students. Having noticed students’ limited selection, the instructor feels the need to broaden students’ knowledge of the different types of educational software including simulation, problem-solving, etc. There is also a need for the instructor to familiarize the students with the publishers of educational software, the various educational software catalogues where they can purchase specialized software through the mail, and the online software.

The instructor reminded the preservice teachers that although Spanish software is hard to find even in such a ethnically diversified city such as Houston, many educational titles can be "repurposed" to fit the needs of bilingual students. A piece of software currently available in the market can be repurposed and turned into useful instructional material for bilingual classrooms.

The technology instructor has noticed that the Bilingual Education preservice cohort group tend to have a good rapport with each other and are excellent collaborative learners in comparison with the regular Elementary Education and Secondary Education cohort groups. I have observed that they helped each other and learned from each other more often then the other cohorts.

The technology instructor is very pleased with the quality of work turned in by the preservice teachers. When compared with the work turned in by regular Elementary Education and Secondary Education preservice teachers, it does not represent any less of quality at all. During classroom instruction, the technology instructor can feel the preservice teachers’ eagerness to learn. This eagerness to use technology is carried on to Block II and Block III as the technology instructor hears all the time from other instructors’ comments on how well their students can use technology. It is hoped that the same attitude can be carried on to their future classrooms.

From the Pedagogical Content Perspective

When delivering instruction for the READ 3303 course, a focus is placed on how to deliver reading and content instruction to school-aged learners in an effective and meaningful manner. Bilingual pre-service teachers must be trained and knowledgeable in all of the same areas as a mainstream teacher. In addition, the bilingual pre-service teacher must also have special training and a higher emphasis on educating special populations including culturally diverse and linguistically diverse student populations. As the bilingual students vary widely in their educational backgrounds, it is important to present instruction using a variety of methods that take learning styles into consideration. This includes making allowances for visual learners, audio learners, and tactile/kinesthetic learners.

One way to approach instruction in this manner is to make use of instructional technology. By incorporating graphic organizers into instructional presentations, pre-service teachers are better able to visually represent content knowledge to their students. Also, by being familiar with what is available through the web and how to do web searches on specific teaching methods, the pre-service teachers are able to take advantage of instructional activities designed for audial and tactile/kinesthetic learners. There is a wealth of information as well as activities already developed and available on the web for use with language minority students with various learning styles and other educational needs. Being able to access this information has been very beneficial to the pre-service teachers when developing lesson plans in reading and in the content areas. Also, being able to communicate electronically with peers, other professionals, and professional organizations has enabled the students to tap into an additional wealth of human resources and share/compare ideas with others for the purpose of enhancing the instruction that children receive in the classroom. For these reasons, participation in the instructional technology
workshops has been invaluable to the students and has also improved their performance in the reading content course.

An observation from the pedagogical point of view is that when the students in the reading content classes are given an assignment to research information related to reading and bilingual education or bilingual populations, they seem to feel comfortable with the task from the beginning and have confidence in their own skills to use the internet web resources. Also, when students need assistance in developing additional ideas or activities related to a certain lesson plan, they are quick to consult their peers, other professionals, and professional organizations for ideas. They make these consultations using their e-mail skills and Internet search skills.

Another observation is that the students tend to use their newly acquired technological skills with rigor. Although the quality of work in the content area demonstrated by the students is high, it is also clear that overall, students tend to spend more time on the technological aspect of the assignment than the content itself. Students have stated numerous times that they enjoy using the technology so much, that they will spend extra hours developing the technological aspect of the assignment, sometimes to the point of overshadowing the actual reading content. This attitude of enthusiasm toward the use of technology is welcomed by the reading content professor, because as mentioned before, the quality of work in the content area is still very high. Also, these students are in their first semester of the blocks. As they move into the second and third semesters, they will be much more adept in using the technology for instructional purposes. The reading content professor hopes this enthusiasm for integration of technology continues in future semesters and into the field as well.

Conclusion

The efforts of the technology instructor and the pedagogical content instructor in conducting the analysis of the Bilingual Education preservice teachers' learning outcomes in a computer literacy course is part of the planned infrastructure to better support the in coming pre-service teachers. With nearly 10% of children ages 5-17 nationwide speaking Spanish at home, and as many as 22% in California and Texas, teachers today face a challenge in ensuring students are given the opportunity to master basic skills. Technology is a great tool in helping the students in Bilingual Education classroom facing the challenge. I noticed that computer is one of the topics that are in urgent need of support for this special population. There are lots of expectations regarding the use of computers in bilingual education. Proper use of computer can help bilingual students to retain their cultural heritage, to fit into the new community, and to become more productive citizens.

Reference

Appendix A
Lesson Plan One

Title: Virtual trip to the Yellow Stone National Park

Subject: Reading and writing: Students expand vocabulary through reading, writing and listening

Grade Levels: 4th. Grade bilingual

Learning Outcomes: Bilingual students get an exposure to a variety of wild animals and their Habitat. New vocabulary will be learned in an effective and enjoyable fashion.

Instructional Materials: CD- Yellow Stone Park, Projector, and computer with windows 3.1 Minimum.

Prerequisite Skills: Basic knowledge of mouse function (i.e.) left button once for select Twice to select.

Pre-computer Activities: Teacher presents poster board with animal drawings with the definition Or explanation of the same. Teacher directs attention of students to the advantages we have with technology by demonstrating the versatility and effectiveness of the software by projecting to the screen a colorful photo of a wild animal and its habitat. Teacher models for students how by clicking different animal name on the menu a new wild animal and its own characteristics can be appreciated on the screen. Teacher repeats this step with 2 or 3 animal to be sure students understand what the software provides.

Activities and Procedures: Teacher divides class into small groups of 2 to 3 students.
Each group selects 2 to 3 animals, which as a group will investigate using the software. They will discuss some characteristics of each animal (i.e.) color, size, food they eat, weather, habitat peculiarities etc. etc. As a group they pick 2 characteristic of each animal and write one page about their findings.

Extension Possibilities: Teacher plans a field trip to the local zoo with the objective that the students Will analyze animals with some a particular characteristic feature to analyze and report back to the teacher.

Closure: Teacher highlights the advantages of technology. Teacher explains that Without having to travel to far places and risking their lives they were able to visit and explore exotic wild lands and animals.

Evaluation: Students are graded on the content and depth of their work.

Appendix B

Lesson Plan Two

Lesson plan Two

Grade Level: 2nd grade bilingual
Purpose: The second grade students will be able to use the Encarta software to do research for their science project.

Objective: The second grade students will use information found in the Encarta software to do research on their science project.

Focus:
- Ask students what other ways they can conduct research other than using encyclopedias, textbooks, journals, newspapers, etc.
- Have them come up with ideas as to how a computer can help them do research.

Guided Practice:
- As a class we will find information on the planets.
- As a class we will discuss the information we found.

Independent Practice:
- Students will each find valuable information for their science project using the Encarta software.
- Students will print information they need for their project.
Tech Ambassadors: The Next Generation of Professional Development

Professor Joanne Clemente
School of Education
New York Institute of Technology
United States
jjclement@nvit.edu

Abstract: This presentation will focus on the results of an ongoing pilot study that involves training both pre-service and in-service teachers, as well as K-12 students, in the integration of technology in the classroom. Through the institution of the "Tech Ambassador" program, students in our undergraduate education program team up with in-service teachers and use a problem solving approach to provide technology enriched lessons in these teachers' classrooms. Through observation of and active listening to the needs of current teachers, these pre-service teachers brainstorm lesson ideas with their college classmates, research appropriate technology solutions, practice delivery, and finally model the utilization of technology in the P-12 classroom under college faculty supervision. The project exemplifies a constructivist approach to learning that uses real-world problems, project-based curricula, and an active learning environment.

Background:

In a January 1999, a report by the Department of Education entitled, Teacher Quality: A Report on the Preparation and Qualifications of Public School Teachers, indicates that "few teachers (20%) report feeling well prepared to integrate educational technology into classroom instruction." Further, A National Survey on Information Technology in Teacher Education, a Milliken Exchange on Education Technology report which commissioned ISTE to survey schools, colleges and departments of education in the U.S. states, "Most institutions report that IT is available in the K-12 classrooms where student teachers get their field experience; however, most student teachers do not routinely use technology during field experience and do not work under master teachers and supervisors who can advise them on IT use." It further concludes that, "the most important finding of the survey is that formal stand-alone IT coursework does not correlate well with scores on items dealing with technology skills and the ability to integrate IT into teaching." Recommendations include:

- "Student teachers need more opportunities to apply IT during field experiences under qualified supervision" 
- "In order to provide models for change, researchers, professional societies, and education agencies should-on an ongoing basis-identify, study and disseminate examples of effective technology integration that reflect the current needs in both teacher education and K-12 schools." (Moursund, 1998)

Another survey conducted by AACTE in found that "Too few students are expected to use computers, televisions, and VCRs to share information in their campus classroom settings." (American Association of Colleges for Teacher Education, 1997) Supporting that finding, a 1997 NCATE task force on technology in teacher education report found that "teachers-in-training are provided instruction in 'computer literacy' and are shown examples of computer software, but they rarely are required to apply technology in their courses..."(National Council for Accreditation of Teacher Education, 1997)

Rationale:

As a fully experienced technology teacher, I want to begin by emphasizing that teaching with technology requires more effort and is fraught with more problems than using chalk, an overhead projector, or a book.
Technology does not always work on request, is rich with glitches that can result from the system, the software, as well as from teachers' or students' lack of experience. A teacher must be willing to give up the tried-and-tested methods he/she currently uses to enter into a somewhat intimidating, somewhat frustrating "unknown" world that utilizes technology. Without experience or trouble-shooting skills, it is easy to get overwhelmed and give up. It is also difficult for many teachers to relinquish "control" when a student is more technologically proficient. Whether we agree or not, we can not overlook these realities. Teachers need more preparation time and more assistance. We cannot just expect results without a commitment to help them develop these new strategies and skills. While many school programs offer staff development programs outside the classroom, this program suggests doing it "live" so that everyone participates and collaborates and the setting is "real." The pre-service teachers' lack of classroom experience is compensated by the current teachers' classroom control and the current teachers' lack of technology skills is supplanted by the student teachers' knowledge, and both of them are supported by technologically proficient college faculty. It's win-win for everyone.

A Response to the Need:

The TechAmbassador Program was developed in response to a twofold need: to train undergraduate pre-service teachers in the classroom use of technology, and to integrate technology into the P-12 classrooms where further education/assistance may be necessary. These needs were authenticated through direct observation and experience. As a member of the full-time faculty in the School of Education at New York Institute of Technology, I have the gratifying experience of training teachers in the use of technology in the classroom and supervising pre-service teachers in the Student Teaching semester. This allows me entrance into various classrooms in and out of the NYC school system. In addition, I am able to draw on my varied computer experience in the corporate world as well as that in the education system.

Firstly, what I have discovered throughout my experiences is this: In-service teachers often have neither the adequate time nor the resources to implement new programs in their classrooms. They are severely limited by the restrictions of curriculum, the pressures of testing, the lack of technology skills and the lack of planning time, in addition to minimal choices in hardware/software. Many are trained in technology outside the classroom or in graduate settings where assignments are theoretical or specific to particular software products rather than based on needs. These teachers need assistance in a way that supports their efforts by bringing training and resources to them in the classroom.

Secondarily, through questioning and observation, I have come to believe that while pre-service teachers are taught the practice of teaching, they do not adequately practice their teaching. This practice, whether classroom or field-based, even within the scope of one educational sequence, is often not only limited but lacking in organization for a rounded experience. Several factors contribute to this, namely: lack of overall planning, varied faculty supervision, cooperating-teacher flexibility and placement issues. Additionally, these same pre-service students, while they may personally use technology, rarely practice its use in the P-12 community. Lessons presented, even in the student teaching experience, tend to follow the pattern of the cooperating teacher, which often only promotes the under-utilization of technology in the classroom. The need for pre-service teacher technology training is now being stressed by the new ISTE standards for pre-service teachers and most states carry that requirement. Several studies (as cited above) have uncovered this under-utilization of technology at the pre-service level. In fact, parenthetically, any teaching experience in P-12 classrooms is often limited. "Art Levine, president of Teachers College at Columbia University, would like to see a greater emphasis on clinical training with apprentices and mentors, similar to the kind of experience new doctors get." (Kantrowitz and Wingert, 2000). Why not, then, work technology into teaching at the grass roots level, so that new teachers endeavor to teach as they are taught at the pre-service level—with technology.

All students (P-12, undergraduate, and graduate) need to be prepared to meet the demands of the 21st century as well as the present. Many national mandates and initiatives support the notion that more technology is needed in schools, but even if technology resources were unlimited, the methods of utilization would still be severely lacking. This initiative focuses on a method of training pre-service and in-service teachers, as well as P-12 students, in the utilization of technology both as resource and as tool.

The Methodology:
The Tech Ambassador Program trains the undergraduate students in our education program who are aspiring to become teachers in the proper utilization of technology in the classroom, and sends them into the classroom of current teachers as “ambassadors.” These students model the integration of technology under college faculty supervision, in various classrooms thereby reaching and teaching current teachers and their students. The program provides many benefits and fulfills the following objectives:

- Each pre-service teacher will be trained in the integration of technology and the curricular requirements.
- Each in-service (current) teacher would collaborate with pre-service teachers to determine which units of study would best utilize the strengths of technology and then host this guest student teacher to demonstrate, model and deliver unit plans that utilize this technology.
- Each pre-service teacher will develop or do research to find specific units that effect technology integration into targeted classrooms.
- Each pre-service teacher will develop plans for implementation in a target classroom.
- Each student teacher will practice delivery of the developed or adapted units in a supportive college setting.
- Each pre-service teacher will model appropriate technology usage for current teachers so that the learning curve is reduced.
- Each pre-service teacher will deliver 2 units under the supervision of the classroom teachers and NYIT faculty.
- Each pre-service teacher will provide turn-key, tested, technology enriched lesson plans for future utilization by current teachers.
- Each in-service teacher would receive assistance and learn how to effectively integrate technology into the curriculum.
- Students in the classroom will become more proficient in using technology as a resource and a tool to meet curricular goals.
- Students in the classroom would experience collegial, cooperative collaboration as a means of achieving goals. Teachers would model what they preach.

These objectives can be measured by the degree to which pre-service teachers meet the goals of the college course, by the degree to which technology is utilized in the target classrooms, and by the increased competence of pre-service teachers, classroom teachers and P-12 students. As the study progresses, all planned units and the journals describing their implementation will be assembled in a book, available in print and online. Surveys of computer integration are distributed to current teachers, the results of which will also be documented. As the study continues, each pre-service teacher will assemble a portfolio to be reviewed by school district administrators for evaluation for potential employment, as an authentic assessment.

The ISTE NETS Standards addressed:

II Planning and Designing Learning Environments and Experiences: Pre-service teachers collaborate with in-service teachers to enrich established curriculum content with technological tools.

III Teaching, Learning and the Curriculum: In-service teachers implement curriculum plans infused with the technology through collaboration with and hosting of TechAmbassadors who deliver technology enriched lessons to K-12 students in their classroom.

V Productivity and Professional Practice: Pre-service teachers practice and model technology integration in real K-12 classroom settings, thereby enhancing both their and their collaborating in-service teacher's professional development.
The TechAmbassador Project:

The TechAmbassador Project is a pilot study to test a new method of addressing the needs of in-service, pre-service and P-12 students. The study can easily be replicated in a college-level education course. The course in which this pilot project was launched is entitled “Curriculum Articulation through Multi-Media” which carries a Field Experience requirement of 20 hours. The students in this class were elementary education students with the exception of one Occupational Education major (Culinary Arts). On the first day of class, the project was introduced, indicating that this study was a fresh approach for completing their field placement hours. During this time, students, as TechAmbassadors, would each be required to collaborate with a partner teacher to help infuse technology into his/her classroom curriculum. All students were eager to be part of this innovation, but at the same time, apprehensive. For example, one wrote, “I feel it will be a great experience…”, while another said, “I feel it is a great program so long as the co-operating teacher has a little knowledge at how to use technology.”

I immediately contacted four schools to request placement for my “TechAmbassadors”. In one case, I revived a contact, a District Director of Technology, who I had met at a conference; for others, I contacted 2 principals who had each hosted one of my student teachers at their respective schools. Finally, I made a new contact for the Culinary Arts student. In each case, the project was well received; however, the Culinary Arts teacher felt he was “helping my student out”, while the others voiced more enthusiastic responses, such as “This is a dream come true!” and “Can I have more?” Placement was a lot easier than expected. In each case, my ambassador and I met with the partnering teacher, who had been invited by the principal contact, to introduce the project. I must stress that partnering teachers were not selected based on technology competency. In fact, the opposite was closer to the truth. I reviewed the course syllabus with each teacher, showing that at least two lessons would be targeted for integration: one mid-semester, one at the end of the term. Additionally, I explained that pre-service TechAmbassadors would be keeping a journal, practicing lessons in the college setting and preparing a research paper. Subsequently, each ambassador filled out a survey and delivered a survey to his/her partnering teacher so that I could ascertain each participant’s level of computer literacy.

For most part, cooperating teachers were anxious for technology integration and looked to the pre-service teachers immediately. We established the guideline that the TechAmbassador would complete at least four period-long observations prior to the delivery of the first lesson. The observations were for orientation purposes in that the TechAmbassador needed to learn the classroom routines, observe the strategies used, observe those students who could use special attention, test the technology, determine the content into which technology could be integrated, etc. TechAmbassadors would then reflect on observations in a journal, prepare to write an observation paper as well as their “research” paper (which basically chronicled their quest for information on their anticipated lessons), and of course, design their turn-key lesson plans which would integrate technology into existing curricula. It should be noted that these lesson plans are four page documents; half of which is targeted to in-service teacher preparation, the other half to student learning.

Each week in class, I facilitated discussions on the weeks’ observations, with each TechAmbassador taking turns at center stage. Anticipated lessons were discussed and practiced in class, while issues of integrated curriculum, classroom management, thematic units were introduced as part of the coursework discussions. As the need for software was uncovered, I, as the instructor, would work with the student either alone or with all students as a group to demonstrate the software that could be used. Often times, students would show each other what they learned independently. During one lesson, we hosted a representative from PASCO who demonstrated computer-connected tools for scientific recording of variables such as temperature, distance/depth, heart rate, etc. At the end of this session, I arranged for a “donation” of a specific software product. (One ambassador was extremely interested in using it in his P-12 classroom.)

The course structure, thus followed a quasi-constructivist approach, in that while certain guidelines and discussions were established by the syllabus, the majority of class time was used to uncover real-world classroom problems and learn about possible technology solutions.

In each partnership between the in-service teacher and the ambassador, relationships developed; some surprisingly quickly and well-connected. In most cases, students were asked to teach even prior to the first scheduled “observed” lesson, which naturally occurred in or about the 7th week of the semester. Fears were soon allayed. Remembering that these ambassadors are undergraduates, there was indeed a certain amount of questions about expectations, grading policies, hours in class, but for the most part, they “assumed the roles”. One particular student was extremely frightened about presenting to a fifth grade class, until one day, she came to my class,
wearing a great big smile, saying, “I taught two lessons today!” Apparently, the partnering teacher trusted her enough to have her teach a Math and an English lesson. Having observed the class, and establishing rapport with the teacher, she was able to do it with little difficulty. The students begged her to stay and do more! Was she changed by the experience? Incredibly so! When I observed her official “technology” lesson, the students remained completely engaged, she assumed control, and the teacher exclaimed, “They behaved better for you than they do for me!” Personal satisfaction! In addition, as an outsider, I observed that while the TechAmbassador introduced the lesson, the teacher busied herself with her own work. But when the technology was introduced, the teacher stopped, sat, and watched attentively. Incidental professional development! I highlight this case simply because it demonstrates an incredible (r)evolution.

Initially, this ambassador was scheduled to work with the computer teacher for a social studies lesson, but since he really did not need assistance, he suggested a newer teacher as an alternative. This “new” teacher was a veteran teacher of 19 years, but this was her first year at this school and she had not yet acclimated to the school’s policies and procedures. She accepted this ambassador so reluctantly that it was 3 weeks into the semester before the ambassador could negotiate a time to observe at a convenient time for the teacher. This teacher happened to have considerable computer background at her previous position but did not seem to see the connection between engaging students with technology and classroom control. In her survey, she wrote that she could incorporate technology (NEC) into some lessons but “I have to gain control of the class first.” Simply stated, this was a major victory for the TechAmbassador.

Other partner teachers had previous training in particular software programs. All responded that they wanted more technology training. One teacher had only seen PowerPoint modeled in her college career, and although she uses word processing and the Internet at home, she has never used these in her teaching. She uses Acelerated Reader (a self paced tutorial) with her class once a day and visits the librarian occasionally for a computer lesson. Another teacher became so frustrated with needing technology “repairs” that she rarely used the computers in her room. Our ambassador noted that merely “rebooting” the machine fixed the problem she was describing. This in-service teacher had a remarkably quiet, industrious third grade class who worked conscientiously and listened attentively. The Ambassador and I both noted how well behaved the class was. This teacher knew KidPix, The Amazing Writing Machine and Encarta in addition to being able to use the Internet. Her philosophy of “teaching the students a new software program and nothing else” seemed to work for the Tech Ambassador as well. This ambassador spent a session just teaching KidPix and then was able to teach Limerick composition, leaving children to use the KidPix program on their own after a brief refresher. Previous to this lesson, the teacher had attempted to use “The Amazing Writing Machine” with her class, only to find that the Techie at the school erased the student work when called in for a repair. The teacher was understandably frustrated once again, especially since she is so accustomed to calm and control. The Ambassador, in addressing this problem, elected to use KidPix for its “better” features, after comparing both programs for the Limerick task at hand. An example of critical thinking about a “real world problem” and other well run lesson!

One science teacher was trained in Gizmos and Gadgets, Millie’s Math House, Sammy’s Science House, Science Court, Magic School Bus but did not have a working computer in the classroom. Therefore that Ambassador partnered with the Social Studies/Computer teacher who was willing to let us use “his” lab so long as we integrated Social Studies. The resulting lesson relied on Internet Research to search for volcanoes in Central and South America, the focus of the Social Studies lessons. We had to use our imaginations!

Another teacher had only used television and video as technology tools. This was the class targeted by the student who wanted to use the PASCO equipment. The student wrote in his journal, “It is evident to me that he uses little or no (computer) technology when he teaches.” This TechAmbassador was faced with multiple problems. First, the PASCO tool arrived later than expected. When the ambassador tried to install the software associated with it, he tried that process on at least four separate computers, before he called PASCO to find out that the PC version only works with the Windows 98 Operating System. At the eleventh hour, he arranged to “borrow” a laptop from the principal of another school in the district to use for the lesson. Would an in-service teacher have the time to pursue this?—would he take the time, especially since his oceanography unit has been working just fine for several years? Unlikely. Another victory for TechAmbassadors!

Thus, the TechAmbassadors were placed in a variety of grades with students of varied abilities and personalities. Each partnering teacher had a curriculum plan he/she was using for the time we spent there, so it became our responsibility to work within that framework. With the exception of the Culinary Arts student, none of the students had taught with technology to P-12 students prior to this experience, even though many had personally used technology and had other field based experiences.
Examples of lessons at mid-term were:

Using Tom Snyder’s program, “Choices, Choices: On the Playground” for a developmentally delayed first grade class learning about cultural diversity. This program takes students through a class thinking exercise on how to treat a new student who is “different”.

Using PASCO’s EchoSounder to determine the formations and depth of an ocean floor for a unit on Oceanography that the teacher admittedly used for several years.

Using KidPix to create illustrated limericks by 3rd graders learning about styles of poetry.

Using Inspiration to develop a concept map about the Solar System and individual planets that would later become the basis for a writing assignment for 2nd graders.

Using the Internet to shop for holiday gifts for a hypothetical family to develop predictions and collaborative thinking in a cooperative learning group setting.

Using spreadsheet formulas to adjust a recipe for more or less servings with high school culinary arts students in a vocational training program.

Using an Ambassador-created Internet Hotlist to do research on volcanoes to prepare for a subsequent PowerPoint presentation with a fifth grade Science class.

The study is ongoing, therefore, at the time of this writing, only midterm reports are complete. For these mid-term observed lessons, as the faculty member in charge of my ambassador, I took the liberty of co-teaching when warranted. I believe that as a professor, it is my job to facilitate teaching and learning, to coach, to allow students to achieve success by guiding them toward a challenging goal. A self-reflection rubric assessment is factored into the mid-term grades. At times, the in-service teachers also participated in the group learning activities. While this may not be the goal of an education program that trains teachers to be independent teachers, it was the goal of the TechAmbassador program to build bridges from Higher Education to P-12 using the next generation of teachers as facilitators. In contrast, end-term lessons will be delivered as independently as possible to achieve success. Results and sample lesson plans will be posted at http://iris.nvit.edu/~jclement/techambassadors.html

In conclusion, the TechAmbassador pilot study is an initiative that brings together in-service and pre-service teachers with the goal of integrating technology into the P-12 curriculum through observation, active listening, collaboration, modeling and reflection. Presenting at the AACE conference will provide much needed feedback to improve the format for yet another “generation” of TechAmbassadors.

Acknowledgements:

I extend heartfelt thanks to the teachers who opened their doors to us. We truly appreciate the warm welcomes we received and the expert guidance you provided. I especially would like to thank the first generation of TechAmbassadors for their courageous and steadfast efforts to integrate technology into the P-12 classrooms. You embody the promise of education reform.
IT in the classroom and its implications for pre-service teacher education.

Lorraine Connell, Faculty of SITE, NTU, Australia. lconnell@darwin.ntu.edu.au

Abstract: I completed six months in a classroom as part of my Doctoral research and I attempted to use IT as a teaching tool with a class of year 1/2/3 children. As a lecturer within the pre-service teacher education course at NTU I left the classroom in 1986 when computer technology was just entering our classrooms as a new teaching tool. In the pre-service course I have been involved in working with students in a competency based IT unit without knowing how IT can work as a tool in our classrooms. This paper attempts to explore my practical experiences and the implications for pre-service teacher education.

IT in the classroom – my knowledge of IT in theory.

In my return to the classroom I was interested in exploring the role that computers could play in the teaching and learning experience. I recognised that the use of IT would require a ‘mind shift’ and a challenge to explore new models of teaching and learning.

Unless educators are willing to reconceptualise curriculum and instruction (and perhaps the organisation and process of schooling itself), they will probably need to be quite patient in expecting transformation to occur through the use of computers and other tools. (Mojkowski, 1990, p14.)

Computers as word processors, as a means of presenting knowledge and understanding through a variety of software programs, and as a source of information (through the internet and CD Roms) means that the teacher is confronted with a totally different teaching tool. A rethinking of the teacher’s role in the classroom is part of this whole ‘mind shift’. Rather than passively listening to the teacher, students are encouraged to discuss and learn ideas from themselves and for themselves through technology. This requires teachers to become participants in the learning and to create collaborative learning situations for both the teacher and student. Mojkowski (1990) refers to the need for teachers to tackle the pedagogical issues of education in the light of these new technologies. He argues that teachers, administrators and researchers have not addressed these three major questions,

1. How should existing curriculum and pedagogy be redesigned to accommodate and maximise the use of the technology?
2. What are the most appropriate ways to bring technology into the curriculum?
3. How can computers and other new technological tools be used as catalysts to revitalise existing curriculum and instruction within and across subject areas?

Dede (1997) would argue that these ‘mind shifts’ also require a total rethink of current ‘chalk and talk’ practices as well as the pedagogical issues that relate to teaching and learning and how technology can enhance the learning environment. Dede (1997) continues to state that teachers will need to reconsider their own teaching strategies, their role in the classroom, the contributions students make to their own learning, the authenticity of the curriculum and their evaluation of student work. Teachers will also need to participate in and recognise the value of collaborative learning.

Zimmerman (1998) argues that schools need to use technology for at least three major reasons,
• As a catalyst for the larger education reform effort of restructuring the way students learn and teachers teach
• Good tools give talented and caring teachers and administrators the power to create successful learning environments
• Students who do not have technology skills will be unable to compete in the economy of the future

Technology in the classroom can allow for more flexible, collaborative and self-directed learning experiences for the learner. Technology can,
• provide other entry points for a learning experience,
• provide opportunities for parents to become more involved in the educational process from home and work via the internet and
• allow for more involvement with the wider community again via the internet and CD Roms.

Warlick (1999) would argue that technology can provide extensive experiences in collaboration. Limited classroom computers require that students often have to work in teams to access information from web sites or CD Roms. As they access the information in groups, they discuss the relevance of information, how to record the information and they make decisions about who does what. In a multi-age classroom more able readers can assist those less able. Students with more advanced computer skills can assist others. Using email facilities means that interaction is occurring with others as well as collaboration as the children compose responses to email messages. Technology can support and enhance student learning, thinking and problem
solving in many ways and teachers need time and training to explore how this can be done. Too often attempts have been made to train teachers in technology skills, when what is needed is time for teachers to think creatively about using technology to enhance what teachers already do — provide for meaningful learning experiences for every child. (McKenzie, 2000) This emphasis on meaningful learning experiences is fundamental to the learning process and it is important to realise that technology can enhance the experience not take it over.

IT offers the teacher another tool to assist in the preparation and planning of meaningful experiences for all children. It can provide many opportunities for students to explore and present knowledge in a variety of ways it provides unique opportunities for

- collaboration
- a child-centred approach to a learning experience
- a flexible learning experience, and
- motivation.

And so I entered my classroom with my research and understanding of IT. I saw the role of technology as a new tool that would allow for more flexible learning to occur as well as more collaborative and self-directed learning experiences for the learner. I used technology to provide another entry point for a learning experience and to allow for more involvement with the wider community by accessing and communicating with them through the world wide web. The reality of the classroom provides the teacher with opportunities to explore these new ideas.

I had four Macintosh computers that were connected to the internet and to the school’s server. All computers had CD Rom access as well as Microsoft word, excel and powerpoint software. I had a small bubblejet printer that worked occasionally. I had a number of personal educational CD Roms as well as access to some school CD Roms from the library. While I often prepared learning experiences that allowed for student direction, I was often frustrated by the equipment. The computers would freeze, access to the internet was often slow, the sound would not work, and/or too many children were around the computers. When the computers worked the learning experience was successful. However I often found the effort involved in planning activities very time consuming.

Activities that I planned for included,
- Activities for reading, maths and or spelling where the children rotate in groups.
- Sending and receiving emails.
- Using as a drawing tool.
- For information gathering through CD Roms and the internet.
- Morning activities — learning games.

From my own reflection during my teaching and research it was evident that some collaborative and self-directed learning did occur when the children worked together during computer activities. Some children continued to pursue research on their computers at home, others were keen to bring in CD Roms with relevant information while others produced further powerpoint generated booklets at home. The children also recognised that they could communicate with their parents, teachers and pen pals from interstate through emails and some children sent emails to the classroom from home during the weekend, or when they were sick. Internet searches, which allowed children the opportunity to access information from the wider community was difficult at times because of the old computers and irregular internet connections. Lack of teacher expertise in utilising the computers and inadequate technical assistance and equipment made it difficult to utilise the technology fully.

However the children did progress; by the end of nineteen weeks all children were able to write up their own stories to send as an email to parents (the initial task in Week 3 took one week, our final newsletter in Week 19 took one hour!) and three children were trained in how to access a CD Rom through the school server, indicating improvement in the use of technology within the classroom.

Implications for pre-service teacher education.

The unit offered at a first year level for our pre-service teachers is a compulsory unit. However the IT component is only six week in length, with a weekly three hour tutorial. Students can access the six topics on-line and either attend or not attend tutorials. The topics include,

- Cut, paste and graphics.
- Emails with attachments.
- Searching the internet and CD Roms.
- Powerpoint and prolight.
- Hyperstudio.
- Databases and spread sheets.

These topics were chosen three years ago after consultation with the Education Department IT personnel.
When I returned from the classroom this unit was the first I taught and I found I was able to give students direct experiences of IT use in all of the above topics. This skills-based unit enables students to utilise the open-ended activities on-line, in their own time and to their level of understanding and competence. The students final portfolio is a sample of all these topics around the theme of ‘ME’, which provides the students with a useful resource for when they enter schools for practicums. This approach to IT is reflected in the use of specialist IT labs and teachers in Primary Schools and I experienced the value of these labs alongside classroom use where follow up activities related to the topic and curriculum area can be pursued.

I now have considerable more confidence in talking about IT in the classroom having had the experience and having tried out what I am talking about. I have also been invited by colleagues to talk about IT in other subject areas and I feel that this will probably be the greatest implication from my experience in the classroom.

It is imperative to re-look at our approach to teacher education and to explore a more integrated approach, similar to the way we encourage our students to work in the classrooms. IT can provide a tool for this integration as reading is integral to the internet and/or CD Rom research required in all subject areas, maths activities through spreadsheets and databases as well as tables and statistics. As the lecturer in Arts Education I can use IT to explore drawing and design techniques, visit an art gallery through the web or a CD Rom and create soundscapes through specialised music programs. Teachers recognise that teaching and learning is always about change and IT is but another tool to add to our growing list of skills, knowledge and understandings. Our classrooms in primary schools and Universities have the opportunity to be exciting places of change and discovery as we work with IT in our teaching and learning.

A Planning Model for Integrating Technology and Educational Methodologies in the Pre-service Teacher Education Program

Pamela P. Cook
Notre Dame College of Ohio, USA
pamsweim@aol.com

Integration of technology into the classroom has been promoted, written about, encouraged, and in some cases mandated for the last 25 years. Standards have been developed by the National Council for Accreditation of Teacher Education (NCATE) and the International Society for Technology in Education (ISTE) to address educational reform at both higher education teacher education programs and PreK-12 learning environments for the inclusion of technology into the learning process. At the university level, constructivist teaching methodologies have been introduced in pre-service teacher foundations and method classes, and technology literacy classes have been added to the pre-service teacher education requirements. Yet findings indicate that teachers who integrate technology into their K-12 teaching on a regular basis are in the minority (OTA, 1995). As Lortie (1975) documented twenty-five years ago, "teachers teach as they were taught". Traditionally, teachers teach by lecture and incorporate technology as an "add-on" or isolated entity from the total learning process. Recent research has identified that attitudinal issues, such as teacher beliefs (Ertmer, Addison, Land, Ross & Woods, 1999, pp.54-72) have hindered the goal of integrating technology and curricular goals in a more enhanced student-centered learning environment. Teachers must re-examine how they plan and deliver learning objectives and need a procedure on how to alter their own teaching practices to include new educational methodology paradigms that use technology as a tool in a restructured learning environment.

Development of the Planning Model

As an education department faculty member of Notre Dame College of Ohio, I am the coordinator of the technology endorsement certificate program. One of the biggest challenges I face has been to help teachers and pre-service teachers identify a process they can use when planning for integration of technology in the curriculum. After spending several weeks introducing the students to the technical aspects of technology (what is a computer system? what is a network?) and educational methodology paradigms (constructivism, directed teaching), the students needed "something" to link educational theory with the creation of a student-centered learning environment that included multi-sensory stimuli and tools; allowed for multiple paths for learning; fostered student collaboration, inquiry-based learning, and critical thinking; and provided students with authentic, real world learning experiences. That "something" was a planning instrument to help them rethink the total lesson in terms of learning objectives, classroom activities, educational methodology, assessment rubric and technology effectiveness.

The Planning Model

In development of a planning model to encompass methodology, standards, technology and learning environment, I looked at 3 stages in the planning for learning process: (1) Knowledge Acquisition and Research (2) Knowledge Organization and Analysis and (3) Information Presentation and Assessment. Learning objectives begin in Stage 1 with students acquiring knowledge in some manner - through lecture, books, interviews, surveys, Internet, etc. The knowledge acquired is then organized in Stage 2 in some fashion for analysis. Organizational components can include reports, spreadsheets, databases, etc. After analysis a synthesis of new knowledge is then presented and evaluated in Stage 3. The presentation/assessment vehicle might be a test, oral presentation, document, web site, slide show, newsletter, etc. In each of the 3 stages of the model, lists of example components were developed with accompanying attributes. These component attributes included: learning objective, type of methodology, and NETS Connecting Curriculum and Technology standard with accompanying performance indicator.

Application of the Planning Model

The Modeling Instruction with Modern Information and Communication Technologies (MIMIC) Project involves a consortium of 5 colleges in the Cleveland Area colleges, including Notre Dame College of Ohio, which provide pre-service teacher education program. MIMIC, funded by a US DOE Preparing Tomorrow's Teachers to use Technology
(PT3) grant, targets three populations that supply teaching models for pre-service teachers: (1) Higher education faculty who deliver methods and foundations instruction; (2) K-12 teachers who supervise field experiences; and (3) Higher education Arts and Sciences faculty. Drawing on the National Educational Technology Standards (NETS) for teacher education developed by the International Society for Technology in Education and in-service professional development efforts generated by Ohio SchoolNet, the MIMIC Project has been designed to implement a context-based and content-specific approach for modeling the integration of technology for pre-service teachers. As coordinator for the MIMIC project at Notre Dame College of Ohio, a small Midwest Catholic liberal arts college, I serve as the mentor of university faculty and cooperating teachers of field experience for pre-service teachers, to support and train them in modeling technology to pre-service teachers.

In my role as mentor, teachers had to re-examine their way of teaching in terms of identifying that curriculum goals, technology integration standards and educational methodologies need to be a unified concept. Each MIMIC Project teacher designed and implemented 3 lessons that modeled technology to pre-service teachers. The planning model ensured that participating teachers would be exposed to a consistent, effective process when planning and revising their lessons. While each teacher selected their topic and grade level, their choices of components were linked to specific methodologies, standards, and technology components that were unique to their specific learning environment. The model provided a consistent framework to plan not only “what”, but also “how”. As mentor, the model helped me identify skills that the MIMIC Project teacher needed at each stage of the process. I could design training/support activities that would meet the needs of individual teachers - these needs included not only technology skills, but also classroom management and alternative assessment skills. After implementation of the lesson, the teacher and mentor could evaluate whether different component choices would have been more effective in unifying methodology and standards. Reflection and evaluation within a framework allow the teacher to "tweak" their succeeding lesson designs to create more effective results while developing confidence.

Benefits of the Model

The benefit of a planning model for the integration of technology and educational methodology paradigms that is linked to a body of standards is that it provides a consistent, step-by-step procedure for a teacher to re-examine what and how they are teaching. The students in my classes provided the following feedback after using the planning model: (1) gave teachers a starting point for lesson planning (2) allowed them to customize - plug-in individual components (content area, grade level, student procedures, assessment methods, teacher delivery style) (3) identified the choices they can make in each stage of the lesson planning process in terms of methodology, standards and technology (4) identified the skills needed as components choices were made and (5) helped them become independent planners.

The cooperating teachers and university faculty that were exposed to the model reiterated the benefits listed above and also added the following: (6) the incremental nature of model increased their confidence that they could effectively add a component that not only fit with their learning goals, but used a technological tool and (7) they could easily structure their existing learning goals into the model framework

Conclusion

The model provided a flexible framework for both pre-service, cooperating and university teachers as pre-service teachers relied on the model for comprehensive planning and existing teachers used the model to unify what they currently were doing integrating curriculum standards and technology initiatives. The components and attributes provide dynamic entities that are added to and modified as technology, standards and methodologies change. As more data is gathered through the MIMIC Project and classroom teaching experience, the model will be updated to enhance its use as a planning instrument.

Abstract:
Recent efforts in the development of national and state curriculum standards focus mostly on the content taught in each discipline and are meant to define the skills and knowledge of the discipline to be acquired by every student. For this to happen, school curricula must be aligned with these standards. In order for the students to gain these skills and knowledge, teachers must acquire a body of knowledge that encompasses what is defined by content standards plus the pedagogical skills that will allow teachers to guide their students in the acquisition of the discipline's skills and knowledge. This paper focuses on the current state of teacher preparation programs and the requirements needed to teach computing and information technology.

INTRODUCTION

The United States continues to lack an agreed upon and well disseminated national curriculum standards in computing and information technology from which to build a foundation in our schools. This is so even though professional organizations have called for infusing computing education at the pre-college level (Tucker, 1996 & 2000; Stephenson, 1997; Deek & Kimmel, 1998 & 1999). The Nation at Risk Report issued by The National Commission on Excellence in Education (NCEE, 1983) recommended “that the state and local high school graduation requirements be strengthened and that, at a minimum, all students seeking a diploma be required to lay the foundations in the Five New Basics by taking the following curriculum during their first four years of high school; (a) 4 years of English; (b) 3 years of mathematics; (c) 3 years of science; (d) 3 years of social studies; and (e) one-half year of computer science. According to the Association for Computing Machinery (ACM) Model High School Computer Science Curriculum (ACM, 1985a), “The need for computer science education is similar to the need for education in the natural sciences. The proposed ACM curriculum takes the form of a recommended comprehensive one-year computing course for secondary schools. It identifies the essential computing concepts that every high school student should understand. The intention is that this course be similar in its scope, depth, breadth, and methodology to typical high school science courses. It should serve all students in the same way that introductory biology, chemistry, and physics courses do. The International Society for Technology in Education (ISTE) has also suggested recommendations for curriculum and teacher preparation (ISTE, 1992, 1997 and 2000). The guidelines developed by ISTE distinguish between computer science as a discipline and educational technology as a tool. As for pre-service programs that prepare teachers to teach computing and information technology, such
college programs are still very limited and teacher certification mechanisms for computer science education are still a long way from being implemented in most states where computing and information technology teachers still come from the ranks of other disciplines. Deek and Kimmel, 1998 and 1999 have addressed curriculum and standards issues and presented a teacher-formulated model that is currently being implemented in the State of New Jersey. This paper focuses on the issues of teacher preparation programs and the requirements needed to teach computing and information technology, giving these models and recommendations for computer science education at the pre-college level.

MODELS OF TEACHER PREPARATION PROGRAMS IN COMPUTING AND INFORMATION TECHNOLOGY

Recently, there have been increased efforts in the development of national and state content standards. The curriculum standards, both nationally and by every state, focus mostly on the content taught in each discipline and are meant to define the skills and knowledge of the discipline to be acquired by every student. For this to happen, school curricula must be aligned with these standards. In order for the students to gain the skills and knowledge, teachers must acquire a body of knowledge that encompasses what is defined by content standards plus the pedagogical skills that will allow teachers to guide their students in the acquisition of the discipline's skills and knowledge. It is understood that there must be a match between the skills and knowledge defined for the students and the acquired skills and knowledge of the teachers. At the same time, it is recognized that teachers must have a greater depth of knowledge than required in the curriculum they are teaching. Deciding what subject matters, and in what depth, is a substantial challenge for educators. For educators in computer science education the situation is exacerbated, since the discipline at the pre-college level is still ill defined, and the distinction needs to be made between pre-service programs that prepare teachers to teach computing and information technology and those that prepare teachers to use computers as an instructional tool in other disciplines.

Deek and Kimmel (1999) have reviewed the current status of secondary school computer science education in the State of New Jersey and discussed curriculum guidelines formulated by classroom teachers. This effort was intended to serve as the stepping stone towards establishing and promoting computer science as a recognized discipline in New Jersey's secondary schools. Computer science is a widely acknowledged discipline in the post-secondary education community and as a profession in our society (Tucker, 1996; Deek and Kimmel, 1998), but the same has not happened at the pre-college level yet.

The lack of recognition of computer science as a high school discipline by state departments of education may be reflected in:

• the exclusion of the discipline of computer science in the implementation of content standards;
• limited, and not well-defined in the few instances where they exist, teacher certification mechanisms for computer science; and
• limited college teacher-preparation programs for secondary school computer science.

As a result, virtually all pre-college computing teachers are certified in other disciplines. For example, the lack of teacher preparation programs in New Jersey has led to teachers of computing and information technology with certifications in diverse areas including mathematics (60% of those teaching Computer Science courses), science, business, and English (Deek and Kimmel, 1999). This situation is common to many states, and as seen in this paper, still encouraged by many states.

As previously stated, the curriculum, certification standards, and well-trained classroom teachers are essential steps towards a recognized subject area. There have been two directions taken in the development of guidelines for the preparation of teachers of computing and information technology: a recommended curriculum of courses and the identification of core competencies needed to teach computing courses. Both approaches have been part of recommendations by national organizations, and both approaches have been adopted within different states. Information and data on teacher certification requirements and teacher preparation programs were obtained from a search of the web sites for state departments of education (CCSSO, 2000). Further information was sought for those states that indicated either certification or endorsement requirements for teaching computing courses in the high schools. This was accomplished by either contacting the departments of education directly and/or contacting (and/or
accessing the website of universities with teacher education programs in those states. The later strategy assumed that the adoption of criteria for the teaching of a discipline by a state department of education would lead to programs of study offered by schools of education at universities in that state. Finally, if a university is offering a program for prospective teachers of computing and information technology, the authors have assumed that they are authorized (or at least acknowledged) by their state to offer such a program, and that such a state does provide a certification or endorsement for teaching in the field. In conducting the search, certifications and programs in educational technology were identified and eliminated from further consideration. The authors recognize that this type of search is neither comprehensive nor necessarily complete. Hence, the results may not be totally representative of the situation across the country. However, the authors believe that the results of the study provide snapshots of the current status of teacher education in computing and information technology, and serve to define future directions.

The first major document to focus on the preparation of teachers of computer science was released by an ACM/IEEE taskforce, which was concerned with secondary school curriculum and teacher certification in computer science (ACM, 1985a & ACM, 1985b). The Task Force made recommendations regarding computer science in the secondary schools and the preparation of high school computer science teachers. While the taskforce recognized at that time that many teachers are expected to continue to come from within the in-service ranks, with little training in computer science, they called on colleges and universities to begin the preparation to offer pre-service teacher certification. In recognition that the current cohort of teachers would have to be the primary source of instructors in computer science until college and universities would be able to implement teacher preparation programs, another ACM Taskforce defined a program of study for retraining of teachers (Poirot, Taylor and Norris, 1988).

Chen (1989) reported on the use of the Delphi approach to develop guidelines for establishing a model curriculum for secondary school computer science teachers. The study sought to establish consensus guidelines for the key courses for a computer science teacher certification program.

An examination of degree requirements, for different disciplines, in different states (Blank and Langesen, 1999) shows a range of 18 to 45 credits required for teaching science and mathematics in the secondary schools. It seemed that programs below 30 credits referred to a minor in the subject, and that a minimum of 30 credits would constitute a major. In fact, eight states required majors in the field without specifying the number of credits, while one state specified a “competency-based program” without stating the number of credits. None of these states' requirements listed computer science as a discipline, an indication that the recognition of computer science as a high school discipline is still not widely accepted. This listing indicates that the recommendations of the ACM/IEEE Taskforce and the Delphi approach would be consistent with a minor in computer science.

A combination of Web search and personal communications indicated that eight states delineated certification standards, indicating some fundamental training for teachers of computing and information technology in the secondary schools. Thirty-one states listed some kind of an endorsement, of which four states show both certification standards and endorsements. Of the 31 states, 10 of the endorsements appear to have an instructional technology/computer applications focus. The results of this search indicate that many states still do not require a computer science degree or a computer science certification. The nature and requirements for the endorsement are quite varied. On the one hand, two states require a specific number of semester hours (18 hours in North Carolina and 12 hours in Louisiana), while on the other hand, the computer science endorsement science requirement for six states is placed in business education. (Note that the certification requirement for computer science for Rhode Island and Oklahoma lies within business education.) One state required knowledge of programming, while another required competency in both programming and data structures. Seven states label the endorsement as instructional technology/computer applications, or computer education. Others provided no specific information on the endorsement. In this search, it was necessary to distinguish between requirements and standards that prepared teachers to teach the subject of computing and information technology versus those that prepared teachers in the use of instructional technology in the classroom. In some states, these situations appear to be interchangeable. It was decided to disregard any listing that appeared to focus on the application of technology in the classrooms rather than on the teaching of computing as a discipline. Below, we provide some specific examples.

Reports have described teacher preparation initiatives in states such as Delaware (Taylor and Norris, 1988) and Texas, Missouri and Florida (Thomas, et. al., 1993). Of those four states, we find that Delaware shows both certification standards and an endorsement in computer science. Florida lists certification requirements through the
University of Florida, while Texas provides an endorsement in computer science. Missouri appears to be using the ISTE recommendations in their pre-service program only for the use of instructional technology in the classroom. The certification requirements of Florida and Delaware are discussed next.

Variations in certification requirements are evident for the eight states identified in the study. As indicated earlier, certification requirements in Rhode Island and Oklahoma fall under business education. The description of certification on the Oklahoma Department of Education website is particularly interesting here. They provide a listing of courses to be taught in Oklahoma high schools (grades 9-12), which include Advanced Programming, Computer Programming I & II, AP Computer Science, and Introduction to Computers. For each course the exact same credentials are listed as follows:

"Computer science – a credential in business education, mathematics, or science with at least six semesters hours in computer training, or any valid secondary or elementary-secondary certificate and 12 college hours in computer training."

Certification in Florida is further developed. They provide several options to meet specialization requirements for certification in computer science for grades K-12 as follows:

(a) An undergraduate or graduate major in computer science or computer science education which includes credit in computer applications and computer programming, or

(b) An undergraduate degree with thirty (30) semester hours in computer science or computer science education to include:

1. three (3) semester hours in computer literacy,
2. six (6) semester hours in survey of computer applications,
3. twelve (12) semester hours in computer programming (including six credits in Pascal and data structures).

These requirements show that computer programming is the most prominent subject of computing. This is consistent with the arguable idea that programming is the only important subject in teaching computing and information technology at pre-college level. However, these requirements provide a starting point for addressing the discipline of computing and information technology as it should be taught at the high school level. This model also implies that a K-12 certification covers the needs of all student populations, elementary, middle and high school grades.

Three states come closest to the concept of a curriculum requirement for certification of teachers of computer science, Delaware, Maryland, and Michigan. They are also reflected in the programs offered by universities in these states. Each of them requires, as a minimum, 18–24 credit hours of courses in computer science, closely paralleling the recommendations of the ACM Taskforce. Delaware and Maryland appear to be the closest to the recommendations of the ACM Taskforce. Delaware requires either a major in computer science or a teacher education major with an 18-credit concentration in computer science. Maryland requires a 24-credit program in computer science. Both the 18 and 24 credit hour programs would constitute a minor. The Delaware requirement includes 12 hours of required courses and 6 credits of electives. The Michigan requirements are reflected in the teacher preparation programs of the University of Michigan and Michigan State University. They include courses in programming (as reflected in the first Introductory Computer Science Course), Assembly Language, and Data Structures, and 1-2 elective courses (a variation between the two Michigan universities).

Several states do appear to require some kind of computing and information technology content for an endorsement, although that might be as little as some competency in structured programming and a basic understanding of data structures (e.g., Utah). As stated earlier, North Carolina and Louisiana require 18 hours and 12 hours, respectively, for an endorsement. Louisiana actually has a “12-hour rule”, which permits a teacher with 12 credit hours in computer science to teach two classes a day in the subject. Kansas lists a set of competencies as standards that teachers must meet to receive an endorsement. The competencies include problem solving in a logical manner with a computer, computer systems, high-level programming language, development of program design.

CONCLUSIONS

State boards of education across the country are recommending a diversity of ways of gaining computer skills (having a computer science degree, taking classes or completing training program) for teachers. However, there is need to have teachers develop a common level of knowledge about the subject. In particular, teachers should be
competent in problem solving/programming, data structure, operating systems, and software applications, including the Internet. Other skills would also be required in order to teach advanced courses. Courses in these subjects would provide teachers with the ability to infuse information technology into the classroom. Unfortunately, it appears that most current computer science endorsements cover a small part of the discipline.

This baseline study appears to indicate very slow progress towards the establishment of teacher certification standards and teacher preparation programs in computing and information technology for high school teachers. Only a handful of states have requirements that could be aligned with the national standards recommended by ACM or ISTE. Not much progress has been made in the decade and a half since the issuance of ACM curriculum recommendations. Perhaps the fact that certification standards and approval of programs are usually covered by regulations or administrative code that must pass through a complex and sometimes bureaucratic process before adoptions can take place is partly to blame. But collaboration among professional organizations in education and computing, colleges and universities, state education departments and teachers can help move this issue forward. There remains another obstacle to overcome and this is the shortage in computing professionals that is facing industry and the difficulties that colleges and universities are dealing with when recruiting computer scientists is now common to K-12 schools.

Abstract: When preparing future educators to teach the concepts and principles of economics to prek-12 students, it is recommended that not only should these educators be provided with experiences in economic theory but also with skills in the area of information literacy. A brief explanation and several examples are given on how and why content area study, information literacy, and teacher preparation can be orchestrated.

Introduction

There are three perspectives to observe when preparing teachers to instruct in the area of economics education. One perspective is that of content development. Teachers must know basic principles and applications of economics. The other perspective is that teachers must have the knowledge of student skills needed to learn information and to make real life applications. And a third perspective is that teachers must have the skills needed to use the best and most modern pedagogy in order to meet the needs of students. Modern pedagogy includes the use of technology.

A teacher education program must recognize all three perspectives. Educators must not only acquire content knowledge, they must also understand the skills needed by preK-12 students to learn and apply that knowledge. Educators must also acquire, understand, and use technology to be able to instruct effectively and efficiently in the 21st century classroom. Therefore, a model teacher education program should include the study of content, the study of student skill acquisition, and the use of technology for learning.

As part of the national standards movement in education, individual states created state-based curricula that provide educators with goals and/or standards in the area of economics education. For example, Kentucky=s Curriculum Framework (Kentucky Department of Education, 1995) maintains that students should understand economic principles and be able to make economic decisions that have consequences in daily living. Kentucky educators refer to this expectation when developing curriculum plans and assessment goals. When studying economics education, preservice and inservice educators often make reference to the academic expectations as defined by their state department of education.

The importance of information literacy is demonstrated by the National Educational Technology Standards (NETS) Project. The NETS Project (Thomas and Knezek, 1999) has
attempted to draw a national consensus on the role of technology in schools. After studying the impact of technology on the education of students, members of the NETS Project proposed a set of standards to guide educational leaders to recognize and address the conditions for effective use of technology to support preK-12 education. The educational technology standards for students include six broad categories: basic operations and concepts; social, ethical, and human issues; technology productivity tools; technology communications tools; technology research tools; and technology problem-solving and decision making tools. Students are to use these technology skill areas in an integrated manner with content learning. Content Aknowing should include application in the context of learning, living, and working in authentic situations.

The significance of technology in teacher education was demonstrated in the release of the NCATE (National Council for Accreditation of Teacher Education) Task Force on Technology and Teacher Education=s report, ATechnology and the New Professional Teacher: Preparing for the 21st Century Classroom,@ (NCATE, 1997). This report explains new understandings, approaches, roles, forms, and attitudes in programs based upon the need to include the implementation of technology in teacher education programs. Information based upon this report is being used as standards for the NCATE accreditation review process. Teacher education programs seeking accreditation from this agency must study and apply these standards.

When observing the NETS Project standards report and the NCATE technology report information and standards, the importance of implementing the use of technology for student learning is clearly apparent. When preparing educators to learn and teach economic principles, the use of technology applications during the process of content acquisition is a logical and necessary process. Therefore, when studying the content area of economics at Eastern Kentucky University, students are required to use technological applications during the learning process. The following information will explain: (A) teacher education and the study of economics at Eastern Kentucky University, (B) basic economics principles recommended by the Kentucky Department of Education in its curriculum framework and core concepts for assessment, and (C) examples of classroom applications of information literacy skills required of students during the study of the content area of economics.

Economic Study and Teacher Education at Eastern Kentucky University

Eastern Kentucky University is a regional, comprehensive institution located in the southeastern part of the state. The student population is approximately 14,000. Economics education courses and workshops are offered at the undergraduate and graduate levels through the Economics Department in the College of Arts and Sciences. Students take economics courses in fulfillment of program requirements in: general education, an economics major, an economics minor, teacher certification emphasis, and graduate subject matter study. Undergraduate teacher education students attend courses and workshops in the area of economics with other majors. There is a specific graduate workshop available for inservice teachers.

Basic Economic Principles for Teacher Education

Educators in Kentucky have recognized the need for students to study economic principles. Kentucky=s Curriculum Framework specifies an academic expectation which declares that students should understand economic principles and be able to make economic decisions that have consequences in daily living (Kentucky Department of Education, 1995). The importance of the study of economic principles such as the study of production, distribution, and consumption of
goods and services is confirmed in the Core Concepts for Social Studies Assessment (Core Content for Social Studies Assessment - Version 3.0, 2000). These assessment goals recommend that students need to understand how economic decisions affect them, others, and the nation as a whole. Students at the elementary, middle, and high school levels are assessed on their ability to address topics such as making informed choices, comparing revenues to costs, analyzing resources, examining opportunities, and performing other economic applications. The area of economics is presented in four broad content statements or assertions as follows:

(A) The basic economic problem confronting individuals and societies is the scarcity or imbalance between unlimited wants and limited resources available for satisfying those wants.

(B) To deal with the problem of scarcity, people and societies create economic systems and institutions.

(C) Markets are institutional arrangements that enable buyers and sellers to exchange goods and services.

(D) All societies deal with questions about production, distribution, and consumption.

When studying economic principles these assessment areas are incorporated into lesson development plans. Educators are to help students learn, understand, and apply these concepts.

Classroom Applications of Information Literacy Skills

Economics is a theoretical science. Consequently, economic theory plays a critical role in studying the results of economic events. Students are required to apply theory to predict the outcomes of economic events. In order to evaluate theory, students must compare theoretical predictions with the actual results of those events. Understanding the implications that flow from such a comparison represents a critical achievement in analytical thinking. In order to successfully proceed in these developmental exercises, a student must learn and apply skills in the acquisition and use of economic data. Such study develops a student's thinking processes associated with comprehending, applying, synthesizing, predicting, analyzing, and evaluating.

The economic decisions that students study involve the application of information literacy skills by society. In making economic decisions, an individual must acquire information, process the information by abstraction, apply economic theory to produce a set of expected outcomes, express the outcomes as a functional understanding, make decisions based on their understanding, and after the fact, evaluate the usefulness of the theory based the actual outcome of the decision.

The modern educational environment has many electronic resources that are used in connection with the acquisition and processing of economic data. The use of computers, networks, and software are high technologies that assist the student in finding, analyzing, and applying economic data sets. These technologies require the skills needed to read and interpret as well as analyze and evaluate, thereby making use of information from print, visual, audio, or electronic sources. Such skills are the essence of information literacy (Rafferty, 1998). In turn, the skills of information literacy provide students with the abilities to produce forms, charts, graphs, maps, and other visual displays of data. These skills are of particular importance in a world where one may need to find or present data in non-print formats. Students need skills with information technologies not just to analyze and evaluate data, but also to acquire the data initially and again later to present the product of their work.

The following are some examples of how the application of information literacy is used to study economic principles:
Students make use of library resources and CD based information sources to compile a profile of the time period in which an economic event occurred.

Students format a word processing document to display the profile as a 'timeline' event that they are studying.

Students make use of library resources, CD based information sources, and internet access to institutional and governmental data bases to assemble a set of economic data that would measure the occurrence of the event they are studying and economic data that would measure the impact of the event.

Students organize their economic data in a spreadsheet format. They apply their skills at presenting the information in this format and their skills at transforming the data into the visual format of a graph that shows an economic measure over the time period of their event.

Students predict what the appearance of the graph would be if it were to comply with the theory that they have studied in their economics course. They apply their analytical skills to examining the consistency of the graph with the theory=’s predictions. Students apply their evaluative skills in explaining the interpretation of the evidence and the resulting implications regarding the theory that they have applied in the exercise.

These exercises utilize and develop information literacy skills as well as makes use of information from print, visual, and electronic sources. Economic concepts are learned by using authentic data. Also, students have the opportunity to apply their learning to real life situations.

**Conclusion**

The acquisition of economic principles is an important aspect of preparing educators to teach economics. When this acquisition process is infused with the use of information technology, students are able to understand the content being studied as well as the use of information technology in the procedure. Theory states that students will teach as they have been taught. Studying economics orchestrated with the use of information technology is a modern and effective method of preparing educators for authentic classroom experiences.

Constructivist Use of Technology: Encouraging Preservice Teachers to Construct an Understanding of their Leadership Role in Promoting Reading Outside the Classroom

A. Keith Dils, Ed.D., King's College, Dept. of Ed., USA, kdils@kings.edu

Laurie M. Ayre, Ph.D., King's College, Dept. of Ed., USA, lmayre@kings.edu

ABSTRACT: In order to facilitate preservice teachers' understanding of the importance of reading aloud to children and of their role as educators of parents and community members, a project utilizing the constructivist use of technology was undertaken. Preservice students were presented with research concerning the correlation between the amount of reading done at home and reading achievement in school (Anderson, Hiebert, Scott, and Wilkinson, 1985). These preservice students were then asked to formulate their own understanding of how they could educate parents about their role in the educational process. The students then converted their ideas into a digital video public service announcement to be run on the local media. This paper/presentation will share how this project was undertaken and will model the use of the digital technology.

Constructivist learning principles—supported by the writings and theories of Dewey (1982), Piaget (1972), and von Glasersfeld (1995)—give teacher educators a way to facilitate learning through experience and reflection. When using this approach, educators do not rely solely on the direct transfer of knowledge from the teacher to the student (as is done with teacher-centered approaches). More wisely, they take into account that “learners do not passively absorb knowledge, but rather construct it from their own experiences.” Accordingly, teacher educators who use constructivist approaches act as coaches who provide students with appropriate learning experiences that lead to learning. These teacher educators also act as knowledgeable guides who can empower students to reflect on those experiences as they relate to the goals of education.

Constructivist principles can also be used to facilitate preservice teachers’ developing role as teacher leaders. According to Odell (1997), teacher leaders are “considered first and foremost to be instructional leaders who are open to continuous systemic change for school improvement” (p. 122). Fullan (1993) has identified teachers as moral change agents. In order to reconceptualize preservice teacher curriculums that would support this role development, Grossman and Richert (1996) emphasize the need to foster certain commitments within the curriculum. These would include commitments towards a) ongoing learning, b) openness to other points of view, c) working through areas of conflict with other school and community members, and d) risk-taking. To develop these commitments, preservice teachers would investigate a real world problem and work with school personnel and/or community members to solve it.

One avenue would be to provide multimedia forays into the world outside the classroom. Just such a foray was recently provided to introductory education students. After having students conduct a review of the literature concerning the positive effects of parents reading to their children (Anderson, Hiebert, Scott, and Wilkinson, 1985), they were then provided with a desktop computer with digital video editing software (iMovie) and a digital video camera. After being taught to use the equipment, the students then used this technology to write, produce, and act in a public service announcement encouraging parents to fulfill this crucial educational role. This student-produced video was to be run on a local cable television station.

Overall, this project was intended to provide an opportunity for preservice teachers to work together to promote parents' reading to their children. Reflective discussions with students suggested that they were motivated to solve this real world problem. They attempted to fulfill this change-agent role by researching the literature, using technology, and collaborating with one another in order to encourage positive educational practices in the community.

Piaget, Jean (1972). To understand is to invent. New York, New York: The Viking Press, Inc.

Abstract: This article reviews current literature on the technical know-how of teachers working with Distance Education (DE) and presents an argument for the importance of teacher training. Based on research being conducted at the Distance Education Laboratory (LED) of the Federal University of Santa Catarina (UFSC), in Brazil, the authors show that there is a shortage of teachers with knowledge of educational technology and the background needed to work as distance educators.

Introduction

The principal objective of this paper is to highlight the necessity for technically capacitating teachers working with distance education, and to present a theoretical and practical approach for this challenge. Preparing distance education teachers for technology use is necessary in order to generate effective communication with students and fully exploit the teaching/learning experience. Teachers should be encouraged to embrace and incorporate information and communication technologies to the extent possible, perceiving them as tools for augmenting the potential of the educational process. Teachers who avoid technology or see it as a threat become increasingly alienated in the context of the information society and sense a continuing loss of control in their professional paths.

Recent research conducted at the University of California shows that 67% of professors perceive they are under constant pressure to keep themselves up to date in relation to emerging technologies and 62% feel that their teaching positions are threatened. According to the researchers, this preoccupation could be preventing professors from using new technologies. The study shows that only 35% of professors actually use the internet for research, and only 38% use computer technology to prepare presentations for the classroom. These statistics are dismal in the light of the rapid expansion of distance education and the benefits offered by the ever-increasing array of Educational Technologies.

Research in process at the Distance Education Laboratory of the Federal University of Santa Catarina indicates that the more than 75% of distance education professors do not have the technical knowledge necessary for conducting distance courses. The authors are in the process of examining the difficulties that our teachers, and others around the world, have in learning about educational technology in order to establish effective solutions.

The resistance of many teachers to the use of technology in the classroom and in their pedagogical approach is well recognized. This phenomenon has been ameliorated by events and programs for technological capacitisation which demystify the image of machines, present strategies and options for professors to choose their own methodological solutions, and which "condition (professors) to be adaptive to various tasks and to constantly seek self improvement" (Preti, 1996, p.16).
Hawkins (1995), describing the errors committed in the process of introducing computers in North-American schools, comments that the greatest mistake was not having initially put the technology in the hands of the teachers, and leaving them to think about how they would like to proceed and adopt these technologies in the context of reform. Hawkins advises that much investment is necessary for helping teachers to think in different and new ways about their profession.

Willis (1994) considers teacher training to be the primordial factor for the success and continuation of any distance education program, because of the big challenges distance educators face. They must recreate their course, adopting the role of "content facilitator" acquiring confidence and efficiency while using technology as the principal communications means with the students. It also involves learning to teach effectively without the visual control provided by direct "eye-to-eye" contact, and developing an understanding and appreciation of the lifestyle and profile of distance education students

According to Mason (1998) in order for distance teaching and learning to improve on existing levels and dominions, it is necessary to include interaction in the process, have teachers play the role of "guide" and understand how to take advantage of the benefits that computer technologies allow. As professors increasingly become familiar with operating computers and with integrating multimedia into curriculum related activities, they will be able to participate more actively in the implementation process of educational technology. The ongoing development of user-friendly machines and softwares is facilitating this journey.

According to Barcia et al., (1998) it is necessary to create interdisciplinary teams in order to diminish the distance between education and informatics, so that teachers maintain confidence and decision-making powers. They should have adequate tools for the selection, indication and presentation of academic content. Educational technology's real value is evidenced when teachers discover its optimal use in the classroom. The authors hope that at the end of the technological capacitation process, teachers will be able to devise their own strategies for the best use of the computer according to their particular didactic content and teaching style. It is also important for them to recognize the necessity of using technology in distance education to provide the students with simultaneous and constructive feedback.

Conclusion

Due to a lack of information and an adequate framework for dealing with technology, many teachers have rejected using educational technology, in part from fear that it would eventually replace them in the classroom. Today the benefits of educational technology and its possibilities for enriching educational content and delivery are becoming increasingly evident and teachers are coming to understand the importance of learning how to incorporate it in their classrooms. In this context, it is important for teachers to understand that any incorporation of education technology should be integrated within a wider educational context requiring different pedagogical strategies, and its incorporation in no way diminishes the importance of the teaching profession.

The principal objective of technological capacitation is to prepare professors for better serving the information society, where technology plays such an important role in all activities and professional areas, and which has generated a great demand to learn how to adapt and manage knowledge and information. The process of technological capacitation of teachers for distance education is challenging in relation to social aspects because it requires a change in attitude and teaching methodology. However, with teacher training programs and support, professors more easily come to understand how to adjust their teaching methodologies in order to better help students construct knowledge at a distance. They can also be encouraged and supported during the difficult process of learning to manage the differences, which unquestionably exist, in communication flows mediated by technology.

Technology Integration into Preservice Teacher Preparation: Recommendations for Practice

Dr. Mesut Duran
School of Education
University of Michigan-Dearborn
United States
mduran@umd.umich.edu

Abstract: The purpose of this paper is to provide recommendations for practice to integrate information technology into teacher preparation programs. The author describes a model for technology integration into teacher preparation programs. This model is based on what he has learned in his recent studies and his beliefs about the things that teacher preparation institutions must do in order to increase the level of technology integration in their own programs. Based on the integration model discussed, the author provides specific recommendations for practice.

As the United States enters the 21st century, teacher preparation programs across the nation are assessing their capacity to adequately prepare new teachers to embrace the use of information technology in the education of young people who will live in a global, information-based society. While investigating the status quo, recent studies have produced somewhat disheartening data. Relatively few teachers (20 percent) report feeling prepared enough to integrate technology into classroom instruction (NCATE, 1999 January). In general, teacher preparation programs do not provide preservice teachers with the kinds of experience necessary to prepare them to use information technology effectively in their future practice (Duran, 2000; Moursund and Bielefeldt, 1999).

The purpose of this paper is to provide recommendations for practice to integrate information technology into teacher preparation programs. In this paper, the author describes a model for technology integration into teacher preparation programs. This model is based on what he has learned in his recent studies and his beliefs about the things that teacher preparation institutions must do in order to increase the level of technology integration in their own programs. Based on the integration model discussed, the author provides specific recommendations for practice.

Integration Model

In general, in order to increase the technology proficiency of new teachers in K-12 classrooms, teacher preparation institutions should increase the level of technology integration in their own programs. To provide a model for technology integration into preservice teacher preparation, the researcher recommends three program components for reaching better preparation of preservice teachers in the use of information technology in the teaching and learning process.

a) A core course in educational computing prior to methods courses.

b) Education faculty who model uses of information technology in their methods and curriculum courses and require their students to do so in the design of their integrated units and field experience.

c) Student teaching experiences with supervising teachers whose students use information technology in their classrooms.

The first component of this model addresses a required educational computing course prior to methods courses. An educational computing course plays a critical role in introducing preservice teachers to fundamental information technology components and skills. It particularly provides preservice teachers with the opportunity to become confident and proficient with information technology tools. Recently, more than 91 percent of higher education institutions require an educational computing course for some or all their preservice teachers as a core component of their technology preparation programs (Vagle, 1995).

The second component of this model addresses faculty use of information technology in their practice. Education faculty need to serve as role models using information technology to facilitate instruction in their curricular areas, allowing students to observe the use of technology in particular disciplines. Faculty use of and attitudes towards information technology in the college classroom will strongly influence the implementation of technology by preservice teachers in their future practice. In methods courses, students should also learn specific software that experts in their fields use as tools of the trade. In these methods courses, students can be more
specific in their analysis of technology integration as it relates to particular tenets of a discipline. However, this component appears to be lacking in preservice teacher preparation programs (Duran, 2000; Moursund & Bielefeldt 1999; Persichitte et al. 1997; Wetzel, 1993; Willis & Mehlinger 1996).

The third component of this model addresses integrating information technology into the field component of teacher preparation programs, particularly into the student teaching experience. It is important to place preservice teachers in classrooms where information technology use is modeled appropriately. Work in the field is a "salient way" to help preservice teachers experience deep learning of how to effectively use information technology in instruction and how to manage actual classroom learning activities within a technology-enriched environment. However, this component also appears to be lacking in preservice teacher preparation programs (Duran, 2000; Moursund & Bielefeldt 1999).

Specific Recommendations for Practice

Based on the integration model discussed above, the author specifically recommends followings:

1. Preservice teacher preparation programs should be engaged in technology planning that focuses on not only facilities but on the integration of information technology into the entire undergraduate curriculum.

2. Most preservice teacher education programs currently require an educational computing course for their education major students. The researcher recommends that the teacher preparation institutions should continue to require this course to its preservice cadre prior to teaching methods courses.

3. Education faculty must be encouraged to model and integrate technology in their courses. Even though a computer on a faculty member's desk is a step, providing professional development in technology usage is crucial. The researcher recommends continues effort for ongoing quality faculty development combined with adequate resources (especially in university classrooms) and support from the administration.

4. Student teachers need more opportunities to observe/apply information technology during field experiences under qualified supervision. This requires a partnership between the teacher preparation institutions and cooperating schools. The researcher recommends that working with school districts, the teacher preparation institutions must plan and provide ongoing professional development opportunities for cooperating teachers and place its student teachers in classrooms where they observe/apply effective use of information technology.

5. The researcher strongly recommends consistency between what preservice teachers learn in their educational computing course (theory) and what they observe in their methods and curriculum courses or in K-12 classrooms (practice).

6. Teacher preparation is a university-wide and community-wide responsibility. Thus, the researcher strongly recommends a collaborative effort of the teacher preparation institutions and other units within a university that contribute to the preparation of teachers.

Standards Based Reflection:
The Virtual Teacher Project

Karen Dutt-Doner
College of Education and Human Development
University of Southern Maine
karendd@usm.maine.edu

Susan M. Powers
School of Education
Indiana State University
powers@indstate.edu

Abstract: In Indiana, the current dilemma facing teacher education programs is how to best teach about and assess students on the standards adopted by the Indiana Professional Standards Board (IPSB), and in particular, the dispositional component found in those standards. The Virtual Teacher Project combined over 32 inservice teachers representing 30 different schools, 170 preservice teachers representing six teacher preparation programs and 8 teacher educators representing 4 universities in an electronic discussion group that focused on connecting standards adopted by the IPSB and INTASC.

Background

Imagine a professional development school and teacher education program where the teachers play an integral part in the preparation of future teachers. Each teacher has the opportunity to impact the learning and preparation of hundreds of future teachers and each pre-service teacher has the opportunity to interact with dozens of veteran teachers. Teacher education students can ask teachers burning questions related to current issues and practices in education. Teachers in turn have the opportunity to reflect upon their professional practice. This type of K-16 learning community was developed in the Virtual Teacher Project.

In 1997, The National Council for the Accreditation of Teacher Educators (NCATE) issued a report entitled Technology and the New Professional Teacher: Preparing for the 21st Century Classroom. This report describes the need for teachers to be able to understand the impact of technology on society, the need for teachers to adopt new roles which allow them to use technology to become more reflective and critical consumers, and the need for teachers to participate in activities that are delivered via informational technologies. This transformation to technology-rich teacher education classrooms is new, but the importance of using technology as a vehicle for delivery of information is apparent. Teacher education programs are then actively seeking means by which they can integrate technology in a meaningful way into their programs.

Reflection is another element that teacher education programs are working to include. Thoughtful reflection is a difficult process that must be developed and nurtured (King & Kitchener 1994). Donald Schon (1987) identifies the important role that reflection plays in professional development and growth. Reflection that leads to critical analysis of performance can be fostered through the creation of multiple opportunities for students to examine different points of view reflectively. Reflection is tied to dispositions in that teachers (in-service and pre-service alike) must want to act upon their reflections to change behavior (Kottkamp 1990).

Finally, a growing set of teaching standards looks not only at performances, but also considers the disposition of the teacher and teacher candidate. While some research supports the notion that dispositions are stable traits (Haberman 1993), a number of theories contrast this notion and suggest that group climate, social influence and social networking can impact attitudes and behavior, and in turn, possibly dispositions (Salancik & Pfeffer 1978). It is therefore a possibility that the dispositions outlined in the various standards are dispositions that could be "taught" to students.
The Virtual Teacher Project:

The goals of utilizing a virtual community of learners were to: 1) increase the understanding of in-service and preservice teachers as it relates to the teaching standards developed by the Indiana Professional Standards Board and the Principles of the Interstate New Teacher Assessment and Support Consortium (INTASC); 2) to provide a forum were teachers could publicly reflect upon their professional practice as it relates to the standards and learn from the reflection of others; 3) to give pre-service teachers access to teachers (who do not assess their performance) to learn about professional practice and related dispositions; and 4) provide a vehicle by which teacher educators could integrate information technology into classroom practice. The project has a two-year span. During this time, preservice teachers, in-service teachers, and teacher educators posted over 4000 messages related to these content standards.

During the first year of the project, three different electronic discussion groups for preservice teachers were developed. The groups were devoted to the EAG standards (Early Adolescent Generalist), the AYA standards (Adolescent Young Adult), or the INTASC principles. Thirty-two select teachers from across the state were recruited to participate. After an introductory workshop focused on learning more about the standards and effectively communicating on an electronic discussion group, the thirty-two teachers were assigned to one of the three groups. The three online groups began discussion in January. The first three weeks of the discussions were slow and limited due to the lag time of the start of college classes and getting students online. By the second week in February, the online discussions were moving along well. Teachers and students discoursed about how to involve parents, classroom discipline, innovative instructional strategies, assessment of students, and the very real issues of school safety raised by the shootings at Columbine. Following feedback from the first year, a team of approximately five teachers covered each of four electronic discussion groups that related to four IPSB developmental standards (Early Childhood, Middle Childhood, EAG, and AYA).

Over a third of the participating students actually participated by sending and responding to messages. The other students remained in the status of “lurking.” However passive, lurking does not prevent students from learning and gaining an understanding of teacher dispositions and reflections. In the second year of the project the discussion list provided opportunities to help students, even the passive lurkers, to draw more direct connections to the standards. Adding online teacher education faculty facilitators to draw clear connections to the standards and the discussion in the second year relieved some burden from the teachers and provide more clarity for the students.

Summary

The Virtual Teacher Project illustrated the impact that electronic discussion groups can have on preservice teachers. It was learned that students often contacted teachers directly to continue discussion. The teachers themselves felt it was in important component in their professional development and the future teaching profession. Finally, it provides a vehicle to accomplish the multiple tasks of technology integration, teacher modeling, reflection, and disposition instruction.

Infusing Technology into Preservice Teacher Education

Josephine Farrall & Barbara Newhart, State U of New York at Oswego, USA

I. PROPOSED PLAN AND SERVICES TO BE PROVIDED

Grant Goals/Method

The Oswego County Goals 2000 Consortium proposes to implement an extensive preservice teacher education model to improve preservice teacher preparation in instructional technology and the New York State Learning Standards. Building upon the 1999-2000 Goals 2000 Preservice Grant, the overall goals and objectives of the 2000-2001 Preservice Program are:

1. Improve Districts’ educational outcomes by providing the key COOS training component in Goals 2000.

2. Include technology as a component of the curriculum for all preservice teachers, and provide ongoing professional development through the entire preservice teacher education experience.

3. Work with local businesses and industries to ensure that preservice teachers are prepared for the rapidly changing world of tomorrow.

4. Develop a cooperative instruction model that integrates technology, the New York State Learning Standards, and the curriculum.

The Consortium proposes the following activities to be implemented during the grant period (September 1, 2000 – August 31, 2001):

September-December 2000

- Finalize and order equipment for new participants and model classrooms. Each new model classroom will be equipped with 4 computers, 1 laptop computer, 1 color ink jet printer, 1 digital camera, 1 LCD projector, any necessary equipment to connect with training networks, and various educational software.

- Install equipment in respective classrooms.

- Administer a pre-survey for faculty and teacher participants.

- Maintain weekly open labs (called) for all participants to continue technology training in teams.

- Plan and implement a two-day (40 hour) week of experience for all participants.

- Plan and implement a two-day (40 hour) week of experience for all participants.

- Set up a Goals 2000 listserve to enable all participants to have a forum for discussing technology infusion, delivering updates, etc.

- Participate in a variety of countywide technology infusion offerings to further support the professional development of technology teams.

- Plan 10 meetings to discuss technology infusion activities. Meetings will be held at a countywide conference.

- Implement revised education courses as well as activities that integrate technology and the Standards in the preservice courses and public school classrooms.

- Education faculty and classroom teachers observe and consult with technology collaborators.

- Preservice teachers observe classrooms through videoconferencing system.

- Update participants regarding technology infusion activities related to technology infusion in the schools. Learning activities will be coordinated between preservice teachers and public school children as much as possible. College faculty and K-12 teachers will plan for future collaborations.

January-June 2001

- Implement revised education courses as well as activities that integrate technology and the Standards in both the preschool courses and the public school classroom.

- Education faculty and classroom teachers observe and consult with technology collaborators.

- Preservice teachers observe classrooms through videoconferencing system.

- Gather qualitative data through observations of implementation and focus groups.

- Administer post-survey for participating faculty, teachers, and school district.

- Complete data collection and analysis data.

- Begin planning for a 3-day summer workshop and weekly labs for teams.

- Maintain weekly open labs (called) for all participants to continue technology training in teams.

July-August 2001

- Plan and implement a 3-day workshop and weekly labs for teams. The workshop will continue the technology integration model, including presentations by participants on "The Benefits of Technology Infusion," review technology and standards training for all teams; provide up-to-date information on School-to-Work and COOS standards; provide time to set goals for 2001-2002 implementation.

- Set up a variety of countywide technology infusion activities. Meetings will be held at a countywide conference.

- Implement revised education courses as well as activities that integrate technology and the Standards in both the preschool courses and public school classrooms.

- Education faculty and classroom teachers observe and consult with technology collaborators.

- Preservice teachers observe classrooms through videoconferencing system.

- Gather qualitative data through observations of implementation and focus groups.

- Administer post-survey for participating faculty, teachers, and school district.

- Complete data collection and analysis data.

- Begin planning for a 3-day summer workshop and weekly labs for teams.

- Maintain weekly open labs (called) for all participants to continue technology training in teams.

7. Business and Industry in Technology Partnerships

Since 1994, the Oswego State University's School of Education continues to implement a Technology Education Partnership with Microsoft. This partnership allows the School of Education to cooperate with the Targeted Instructional Staff Development Grant group which supports Oswego County's Professional Development Schools and involves business and industry in developing technology partnerships. In addition, the Co-Directors of Project SMART, a program that helps elementary and middle school educators develop hands-on interdisciplinary math and science units in collaboration with local businesses and industries, are participants in this grant. "Kids at Work," a component of Project SMART, is a validated NYS State Sharing Success Program.
This collaborative project involves several Onondaga State University campuses: 18 education faculty, two arts and science faculty, and over 1000 preservice teachers in ten different courses.

The Curriculum and Instruction Department has a new participation for the 2000-2001 school year. Additionally, the Dean of the School of Education, the Provost, and President of SUNY Oswego endorse this project.

5. Local Educational Agencies

Oswego County has maintained a tradition in collaborative efforts in teacher education. The Oswego County Goals 2000 Consortium consists of 12 elementary, 9 middle, and 9 senior high schools in Oswego County's 15 public school districts: Attica-Plainville, Baldwinsville, Camillus, Central Square, Fulton, Hamilton, Mexico, Oswego, Phoenix, Pulaski, and Sandy Creek. Collaborating institutions include: the Oswego County Board of Cooperative Educational Services (Oswego ROCES), Oswego County Teacher Center (FETC), the Special Education Training and Resource Center (SERTC), the State University of New York at Oswego (SUNY Oswego), and the Oswego County Workforce Preparation Partnership.

Oswego City Schools will also provide some of the technology training for the grant as well as outstanding teachers who are experienced in technology integration will serve as teachers for the project. Oswego City Schools have implemented extensive technology plans during the last five years that includes not only the acquisition of equipment but also a sound staff development plan. The 2000-2001 proposal plans to utilize Oswego's technology expertise in providing in-service and service in participating faculty and classroom teachers.

6. Supporting High Need Populations and Low-Performing Schools

Schools choose to participate in the Consortium on the basis of a combination of need, interest, and ability. Pursuant to a consensus of Oswego County Superintendents, the Oswego ROCES invited component school districts to designate a liaison on the development of a Consortium proposal. Oswego County University also accepted this invitation.

Oswego City Schools proposed a project that will enhance the opportunity of approx. 1,000 square miles located around the southern center of Lake Ontario. About two-thirds of an adult (121,771/ 1990 Census) people live in the cities of Fulton and Oswego. The remainder lives in rural or non-rural homes. Oswego County has very high percentages of adults with less than a high school education (23.5%) and of children living in poverty (17.4%). With several major plant closings/layoffs in recent years, Oswego County’s unemployment rate is consistently high, nearly twice the New York State average.

Eight of Oswego County’s 9 public school districts are among the state’s ten poorest school districts, five of which are Fulton, Hamilton, Pulaski, American Fork, and Sandy Creek School District. Bellevue, Elementary in Syracuse and Binghamton are also high needs schools. The proposed initiatives will be implemented at Hannibal High School, Kenney Elementary (Hannibal), Langs Elementary (Pulaski), Lure M. Sharp Elementary (Pulaski), Parish Elementary (APW), Sandy Creek Elementary, Oswego High School, Bellevue Elementary (Syracuse) and Conners, RS (Manhattan).

7. Project in Which the Proposed Budgets Support the Project

In this proposal, budgets include: (a) funds to hire 2 Project Directors (1/4 time—fall semester) and 1 full-time Project Coordinator. The Project Directors will receive comped travel expenses and salary and the Project Coordinator will receive a full-time salary. (b) funds for equipment to purchase equipment and technical staff to maintain and service the technology. (c) funds for professional development to support staff to attend conferences and workshops.

8. Coordination of Other Funds

The 1999 Goals 2000 Preserve Grant established the purchase of over $91,341 worth of technology equipment, all of which will continue to be used in the implementation of the 2000-2001 school year. In addition, informed planning and budgeting for future years is being conducted, allowing for the effective and efficient use of resources.
standards in their classrooms. Obviously, students enrolled in Reading in the Content Area and Reading Introduction in Elementary Schools will receive more in-depth instruction in English Language Arts and mathematical concepts teaches the MST course. MST students are actively involved in hands-on activities and projects that foster problem-solving skills and enable students to maximize their creative potential. Preservice teachers enrolled in Secondary Science Methods and Methods of Teaching Technology Education will experience the integration of math, science, and technology by observing the implementation of the MST course on numerous occasions, conducting integrated MST experiments and learning methods of integrating MST in math and science instruction.

In addition to Secondary Math Methods Courses, students will have the opportunity to observe classroom teachers utilizing a variety of instructional and assessment methods with a diverse population of students. Since the Secondary Math Methods Courses will be working with Hannibal High School to develop and implement an integrated MST Course, math and science preservice teachers will also experience firsthand the role of mathematics and science in the lives of students receiving special services. In addition, these districts have created inclusive classrooms to adequately serve their diverse populations. Thes Syracuse and NYC classrooms provide culturally and linguistically diverse contexts for inclusion and social development of learners.

3. Role Divergence in Teaching/Teaching of Technology

The MST standards are the foundation of the integrated MST course at Hannibal High School. An MST team that consists of education methods faculty, content-area faculty, and classroom teachers will design an MST course that is consistent with education methods faculty, content-area faculty, and classroom teachers. The MST standards will be addressed in the following courses: Reading in the Content Area, Foundations of Literacy, Reading Instruction in Elementary Schools, Secondary Science Methods, and Methods of Teaching Technology Education. MST students are actively involved in hands-on activities and projects that foster problem-solving skills and enable students to maximize their creative potential. Preservice teachers enrolled in Secondary Science Methods and Methods of Teaching Technology Education will experience the integration of math, science, and technology by observing the implementation of the MST course on numerous occasions, conducting integrated MST experiments and learning methods of integrating MST in math and science instruction.

In addition to Secondary Science Methods and Technology Methods, MST standards will also be addressed in Elementary Methods of Instruction. These teams will address the Task Force's recommendations as they revise education courses to prepare preservice teachers in technology integration and implementation of the NYS Standards.

The school districts of Hannibal, Pulaski, Oswego, Alaska-Parish-Williams, Fulton, Syracuse, Sandy Creek, and Manor have a high number of students receiving special services. In addition, these districts have created inclusive classrooms to adequately serve their diverse populations. The SYX and NYC classroom teachers will have the opportunity to observe classroom teachers utilizing a variety of instructional and assessment methods with a diverse population of students. Specific NYS Standards will be addressed as follows.

Math, Science, Technology

The MST standards are the foundation of the integrated MST course at Hannibal High School. An MST team that consists of education methods faculty, content-area faculty, and classroom teachers will design an MST course that is consistent with education methods faculty, content-area faculty, and classroom teachers. The MST standards will be addressed in the following courses: Reading in the Content Area, Foundations of Literacy, Reading Instruction in Elementary Schools, Secondary Science Methods, and Methods of Teaching Technology Education. MST students are actively involved in hands-on activities and projects that foster problem-solving skills and enable students to maximize their creative potential. Preservice teachers enrolled in Secondary Science Methods and Methods of Teaching Technology Education will experience the integration of math, science, and technology by observing the implementation of the MST course on numerous occasions, conducting integrated MST experiments and learning methods of integrating MST in math and science instruction.

In addition to Secondary Science Methods and Technology Methods, MST students will also have the opportunity to observe classroom teachers utilizing a variety of instructional and assessment methods with a diverse population of students. Specific NYS Standards will be addressed as follows.

English Language Arts

The ELA standards will be addressed in the following courses: Reading in the Content Area, Foundations of Literacy, Reading Instruction in Elementary Schools, Secondary Language Methods, and Methods of Teaching Foreign/Second Language. MST students are actively involved in hands-on activities and projects that foster problem-solving skills and enable students to maximize their creative potential. Preservice teachers enrolled in Secondary Language Methods and Methods of Teaching Foreign/Second Language will experience the integration of math, science, and technology by observing the implementation of the MST course on numerous occasions, conducting integrated MST experiments and learning methods of integrating MST in math and science instruction.

In addition to Secondary Language Methods and Methods of Teaching Foreign/Second Language, MST students will also have the opportunity to observe classroom teachers utilizing a variety of instructional and assessment methods with a diverse population of students. Specific NYS Standards will be addressed as follows.

Math, Science, Technology

The MST standards are the foundation of the integrated MST course at Hannibal High School. An MST team that consists of education methods faculty, content-area faculty, and classroom teachers will design an MST course that is consistent with education methods faculty, content-area faculty, and classroom teachers. The MST standards will be addressed in the following courses: Reading in the Content Area, Foundations of Literacy, Reading Instruction in Elementary Schools, Secondary Science Methods, and Methods of Teaching Technology Education. MST students are actively involved in hands-on activities and projects that foster problem-solving skills and enable students to maximize their creative potential. Preservice teachers enrolled in Secondary Science Methods and Methods of Teaching Technology Education will experience the integration of math, science, and technology by observing the implementation of the MST course on numerous occasions, conducting integrated MST experiments and learning methods of integrating MST in math and science instruction.

In addition to Secondary Science Methods and Technology Methods, MST students will also have the opportunity to observe classroom teachers utilizing a variety of instructional and assessment methods with a diverse population of students. Specific NYS Standards will be addressed as follows.

English Language Arts

The ELA standards will be addressed in the following courses: Reading in the Content Area, Foundations of Literacy, Reading Instruction in Elementary Schools, Secondary Language Methods, and Methods of Teaching Foreign/Second Language. MST students are actively involved in hands-on activities and projects that foster problem-solving skills and enable students to maximize their creative potential. Preservice teachers enrolled in Secondary Language Methods and Methods of Teaching Foreign/Second Language will experience the integration of math, science, and technology by observing the implementation of the MST course on numerous occasions, conducting integrated MST experiments and learning methods of integrating MST in math and science instruction.

In addition to Secondary Language Methods and Methods of Teaching Foreign/Second Language, MST students will also have the opportunity to observe classroom teachers utilizing a variety of instructional and assessment methods with a diverse population of students. Specific NYS Standards will be addressed as follows.
C. Teacher Knowledge of Standards and Instructional Technology

In addition to the Standards, preservice teachers will communicate with classroom teachers regarding their integration of all learning standards into their curriculum and how they use technology as a means of helping all children achieve and exceed learning standards.

5. Enhancing Teacher Knowledge of Technology in Education

In conjunction with the 1994 Oregon School-to-Work Opportunity Act, this program will extend existing community and education partnerships to help students gain the skills necessary for bridging the gap between school and work. The Consortium will be working closely with the Oregon County Workforce Preparation Partnership and Project SMART to provide training and School-to-Work implementations. Teams will create STEM activities to be implemented in the participating classrooms. Preservice teachers enrolled in the participating education courses will observe the implementation of these work-based and school-based activities as well as team methods of implementing STEM activities in the classrooms. Preservice teachers will be required to conduct interviews that integrate work-based and school-based activities.

6. Staff Development of Teacher Education Faculty

Last summer, under the 1999 grant, 11 college faculty participants attended five days of training in technology processes and integration to support NYS Standards for classroom instruction, as well as after-school labs. However, there is still a great need to provide and develop new teachers for the next year's participants as an extension for this year's new faculty. Building upon training learned from the 1999 grant, the 2000-2001 proposal will provide staff development to 18 committed education faculties and 2 content-area faculty. Staff development will consist of a 2-day fall workshop plus 3-3-day workshops in July or August, as well as weekly online sessions. Workshops will also provide time to collaborate with classroom teachers and technology colleagues in the development of classroom activities and the revision of education courses. Faculty who participated in the 1997, 1998, and 1999 grants, Oswego City Schools, Oswego BOCES staff, and Project SMART disseminators will provide training. Follow-up sessions will provide team participants with the opportunity to share implementation activities and troubleshooting implementation problems.

7. Collaborations between Oswego State University and K-12 Teachers

Each preservice team for the 2000-2001 proposal consists of at least one K-12 teacher, at least one college education faculty member, and either a technology collaborator from the college or K-12 school or a content area collaborator from the college who also teaches preservice teachers. All teams participate in summer training and planning as well as on-going collaboration on various implementation and evaluation projects throughout the school year.

Goals 2000 Preservice Teams

NYS Team

Math methods faculty: Mary Reeves
Technology faculty (Consultant): Vern Tryon
Elementary Science/English faculty: Jean Ann Stimmel
Earth Science teacher: Nonna Dunning
New Student Faculty: TIA (search underway)

ELA/Collaborative Team

ELA Methods faculty: Sharon Kane
Math faculty: Sue Goforth
Oswego HS English teacher: Sharon Marley

PSO Elementary Team

Graduate Research methods faculty: Beth Maisel
Elementary science teacher: Peggie Sorensen
Elementary science teacher: Maria Hendricks
Technology Collaborator: Pat McEuen

Community Vog CTSK Education Team

Reading Graduate faculty: Beth Schmoker
Elementary methods faculty: Audrey Hurley
Oswego CTSK Director: Barbara Pany

Elementary Methods (Ohio) Team

Elementary methods faculty: Jon Parnell
Laura Shaw Elementary Teacher: Allen Woods; Christina Kent; Christine Macaulay

Secondary Language Methods Team

Secondary Language faculty: Joan Arin
NYC teacher: Susan Taylor

Elementary Science/Social Studies Methods Team

Science Methods faculty: Sue Willet; Ann Koon
Science faculty: Dive Jackson
Elementary science teachers: Nancy Lawn, Mary Lee O'Brien; Pam Bulwagga
Social Studies Methods faculty: Viggo Tuchini
Elementary teachers: Beth Taylor; Denise Holmes

THE Consortium's project in preservice teacher education will be augmented with rigorous formative and summative evaluations. Like other aspects of this 2000-2001 proposal, the evaluation plan for this project will be developed by the Consortium and reviewed for 1999-2000. During the 1999 Goals 2000 grant, several survey instruments were developed and administered to determine the impact of the project on students.

B. Student Performance

A baseline survey of students enrolled in the participating K-12 classrooms will be evaluated in a variety of ways. First, Surveys and interviews will be conducted with students at the beginning of the school year to determine a baseline of data. This baseline of data will identify students' attitudes and current use of educational technology. Surveys and focus groups will be conducted throughout the school year to determine the impact of the project on students' attitudes toward technology, use of technology, and integration of technology into their classroom curriculum. In addition, a technology audit of the schools will be conducted to assess the impact of the project on technology use.

C. Teacher Knowledge of Standards and Instructional Technology

Experienced CSOs disseminators will provide training for all participants from Project SMART's Kids at Work project to ensure that CSOs standards are infused into existing curricula.

Social Studies

Social Studies Standards will be studied in the Social Studies Methods course and infused in the Elementary Methods block.

All NYS Learning Standards

All of the NYS Learning Standards, with particular emphasis on CSOs, will be addressed in the Social Studies Methods, methods of instruction, and Foundations of Education courses via e-mail, videoconferencing ("Netmeeting"), and web-presenting programs. In addition to learning the Standards, preservice teachers will communicate with classroom teachers regarding their integration of all learning standards into their curriculum and how they use technology as a means of helping all children achieve and exceed learning standards.
numerous opportunities for the participating institutions and individuals to collaborate. The following activities have been accomplished:

- Implementation of technology integration training for higher education and K-12 faculty and their public school and college students, incorporating videoconferencing links between contexts.
- An urban middle-school class with 25 students, a 6th grade elementary classroom with 25 students, a 5th grade elementary classroom with 25 students, and a team-taught 4/5 urban inclusion classroom.
- Integration of language arts, social studies, and integrated MST instruction. Student achievement of respective standards was demonstrated at higher levels through the performance-based assessments that used computer applications (Microsoft Office, Encarta, KidPix, ClarisWorks, Claris Slide Show, HyperStudio, Inspiration, ZAP, Internet research) on a regular basis to complete performance-based assessment tasks.
- Planning and creation of appropriate health and social services, effective mechanisms and appropriate paths to the workforce as well as to higher education, innovative use of technology, utilization of quality management services.

As a result of the following, we were awarded $318,000.00 from Grants 2000 funding for the 2000—2001 year.

As a result of this project, there was a definite change in the way students received instruction in their classes, which resulted in an improvement in student achievement. Students' lessons and tests of study were focused on the State testing standards and enhanced by the judicious use of technology. Student achievement and attitudes were evaluated through observation of student use of technology in inquiry-oriented projects, student performance-based projects, focus groups with students from all of the participating districts, and pretest and posttest surveys. The participating students integrated a wide variety of computer applications (Microsoft Office, Encarta, KidPix, ClarisWorks, Claris Slide Show, HyperStudio, Inspiration, ZAP, Internet research) via a regular basis to complete performance-based assessment tasks in language arts, social studies, and integrated MST instruction. Student achievement of exemplary standards was demonstrated at higher levels through the performance-based assessments that used digital camera technology, videoconferencing, and interactive software. In addition, students' attitudes were positive towards the technology integration. They claim that technology empowered them, since they could learn more because they could go to "www.all.com" and ask any questions they had. Fourth graders indicated that they used word games like ZAP that helped them with the State science test. One student commented that, "I didn't even know about ZAP last year." What evidence do you have that systemic change has resulted from this project and will continue after the grant period ends (e.g., comprehensive coordinated improvement, coordinated access to appropriate health and social services, effective mechanisms and appropriate paths to the workforce as well as to higher education, innovative use of technology, utilization of quality management services)?

The acquisition of equipment and videoconferencing abilities, creation of one K-12 model classroom (a low-income, rural first grade classroom with 20 students, a suburban first grade classroom with 20 students, an urban middle school class with 25 students, a 6th grade elementary classroom with 25 students, a 5th grade elementary classroom with 20 students, a team-taught 4/5 urban inclusion classroom with 30 students), a 6th grade team-taught inclusive class with 50 students, a High School English classroom with 25 students, and a High School integrated MST classroom with 20 students), and implementation of technology integration existing for higher education and K-12 faculty and their public school and college students, incorporating videoconferencing links between contexts, have all created numerous opportunities for the participating institutions and individuals to collaborate. The following activities have been accomplished:

- Video links between eight preservice teacher education courses and respective K-12 classrooms, with four new higher education faculty being added in the upcoming year.
- Review of all preservice teacher education courses to infuse technology, and provide technology-rich field placements. Dosier faculty from the school of education and arts and sciences will be involved in this year's grant and will focus on developing a comprehensive scope and sequence of technology-related activities, based on the NCATE standards for technology.
- Teams of teachers and teacher educators partnering via the videoconferencing presented findings of their research on the effectiveness of technology infusion at international, national and state level conferences (IE-MEDIA, NSTA and the NYS-SUNY Technology Infusion Conference). All of the teacher educators participating in this year's grant are mentoring other teacher education faculty on technology infusion. This mentoring is built into this year's grant. A similar mentoring conference (ED-MEDIA, NSTA and the NYS-SUNY Technology Infusion Conference).
- Video links between eight preservice teacher education courses and respective K-12 classrooms, with four new higher education faculty being added in the upcoming year. Eight new higher education faculty having teaching in the K-12 classroom.
- Collaboration between K-12 and higher education faculty will continue in the interaction of preservice teachers. Preservice teachers will continue to observe model classrooms through the videoconferencing system.
- Preservice teachers will continue to experience technology integration in their education courses that is more coordinated across the program, at more advanced levels, in more courses.

What changes in teaching and learning have resulted from the acquisition and use of technology supported by this grant? How are teachers teaching differently? How are students learning differently?

BEST COPY AVAILABLE

1812
Oswego State University’s School of Education has developed a conceptual framework centering on authentic Mooring for all students with a commitment to social justice. Technology infusion activities have also focused on these goals, supporting a constructivist pedagogy. Since educator training focused on use of the computer as a tool to support learning, educators implemented numerous lessons that used technology for the creation of student products and the facilitation of student performance-based assessments. Teachers implemented lessons that focused on students using technology in meaningful and authentic ways that are reflective of technology use in the workplace. Students have come to realize that computers are not just for e-mail, games, and “skill/drill” activities. Preservice teacher surveys and focus group data evidenced profound changes in their vision of technology infusion; it indicated that they are focused on how they can use technology to enhance student learning. Finally, students also learned that computer-generated products increase the quality of work among special needs students since handwriting and spelling did not impede their products. Therefore, students with special needs were able to produce very impressive products that clearly demonstrated what they learned, which in some cases provided them with a level playing field.

Because of this project, what are teachers and administrators doing differently to engage in constant review of professional practice and inquiry for improving teaching, learning, and student performance?

The project used an action research model, in which all participants (K-12 teachers and college faculty) were involved in survey construction, focus group question generation, administering surveys and conducting focus groups, and analyzing data. Themes generated through this process were compared to those generated by an outside evaluator, as a member checking procedure. Teachers found this action research model to be a powerful form of professional development. Such action research projects, focused on the analysis of student learning of standards-based curriculum, were also incorporated into the preservice courses. Proportional surveys as well as focus groups data indicated huge increases in teacher proficiency in all areas, particularly methods of technology infusion. Teachers found these conducting these groups and examining survey data of their students offer new insights into the teaching-learning process.

What changes have occurred as a result of this project to improve preservice programs for teachers, pupil personnel services professionals or school administrators to equip them with the subject matter and pedagogical expertise—including the use of instructional technology—necessary for preparing all students to meet the standards?

The impact of this grant on our preservice program was measured through pre/post faculty surveys, pre/post preservice teacher surveys, focus groups with preservice teachers, observation of technology use in preservice courses, and analysis of course syllabi and student work. It was found that:

- Preservice teacher proficiency of technology—All areas increased significantly. All areas increased at the highly significant (.001) level, except Database and Spreadsheets.
- Faculty use of technology in the classroom increased in all areas except Spreadsheet, Instructional Software, and Hypertext. 10 out of 17 areas increased at the highly significant (.001) level.
- Examination of preservice teacher portfolios evidenced increased ability to plan standards-based lessons and use technology to enhance student learning.
- Focus group data reflected significant changes in preservice teachers' visions of technology infusion, towards a more constructivist orientation that viewed technology as a tool to support student learning. Their views of how you can use technology have broadened. Where there might be limited their thoughts to word-processing—"now the sky is the limit."
- On the basis of the Goals 2000 data, the School of Education passed the NCAE standard on technology in our spring site visit from NCATE.

Using these results, the Departments of Curriculum and Instruction is committed to engaging more faculty in the Goals 2000 project, and is empowering this group to develop a program-wide scope and sequence for technology infusion in all teacher education courses. We will report involvement in 16 faculty in the upcoming year, and technology infusion will occur at each level of the program. We have learned that it is important to use a team approach that incorporates effective technology infusion in K-12 classrooms as well as providing technology rich field experiences. This project has resulted in broad-based faculty reflection and dialogue on how technology fits into the education curriculum, as well as extensive program restructuring.
Anchored Instruction Using WebQuests in a Post-Baccalaureate Teacher Education Course

Donna Ferguson, Ph.D.
College of Education
University of Northern Colorado
United States
dferguson@edtech.unco.edu

Abstract: This paper discusses the process of designing a post-baccalaureate Educational Technology class for pre-service teachers. The class used an anchored instruction model based on WebQuests to ensure student exploration, modeling of technology integration, and the wide range of abilities of all students were addressed. The design process, class content, and student evaluations will be discussed.

Introduction

Teacher education coursework in Educational Technology has traditionally required students to learn software tools that will support their future role in the K12 learning environment. These courses have usually been taught in a didactic manner where the instructor demonstrates the software and then asks students to replicate a product. A didactic model is in contrast to the technology infusion model the instructor hoped to achieve. While learning the tools of the trade is necessary, it is also important to model for pre-service teachers the way technology integration can look.

The history of anchored instruction goes back to Dewey (1933) who advocated learning by doing. More recently, the Cognition and Technology Group at Vanderbilt have advocated anchored instruction as a way to support learners with a wide range of abilities and backgrounds. Students are taught over time how to take responsibility for their own learning and teachers become co-facilitators or coaches of learning. Bransford, Sherwood, Hasselbring, Kinzer and Williams (1990) suggest that curriculum materials need to allow the learner to explore, actively manipulate, and question information.

Design Process

While preparing a post-baccalaureate pre-service teacher education course in Educational Technology, the instructor decided to anchor the coursework on WebQuests in order to allow student exploration within the learning environment and meet a wide range of abilities. WebQuests are being used in elementary, middle, and secondary classrooms and it has been suggested that anchored instruction could be an effective approach in higher education (Bauer, 1998). The process of designing a 500 level class (Applications of Educational Technology) followed that advocated by Dodge (1997) and March (1995) in order to bridge the transition between the traditional didactic approach and a student-centered focus. The overall design of the class had four stages: a) determine outcomes, b) draft the project framework, c) develop the rubrics and d) design the tasks.

The six project outcomes of the class were based on the approved University of Northern Colorado curriculum for ET 501, Applications of Educational Technology. These outcomes were then tied to the Performance-Based Standards for Colorado Teachers, as well as National Council for Accreditation of Teacher Education (NCATE) and International Society for Technology in Education (ISTE) standards. The six projects included one activity based on each of the following: word processing/desktop publishing, spreadsheets, multimedia authoring, presentations, web authoring, and software evaluation.

The framework for the class followed a somewhat different pattern than that advocated by Dodge (1997) and March (1995) because of the variety of projects. It did include the subject (project software program), and expected finished project. The audience for each project was student dependent due to the wide range of content and grade level programs. Each of the finished projects was anchored to a specific WebQuest
with support from online tutorials, class notes, discussion questions, rubrics, web resources, course text, and in some instances, PowerPoint presentations.

Once the framework for each activity was completed and linked to specific standards, the rubrics were developed. Each was a scaled set of criteria for evaluating students' projects and communicating to students what was expected for the end product. All of the rubrics had four performance levels (non-proficient, partially proficient, proficient, advanced) modeling the way most projects are graded in the K-12 educational system of Colorado. Categories for the individual projects differed depending on the intended final product. The final step in the creation of the rubric was to write the descriptors for each category and proficiency. The criteria for level three was written first as the standard of what the students were expected to be able to do.

The final phase of this process was to design each task or end product. Each task had an introduction, a short, clear statement describing the activity to the students. The activity section described what the end-result of the learner's activities should be. Proficiency was shown through a variety of products (i.e., brochure, newsletter, lesson plan, story, budget, grade book, graph, HyperStudio stack, multimedia presentation, WebQuest). The resource section included sites on the Internet (tutorials, design criteria, relevant information, rubrics, class notes, WebQuest URLs, PowerPoint presentations, discussion questions) and physical resources (texts, research articles, content books).

Findings

The 50 students in the three sections of ET501, to this point, have been positive and enthusiastic about the instructional techniques (anchored instruction, WebQuests, self-paced learning) of the class. At the end of the term, a Likert scale, attitude survey will be administered in order to assess the success of anchoring the class instruction on WebQuests. Data gathered from students will be analyzed at the end of the term (Fall, 2000) and discussed at the time of the presentation.

Virtual Learning, Web Videos, and Elementary Mathematics Teacher Education
by
Janice L. Flake

This project has been to build a collection of virtual learning experiences for teacher education in the form of viewing and analyzing videotapes of interviews of children discussing their mathematical concepts and problem solving. The intended audiences are both preservice and inservice teachers.

Many times in prospective teachers in teacher education programs often have little experience with students prior to their internship, or they have lots of field experience that is not necessarily connected with theory. The bridge between theory and practice varies greatly, and sometimes the bridge is a big gap. It is difficult to make connections between the abstract theories and the real world of practice. To treat theory in the absence of experiences with children will likely result in the theory quickly being abandoned or forgotten. At the same time building a class based heavily on field experiences has its problems as well. The experiences are often random, may or may connect with the underlying theories, and risk the possibility that the students never make the links between theory and practice. Furthermore, consequences of actions can affect real students and sometimes do damage to the students, and the supervision of field experiences often is labor intensive and/or not easy to do. In addition the actions in a classroom are multidimensional and often difficult to isolate and control one variable at a time.

In 1972-73 I had a vision of building a simulated teaching laboratory. Initial efforts occurred with a PLATO program where I created a program that allowed perspective teachers to instruct simulated students (see Flake, 1973). The results were very encouraging. Participants in the study commented that they began to think of these simulated students as real; they also liked the notion that they were not doing permanent damage to the simulated students; and after going out into the schools the participants reported back that the real students behaved just like the simulated students. In addition a very popular button that was added at the request of the students was the restart button, where participants were not happy with the way things were going and just wanted to throw out that class and start all over again—phenomenon that does not normally happen with real classes. Furthermore, the simulation provided a common experience for class discussion of alternatives for interacting with the simulation. Brown (1999) found similar results as described above.

Flake (In-Review) describes a project involving 268 videos already posted on the Web of interviews of 23 children in K through 5 doing mathematical tasks illustrating their understandings of mathematical thinking following the major strands in mathematics that have been identified by national and state mathematics standards. Prospective teachers use these videos to study the students' responses and build connections between theory and practice. Samples of these videotapes will be presented at the VideoFestival.

Object: An Important Concept for Pre-service Teachers to Learn Technology

Tianguang Gao
Department of Curriculum and Instruction
Purdue University
United States
tgao@purdue.edu

Abstract: This paper discusses the importance of the concept of objects for pre-service teachers who are learning technology. Educational information is composed of different objects: text, graphics, audio, video, data, and table. Each object has many attributes. Many operations can be performed on objects. These operations are directly related to menus of application programs. Objects, attributes, and operations form concept maps corresponding to specific objects. Mastering these concept maps benefits students' understanding of the structure of software, learning of new software, and implementing multimedia material.

Introduction

Computer software application programs are an essential part of computer technology in the information age. There are many application programs available right now and more will be coming out. It is impossible for anybody to learn all the software applications in his/her discipline. But it is possible to know the basic structure of software and the basics of using software. This is true for pre-service teachers. To meet the technology standards for educators in twenty-first century, pre-service teachers should be proficient in using technologies for learning and teaching. Learning how to use the commonly-used software or application programs in educational settings is an important aspect of using technologies. Just as the object concept is very important for designing software with programming languages like C++, Java, and Perl, the object concept is also very important for pre-service teachers to learn how to use computer software. The following sections will discuss object concept, attributes of an object, operations performed on objects, concept maps related to objects, and benefits of learning the object concept.

Objects

Educational information can be represented in many forms and delivered with different media. Each form of information can be viewed as a kind of object. There are five basic types of objects that represent the educational information delivered through instruction: text object, graphics object, audio object, video object, and data object (Verduin & Clark, 1991; Heinich, Molenda & Russell, 1993).

A text object can be a letter, a word, a sentence, a paragraph, or paragraphs. The text object has always been the basic and fundamental format of information in education and will continue to be. Because of its long history, it is familiar to students, inexpensive to produce, and portable. But it can give only a vicarious experience of reality and may not be understood very well if students do not have the necessary experience to comprehend a concrete illustration.

A graphic object can be a picture, a drawing, a chart, an animation, or any kind of combination of them. It can illustrate difficult concepts, reflect the creativity of human beings, and depict the realism in different levels.

An audio object can be a recorded natural or artificial sound clip, or a piece of music. It can present stimulating verbal messages more dramatically than text can, reflect natural sound resources, and express various feelings.

A video object is the body that contains time-varying-picture images, possibly with color and coordinated sound. Video provides realistic experiences through showing/documenting places, viewpoints, complex and
dynamic changing processes, slow/fast motion, real world events, and chronological sequence.

A data object can be any number, date, and/or any unit of the above objects.

In addition to the above, another element, table, is heavily used in some application programs such as Word and web development packages. A table is an information container that is composed of various numbers of rows and columns and allows the user to organize information in many nice and neat ways. Because it always comes with other kinds of information together, it can be viewed as an object.

Attributes of objects

Each kind of object has many attributes. These attributes determine the appearance of the object and the ways that information can be represented and manipulated according to a predetermined design. Different software applications deploy different attributes of an object depending on the purposes of the software. Attributes of an object can be divided into two types: basic and extended.

The basic attributes of an object exist in general purpose software and define the primary aspects of the object. Below is a table showing the basic attributes of some objects.

<table>
<thead>
<tr>
<th>Object</th>
<th>Attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text</td>
<td>Font, size, alignment, color, style, line spacing, borders, and shading</td>
</tr>
<tr>
<td>Graphics</td>
<td>Size, position, border, layout, brightness, color, file format, and contrast</td>
</tr>
<tr>
<td>Audio</td>
<td>Volume and loop</td>
</tr>
<tr>
<td>Video</td>
<td>Position, position, border, and play control</td>
</tr>
<tr>
<td>Table</td>
<td>Border and shading, number of rows and columns, and alignment</td>
</tr>
</tbody>
</table>

Besides the basic attributes, many software application programs add more attributes to the objects depending on the special requirements of the software. In Web development, software packages like Netscape Composer, Dreamweaver, and Frontpage add alt, hyperlink, transparent, rollover, target, and interlaced to graphic objects to fit the new features of the software. In the same way, table object has colspan, rowspan, colored borders, cellspadding, cellspacing, background color, caption, heading, width, and extra HTML attributes besides the basic ones mentioned above. Adobe Photoshop adds more attributes to the graphics, some of which are resolution, effects, image mode, histogram, and layer. Extended attributes of objects give the user more freedom to control and manipulate the objects for special purposes in addition to the basics.

Operations on objects

In every kind of software, a file is an essential container for the user to work with. A file is composed of one or more objects. For example, pure text can form a Word file; text plus graphics also form a Word file. Therefore, a file can be viewed as an object or objects. In order to make use of various objects while working with a file, various operations on objects are designed. Some of them are almost universal; some are specially designed. Corresponding to the attributes of an object, there are two types of operations: basic and extended.

Basic operations are the operations performed on the basic attributes. File, edit, and format (or menus similar to format) are the three basic menus. All the files can be manipulated through the File menu with the commonly used new, open, close, save, save as, import, print, and print preview operations. New creates a brand new file to let users put object or objects on it. Open opens an existing file for editing. The products (saved files) created by software can be viewed as objects as well. For example, Dreamweaver treats products from Flash, Fireworks, and shockwaved materials as objects that can be integrated directly into the file. For each kind of object, undo, copy, cut, paste, select all, find and replace operations can be performed through the Edit menu. To change the attribute(s) of an object, the Format menu can be used to make the needed change(s). File, Edit, and Format are the three basic menus seen in various software packages.

If a software application program can incorporate more objects into the file, either an Insert or Import menu is designed to bring them into the file to work with them. For example, Microsoft Word, PowerPoint, Excel, and Access have an Insert menu. These menus plus the Help and Window menus are almost the same for every kind of software. With these menus, users can perform general tasks regarding manipulation of objects.
(except the table object). Other menus in the software are supportive. In programs that incorporate a table object, there is a Table menu or a menu specially designed for table object to perform: insert row (column), delete row (column), split or merge cells, and change attributes of a table.

Extended operations on objects refer to the operations that can be done through special software focusing on a specific kind of object regarding the extended attributes. Adobe Premiere focuses on video object. Microsoft Word and PageMaker mainly focus on text objects. Adobe Photoshop, Image Composer, Photo Editor, and Fireworks focus on graphics. Microsoft Excel and Microsoft Access focus on data object. Take Adobe Photoshop as an example. Operations like filter, adjustment, rotate, extract, add layer mask, and add types are added to the basic operations on graphics.

Concept maps of objects

A concept map is a graphical representation of concepts and their interconnections. It is believed that concept maps reflect the student’s cognitive structure, enabling both teachers and students to determine the level of understanding of material attained before, during, or after instruction (Burke 1998). The purpose of a concept map is to identify key concepts and the relationships in an instructional setting under various levels of abstraction with a visualized diagram. Research has shown that a concept map is very helpful as an instructional tool, a tool to access a student’s knowledge structure, a tool to evaluate a student’s learning, and a navigational tool in hypermedia (Lee, 1997).

Objects, attributes, and operations can be represented by concept maps of objects: basic concept maps about objects and extended concept maps about objects. The basic concept maps depict the objects, their basic attributes, and basic operations on them. Basic attributes of and operations on objects are universal. Teaching pre-service students the object concept while they learn how to use software like Word, PowerPoint, Excel, and HyperStudio will enable them to develop concept maps of objects. With the concept maps, students can manipulate the objects effectively and efficiently while they learn technologies and perform tasks with technologies. Below is a concept map of a general object.

![Figure 1. A basic concept map of an object](image)

A concept map not only allows people to connect ideas they already have, but also to connect new ideas to knowledge they already have, and to organize ideas in a logical but not rigid structure that allows future information or viewpoints to be included. Extended concept maps about objects can be formed by adding more attributes and operations to the basic concept maps, which leads to the expanded knowledge structures and to the potential to perform more complex tasks. Below is an extended concept map that can be formed from the graphic object in Adobe Photoshop.
Benefits of object concept learning

Mastering the concept maps of objects benefits three aspects of students’ learning about technology. Concept maps help students understand the structure of software. Knowing the concept maps of objects, the learners can understand the essential part of the software interface and supportive menus. For example, in Microsoft Word, *File, Edit, Format, Table, Window,* and *Help* are the main parts of the interface. *View, Insert,* and *Tools* are supportive menus. Therefore, learners can understand the structure of software effectively.

Concept maps help students learn how to use new software. In education settings, different software employs different objects. Some use one, some use two, and some even use more. If the object concept and concept maps are stressed from the beginning of using software such as Microsoft Word, this will be very beneficial for students to learn other software like Excel, PowerPoint, and HyperStudio. Microsoft Word usually uses text objects and graphic objects; Excel usually uses graphic objects and data objects; PowerPoint uses text, graphics, audio, and video objects. With more specially designed software, such as Adobe Photoshop, extended concept maps help the learning process.

Concept maps can also help students implement multimedia instructional materials. The object concept is critical to many multimedia application programs such as HyperCard, HyperStudio, Authorware, Dreamweaver, and Frontpage. These multimedia software packages integrate text, graphics, audio, and video information into multimedia learning materials. The process of implementing multimedia instructional materials with these programs is a process of manipulating the text, graphics, audio, and video object to a design. The concept maps greatly benefit the manipulation of objects used in the implementation process.

Summary

From the above discussion, we can see that object is an important concept for learning technology. Categorizing educational information into different objects helps students learn concept maps, which consist of objects, attributes, and operation while they learn the technology. This object-oriented strategy not only benefits the students’ current learning of technology, but also helps their learning of new technologies in the future.

Abstract: Ensuring that pre-service teachers are prepared to integrate technology into their teaching is a top priority for teacher education programs today. One way to help achieve this goal is to model the integration of technology throughout the teacher preparation program. This pilot study examines the integration of technology into a language arts methods course and the effects of this integration on pre-service teachers.

Introduction
The role of technology in society has become an increasingly important issue in the public school. Reports on numbers of computers in public schools show that 98% of all schools now own computers, which puts the current student to computer ratio at about 10 to 1 (Coley, Cradler, & Engel, 1997). It is imperative for educators to help prepare students in the use of technology in everyday tasks. One goal of pre-service teacher education programs is to help prepare these future teachers to become proficient in the integration of technology into the curriculum. Federal and state agencies (US Department of Education, Texas State Board for Educator Certification) as well as educational organizations and society have an expectation for the use of technology in schools. Institutions of higher learning have approached this expectation in a variety of ways. The primary mode in which teacher preparation programs have chosen to meet this need is through a separate course in educational technology course that is part of the pre-service curriculum (Thomas, 1996; Thompson, Schmidt & Hadiyani, 1995; Zachariades & Roberts, 1996). This separate course tends to present computers and technology as an isolated subject. This tends to model the use of technology as a separate component or 'add-on' rather than the integration that is vital in today’s society (Jensen, 1992; Novak & Berger, 1991). Technology use has not been central to the pre-service preparation experience of most colleges of education. Most new teachers graduate with limited knowledge of use of technology integration strategies in their day-to-day teaching (US Congress, 1995; Byrum & Cashman, 1993; Davis, 1994).

It seems unreasonable to expect that pre-service teachers would be able to integrate technology effectively after taking an isolated technology course. Integrating technology into pre-service programs must become the norm if future educators are to use technology effectively in the classroom. One way to help ensure that pre-service teachers get the most from their technology experience in the preparation program is through effective modeling of technology integration throughout courses in the pre-service program (Bias, 1995, Wetzel, 1993, Ehley, 1992). When pre-service teachers participate in a preparation program that models the integration of technology, these students are much more confident in their own technology use as well as gaining ideas for use in their own teaching practices (Stuhlman, 1998).

The Study
This pilot study proposed the integration of technology into the undergraduate teacher education program by modeling the use of technology in different courses throughout the program. This pilot study focused on technology integration strategies in a language arts methods class. To help with the integration
of technology as part of this methods course, participant’s integrated technology into their lesson plans in many ways. This included the use of educational software, desktop publishing, Internet teaching resources, presentation software, HyperStudio® and WebQuest®. Additionally, the instructor modeled each of these applications throughout the course. This modeling demonstrated to participants how technology integration occurs without becoming an add-on to the curriculum.

Participants for this pilot study consisted of undergraduate elementary education students enrolled in the Language Arts methods course in the fall of 2000. All students enrolled in this course also enrolled in Math, Science, and Social Science methods at the same time. There were 72 students enrolled in methods who participated in this study. All participants have taken the basic computer course required by the university. Participants attended the language arts methods class one day a week for three hours in a field based setting at a local elementary school. Participants attended class two days a week and observed and interacted all day in an elementary classroom two other days of the week.

All participants completed a computer use survey focusing on confidence with use of computers. Administration of the survey again at the end of the student teaching semester adds more information for this study.

Before the implementation of this study, the Language Arts methods course contained several varied assignments in order to make sure that students understood language arts concepts and strategies. These course assignments consisted of the following:

- Internet resources- a list of useful resources for teachers of language arts in grades K-8.
- Classroom design – a drawing of the students’ ideal classroom including all items, centers, room arrangement, etc... These were hand drawn and labeled.
- Language arts mini unit- consists of five lesson plans written around a theme, a web summary of the unit, and an annotated bibliography of fiction and nonfiction books related to the theme.
- Portfolio- in concert with the other methods courses, a compilation of process, product and performances of competencies related to the Texas teacher certification exam.

For this pilot study, the instructor for the language arts methods course and a member of the instructional technology faculty planned together to make changes to the course assignments. The Internet resources assignment and the portfolio assignment did not change but other assignments did in order to reflect the integration of technology into the projects. The classroom design changed so that students were required to draw their ideal classroom design using the computer rather than drawing it by hand. A paragraph reflecting on this design became a part of this assignment as well.

- For the language arts mini unit several changes were made:
  - A typed web summary with text boxes replaced the hand written web summary of the unit.
  - Participants were required to create a newsletter for parents introducing the unit.
  - The annotated bibliography must come directly from web resources.
  - Four of the five lesson plans required the integration of technology into the lesson. These included the integration of educational software, use of presentation software, use of Hyperstudio® and the use of a Web Quest®.

Participants in this study did not have experience with any of the technology application tools required for each of these assignments so it was necessary to teach them the skills needed to utilize each of these components. The IT faculty member taught application skills using mini-lessons. These mini-lessons took place in the field-based classroom at the elementary school where the methods class met. The language arts instructor and the IT instructor rotated groups through a small media center with eight computers. This helped to demonstrate to participants how to utilize integration with a limited number of computers.

Since this study examined the use of modeling integration throughout the semester, it was imperative that modeling of technology takes place in the appropriate manner during methods instruction. The faculty member for the language arts methods class did most of the integration modeling. An instructional technology faculty member served as mentor and support for the language arts instructor and modeled technology integration for the students. Examples of modeling technology during instruction included the following tools:

- **PowerPoint® for presentations** Utilization of this tool occurred several times during the semester to present information to the participants on various subjects related to reading and language arts. Participants had handouts of the presentations for use in note taking and to save as a study aid or resource for the future.
- **KidPix® for demonstrating interactive writing** During a presentation on emergent literacy, students role-played as kindergarten students while the instructor modeled interactive writing with this program.
Participants dictated story ideas based on a book read in class. The instructor recorded these ideas using KidPix©. Interactive writing also allows the young emergent reader to come up to the front of the classroom and write in the words they know. Modeling of interactive writing took place as well using the computer and software rather than the traditional chart tablet. Participants were able to see technology integration in an appropriate manner and to understand the process of interactive writing.

Word processing software Use of word processing software occurred many times during the course. On the first day of class, the participants completed a KWL chart listing what they Knew, and Wanted to know about language arts. What they Learned was added to the last column at the end of the semester. The methods faculty created a chart using word processing software and filled it in as participants thought of concepts that fit in each category. Generation of a newsletter as an example also utilized this software. The newsletter described course content and serves as a model for the newsletter participants would create for the introduction to their mini unit.

Internet The methods faculty modeled the use of the Internet as a means to locate teacher resources related to language arts and other areas. Additionally, the faculty members provided examples of WebQuests© for students to use in adapting or developing their own (for the lesson requiring the integration of a WebQuest©.

Educational Software Individual copies of educational software were set up in stations in the classroom so that participants could review them. Participants incorporated educational software into the second lesson plan of the thematic unit.

Hyper Studio® A Hyper Studio® card stack was created by the language arts and instructional technology faculty members to serve as a demonstration of how this tool could be used in classrooms.

Implications

The changes in course assignments produced several changes in the final products completed by the participants. The computer drawn classroom designs were much neater and more concise than the hand drawn ones turned in during previous semesters. Students had to take more time when deciding where objects should go in the classroom. Although color was not required for this assignment, many participants opted to add color to the design where few did in earlier semesters. Similarly, the unit summary web was much neater when done on the computer than when it was hand drawn in previous semesters. This made both projects easier to read and understand. Students commented that although they would not have used the computer for either of these assignments unless it was required, they thought the results were better. Participants felt that the initial use of the computer to draw the classroom design was more time consuming that if they had drawn it by hand but decided that the next time they had to do it would be easier and faster.

Although the quality of lesson plans did not really change, participants were able to integrate technology into their lesson plans without making the technology the whole lesson. Because of the way the technology components became a part of the class, students were able to do the same with their own lesson plans. Students in previous semesters would not even attempt integrating any of the technology tools into their lesson plans. For the first time, students also included their technology implementations into their final portfolios.

The use of technology in language arts lesson plans also crossed over into the other methods areas of math, science and social sciences. Participants were able to use what they learned to apply in these other courses as well. Participants often wrote lesson plans that integrated language arts and science and turned these in to both instructors. In this way, their use of technology for language arts also influenced lesson planning in other areas. The participants frequently and enthusiastically shared their experiences of integrating technology into lessons developed for the other methods classes, especially with the instructional technology faculty member. One particular example stands out where the participant developed an interactive bulletin board for the social studies methods course on the election. This assignment included activities for using the Internet to search for information on the candidates, as well as participate in an election WebQuest©.

Participants showed an increased use in technology of all kinds. Several participants utilized email to send in lesson plans. This was not the case in previous semesters. Participants were also more willing to use email to ask questions about the course than they had in past semesters.

Since this is an ongoing pilot study, there are changes are being made to the program following the completion of this first semester. One problem with this study was that too much technology
information was crammed into one methods course. It was extremely difficult to include all the regular course content and the technology skill lessons needed to complete the assigned projects. During the next phase of the study, technology skill mini-lessons have been integrated throughout the methods courses in order to make the time spent more equitable between the courses. In addition, some time in the computer lab on the university campus before the courses are field based. This will allow participants to gain some of the skills they need before going out into the field based school where it is harder to find computers to work with.

Conclusions
This ongoing pilot study has shown that integration of technology into the pre-service teacher program can be beneficial. There was an increase in the quality of student projects after exposure to technology integration than in past semesters. Participants seemed more willing to use technology overall after their exposure to it in class. The increased use of email and the willingness to use technology in lessons for courses that did not require it are examples of this.

It is important to note that participants were able to draw on the technology skills learned early in the semester for projects later in the semester. Participants learned to make text boxes and other shapes for their physical classroom design. When it came time to work on the newsletter, one participant volunteered to show the rest of the class how she used text boxes to make her newsletter. This is a great example of a student using this prior skill to apply it in a new and appropriate way. The class this particular example was in completed their newsletters before the other two sections of the class did.

The changes occurring in the undergraduate teacher preparation program to integrate technology are ongoing and will be cyclical in nature. One participant in this semester’s course was teaching a lesson out at her field-based school. The lesson happened to be a lesson that integrated a PowerPoint presentation. The school principal entered the room and was very impressed with the lesson. He then asked this student if she could teach the rest of his faculty how to use PowerPoint. This is one of the reasons that modeling the appropriate use of technology is so important. The university students will show what they are learning and will be able to assist in-service teachers with their technology integration. More of this will occur as the students move from methods to student teaching in the next semester. Participants who completed methods and moved on to student teaching will remain in touch with the faculty during student teaching through email. At the end of the student teaching semester, they will complete the computer use survey again to compare with the results of the first survey. It is anticipated the computer use and confidence will increase by the end of the student teaching semester.

This study will continue as the methods courses change again for the Spring 2001 semester. These changes should bring about positive effects on the use of technology as an everyday tool in the classroom. As the State of Texas puts an increasingly higher emphasis on the use of technology in the classroom, undergraduates in the teacher preparation program need as much technology integration as they can get. Changes in state certification in Texas are forcing universities to cut some courses in order to make room for others and the technology for teachers course is one that is likely to be reorganized in the course rotation. Integration of technology into all undergraduate education courses will help with the problem of the loss of this course. Based on the changes in technology use noted for the participants in this study, there will be an even greater change for upcoming students as technology use trickles down to other undergraduate education courses before the methods semester.

Abstract: Over the last decade Marietta College has integrated technology into its teacher education program. During that time students found it difficult if not impossible to utilize their knowledge and skills of technology in the K-12 arena. In an effort to accommodate students, the college engaged in multiple projects with the local schools to provide sites and experiences that demonstrated "best practices" for integrating technology in the K-12 curriculum. This paper discusses how some of the projects involved students and teachers from local schools, as well as college teacher education students and their faculty. As a result of these projects, Marietta College is making progress toward eradicating the barriers of teacher attitude and lack of willingness to allow teacher education students to try new technology in their classrooms. In addition, these future teachers see first hand how technology can enhance student success, thus insuring technology as an indispensable tool in the classroom.

Integrating technology into the Teacher Education program at Marietta College has been a priority for the last decade. However, while the college worked diligently to secure hardware, software, lab equipment, network services, course requirements, and pedagogical acceptance among faculty to facilitate this integration, our students frequently failed to utilize their knowledge of technology in their K-12 fieldwork. Barriers facing our students were numerous: lack of equipment in the public schools, lack of commitment to and knowledge about technology among local teachers, a mismatch of platform capabilities, and students' less than enthusiastic belief that technology could be integrated meaningfully into the K-12 curriculum. Because of these obstacles, the Education Department created new strategies, methods, and activities for addressing this "broken pipe" between higher education and K-12 educational technology.

Students in the Teacher Education program at Marietta College are required to take a course entitled Technology in the Classroom during their freshman year or immediately upon transferring into the college. This course acquaints students with research and best practices for integrating technology into their field of education. In addition, students learn software that is utilized for assignments in most of their other education courses. These assignments vary from simple to complex, incorporating such technology as graphics, sound, digitized video, digital photography, multimedia, and web page design.

Over the years, students enthusiastically completed their technology related assignments, but became frustrated when they attempted to utilize them during their field placements. Often the local schools' computers were outdated or utilized a different platform than the one used by the college students. Sometimes the cooperating teachers saw no value in allowing the students to utilize technology during their field work. The department began developing new methods and strategies to combat these problems.

First, only cross platform software was chosen for use. Second, where computers were in short supply, students were permitted to take department laptops to present lessons planned for field experience classrooms. Third, Zip disks and drives, which could be attached to school computers, were used for large multimedia projects,
writing projects with Hyperstudio, teachers incorporate digital photos which become writing prompts for the electronic book is printed and taken home by the proud authors who are able to read it to their parents. Students are able not only to see the story but to hear it in the background, ideas for writing abound. Children could be represented on their web pages. College students and education faculty worked on site with students in the school’s computer lab as they investigated their books and learned to make web pages with Site Central. In addition to the class of fifth grade students and their teacher, the project attracted the interest of other teachers in the school. Once posted on the web, this project provided the opportunity to share students’ work with parents and other teacher education students.

Additional opportunities to model effective technology integration are afforded through Marietta College Reading Clinic programs. A four week summer program, Summer Reading Camp, provides a practicum experience for undergraduate and graduate students who are seeking reading certification. Graduate students who teach in the summer program are typically practicing K-12 classroom teachers while undergraduate students are senior level teacher education students. Children who attend Reading Camp have been recommended due to poor literacy performance at school. The majority of these children also exhibit negative attitudes toward reading and writing. Teachers are required to address literacy needs using a variety of good children’s literature and through the daily integration of technology. Practicing teachers and teacher education students are able to see the how technology can be used as a tool to enhance instruction and motivate reluctant readers and writers. Teachers use Kid Pix, Hyperstudio, and The Amazing Writing Machine to create lessons which facilitate literacy growth. Frequently, the practicing teachers are able to benefit from the modeling of technology use by undergraduate students who work with them in teaching teams. Projects utilizing pattern writing, language experience, and text for wordless picture books have successfully used technology as a way to encourage student writing.

Hyperstudio is a useful tool for Reading Camp teachers to create templates to encourage student writing. Students are able not only to write responses on stack pages, but can also record themselves reading their text. One example of this successful use of Hyperstudio involves wordless picture books such as David Wiesner’s *Tuesday* which are scanned and incorporated into Hyperstudio stacks for student response. When first and second grade students are able not only to see the story but to hear it in the background, ideas for writing abound. Children work in small groups to collaborate on their story and take turns adding text to pages with scanned images. This electronic book is printed and taken home by the proud authors who are able to read it to their parents. In other writing projects with Hyperstudio, teachers incorporate digital photos which become writing prompts for the students. And finally, wherever possible the internet was used for accessing instructional material. These strategies solved most of the hardware and compatibility problems.

Addressing the problems of teacher enthusiasm for and willingness to integrate technology into their curriculum proved to be the most difficult obstacle to address. In attempts to change teacher opinion and create a technologically friendly climate, the Education Department began designing projects with local school teachers that incorporate technology into the teaching/learning process in meaningful, creative ways that complemented the K-12 curriculum. These activities, at times, brought K-12 students and teachers to the college to work with education students and faculty. Other activities involved taking education faculty and college students to schools to work with K-12 students. Through these projects, the potential of integrating technology into the K-12 curriculum was witnessed by K-12 students and their parents, teachers, administrators, college students, and college faculty.

One of the first attempts to model effective use of technology in K-12 curriculum involved work with talented and gifted seventh grade language arts students from Marietta Middle School. The education department was approached by the Middle School gifted teachers for ideas about how to adequately challenge these students. This led to the design of a project which linked children’s literature, social studies, and technology using student-created multimedia projects. Led by two education faculty members, teacher education students assisted the seventh graders and their teachers as they learned to create Hyperstudio stacks about historical fiction selections during biweekly language arts periods spent in the college computer lab. Seventh graders were able to search internet sites to learn more about selected aspects of their books, scan photos and artifacts which related to the time periods of their books, create video clips which demonstrated various aspects of the time period, and digitize music to accompany their projects. Student projects were shared at an open house held for parents and school staff. Through this project, parents, teachers, and education students were able to see how multimedia can become a tool for integrating curriculum, encouraging critical and creative thinking, and fostering student enthusiasm for learning. After several projects with middle school talented and gifted students during a period of three years, it became evident that the gifted teacher and the middle school principal recognized the value of technology with this particular group of students. At this point, education faculty saw the need to model how technology can facilitate curriculum goals with heterogeneous groups of students and with students at different grade levels.

In an onsite program at Washington Elementary School, a class of mixed ability fifth graders was selected to work with students from the adolescent literature course to read historical fiction selections and create web pages about the books. Books were selected which could be tied to the fifth grade social studies focus on Native Americans. Students were asked to consider aspects of the cultural and historical contexts of their books which could be represented on their web pages. College students and education faculty worked on site with students in the school’s computer lab as they investigated their books and learned to make web pages with Site Central. In addition to the class of fifth grade students and their teacher, the project attracted the interest of other teachers in the school. Once posted on the web, this project provided the opportunity to share students’ work with parents and other teacher education students.

Once posted on the web, this project provided the opportunity to share students’ work with parents and other teacher education students.

Additional opportunities to model effective technology integration are afforded through Marietta College Reading Clinic programs. A four week summer program, Summer Reading Camp, provides a practicum experience for undergraduate and graduate students who are seeking reading certification. Graduate students who teach in the summer program are typically practicing K-12 classroom teachers while undergraduate students are senior level teacher education students. Children who attend Reading Camp have been recommended due to poor literacy performance at school. The majority of these children also exhibit negative attitudes toward reading and writing. Teachers are required to address literacy needs using a variety of good children’s literature and through the daily integration of technology. Practicing teachers and teacher education students are able to see the how technology can be used as a tool to enhance instruction and motivate reluctant readers and writers. Teachers use Kid Pix, Hyperstudio, and The Amazing Writing Machine to create lessons which facilitate literacy growth. Frequently, the practicing teachers are able to benefit from the modeling of technology use by undergraduate students who work with them in teaching teams. Projects utilizing pattern writing, language experience, and text for wordless picture books have successfully used technology as a way to encourage student writing.

Hyperstudio is a useful tool for Reading Camp teachers to create templates to encourage student writing. Students are able not only to write responses on stack pages, but can also record themselves reading their text. One example of this successful use of Hyperstudio involves wordless picture books such as David Wiesner’s *Tuesday* which are scanned and incorporated into Hyperstudio stacks for student response. When first and second grade students are able not only to see the story but to hear the background, ideas for writing abound. Children work in small groups to collaborate on their story and take turns adding text to pages with scanned images. This electronic book is printed and taken home by the proud authors who are able to read it to their parents. In other writing projects with Hyperstudio, teachers incorporate digital photos which become writing prompts for the
students. One successful project followed the reading of *Wacky Wednesday* by Theo LeSeig with first grade students. Students and teachers posed for digital photos while reading a book in a "Wacky pose." After the teacher inserted the photos in the Wacky Wednesday Hyperstudio stack, students were able to write and record sentences to describe the pictures. The class's version of Wacky Wednesday was a popular attraction during the community open house on the final day of Reading Camp.

Figure 1: A Reading Camp student's contribution to the class's "Wacky Wednesday" HyperStudio stack.

Broderbund's Kid Pix and Amazing Writing Machine are additional writing tools which have proven to be effective with reluctant readers and writers. Reading Clinic teachers use digital photos and discussions of classroom experiences and field trips to prompt student ideas for group language experience stories. In other lessons, students may use a predictable picture book as a pattern for their own Amazing Writing Machine or KidPix books. Students are then given the opportunity to illustrate their contributions on the KidPix screen or the Amazing Writing Machine page. The intriguing clip art and paint tools coupled with the child friendly interface of these programs has allowed many of the Clinic students to feel like successful authors when their books are printed and shared with other students and parents. The capacity for Amazing Writing Machine to read the students' words is a popular feature with students and encourages them to double check spelling when the computer doesn't read the story properly. KidPix allows the students to record their own voices reading their work. Teachers have noted that this appeals to many children who are otherwise reluctant to read in front of a live audience.

Figure 2: KidPix slides created as part of a Reading Clinic language experience slide show.

The integration of technology into Reading Clinic lessons has been facilitated with the purchase of laptop computers which enable teachers to sit on the floor with collaborative groups of three to four students while the language experience story is discussed and constructed or while students share their creations with peers. The greatest advantage of the laptop computers has been to allow undergraduate Reading Clinic teachers to take computers with them as they conduct one on one tutoring with children at school sites. In this way, the college
students are able to insure that they will have the necessary software need for the lesson and they are able to work in a variety of locations in the school building. Teachers working in the building are able to observe the college student tutors working with technology and have begun to indicate an interest in the applications they are using. Children frequently return to classrooms after tutoring sessions with a desire to share their excitement about working with technology with their teachers.

In a series of small steps, Marietta College is making progress in eradicating the barriers of teacher attitude and lack of willingness to allow teacher education students to try new technology in their classrooms. More importantly, teacher education students are successful participants in the integration of technology into their lesson plans with K-12 students. As future teachers see first hand how technology can enhance student success and engagement in learning, its future as an indispensable tool in the classroom is insured.

College of Education
North Carolina State University
United States

Abstract: Mandatory technology requirements for student teachers have put faculty in teacher education programs in the position of being responsible for a learning environment enriched with technology. This paper addresses the processes being used by NC State faculty in the College of Education for infusing technology in all levels of classes (foundations through clinical semester) and across disciplines. MentorNet, a PT3 project, forms bridges between current and future educators by challenging and supporting each other in the creation and critical application of emerging technologies for 21st century classrooms.

Introduction

The state of North Carolina has a set of Technology Competencies for Teachers which grew out of a report from a statewide Technology Users Task Force in 1995. Aspiring teachers must demonstrate these competencies in order to receive an initial license to teach (NCDPI). The mandatory technology requirements have put faculty in teacher education programs in the position of being responsible for a learning environment enriched with technology. North Carolina's Department of Public Instruction has made meeting the competencies more serious by requiring preservice students to develop technology portfolios. The MentorNet project (http://www2.ncsu.edu:8010/ncsuicep/mentornet/) addresses this issue by developing collaboration within and among programs to help students develop teaching portfolio artifacts throughout their coursework culminating with clinical practice and portfolio assessment by teacher supervisors and cooperating teachers. A technology thread serves as a bridge across programs including Content Area Reading, middle school interdisciplinary projects, a science education technology methods course, a mathematics education technology methods course, and a high school social studies professional semester.

WebQuests: Scaffolded Instruction for Content Area Reading on the World Wide Web

An instructional assumption that is regularly made by educators is that the hypertext nature of the WWW and the freedom of choice that it affords will facilitate students' understanding and use of large amounts of textual information. In some studies of hypertext, however, readers actually found hypertext more difficult to read than linear text (see Gordon, Gustavel, Moore & Hankey 1988; Rouet & Levonen 1996). Related to this issue, Shapiro (1998) found that her hierarchical system of information did not present a reader-advantage over a linearly-ordered one with respect to knowledge retention or quality of written essays. Shapiro concluded that in order to make hypertext advantageous as a learning tool, supportive links must be included to prompt readers to think explicitly about the information relationships they are encountering. A second assumption often made by educators is that students can critically evaluate their web-based resources, a task that has been historically relegated to editors of traditional print publishing companies. Since the flexibility inherent in web-based learning may allow too much freedom for some students to handle, teachers must determine how much freedom
is appropriate and simultaneously teach students strategies for handling their new freedom. Fortunately, a number of recently designed online tools and activities address the potential problem of unlimited freedom.

One particularly promising organizational tool is the WebQuest (Dodge 1995). This web-based set of instructional activities can provide instructional scaffolding as teachers and students take advantage of the WebOs informational resources in a directed, focused way. WebQuests are inquiry-oriented units of study that propose an open-ended problem for students to solve with the resources put at their disposal in the hypertext environment. A thorough description of WebQuests can be found at http://edweb.sdsu.edu/courses/edtec596/about_webquests.html.

WebQuests are undergirded by key instructional principles that: 1) allow teachers and students to set a purposeful context for reading in which everyone can participate; 2) give readers access to information on a topic at serveral levels of readability/difficulty; 3) provide multimedia (e.g., audio, video) dimensions to enhance the learning/reading process; 4) create opportunities for students to participate in social construction of meaning and consensus building; 5 create opportunities for students to synthesize ideas across multiple source documents; 6) provide scaffolding for cognitive processing of text (see Spires & Estes, in press).

WebQuests are particularly useful as a technology point of entry for students in Content Area Reading (see http://www.courses.ncsu.edu/classes/eci541001/index.html), a course that is required across degree programs. By requiring the development of a discipline-based WebQuest within the Content Area Reading course, students may use this web-based instructional product as part of their required technology portfolio as well as an instructional tool in their school-based internship experience. WebQuests are particularly appropriate in that they can be created as high-tech or low-tech projects, commensurate with a student's comfort level with technology. Since a primary aim of the Content Area Reading class is to help students explore theoretical and practical challenges of web-based reading and learning, a WebQuest is an appropriate instructional tool to help achieve this goal.

The Wetlands Preservation Project

The Wetlands Preservation Project brought preservice teachers in all core disciplines together with 100 middle school students and their teachers who sought a capstone eighth grade service learning experience (Arnold & Beal 95). Working with churches (Partners for Environmental Justice), state and city government, neighborhoods and North Carolina State University, the eighth graders conducted action research to become fully informed about wetlands, law and politics, city history (Beal 92) and environmental justice.

With the help of classroom and preservice teachers, the middle school students used web research, GIS technology, Excel and Power Point, topography maps, neighborhood interviews and conversations with city officials. Teachers guided and learned along side their students as they incorporated all forms of learning into this theme-based unit. They used math to draw and plot maps of the area, made flow charts of the problem cycle, prepared cost analyses and developed spread sheets that indicated the use and abuse of the wetland area. Their personal writings - essays, poems and songs - reflected a new found appreciation for the beauty and solitude of the wetland. In social studies they addressed the issue of environmental justice, examining the wetland area in light of land use and city services affecting residents of the area. GIS enabled them to study area demographics and determine that the area has long lacked for amenities that other parts of the capital city enjoyed. Letters to the members of city council and the mayor helped alert city officials to the need to carefully study city plans for the wetlands. Initially, science drove the unit, as students increased their knowledge base about wetland form and function. They studied the land and the hydrosphere, change over time, population dynamics, river systems and erosion.

As students took wetland theory to practice and examined their own cityOs wetland, they discovered that being knowledgeable is not as simple as textbook learning in one core subject, but that, like life, learning must be integrative. The wetland project enabled them to use and acquire life skills by becoming involved and active in a community issue. Together with preservice teachers, students prepared a technology enhanced presentation about their wetland research for a university-wide Spell of the Land symposium. They presented their findings about the wetland issue in the form of poems, songs, reflections, a ten foot mural and a digital slide stream presentation with voice over reflection and music. Because preservice teachers were involved from the projectOs inception, they experienced all aspects of teaching - brainstorming, planning, teaching technology skills in the context of the project, managing numerous groups with many different assignments,
OutVentures Incorporate Technology and Science

One of the education courses in the Science Education program has been restructured to focus on student practice of instructional technology and on student development of digital products for instruction (http://www.ncsu.edu/sciencejunction/route/usetech/index.html). One venue that allows students to practice the technology they are learning to use in the classroom and the lab are “OutVentures” (Outdoor Adventures). Activities are scheduled on a monthly basis to engage the Juniors taking the course to use the technology outside of the classroom and to develop instructional materials around the data they collected. Students who have already taken the course are also invited to the OutVentures. One such OutVenture was capturing the images of the January 1999 lunar eclipse. Web pages were developed from the images to promote earth-moon-sun motion inquiry activities, and provide service to the larger community by making these projects available to teachers.

Developing Teachers’ Techno-Mathematical Knowledge

According to the National Council of Teachers of Mathematics, "technology is essential in teaching and learning mathematics; it influences the mathematics that is taught and enhances students' learning" (NCTM 2000, p.11). The use of the word essential in this statement has many implications for school mathematics, as well as mathematics teacher education. Not only are teachers charged with a vision of transforming their teaching and students' learning of mathematics, but teacher educators are challenged to prepare teachers who can utilize technology as an essential tool in developing a deep understanding of mathematics, for themselves and their students. Thus, teachers must develop techno-mathematical knowledge, which consists of several elements:

1. Solving mathematics problems and constructing mathematical ideas utilizing technological tools
2. Using technological tools to justify mathematical ideas and engage others in meaningful mathematics
3. Designing experiences with technology that will allow others to develop techno-mathematical knowledge.

This includes designing lessons with appropriate tasks and questions, as well as interactive technology templates using dynamic geometry tools, spreadsheets, or web-based technologies (e.g., java, Shockwave).

A traditional approach to mathematics teacher education assumes that the skills needed in mathematics, pedagogy, and technology are distinct entities. In many mathematics teacher education programs, preservice teachers learn their mathematics content separate from their pedagogy content and separate from basic technological skills. These preservice teachers are then expected to make use of these separate skills in a classroom as a mathematics teacher. Some teacher education programs do combine content with pedagogy courses, but still have separate technology courses that are often taken jointly by preservice teachers from a variety of disciplines and grade level concentrations. The message behind this type of teacher preparation is that technology is an add-on “subject” rather than a subject-specific learning tool. Garofalo, Drier, Harper, Timmerman, and Shockey (2000) set forth guidelines advocating for an integrated and appropriate use of technology in mathematics teacher preparation.

Teaching and learning mathematics effectively in a technological classroom requires multifaceted knowledge that extends beyond what is typically learned in mathematics methods courses. The work of Garofalo et al (2000) can help teacher educators weave appropriate technology experiences into existing mathematics methods courses. As part of the sequence of courses required in the secondary mathematics education major, students take a course on teaching and learning mathematics with technology. The goals of the course are to have students revisit their own learning of school mathematics topics using technology. The preservice teachers gain a deepened and broadened understanding of school mathematics, learn how to use
powerful interactive technology tools, and develop techno-mathematical knowledge needed for engaging their students in learning powerful mathematical ideas with technological tools.

Developing Critical Perspectives and Ethical Practices in Technology Applications in Social Studies

The North Carolina technology portfolio requirement for initial-license teaching candidates has impacted all subject area methods classes. To Social Studies Methods classes, this component adds another dimension to the methods through which the multidiscipline of Social Studies will be taught and learned. Because of the portfolio requirement's recent development, there is little in the way of research on Technology Portfolios in Social Studies teacher education.

For the Methods instructor, this poses certain challenges in an already "loaded" course. In the first year, the response was to add two technology sessions, training students in Power Point and requiring that they construct a (minimum) 6-slide presentation that imported resources from the Web with relevant citations. In the second year, a computer lab each week was added across the 8-week pre-practicum intensified Methods schedule. By the third year, fortunately, courses that appear earlier in our program had also been adapted. The students' previous experience was built upon with designing WebQuests housed on remote sites such as "Filamentality" (http://www.kn.pacbell.com/wired/fil/). Students designed websites that coordinated with their unit design specifically for the course they would first teach in the practicum. North Carolina also requires a Beginning Teacher Portfolio that includes a unit plan of 5 consecutive lesson plans. Students design a unit of 10 days duration that must include the eight intelligences (Gardner 1983) plus a technology component. As one might imagine, these units are densely packed. The methods classroom experience indicates that students, lacking other models, simply adopt this model as their unit planning model and take seriously the importance of engaging the multiple intelligences as well as technology inclusion.

In requiring the website, students are asked to compose in Netscape Composer since that would be available in the greatest number of schools, no matter what their technology resources. This proved very useful to students. At the same time a website was built for the Methods class which links each of the students' sites as well. Students worked collaboratively, sharing links and Internet treasures. An important first step in this was a discussion of Boolean searches that would include certain key phrases such as "lesson plan," "simulation," "learning activity," "jigsaw," or whatever was desired. The purpose was to instill a reaction/response that would make the Internet the first source of instructional resources. Work on search strings, it turned out, was essential before the Netscape Composer lessons.

There were 2 Netscape Composer lessons, with 3 weeks in between. Each lesson was approximately an hour long with an hour practice or execution. In the first, we learned how to link internally and externally to pages of our own and on the Internet. In the second lesson, we learned how to post these onto the university webspaces set aside for student use. Each of the sessions was led by an undergraduate with technology work/study experience. One of the most important lessons in technology infusion is to let student teach one another. People learn and apply these new technologies on an as-needed basis; therefore in any group there is "distributed cognition" that the instructor must initially facilitate. Once a collaborative norm has been established, the resource sharing and co-teaching and learning become routine. I have written in the past about "modeling learning" (Alibrandi, 1997). In this case, the undergraduate was teaching all of us; myself included. I believe that if instructors model learning to students, that there will be a more fluid approach to learning and teaching that will influence novices to be more open to distributive and other types of collaborative learning in their own classrooms. We have been very pleased with the (what I call) "uptake" by cooperating teachers who have responded positively to having a ready-made customized website.

We point to websites that may be helpful and describe the evolving adaptations that have been made in Social Studies Methods classes to accommodate the changes. Even as this process has become more "seamlessly" integrated, several questions remain that have implications for the teaching of Social Studies Methods. These are: Will there be adequate time to address the increasing methods of technology integration within existing course structures? Do Methods students learn as much, more or less about teaching Social Studies as they construct technology portfolio products? Will the portfolio products be useful in currently-equipped classrooms? How and when will it be appropriate to research Social Studies students' learning with technology? Finally, as we integrate technology into Methods classes, how do we exemplify the reflective nature of the NCSS theme of Science, Technology & Society by developing critical perspectives and ethical practices in technology applications?

Abstract: Success in the elementary classroom demands that teachers understand and have a working knowledge of educational technology. In 1999 the Education Department at Rollins College set the goal that all education students would graduate with the skills needed to effectively use technology in the K-12 classroom. Using the competencies as a guide, a new educational technology course was designed and implemented in Fall 2000. This paperless, self-paced course uses e-mail messages to guide the students through the basics of a specific software program such as Word, Internet and databases searches, Excel, PowerPoint, and Netscape Composer. The exercises develop the technological skills necessary for other education courses. Pre and post surveys showed a positive change in computer skills and confidence in using technology. The dynamic course design incorporates the latest technology and provides the foundation necessary for teachers to adapt their knowledge to new technology as it develops.

To be successful in today's classroom teachers must understand and have a working knowledge of educational technology. With each passing day computers become a more integral part of the elementary curriculum, for instruction in and out of classroom, student assessment, and communication with parents and the community. Technological literacy is essential to be an effective teacher. This need is reflected in Florida Department of Education (FDOE) mandates (DeTure 99). Use of computers is specified as one of the twelve Accomplished Practices required of all pre-professional and professional teachers and is inherent for Florida state approved teacher education programs. Yet, the explosion of technological knowledge challenges even the most willing pre-service teacher.

The Education Department at Rollins College investigated a variety of options for helping pre-service teachers become technologically literate. Beginning with the 2000-01 Academic Year the Department instituted a systematic approach for elementary education students to develop their technology skills. Prior to this time, although students were exposed to some elements of educational technology in their course work, a technology course was not part of the teacher education curriculum. While pre-service teachers were advised to take short courses offered by the Information Technology Department, these courses were not designed to address the specific needs of teachers. The most successful approach for infusing technology into the educational curriculum was its integration into a biological science content course specifically designed by the authors for pre-service teachers (DeTure, et al. 90). The technology components were utilized by students concurrently enrolled in the science content course and the science methods course. Two problems emerged with this approach. One was the proliferation of the uses of technology, and the limited amount of course time to teach this material in a science content class. The second was that the science content course was not required of all majors, so many graduates did not have even this limited exposure to technology. Students not enrolled in the biological science content course were left to their own devices for developing their technology skills beyond the basic Internet searches used for activities and research in their education courses.

In the Fall of 1999 the Education Department, as part of the program evaluation plan, set the goal that all education students would graduate with the skills needed to effectively use technology in the K-12 classroom. The ensuing discussions, in conjunction with the review of state standards and FDOE mandates, led to the establishment of a set of computer competencies for elementary teachers. The Education Department concluded that the most practical approach to ensure that all students would meet the goal was to develop a required course to provide the foundation for the technological skills needed throughout the curriculum. During Spring 2000, the
Education Director approached the instructor of the biological science content course to explore the possibility of deleting the technology components from the biology class and expanding this material into a new technology course. Using the competencies as a guide the education faculty and the biology instructor jointly designed the specific content and order of coverage for the course. This ensured that the needs of the students would be met and that students concurrently enrolled in other education courses would have the computer skills required for success in those classes. The design of this course was intended to be dynamic in order to incorporate the latest technological advances as they occur.

The new technology course was first offered as a pilot course and co-requisite for the science methods course in Fall 2000. All class sessions were attended by the science methods instructor in order to facilitate integration of the technology into the elementary science curriculum. This paperless, self-paced course met once each week for 75 minutes. Before each class session students were e-mailed instructions to guide them through the basics of a specific software program. Over the course of the term the students were introduced to e-mail, word processing, Internet and databases searches, Excel, PowerPoint, and Netscape Composer. The exercises were designed to develop the skills necessary to apply this technology in their other education courses. For example, students in the educational statistics course used Excel to solve problems and to graphically illustrate data, and science methods students used PowerPoint for their science curriculum presentations.

At the end of each class students were assigned a homework problem requiring them to apply what they learned in the session. Students worked individually but were encouraged to use the instructor and classmates as resources. In addition to the practice element and to further insure mastery of the material, each student constructed a technology portfolio demonstrating their ability to use each software application and its relevancy to the elementary classroom. This web-based portfolio also serves as the initial model for the student's electronic performance portfolio required by the Education Department for graduation. Uses of electronic portfolios is further developed in upper level curriculum courses. The instructor of the educational technology class acts as a consultant for the computer segments in the education courses that apply this technology.

All assessment was and will continue to be performance based inherently containing a mastery component. Homework assignments were submitted early, reviewed and commented on by the instructor prior to the due date giving the students the opportunity to revise and resubmit their work. All portfolio entries were reviewed through peer evaluation; entries could be altered throughout the term and were only graded at the end of the course through an oral presentation for a mock interview with a school principal.

The need for an education oriented technology course at Rollins was documented in part by a technology literacy survey completed by all students in the biological science content course. Students enrolled in the new technology course completed a similar survey as pre and a post test to measure student perception of changes in their computer skills and their confidence in using technology. Survey results showed an increase in confidence in the use and application of computer technologies. Students reported a marked improvement in their ability to use the specific software introduced in the course. Anecdotal observations also indicated that these students served as technology mentors in their other education classes. Long-term assessment of the course will involve evaluation of the students throughout their academic program and in post-graduation follow-up studies conducted annually by the Education Department. The amount and effectiveness of computer usage by the students who have completed this course will be measured and compared to other new in-service teachers who have had not completed a similar course in educational technology.

While the initial indications regarding this approach to improving the technological skills of pre-service teachers are positive, it is understood that no single course can address all the technological needs of the students. This course at least addresses their initial basic needs and provides pre-service teachers with the foundation necessary to adapt their knowledge to new technology as it develops.

Teacher Education Changes, Transitions, and Substitutions: Technology to the Rescue!

Lynn Hartle, Univ. of Central Florida, USA

When, a new updated Early Childhood teacher education program with an entirely different set of courses had to be created to meet a new set of state competencies, a flexible course - Early Childhood Practicum was crafted to ease the transition and provide coursework for twenty-three students who needed a total of seven different courses in to graduate. The course individualized the learning so each student could complete the required competencies.

Technology came to the rescue as means for me to use email to keep track of pairs of students who worked with teachers in several schools on inquiry projects to improve teaching and learning for young children. The course design also included five face to face college class meetings and creation of a video tape. Successes of this learning experiences were win-win for teachers in the field and students. Since so much of the responsibility for creating and implementing the inquiry project was a collaboration of teacher and college student, the motivation levels were high and most results highly successful. As the professor, my job was made easier when the excitement levels reduced the need for an intensive mentoring on my part.
Abstract: The emphasis on knowledge attainment, higher order thinking skills and real-world learning opportunities within teacher education offers numerous opportunities for preservice teachers to develop a conceptual framework through which their future educational profession is viewed. The introduction of instructional technology into the educational environment offers the opportunity to represent such knowledge and understanding within a graphic format.

Introduction

The emphasis on knowledge attainment, higher order thinking skills and real-world learning opportunities within teacher education offers numerous opportunities for preservice teachers to develop a conceptual framework through which their future educational profession is viewed. The introduction of instructional technology into the educational environment offers the opportunity to represent such knowledge and understanding within a graphic format.

Graphic Representation of Information

Not only does the graphic representation of information throughout the learning experience develop a visual framework for the preservice educator's understanding of the theories and concepts being presented, but the opportunity for preservice educators to graphically represent their own developing conceptual framework of understanding further encompasses a rich opportunity for reflection, discussion and possible revision of the graphic representation towards a fuller understanding of the personal, developing conceptual framework. Further, the preservice educators is developing an understanding of graphic representations within a learning environment, as well as offered the opportunity to view an instructional model that will be emulated within the PreK-12 instructional environment.

As an example of information developed into a graphic representation, the Instructional Technology specialization area of the University of Houston - Clear Lake's School of Education offers a philosophical orientation to all learners, so as to delineate the theoretical underpinnings of the specialization area. While a textual explanation is necessary, graphic representations of the textual information aid in the conceptual understanding and begin to develop a graphic realization and understanding of the reader's conceptual framework associated with the Instructional Technology specialization area. For example, following is a graphic representation of the Instructional Technology's philosophical orientation:
Although this is an attractive graphic representation, which aids the user in realizing the main aspects of the information and how it fits together, the simplicity of the design respects the integrity of the information and the creation of a visual understanding; this understanding offers the user a conceptual framework through which to further integrate the philosophical orientation of the Instructional Technology specialization area.

Further, a second graphic that presents the Instructional Technology specialization area’s philosophical orientation towards a student-centered model of instruction displays two representational models for the user’s understanding: teacher-centered model of instruction, student-centered model of instruction. Through the representational modeling of the theoretical models of instruction, the user can create a thorough understanding of the Instructional Technology specialization area’s focus upon the student-centered model of instruction that is apparent and modeled within the Instructional Technology courses offered.

The graphic representation of advanced theoretical viewpoints that are deemed important by faculty within the Instructional Technology specialization area aids the user in the creation of a conceptual framework of understanding through which the textual information can further delineate the knowledge obtained.

Conclusions

The opportunity to model the art of graphic representations of information within a learning environment aids the preservice teacher in the developmental process associated with realizing their own developing conceptual framework. Also, the preservice teacher observes the modeling of such a task, as well as the higher order thinking skills associated with this activity. The preservice teacher’s understanding of their developing conceptual framework is imperative towards the professionalism associated with the field of education; through the graphic representation of such information, the preservice teacher will integrate the technological aspects of their training within an instructional environment. The simplistic representation of integrated knowledge and understanding is both difficult and imperative towards the development of the preservice teacher’s higher order thinking skills and professional future. Graphic representation of a learner’s conceptual framework may appear simplistic, yet this powerful activity emphasizes the preservice teacher’s understanding of the profession, as well as areas of strength and possible areas of further growth.
Computer use in pre-service and in-service teachers

Brad Hokanson
University of Minnesota
bhokanson@che.umn.edu

Abstract: This study examines survey data from pre- and in-service teachers and makes observations from that data regarding computer use. The three main observations include; broad and common use of simple elements such as email was found; minor differences were found between men and women in technology use; and participants increased their use of the internet for purchases and class registration during the study period. The teachers appeared to parallel computer acceptance in general society. As society embraces technology, so too will our newer teachers.

Introduction

The major portion of the impact of instructional technology will come through improved and continued education of in- and pre-service. The teachers existing knowledge, their use of computers, and their technology oriented activities all affect their learning in such courses, and their preparation as teachers.

This study uses data collected in a course entitled "Teaching via the Internet". The course was offered at the University of Minnesota's College of Education. A survey was conducted of each section by the instructor and was designed to support course instruction and not as part of a designed study. The questions dealt with computer use instead of investigating domain specific topics such as pedagogy, curriculum, or psychology. Data was collected over three academic years from five sections of the course. Each student was asked for their name, email address, and eleven multiple choice questions.

All data was examined post hoc, and was an examination of existing materials. The study has focused on a number of research questions. Each is examined in detail below. How computer use by teachers changed over the past three years, how that changed paralleled society as whole, and how gender differences in computer use are evident in teachers.

Use of the internet and computers has changed markedly over the period of the study and the results of this study illustrate that change. Over the past few years, we have witnessed exceptional growth in the use of the internet for commercial and educational activities. One would expect teachers, as learned professionals to act as early adaptors of technological innovation. Their use and involvement with computers and the internet should at least reflect, and to some extent precede computer use in the general population.

A final concern examined in the study dealt with gender differences in computer use. While the issue of gender and computer use is a substantial topic and one worthy of further study, this study only briefly examines differences by gender.

Results

Demographics: A total of 86 students completed the survey; 54 were female, and 32 were male. Respondents by year totaled 34, 32, and 19 students. The male-female ratio varied over the three years, but remained majority female in each year.

Chronological Differences: The number of computer owners remained relatively constant at about 82%. In comparison, the rate of use found by the NPR/Kaiser/Kennedy study was 69% for all adults under age 60. Participants in these classes said they use computers at a higher rate than the national average.

Almost all of the students reported 'surfing the net' in the final two years of the study. Buying something over the Internet, however, rose from a relatively rare phenomenon to a fairly common, well adapted one over the two years of the study. In the final sampling, over two thirds of all students had purchased something via the internet, and almost half had made multiple purchases; about a five fold increase in both measures. This change was statistically significant between the first and second years, the first and third years, but not between the second and third years of the study.
Similarly, registration procedures for the course reflected this evolution. About half of the students in the first year of the survey (1998) used the internet to register; in the final application of the survey (2000), about eighty percent registered via the net. Most of the change occurred at the "expense" of in person registration.

**Gender Differences:** Data from each of the sections of the course was combined and examined for gender related differences. Ownership of personal computers was about the same for men and women (84% v 81%). A significant difference was, however, found between genders and their purchases over the internet (t = 3.0%). 31% of women reported one or more purchases via the Internet, whereas 47% of men reported making a purchase. The significance was driven by the larger number of men reporting multiple purchases over the internet. (15% v. 41%).

A significant difference was also found in the means students used to register for the class (t= 2.9%). Women used the internet less (57% v 65%) and the fax more (23% v. 3%) than men. Men registered in person in greater numbers (32% v. 21%). There were not significant differences between the individual methods of registration by gender.

**Observations/Conclusions**

There is a base line of technological understanding that is fairly broad among pre-service and in-service teachers; most will have and use computers, access the internet, and evolve in their use of the technology with the rest of society. As computer use expands and develops in society, it appears that new and experienced teachers will continue to develop their computer/internet use and expertise, paralleling the general population. Men may adapt the new technologies sooner than women.

It is clear that while this limited study provides an insight into the a small portion of the newer teachers of this country; additional questions and observations must be made about teachers and computer use. Computer use will continue to develop and change; the educational impact will follow closely behind.

Abstract: This paper describes a staff development process used to support technology development of both faculty and preservice teachers at a large state university. The authors explain the progressive and innovative slant of the integration model, the three-day training and writing workshop for faculty, and the description of a pilot project using a technology-rich, integrated curriculum on Florida Black Bears to train preservice teachers.

Introduction

In 1990, a critic of the teacher preparation process proposed an interesting idea to the education community. The critic suggested that if one hundred years ago, a teacher had been cryogenically frozen and brought back to life in 1990, the teacher could just pick up their piece of chalk and without missing a beat, continue teaching. In the tradition of Eric Carle’s (1993) Brown Bear, Brown Bear, What Do You See? a group of teacher educators involved in faculty development and a writing technology team in the year 2000
asked ourselves a similar question about what do we see in terms of technology and teacher education, do we see any changes, would we see any changes if we came back after one hundred years, and what do we want to see in the year 2000-2001? Using the content areas surrounding the Black Bear, we (as teacher educators) participated in a three-day training and writing workshop as part of PT3 (Preparing Tomorrow's Teachers for Technology) funding. The outcome of which was to create a technology-rich, fully integrated curriculum piece to model for our preservice teachers. This paper tells the story of the process of creating "Black Bear, Black Bear" and how we plan for integrating technology.

What have we seen? How technology has been integrated in the past

In a recent issue of the Journal of Technology and Teacher Education, Hruskocy, Cennamo, and Ertmer (2000) reported that "although computers have been in the schools for nearly two decades, the Office of Technology Assessment (OTA, 1995) reported that relatively few of the nation's 2.8 million teachers use technology in their teaching" (p. 69). For the most part, the technology is becoming available, but the problem seems to be that teachers don't know how to integrate technology into their instruction. Not surprising, since the faculty who trained the teachers during these last twenty years were trained themselves before computers were even a consideration.

Throughout the research literature, teacher educators have reported many ways to use technology to enhance the content areas and to assure the preparedness of our preservice teachers. Like Hruskocy, et al. (2000), Stuhlmann (1998) describes a model developed at Louisiana State University for preservice teachers that trains elementary students to work with teachers and teacher educators. Others have given accounts of mentoring programs using graduate students and education faculty to infuse technology into methods courses (Sprague, Kopfman, & Dorsey, 1998; Zachariades & Roberts, 1995). Falba, Strudler, Bean, Dixon, Marks, McKinney, & Zehm (1999) formulated a team of teacher educators to use new technology across individual content areas in order to choreograph change in teacher education programs. They reported minimal effects in specific courses, but found positive overall effects. Thorson (1999) reports successful integration of technology within science and math courses. Cooper & Bull (1997) offer guidelines for integrating technology in teacher education programs by looking at past practice. They recommend taking the direction of working to integrate technology through the teacher education faculty. Their paper notes that teacher educators who are comfortable with technology tend to create technological leaders as their product. As evidenced by most of these published reports, movement toward integrating technology seems to be effectively applied to separate methods courses and to be routed through the individual teacher educators.

What do we want to see? Moving in a new direction with a PT3 grant

Responding to the need for integrating technology in a meaningful way, our technology team submitted and received PT3 (Preparing Tomorrow's Teachers for Technology) funding. The purpose of this grant initiative is to provide a systematic program and process of instruction with increasing levels of technology integration. The levels culminate with an intensive "TechIMPACT" experience for preservice teachers during their final internship. These interns are to be placed in technology-rich schools in diverse teaching settings with technology-proficient teachers. This total process will ensure that preservice teachers who graduate from the teacher preparation program are truly technology-proficient and ready to teach in the new millennium.

The levels of technology integration include foundations courses, methods coursework, Internship I, and Internship II. Like many of the successful programs reviewed in the research literature, individual coursework throughout their program will infuse technology in the following incremental ways. Foundations courses provide basic theory and use of technology. Methods courses provide specific practice in using technology to teach content areas. Internship I provides preliminary practice for teaching technology-based connected lessons, and Internship II provides support during the integration of technology throughout the subjects and throughout the elementary day with themed-use being a goal. Seamon (1999) explores a similar multi-level, interdisciplinary approach. She proposes problem solving as a conceptual framework to create scope and sequences for integrating technology into the elementary
curriculum. This multi-tiered and integrated approach is to be followed throughout our preservice teachers' curriculum and then modeled in a way that they, too, will use technology in content-rich ways to learn in authentic ways and to solve real world problems. To obtain such growth in our preservice teachers throughout their coursework, the process must be systematic and involve all teacher education faculty in the program. The PT3 grant (Lynch & Mitchell, 2000) has afforded our institution the opportunity to find ways to integrate technology in meaningful and seamless ways.

While four objectives clarify the vision of this grant, this paper focuses on the fruition of the first two of these objectives. All four objectives aim to:
 (a) develop learning communities to provide specific technology integration training and support for faculty connecting the College of Education and the College of Arts & Sciences,
 (b) develop learning communities to provide systematic training and support for preservice teachers to integrate technology into their curriculum,
 (c) develop learning communities to provide internships in technology rich schools in diverse settings, and
 (d) develop learning communities to facilitate change providing a structure to transform education that will sustain technology integration including methods to evaluate, share internally, and disseminate information nationally.

First, students are enrolled in a Technology for Educators course, usually taken in the sophomore year. This course provides preliminary study, which develops the foundational understanding of how technology should and could be used, and is the course upon which future levels build. Since this course may be taken at the community college level, university and community college faculty have begun to dialogue to maintain and increase consistency for students.

The next portion of the PT3 grant requires that students have technology integration modeled in their methods courses followed by intensive “TechIMPACT” modules for Internships I and II. The teacher education faculty that attended the first three-day workshop created these modules. The Internship II module for elementary preservice teachers revolves around the “Black Bear, Black Bear” curriculum that evolved from our writing team. We wanted to extend the ideas gained in the level, which included their methods, courses to show how technology can be seamlessly integrated into all curricular areas using a theme rather than only into a particular curricular area.

What do we see? We see technology integration starting with me: Faculty development training

To have technology modeled by faculty for preservice teachers requires that faculty are comfortable using technology (Cooper & Bull, 1997). The initial series of training days was established to share a common understanding of how technology integration can be successful using specific approaches and a theme. This faculty development plan was based on National Council for Accreditation in Teacher Education (NCATE) and International Society for Technology in Education (ISTE) Standards (Thomas, 2000). During the initial PT3 training for our institution, twenty participants from the Colleges of Education and Arts and Sciences formed the first learning community. Systematically and closely following the InTech model developed in Georgia, faculty were immersed in a technology-integrated, constructivist workshop developed around the theme of the environment. Most faculty arrived at the staff development expecting standard technology workshop sessions highlighting a particular software application without much content upon which to apply the technology.

Instead of technology instruction only, participants were required to use technology as a tool for learning about the environment. The workshop facilitators modeled technology infusion across authentic learning problems and all curricular areas, showing us how it all related to the theme of the environment. For many of the participants, this completely different approach allowed them to see an entirely new role that technology could play. Technology was the tool for learning about the environment and for solving problems in science, math, social studies, music, movement, and language arts, rather than technology being the focus. The excitement of learning about technology in this way led many teacher educators to race home and revise syllabi for the semester that was starting in five days.

The goals for the three-day experience included: (a) creating curriculum-focused, theme-based technology integration modules for Internship II students; (b) determining how to include all college of education faculty in the discussion of developing a program-wide look at technology, so that each
preservice teacher has similar experiences; and (c) developing a learning community of faculty through which ideas are shared and instruction is enriched by collaboration and dialogue.

What do we see? We see interdisciplinary teams completing the scene

At the end of a three-day period, teacher education faculty formed interdisciplinary writing teams to take what we had experienced and create a series of integrated lessons for Internship II students incorporating International Society for Technology in Education (ISTE) Standards. Our writing team narrowed the theme of the environment to write the module entitled "Black Bear, Black Bear" related to the Florida Black Bear. These connected lessons (modules) were designed to re-create for the interns an experience similar to what we, the teacher education faculty, had experienced with the technology being integrated as a teaching and learning tool.

The writing teams were formed based on grade levels of interest. Our elementary writing team was truly interdisciplinary, consisting of special education, language arts, math, music and foundations faculty members. The team selected the Florida Black Bear as the content focus for its module. The Florida Black Bear had been the focus of materials published by the Florida Fish and Wildlife Conservation Commission and the Defenders of Wildlife. With the expert guidance of Linda Cronin-Jones (1999), these agencies have created an exemplary resource for elementary teachers in Florida to teach an integrated unit on the Florida Black Bear. The writing team’s efforts were to overlay and enhance the already superior resources created for use in Florida schools with applications of technology. The hope of the writing team was to show that technology could be integrated in a seamless fashion that highlights the curriculum and enhances student learning, not necessarily to spotlight technology. After being exposed to the various uses of Inspiration, digital cameras and iMovie, the resources of the Internet, Webpage development, database spreadsheets, HyperStudio and PowerPoint formats, Microsoft Publishing, TrackStar and WebQuest templates, and Timeliner over the course of several days, the team immediately began to see a continuum of technological aids that could be integrated into the unit on the Black Bear to enhance the overall results.

Certainly, elementary school students could have learned about the Black Bear without these technological aids, but when technology can be an overlay, the students benefit and are better prepared for the seamless role technology will play in their world as adult learners and workers. After an intense brainstorming session, each member took a daily lesson plan to be retooled and rewritten through technology. ISTE standards as well as the Florida Sunshine Standards were correlated and included in the lesson plan as well. The writing team pictured our preservice teachers in Internship II experiencing technology integrated into the Black Bear unit throughout five model lesson plans. Following these five lessons, the interns themselves would be asked to find their own paths to technological integration by retooling one lesson plan themselves. In this way, the writing team will be able to assess not only their awareness of technology integration, but to assess the application or implementation level as well. This way of thinking somewhat mirrors the three levels of the original PT3 grant: capacity, implementation, and catalyst levels (U. S. Department of Education, 1999) as well as the focus and intent of the ISTE Standards.

Implementing the pilot study: We see TechnoloGEE!

Preservice teachers have taken a Technology for Educators, but the focus of the course was not on integrating technology within lesson design for instruction. Lesson design and implementation is specifically taught in separate methods courses at the university. Often, preservice teachers will not and do not make the technology connections with instruction. Technology implementation most often occurs to complete research using Internet services and to create presentations (PowerPoint). Although technology is listed as a component for lesson design, data collected from other preservice teachers enrolled in methods courses would not usually include technology. Most preservice teachers indicated “not applicable” in their lesson design planning forms when considering technology within their lessons.

To pilot the Black Bear modules in the fall 2000, the target course to teach the Black Bear, Black Bear modules was a methods course, where initial lesson design was taught. The preservice teachers were taught how to write lessons plans. Copies of these initial lesson plans were collected. Upon analysis, these lesson plans were very similar to previous years as to the use, or lack, of technology. Subsequently, these
same preservice teachers then participated in the technology integration modules as designed. Within the methods class, the preservice teachers experienced the various types of technology that had been infused into the environment curriculum. Over a period of several weeks, the preservice teachers experienced technology within the professor’s instructional process. After each lesson, the participants were asked to reflect upon their learning and the use of the technology. Specific ideas were generated after each session and posted for the members of the class. In addition, written feedback was requested.

At the end of the semester, the preservice teachers in this course will be asked to revise their original lesson plans to include technology. Results of the Black Bear pilot program using the technology-rich, integrated curriculum to train preservice teachers will be evaluated and used to refine this experience before it is implemented with all preservice teachers during the spring semester.

What have we seen? Concluding remarks

Exposing teacher education faculty and preservice teachers to technology is not enough. Both entities must understand how to integrate technology in a pedagogically sound way so that the curriculum itself is highlighted and the technology is a means to an educational end. By instructing teacher education faculty in the integration process and aligning the learning process around the theme of the environment, teacher educators could easily see the power of what we learn as well as how we learned it. Technology plays a vital part as a tool for learning. By asking faculty participants in the writing team to create modules integrating technology around a similar environmental theme, faculty will now be better equipped to model for preservice teachers how technology can enhance a particular content area as well as to intensify the total learning process around a theme. In this way, preservice teachers can use the technological and content knowledge experienced during their internships and gained from modules like our “Black Bear, Black Bear” to reform their own teaching. Truly, “Black Bear, Black Bear” will be seeing teacher educators and consequently preservice teachers using technology effectively.

Abstract: As the need for meaningful technology integration has increased, various programs have been developed to support and help pre-service teachers accomplish this complex task. Decisions-makers for teacher-education programs could benefit from instructional information that highlights the strengths of these various development programs. This paper describes VisionQuest©, a CD-ROM teacher development tool, designed specifically to help teachers gain the critical skills needed to effectively use technology in classroom learning environments. VisionQuest© uses an instructional method that focuses on creating a vision and developing a personalized implementation strategy to achieve sound technology integration. This tool helps users reflect on exemplary cases, thereby engendering thoughtful consideration of the visions and strategies that enable exemplary use.

Introduction

According to the most recent report of the National Center for Education Statistics (NCES, 2000), 99 percent of all public school teachers now have access to computers or the Internet in their schools. However, nearly 70 percent of teachers still report not feeling well prepared to use computers and the Internet in their teaching (NCES). According to the 1998 Technology in Education Report (Market Data Retrieval), only 7 percent of schools, nationwide, boast a majority of teachers at an advanced skill level (i.e., able to integrate technology into the curriculum). Even among our newest teachers, instructional use is not as high as might be expected. Although beginning teachers report wanting to use computers, they often find it difficult to do so when so much of their time is consumed by routine classroom tasks related to organizing and managing instruction (Hruskocy, 1999; Novak & Knowles, 1991). Furthermore, teachers report finding "little incentive to tackle the technical and scheduling problems associated with technology unless they have a clear vision of how the technology can improve teaching and learning" (Office of Educational Research and Improvement, 1993, p. 83).

Thus, the barriers that teachers encounter when trying to integrate technology appear to be less related to a lack of resources and more related to teachers' pedagogical visions and beliefs. Based on recent survey results, NCES (2000) advocates a renewed emphasis on relevant technology educational experiences:
• Teachers with more hours of professional development reported feeling better prepared to use computers and the Internet for classroom instruction. Teachers with fewer hours of professional development reported feeling unprepared to use computers and the Internet.

• Teachers with more hours of professional development tended to use computers for constructivist activities like problem solving or graphical presentations. Teachers with fewer hours tended to use the computers for activities like drill and practice.

Traditionally, technology courses for pre-service teachers have focused on increasing their technical skills and competencies for using specific software applications with little time spent promoting educational best practices related to technology integration. As a result, even though most pre-service teachers recognize the importance of technology integration, visions for integrated practice remain narrow and unimaginative. Although pockets of exemplary technology practice exist, few pre-service teachers have opportunities to observe integrated technology practice in local schools or to examine the beliefs and visions that support exemplary use.

University and college faculty who are responsible for creating programs and/or courses that prepare future teachers to integrate technology in meaningful ways need to be aware of the various programmatic efforts that address these technology development concerns. To facilitate the decision-making process, several key elements need to be considered when selecting an appropriate development tool. An effective tool (Becker & Riel, 1999) will present pre-service teachers with the following set of learning activities:

• Discuss pedagogical beliefs supporting classroom practices of technology-using teachers
• Identify critical similarities and differences among teachers' beliefs and practices
• Outline strategies for increasing technology use among teachers who currently operate at different levels of use

Solution

To help pre-service teachers develop the complex skills associated with effective technology integration, the VisionQuest© CD-ROM was designed to address the previously identified concerns. Specifically, this tool uses electronic models as a means for pre-service teachers to create visions and develop strategies for sound technology integration. Exemplary models comprise a powerful means for helping pre-service teachers develop robust visions of, and effective strategies for, technology integration. Our intent is to encourage future teachers not just to use technology but to use it in ways that align with educational best practices.

VisionQuest© affords users the opportunity to examine different uses of technology through classroom video examples of exemplary technology-using teachers. The digitized video examples transport users into the classrooms of exemplary teachers so they can examine the instructional practices, classroom organization, and curricular emphases of exceptional users of technology. They can see for themselves the roles played by the students, the teacher, and technology in a classroom where technology is integrated. Users can examine how teachers' visions guide their uses of technology and how visions are translated into classroom practice.

To promote pre-service teachers' development as exemplary technology-using teachers, VisionQuest© provides opportunities to compare one's existing beliefs and approaches with those of the teachers observed. As pre-service teachers consider different ideas and teaching approaches (exemplified on the CD-ROM), changes in beliefs and subsequent practice are fostered.

Description

VisionQuest© uses the metaphor of a journey as its underlying organizational structure, incorporating and building on three main components of a journey: road map, path, and destination. Embedded within this metaphor is the powerful image of a vision that serves as both the beginning and ending point of a journey, as well as a guidepost along the way.
Users explore the three major components: 1) how teachers planned for integration (their visions and beliefs), 2) how teachers implemented technology within their classrooms, and 3) how teachers assessed the impact of their efforts. Within each component, the users can investigate the following list of topics.

**Teachers' Road Map: Planning for Technology Integration**
- Forming a Vision for Technology Integration
- Getting Started with Technology Integration
- Identifying Incentives and Overcoming Barriers to Technology Integration

**Teachers' Path: Implementing Technology Integration**
- Classroom Roles within an Integrated Classroom
- Classroom Organization within an Integrated Classroom
- Curricular Emphases within an Integrated Classroom

**Teachers' Destination: Assessing Technology Integration**
- Teacher Assessment within an Integrated Classroom
- Student Assessment within an Integrated Classroom
- Sample Assessment Tools used within an Integrated Classroom

Within each topic area, users explore the paths that three sets of teachers (high school, middle school, and elementary) have taken to achieve their current levels of technology use. Each case contains a variety of elements that illustrate how teachers' visions for technology use are translated into practice. In the Road Map component, users examine how teachers' pedagogical visions of classroom practice have shaped their journeys including how they got started, the roadblocks and challenges they faced, as well as the incentives that propelled them forward. To support each component, several classroom video examples comprise the center of each case. Specific videos include teachers' interview comments, reflections on lesson effectiveness, descriptions of how lessons evolved, and discussion of supporting pedagogy.

As pre-service teachers work with this tool, they begin the process of creating visions and developing strategies to prepare them to integrate technology in meaningful ways.

**Instructional Strategy**

A key to the success of an instructional program is the strategy used to design and implement the instruction. In designing the VisionQuest® CD-ROM, we not only considered the design of the media, but also a sound strategy for implementation. The VisionQuest® teacher development model (Fig. 1) (adapted from NCRL, 1997) serves as the underlying framework for the implementation of the CD-ROM. The main goal is to facilitate the growth of pre-service teachers' visions for teaching and learning with technology by engaging them in reflective and collaborative activities that nurture and sustain their development.

The six-step model facilitates reflection on, and the transformation of, classroom practice. Teachers are challenged to reflect on their current knowledge and classroom practices, relative to technology integration, and then, after observing exemplary models included on VisionQuest®, develop and pilot personal solutions to relevant classroom issues. Through a collaborative and reflective process, teachers gradually develop their own understandings about how to integrate technology in ways that address relevant curricular and pedagogical issues within their classrooms.

Following the model, pre-service teachers are asked to reveal their current ideas and beliefs about a specific component of technology integration (e.g., classroom organization, assessment). Next, they explore the beliefs and practices, relevant to this particular theme, illustrated by the featured teachers. In conversation with peers, pre-service teachers then consider the critical similarities and differences across cases, as well as make comparisons to their own beliefs and practices, revealed earlier. Recognizing that even exemplary technology integration is ever-changing, users will be challenged to articulate testable
suggestions that refine observed practices. In a continually "evolving expert" process, pre-service teachers will be encouraged to pilot their ideas and refine their own practices as they continue along their unique integration journeys.

Figure 1: VisionQuest© Teacher Development Model

Project Significance

Although most teachers today recognize the importance of using technology in their classrooms, Roblyer (1993) lamented that educators lack a clear vision as to how technology can be used to achieve new goals or implement new teaching practices. Given that most technology training (educational computing courses, in-service workshops) emphasizes learning about computers rather than teaching/learning with computers, it is not surprising that few teachers can envision, let alone achieve, integrated technology use. Researchers for the Apple Classrooms of Tomorrow (e.g., Fisher, Dwyer, & Yocam, 1996) have suggested that novice technology users may benefit from reflecting on the beliefs and practices of others who have already achieved integrated practice.

VisionQuest© is designed to support the professional development of both pre- and in-service teachers by providing electronic access to models of technology-using teachers. First and foremost, VisionQuest© facilitates the growth of pre-service teachers' visions for teaching and learning with technology. As such, this technology development tool helps these teachers achieve those visions by engaging them in reflective activities that nurture and sustain the change process. By illustrating the best practices of exemplary teachers, this visioning and strategic tool has the potential to inspire reluctant pre-service teachers to initiate their own technology integration journeys. Finally, by increasing the number of technology-using teachers who enter the workforce, we also increase our potential to effect meaningful student learning.

Acknowledgments

Portions of this work were supported by the Multimedia Instructional Development Center at Purdue University and the Herrick Foundation of Michigan. The authors wish to thank the participating teachers and their school principals for their hospitality and efforts during this project. In addition, we thankfully acknowledge the assistance of the Educational Technology development team during the creation of the VisionQuest© CD-ROM.
Mentoring and Assessment: A Case Study of Initial Teacher Education and In-Service Development.

Chris Jones  
School of Education, University of Sunderland, United Kingdom  
chris.jones@sunergland.ac.uk

Abstract: This paper concentrates on the issues pertaining to the determination and accreditation for Qualified Teacher Status in Information Technology in England and Wales, and the role that School Based Tutors have in this process. The major problem faced in initial teacher preparation is that while there is broad agreement that high levels of practicum are important, the lack of suitably qualified teacher mentors in Information Technology is hampering the effective preparation of newly qualified teachers. This paper looks at one model for effective mentor support.

Description

The role of assessment in the professional year at the University of Sunderland, School of Education is complex in that the assessment provides both formative and summative data, which informs and validates the requirements of a number of external and internal forces. The assessment of secondary student teachers following the professional year falls into a number of different categories and is monitored by a range of mentors as it happens, and also at specified end-points. Broadly speaking the work undertaken by the student teachers can be broken down thus:

<table>

Critical Evaluation

As can be seen in Table 1 the university subject tutor in the model employed for secondary teacher education at the University of Sunderland is a major player within the mentoring and assessment process: almost all the assessment is monitored and validated by the UST. This said, the relationship between student teacher, subject school based tutor and university subject tutor is very important in the collection and validation of evidence for the monitoring and validation of the teaching standards. At the heart of the whole process are the teaching standards as defined in Circular 4/98 (DfEE, 1998). All assessment throughout the programme leading to the development and provision of evidence for the students' knowledge, skills and understanding (KSU) in relation to the teaching standards. While the specific set of teaching standards remains firmly at the heart of the programme, the ICT standards and the subject have been further developed to provide the student teachers (and SSBTs) in their moderation role with more areas of KSU to evidence for their portfolios.

Although there is broad agreement among the student teachers and the SSBTs with whom I work about the benefits and drawbacks of the teaching standards, there are difficulties beyond those raised by Whitty and Willmott (1995 p217). Student teachers and their SSBTs often need support in their understanding of what the standards actually mean in the context in which they find themselves. The interaction of the UST is crucial here in enabling contextualisation, interpretation and progression to take place. The problem of reductionism, of a 'surface approach' to teaching standards will be discussed further in the next section. However, it is important to note here that the UST is not just a conduit for assessment but is a major player within the mentoring and assessment process as well as being a major player in the moderation and validation process. The UST is responsible for ensuring that all the assessment is monitored and validated by the UST. This said, the relationship between student teacher, subject school based tutor and university subject tutor is very important in the collection and validation of evidence for the monitoring and validation of the teaching standards. At the heart of the whole process are the teaching standards as defined in Circular 4/98 (DfEE, 1998). All assessment throughout the programme leads to the development and provision of evidence for the students' knowledge, skills and understanding (KSU) in relation to the teaching standards. While the specific set of teaching standards remains firmly at the heart of the programme, the ICT standards and the subject have been further developed to provide the student teachers (and SSBTs) in their moderation role with more areas of KSU to evidence for their portfolios.

Critical Evaluation

As can be seen in Table 1 the university subject tutor in the model employed for secondary teacher education at the University of Sunderland is a major player within the mentoring and assessment process: almost all the assessment is monitored and validated by the UST. This said, the relationship between student teacher, subject school based tutor and university subject tutor is very important in the collection and validation of evidence for the monitoring and validation of the teaching standards. At the heart of the whole process are the teaching standards as defined in Circular 4/98 (DfEE, 1998). All assessment throughout the programme leads to the development and provision of evidence for the students' knowledge, skills and understanding (KSU) in relation to the teaching standards. While the specific set of teaching standards remains firmly at the heart of the programme, the ICT standards and the subject have been further developed to provide the student teachers (and SSBTs) in their moderation role with more areas of KSU to evidence for their portfolios.

Although there is broad agreement among the student teachers and the SSBTs with whom I work about the benefits and drawbacks of the teaching standards, there are difficulties beyond those raised by Whitty and Willmott (1995 p217). Student teachers and their SSBTs often need support in their understanding of what the standards actually mean in the context in which they find themselves. The interaction of the UST is crucial here in enabling contextualisation, interpretation and progression to take place. The problem of reductionism, of a 'surface approach' to teaching standards...
the learning taking place, is certainly apparent; but beyond the simple 'what do I need to do, specifically, to achieve this standard?' many student teachers are keen to search for the meaning inherent within the standards. This could be seen as student teachers and their SSBTs' beginning to think in terms of the standards as elements in the process of reflective practitioner development (Schön, 1996, Boud, Keogh and Walker, 1996 p52). More often than not however this search for meaning veers towards the pragmatic: what counts as evidence, how much evidence do I need before I can be considered to have met the standard?

The answer is, naturally, not straightforward, and for many students the problem of evidence collection becomes their focus as they progress through teaching practice. Rather than being part and parcel of a reflective and reflexive response to the experiences they have on teaching practice the view that the portfolio is very important leads to the generation of masses of data and a mechanistic approach to the process.

Where the evidence is generated as a result of observations of teaching, reference is made against the narrative to the relevant teaching standard (see Fig. 1). The danger here is that when a student teacher sees the reference to A3 then the assumption is that A3 can be claimed and referenced within the portfolio. The question of whether or not the student understands why A3 can be claimed might not even enter the frame. The fact is - it is referenced and can therefore be ticked off.

**B1 B3** You introduced the session well - your exposition of the learning outcomes clearly identified to the students the structure and approach that they would experience during the learning session today. You had planned some leeway into the session to allow for student drift owing to the change of venue, which was necessary, since you had invited in a visiting speaker.

**A3** The students obviously had the background knowledge available to them in order to answer the questions that Steve threw at them. They appeared confident and able. Your brief to Steve had been clear in that he was able to pitch his delivery appropriately to meet the learning needs of the students.

**Figure 1 Example of Feedback Sheet for Student Teacher**

The danger of following such a 'narrowly mechanistic approach' (Furlong, 1995, p230) is that while it enables student teachers to see what it is they have to do in order to meet the requirements, it removes elements of creativity and values from the teaching process. It reduces the concept of the 'teacher as professional' to that of the 'teacher as technician'. Furlong (op. cit.) would have it that such a consequence would be self-inflicted. I agree that the standards do establish a minimum entitlement for all student teachers, that there is a rigour in terms of systematic training and that they help to focus and structure our judgements of student teacher performance. The notion of the self-inflicted wound is not, in my view appropriate. It is the assessment of the assessors that drives the standards, the whole standards and nothing but the standards as the tenet for initial teacher education.

The OFSTED criteria for the inspection of providers of initial teacher training make it clear that students must "when assessed, demonstrate that they meet the standards set out in circular 4/98, ... and for the use of ICT in subject teaching." (OFSTED/TTA, 1998, p 7) The evidence then for assessing the providers of initial teacher education is to be derived from observations of how the students are meeting the standards - all the standards. Beyond the teaching standards, there are the ICT standards, and for those subjects for which a national curriculum for ITT is not defined, the institutionally developed subject standards which demonstrate that a student is educated to degree level in the subject, and can apply that knowledge effectively within GCSE and A Level teaching.

What this means is evidence - portfolio evidence. The concept of student teacher as burgeoning reflective practitioner disappears under a mountain of paper. Referring back to Table 1 it is clear that the student teachers at the University of Sunderland have to undergo a lot of assessment in their thirty-six weeks of study. This pattern is repeated all over the country - and not just in England and Wales; Scotland too has a perceived problem of 'competence overload'.

The SOEID guidelines for initial course list some 48 competences. The ICT consultation document takes just two of these and elaborates them to suggest another 46 competences relating to them. If the same elaboration were appropriate for all 48, we would have a total of 1104 competences in total. It is not my intention here to... tackle the more fundamental argument relating to the notion of competence based approaches in general, rather I wish to use this example to suggest that initial courses are in danger of being overwhelmed by this process of accretion. (Ward, 1999)

The danger of the competency model of teacher training, while demystifying the process of change from student through to student teacher and onto proto-professional (Whitty, 1995, p202, Whitty and Willmott, 1995, p217), is that it breaks the whole process down into a set of individually achievable targets which can, as separate entities, be recorded and evidenced. This may not, in terms of the NVQ 'can do' approach to vocational training, be a bad thing, and the discourse between Whitty and Pring (Moon and Shelton-Meyes, 1995, p235) highlights the dilemma that both university and school-based teacher educators have to face. The whole question of when is a teacher more than the sum of the parts is very important in the process of making and recording our judgements of student teachers and their performances, both as academic students and as developing teachers. Moon and Shelton-Meyes (op. cit.) describe how the OU model has gone some way towards mitigating the attempts 'by assessors to tick-off competences in a discrete and isolated way' (p237). The inclusion of a values element which requires student teachers to develop the view that the portfolio is very important leads to the generation of masses of data and a mechanistic approach to the process.
model they describe is the notion of progression (from novice to expert - Berliner, 1994) within the individual standards and also recognition that the standards should be seen not as separate entities but rather as contributory elements which describe the whole teacher.

There is, however, within this, a certain dichotomy that can obfuscate the training process and begin to re-mystify it. As Pring (1995) would have it, you either are, or are not competent. The definition and application of a set of standards appears clear and uncomplicated. The pattern is set and there are, seemingly, definite pointers which delineate both the process to follow and the evidence indicators necessary for successful completion. The contradiction, or indeed the difficulty, for some comes from the demand for quality: the requirement for the student teacher to understand and apply the principles that underpin the standards.

This was a tangible dilemma for the ICT partnership in Sunderland. How were we to clarify the 'conceptual mess' (BERA, 1992) that the standards presented to us? Our partnership meetings allowed us opportunities to discuss and challenge the notion that the standards, if achieved, presented us, absolutely, with a passing student. Taking the Berliner scale (op. cit.) as our starting point, we looked at what it was that separated the novice student teacher from the competent one. We also looked at what it was that indicated a student teacher who was likely to progress during the induction year, and beyond, to expert status.

The importance of this discussion became clearer for the SSBTs as we began to tease out some of the distinctions. The student teacher beginning a first placement has more to deal with than the standards - there are at least two stages to go through (Maynard and Furlong, 1995) before assessment plays a part. And the SSBTs had different role to play in this also. The difficulty of balancing the nurturing role (Anderson and Lucasse-Shannon, 1995) with that of assessor and judge had to be recognised: and in doing so the SSBTs began themselves to see that the competency model was not sufficient in itself as the modus-operandi for teacher training. The recognition that they too played a part in professional growth and could begin to vocalise the associative benefits of the reflective practitioner model of teacher education (Elliot and Calderhead, 1995, Maynard and Furlong op. cit.) allowed us to begin to analyse the standards and to look at them as the basis for a more developmental and reflective model of student teacher assessment (Berrill, 1992).

The explicit inclusion of reflection and consolidation on the part of the SSBT into the mentoring and assessment process acknowledges that:

The teaching profession is complex and heterogeneous, and the development of competency standards needs to take account of both the similarities and differences between various categories of teacher (e.g. beginning teacher, master teacher, primary teacher, secondary teacher, teacher of adults) and the variety of different specialities within these categories. (Hager and Goncea, 1996).

There was a pragmatic element too in all this. The course was being re-inspected by HMI this academic year, and while all aspects of the programme were under review, the whole area of how the partnership was addressing the 'accuracy and consistency of the assessment of trainees against the standards for QTS' (DfEE/TTA, 1998, p7), was an area for specific examination.

This being so, the team began to distil our understanding of the Berrill scale we had reviewed and to begin to incorporate these within the teaching standards and OFSTED's criteria for the grading of cells within the framework. This meant identifying a four-point scale in line with the expectations set down in the framework:

<table>
<thead>
<tr>
<th>Provision</th>
<th>Quality</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 Provision is consistently of very good quality with several outstanding features;</td>
<td>Very Good</td>
</tr>
<tr>
<td>2 Provision is of consistently of good quality with no significant weaknesses;</td>
<td>Good</td>
</tr>
<tr>
<td>3 Provision complies with the Secretary of State's criteria, but requires significant improvement to ensure that the trainees are enabled to reach a good standard of teaching;</td>
<td>Fair</td>
</tr>
<tr>
<td>4 Provision does not comply with the Secretary of State's criteria;</td>
<td>Poor</td>
</tr>
</tbody>
</table>

We arrived at a series of statements which exemplified the nature of the performance which underpinned the achievement of the teaching standard whereby a student teacher could be deemed to have provided evidence for the standard - or not as the case may be. While the students themselves were not specifically made aware that they were being assessed in relation to the exemplification, the exemplification grid was seen as central to their professional development and set an expectation that, for each standard, they would be working towards achievement in the cells at the left hand side of the page.

This, as in the Open University model, enabled students to demonstrate clearly that as they were developing and collecting evidence for their teaching standards portfolio they were developing also a foundation of evidence for their capability in relation to their professional qualities (Moon and Shelton-Mayes, op. cit., p 237). They were also working against clear criteria that enabled both themselves and their assessors to make summative judgements about their level of performance.

What it has also done is to focus the SSBTs in on the meaning and application of the standards. Rather than seeing them as a mechanistic tick list, the exemplification document encouraged discussion about the standards in a way that encouraged reflection at all levels. SSBTs were more focused in their feedback to the students and were in many respects more able to be objective in their judgments and commentaries. The students too commented favourably on the system in their feedback about the programme at the end of the year:

- My mentor was able to give me specific feedback about how I might improve in my approach to classroom management. This had happened during my first teaching practice - but the reference to the matrix seemed to make it much more focused.

- I was able to use the exemplification of the standards to help me to set my own agenda. It made me realise how important it was for students to action plan and to set realistic targets for development; it improved my understanding of the teaching of GNVQ Advanced IT to no end.
What clearly happened for some students, I dare not claim that it happened for all, was that the pragmatism of the matrix helped them to become more reflective about the nature of the programme, and about teaching itself. The HMI inspection became, in many respects, incidental: the change to our approach which had been fostered by our previously poor inspection results took on a life of its own and enabled both SSBTs and student teachers to be much more confident in their analysis of their strengths and weaknesses.

There were students and SSBTs who simply saw the exemplification sheet as 'yet another document' to deal with. It was seen as part of the bureaucracy which for some simply slotted into the notion of the professionality community that is increasingly coming under the dictates of central government (Hoyle and John, 1995, p160). While these participants presented a minority opinion - that opinion is valid in that the professional year has generated a number of booklets and help sheets that define and illuminate the structure and process of the programme. Consolidation is necessary in order to continue the process of demystification and to continue to encourage a reflective and reflexive approach to the teaching standards.

Summary and Recommendations

The progress made towards reflective practitioner status, by both student teachers and SSBTs, as a consequence of the assessment of student teacher competency owes something to the application of elements of total quality management within initial teacher education (Bank, 1992, Lunt and Downey, 1994). The focusing in on strategies for improving the data collection for assessment and review processes, for both internal and external audiences, has provided opportunities for changing practices and raising the performance threshold (for individuals and for the partnership as a whole). Hoyle and John (op. cit.) in their review of government policy and its impact on teacher formation, while expressing some concern about impending de-professionalisation, offer a view which reflects appropriately the effects of the work on the measurement of student teacher performance against the standards, and which indicates that many teachers "have been enhanced professionally by the greater contact and involvement with teacher educators." (p161)

Working together to come to a common and agreed format for the exemplification of the teaching standards has enabled the training of teachers of ICT to begin to focus on what it is that establishes the foundation for successful subject teaching within a professional and accountable context. The distinction between the teaching standards and the notion of simple competency has been an important one for us to make. The acceptance that being competent is but part way towards being a teacher and also that the notion of levelness can be applied to the standards in order to begin the process of personal and professional action planning is important also. What is interesting in the current climate is that the language of the teaching standards, the application of portfolio development and the notion of performance assessment are part and parcel of the threshold standards recently applied to teachers at the top of the pay scale.

This paper has concentrated mainly on the way the partnership between the UST and the SSBTs has contributed to the assessment of the teaching standards. The integration of a competence model with that of reflective practitioner has been worthwhile in terms of student confidence in their preparedness for teaching as measured at the end of their programme of study. There are other areas for development within the programme where the partnership can usefully work together to improve the quality of the experience for the student teacher. Table 1 demonstrates clearly that the professional year is over assessed and presents a burden on the students which can be lessened without undermining steps to ensure that they have met all the standards (both explicit and implicit) defined by the programme. This has to be a clear target for the next academic year: the addition of national tests for literacy and ICT on top of that for numeracy is one driver for a review of assessment. We have to question again the type and quality of evidence that exemplifies a standard and establishes the competence embedded within it. This will certainly provide a focal point for at least one of the partnership development meetings during the next academic year.

Ellen Evans. PhD student. Boston College Lynch School of Education. Department of Teacher Education, Special Education, and Curriculum and Instruction. Boston College. Chestnut Hill, Ma. USA. Email: evansec@bc.edu

ABSTRACT: Faced with a new generation of pre-service teachers, teacher educators may easily assume that these young men and women are technology savvy and have mastered the skills required to word process, create presentations, surf the web, email professors and friends, and conduct their research online. Nevertheless, these same pre-service teachers may express anxiety and doubt about their ability to incorporate technology into their future classrooms. Our study, based on interviews with pre-service teachers, looks at this disconnect between using technology with confidence for personal use and using technology as an educator. We consider possible sources for this disconnect, and offer an alternative conception of technology in education we call "technological pedagogical content knowledge" (TPCK) which extends beyond computer proficiency to understanding the effect technology may have on student's conceptions of subject matter, the inevitable challenges that accompany technology, and the judicious use of technology when new forms of representation are most appropriate.

Introduction

In an age of technology related standards for students (ISTE, 2000) and teacher education programs (NCATE, 1997, CEO Forum, 2000) pre-service teachers feel the weight of knowing that the schools in which they will eventually teach require them not only to be personally proficient with computers, but also translate that proficiency into an effective use of technology in their classrooms. Schools of education and schools as potential employers often assume that these young teachers, many in their early twenties, have been inculcated into the use of technology from a young age. We imagine that this up and coming "generation" of teachers is technology-savvy, having grown up word processing their assignments, taking weekly trips to the computer lab, and mastering Nintendo. And our assumptions may not be far off. Pre-service teachers have had more exposure to technology, and as a result are quite comfortable surfing the web, emailing professors and friends, and conducting research online (Brown, 2000; Tapscott, 1997). But how does this measure of comfort translate to the classroom? Not well, according to our research with pre-service teachers. We found that pre-service teachers who feel comfortable with technology in their daily lives express reservations about using technology in their future classrooms. The source of this disconnect we have defined as a lack of "Technological Pedagogical Content Knowledge."

Question

Shulman (1986) defines pedagogical content knowledge as that form of pedagogical knowledge that "goes beyond knowledge of subject matter per se to the dimension of subject matter knowledge for teaching...the particular form of content knowledge that embodies the aspects of content most germane to its teachability." For Shulman, pedagogical content knowledge involves ways of representing subject
matter so that it is comprehensible for students, and understanding the kinds of preconceptions and misconceptions students may have as they embark upon learning the new subject. Likewise technological pedagogical content knowledge (or TPCK) extends beyond proficiency with technology for personal use to an understanding of how technology can be integrated with subject matter in ways that open new avenues for student understanding of the subject matter and the technology itself (Jonassen, Peck & Wilson, 1999; Barab & Duffy, 2000). In our conception of a teacher's TPCK, the teacher has the ability to use technology judiciously, when new, technologically enabled forms of representing subject matter knowledge are most appropriate. He or she understands the effect technology may have on her student's conceptions of the subject, the extent to which student's use of technology may actually impede understanding of a subject, and the inevitable challenges that accompany any new technology.

In this study, we sought to determine the level of preparedness and comfort teachers exhibit as they begin to integrate technology into their practice in order to better help them understand how technology can potentially transform their teaching. We also wanted to get a sense of how teaching with technology fits into our student teachers' evolving pedagogical content knowledge.

Methodology
Using a grounded theory methodology (Strauss & Corbin, 1990), we eschewed coming to this study with any one specific theory to prove or disprove; rather we focused on collecting and studying our data to see what theories, if any, could be generated. Eleven pre-service teachers at a mid-sized New England private university, all of whom were students in a course entitled Transforming Classrooms with Technology, agreed to take a survey and participate in interviews. The semi-structured interviews lasted approximately 20 minutes, were audio taped and later transcribed (See Appendix A for a list of the interview questions.)

Our initial review of the data revealed three areas related to teacher education that seemed to contribute to the pre-service teachers' lack of confidence in their ability to incorporate technology into future classrooms. Once identified we then used these areas to code the interviews, altering and refining our codes as needed. Ultimately, these areas were defined as Modeling, Usage, and Pedagogical Fit.

The first area we call modeling, which, for the purpose of this study, encompasses the kinds of modeling pre-service teachers encounter in their K-12 experiences and in their pre-service years. Our idea of modeling here has strong ties the to notion of “hidden curriculum” or the “content of the messages that are transmitted to students through the underlying structure of meaning in both the formal content as well as the social relations’ in teacher education programs beyond that conveyed by the stated curriculum” (Ginsburg & Clift, 1990). We have altered this definition to include the messages conveyed by the formal content and social relations in teacher education programs and in the schools our pre-service teachers attend as both students (K-12) and as future educators. Thus, modeling is defined as those messages received by students through formal, stated curriculum; the actions of their teachers, professors, and cooperative teachers; and the underlying social relations they perceive in the use of technology in education (see also Carlson and Gooden, 1999). We also consider how these aspects of modeling have engendered certain preconceptions about teaching with technology.

The second area of concern we have defined simply as “usage.” How have our pre-service teachers used technology in the past? How do they currently use technology in school, at home, and in their practica? By asking these questions we gain insight into our students' level of comfort with technology and the extent to which they mesh with current assumptions about young people and their technological prowess.

The final area we have defined as "pedagogical fit." We encouraged students to design their ideal classroom and discuss how technology relates to their philosophies of teaching, student learning and curriculum building. Our students' visions of themselves as future teachers who use technology are a revealing look at how, even at this stage, they have fixed certain limitations and potentialities into their conceptions of teaching with technology.

Results

Modeling
As we described earlier, our concept of modeling includes both the stated, formal curriculum, the actions of their teachers, and the social relations they perceive in the use of technology in education. In terms of a formal curriculum, our School of Education has incorporated two classes, Computer Applications for Educators and Transforming the Classroom with Technology. Our students noted, however, that these
courses were not required either as a graduate or an undergraduate. "I'm not very familiar with computers...it's not like a requirement in education or anything...and then my senior year my dad was like (because he's really into computers) you should look into it for an elective."

Our students also came away from their methods courses with both positive and negative attitudes towards various forms of technology, depending on how successfully it was modeled in class:
"I think it's important to have an overhead. The more and more methods classes you get into now that's what they stress...Well, I guess I'm biased because I spent four semesters with the same teacher for my math and she is always using overheads...so she's gotten me in the mind set of thinking."

"A couple of years ago in one of my Ed classes I was supposed to create a web site and I got through the whole thing and we had trouble I guess finishing it or getting it on the computer, it never ended up working so from then on I haven't tried to make any more web sites—it was a tad bit frustrating. I'm not sure what happened, a lot of people had trouble with it, and the professor ended up not counting that project."

In their practicum experiences, students who observed their cooperating teachers using technology came away with strong notions of the possibilities and limitations presented by technology. Most students said seeing their cooperating teachers use computers was important for their understanding of how technology works in the classroom:
"I still would love to see teachers that are using it now before I go out [to the practicum]. I can take out a program and try it but I won't know how it works until I really see kids with it, so any time I get an opportunity to see teachers using it I think its great and I'm excited. As much as I feel comfortable using it I'm always looking in my pre-pracs to see it out there..."

In addition, students expressed concern over the deep divide in funding between school systems in various parts of the area and recounted some of the frustration that accompanied poor quality hardware in districts that could not afford better resources:
"When I did my full practicum the computers in the class were down the entire semester I was there, it was awful. A couple of the other classrooms were working, there were like 3 computers in each class. The program...was a bunch of English and science and social studies activities the kids can use, but you can't do much else on it besides that. It was part of a...technology grant but I couldn't do any work on the computers... so that was a little frustrating."

Students also worked closely with the cooperating teacher to develop lessons and units. The cooperating teacher counted on the pre-service teacher's knowledge of computers and ability to research effective software programs.
"She [the cooperating teacher] loves the fact that I can't wait to bring in different things... like we were doing a unit on money and I brought in this money program but I never got to see anyone use it and she was just getting into it. She needed someone like me...the two of us worked out great together."

Another student, however, felt the pressure of having to impart her knowledge to other teachers:
"[When] they found out I was a math computer science major, it was like bombardment of 'show me how to do this, show me how to do this.' I did Kid Pix and all of a sudden I was presenting to the whole faculty how to use Kid Pix. It was good to see that they want to know and they were interested in using it. But some people didn't know how to print—they didn't know where the print function was." In fact, a number of our students expressed apprehension with being expected to assume a leadership role in modeling the use of technology in their courses and for their colleagues as a first year teacher.

Usage

Without exception, our pre-service teachers said they had grown up with computers in their home and in their schools. They each felt comfortable word processing, emailing, and searching the Internet. Some even had programming experience using LOGO or Hyperstudio in elementary school and high school. Despite similar backgrounds, however, students varied widely in their descriptions of themselves as computer users. Some students saw themselves as a "computer person," confident in their ability to translate their skills into a variety of settings. For these students, using technology in teaching was simply an extension of their identity. One student said, "I'm not typically a Barbie person—I used to love to play with Legos...we'd spend hours putting them together and I loved trying to figure...like even now my dad will call me and ask how I do this on the computer." Conversely, other students focused on what seemed to be a rather ill-defined set of technology skills that had escaped them but which they felt others had mastered. For example, a student told us she had learned LOGO in elementary school, word processed all
her papers, conducted research on the internet, and had a computer at home while growing up. Nevertheless, she described herself as "very basic": "my whole family is good with computers; I just never felt comfortable with them because I didn't really know how to use them but I'm slowly learning now."

**Pedagogical Fit**

At this point in their education, our pre-service teachers had already begun forming a teaching philosophy, and when asked how technology fit into that philosophy, some of the responses showed a measure of uncertainty. They felt sure that technology would play some role, but just what that role entailed was unclear:

"Right now, because I don't know enough to teach my students how to use it I might not want that much [technology in the classroom] but if I was very confident in using the computer and programs and things like that I would want a lot of technology in the classroom."

Other students' conceptualizations of themselves teaching with technology were defined in opposition to what they observed in their practicum:

"In my teaching I'd use it as an integral part. I think it goes hand in hand with instruction. I don't like to get up in front of the classroom and teach, I'd rather have kids working on the same topic area but doing different things, you know, like a computer center, and then kids working on other stuff, and I'd use that at the same time. I think now with a lot of older people in the teaching profession that it's [technology] just used as an enhancement. It's used like 'I don't have anything else to do so put the kids on the computer' because the teachers don't know how to use it."

**Implications**

Our student's responses suggest that we must be aware of the messages sent by the pre-service experience (both coursework and practical), and the ways in which technology is utilized in those contexts. In addition, our use of technology for teaching must not be seamless. We should make explicit exactly how technology functions in our classes, how it affects student understanding, and how it presents challenges our students must be prepared to handle with grace. Teachers of education should look to our student's past experiences and encourage them to discuss how technology has played a role in their lives. We cannot assume that our students come to us as blank "technology" slates. They have had encounters with technology, both positive and negative, throughout their school years and these encounters have left their mark. At the same time, we cannot assume these same encounters with technology sufficiently encompass all that a student needs to know in order to use technology effectively in his or her teaching. Despite what some teacher educators think, as suggested in a recent survey of technology use in schools of education (Leh, 1999), basic word processing and Internet search skills are only part of the knowledge teacher need to use technology judiciously and effectively.

Throughout this study, we were continually stuck by the prevalence of what we came to think of as the "3 or 4 computers in the back of the room" model of technology. For a majority of students, this "add-on" technology use, where students are sent to work on computers in the back of the room for remediation or enrichment, is the extent of their understanding of how technology fits in the classroom. In our course, then, we offer our students a much more complex picture of technology in education. We encourage them to consider that despite the push for technology in classrooms, there is little consensus that technology provides a positive impact on student learning or, in our current outcome driven society, on standardized tests (Jones and Paolucci, 1999; Mellon, 1999). By assuming that technology in schools is a given, predetermined expectation, rather than exploring with our students essential questions about access and impact on learning, we do them a disservice. Pre-service teachers should be actively engaged in creating their own informed opinions and perspectives on technology in their classrooms, and not be passive recipients of an overly simplified view that may be garnered from reading national technology standards (ISTE, 2000) alone. Another side of this complex picture is that of the relationship between learning theories and strategies and technology. Students should be engaged in thinking about how technology can be integrated into the various learning strategies to which they have been exposed in Schools of Education. It is unthinkable to position a single learning strategy as the best method for teaching; rather students are presented with a number of approaches that can be implemented depending on the students, the classroom and school context, the nature of the material, etc. And yet we easily might offer a single approach to technology driven by a single strategy, i.e., using drill based software programs in support of a delivery model of knowledge in education.
Finally, the overall message of our course is to encourage an innovative, responsible, and critical approach to technology in education in each of the areas we mention above. In other words, we seek to help our students develop a level of TPCK, an understanding of how technology can be used to teach content in rich and meaningful ways and the far-reaching implications of that use. The missing component in our program, and we presume in a majority of teacher education programs, is the facility to place our student teachers in classrooms with experienced teachers that possess a sophisticated level of TPCK. It is imperative that our cohort of Twenty-First Century teachers, early on, have the opportunity to “work at the elbows” (Collins et al., 1989, Barab & Hay, 2000) of expert teachers integrating technology as a meaningful part of classroom instruction.

Appendix A

Questions from Semi-structured Interview

A. Background information
   1. Talk a little about your personal use of technology—any projects, web sites, etc. you would like to describe or show us?
   2. As both a student and a teacher, describe some of your experiences with technology in the classroom (how did you use technology and, if relevant, how did you teach with it?).

B. Technology and classroom instruction
   1. When you think of the word “technology” what comes to mind? What comes to mind when you think of technology in classroom?
   2. Describe your experiences with technology in K-12 courses.
   3. What is your opinion of equity issues and technology (is technology a divider or an equalizer)?
   4. Do you see technology as an enhancement to curriculum & instruction or an integral part of curriculum & instruction?

C. Overall
   1. What does it mean to you to “transform classrooms with technology”?
   2. Describe or sketch your ideal technology classroom.
Using Dreamweaver 3 For Generating Preservice Web-Based Teaching Portfolios

Abstract: One of the tasks that our students have in our Educational Psychology / Introduction to Teaching sequence is that of creating an assessment and professional portfolio. This assignment becomes the foundation for their continuing portfolio, which they build on in the remainder of their Education coursework, and becomes the basis for their professional portfolio. Last year, for the first time, we changed our format from a portfolio that was stored in a binder to one that is stored on the World Wide Web. We found that this allowed us to assess our students in a way that also gave them an important tool as they enter the teaching profession. Challenges that we faced in this having our students complete this assignment, responses to those challenges and outstanding questions are addressed.

Background

Colleges and departments of education have shown a growing interest in performance assessment. The stiff competition for teaching jobs has resulted in a chorus of voices telling both prospective teachers and practicing teachers, “You ought to develop professional portfolios” (Campbell, Cignetti, Melenyzer, Nettles, & Wyman, 1997). In our Educational Psychology and Introduction to Teaching courses, we found ourselves joining that chorus about five years ago with the addition of a final examination in the form of a portfolio assessment. Our expectation was that our students would continue to develop their portfolios until the end of their preservice education and would also use them as part of their professional growth in their teaching careers.

In addition to viewing portfolios as a good thing to do for our student’s professional growth, our accrediting body’s increased emphasis on performance-based assessment tools was moving us toward using portfolio assessment. The Interstate New Teacher Assessment and Support Consortium (INTASC) standards require, among other things, that beginning teachers demonstrate entry-level competencies of teaching through the development of a portfolio (Bullock & Hawk, 2001). The INTASC standards have been incorporated into the National Council for the Accreditation of Teacher Education (NCATE) new accreditation process for teacher-education programs. Thus, the new NCATE standards have been developed with an increased focus on the performance of preservice teachers, as they become teacher candidates. When Arthur Wise (1998) announced the new direction for NCATE, he noted,

The emphasis on performance has been spurred by a realization among policy makers that changes in curriculum and courses have not significantly increased student achievement. The number one factor in enhancing student learning is the capability of the teacher. How to determine quality and knowledge are central questions as NCATE develops its performance-based accreditation system. (p.1)

1867
Because the NCATE standards are a critical element in our education program's review process, we have found increasing institutional support for requiring a portfolio in our course. Dorothy Campbell (2000) and her colleagues note that the key question that a quality teacher-education portfolio hopes to answer is "What do candidates know and what can they do when they graduate?" That question will continue to shape the content of our portfolio assignment. Currently the content is based on the major content areas of the course but it will increasingly need to represent a significant portion of our department's response to and adaptation of the INTASC standards.

Portfolio Components

While the content of our portfolio will undergo significant change during the next few years the basic components will likely remain the same. Bullock and Hawk (2001) identify four portfolio components: purpose, audience, evidence, and reflection. The purpose is for students to demonstrate their knowledge, skills, abilities, values, and beliefs about educational psychology and classroom practice. The content will expand as the students continue their professional course work. Students design their portfolios with both external reviewers and themselves as the audiences. External reviewers are currently their peers and the course instructors, but the review process will likely soon involve some sort of exit committee as the students become teacher candidates. Evidence currently collected includes papers that synthesize knowledge, lesson plans, units, use-of-technology examples and other professional documents. The students write reflective introductions to each section of the portfolio, explaining and reviewing the content to be encountered by the reader.

Initially a standard paper/notebook portfolio was the final outcome. Students presented their portfolios at the end of the course to a group of peers in a mock interview setting. As the course instructors, we then evaluated the portfolios as a final examination for the course. The portfolios were then returned to students with comments and suggestions for revision. The students were encouraged to revise and develop new material as they moved toward teacher-certification.

The final products were often well designed and clearly showed what the students had learned. But they were also large and cumbersome and did not seem to be all that useful as a beginning step toward a professional portfolio. We suspected that, while these portfolios would give those hiring our graduates an adequate and accurate picture of the student's knowledge and skills for teaching, they were not being used very often. Having only one large printed portfolio meant that a student would likely not use it except as part of an interview and often near the end of the candidate selection process. Thus a desire for more portability led us to explore other media as vehicles for the portfolio. Initially we thought that the students might create a CD-ROM that included all of their written work and could also easily incorporate video and other visual artifacts. These could be produced in multiple copies. However, as we were beginning to move in that direction, easy world-wide-web design tools became available. Thus during the spring semester of 1999, we made our first attempt at a web-based portfolio.

Challenges

We faced a number of challenges in our attempt to move our students from paper portfolios to web portfolios. Some of them were relatively easy to address while others were more difficult.

The first challenge was to determine whether we had the technological resources at our disposal to make this assignment possible for our students. If the college's Information Technology department would not support students having ready access to computers and software that will allow them to do this task with relative ease then a web-based portfolio would not be possible. We were fortunate that, in addition to many of our students having their own computers, our college has a well equipped computer center and residence halls where students have access to computers with web authoring software, in our case, Macromedia's Dreamweaver 3.

Dreamweaver was a choice that we endorsed for a variety of reasons. The program is easy to use with a WYSIYG interface. The commands are intuitive, using many of the same features found in most software
so the learning time for those who are computer literate is minimal. The program is also very powerful, allowing the students to easily do simple web creation but also giving them the opportunity to do more sophisticated things (such as the inclusion of frames) if they wish to do so. Dreamweaver also includes an ftp client, which makes uploading of the web page to the college's site (or to another site of the students' choosing) relatively simple.

Even with the opportunity to use computers and the availability of software, some students were resistant to the idea of creating web portfolios. Some of them were under the impression that this would involve a lot more work than paper portfolios. Others who were uncomfortable with the use of computers were frightened of the prospect of being forced to use computers to such a great extent for something with which they were unfamiliar. We addressed this issue a number of ways. First of all, we chose to begin this project in a semester in which our class sizes were relatively small, only about 24 students between the two instructors. This allowed us to give added attention to those students who needed additional support with the technology. In addition, we met as a class with a member of our Information Technology staff who taught the introductory lesson on the use of Dreamweaver. This instructor and others in the IT lab were available for assistance other times as well.

Even with the promise of support, some students were unconvinced that creating a web portfolio was a good idea. We had coincidentally scheduled a class session in which three local high school principals visited our class and answered questions regarding expectations for new teachers and other educational issues. One of the first questions that our students asked challenged the notion that new teachers needed to be technologically adept. Specifically, one student wondered what these principals thought of web portfolios. The response from the principals was overwhelmingly positive about the portfolios, pointing out that it allowed them as potential employers to have access to some information about the prospective teacher easily, without going through all the steps of requesting information from the college. They also said that they look to their new teachers to bring a certain technological expertise to their school. They recognize that their current staffs have many teaching skills but could use help in including new technology into their teaching. They hope that younger, more technologically savvy teachers can help their schools better meet the needs of students in a technological society. Hearing these sentiments from school principals was compelling for our students. Complaints about the assignment diminished almost immediately.

Once we got into the project, though, we realized that more conceptual challenges needed to be faced. Our traditional portfolio assignment included a number of essays written by our students. For example, they were required to write papers that indicated their view of the learner and the curriculum. Other mandatory written materials include a complete management plan and at least one unit plan. While it is technologically easy to convert word processed documents to web documents, we realized that technology was only part of the issue. Merely transferring essay to the web may lead to ineffective presentation. In researching web design issues we discovered that in reading web content "It was more than three times as common for users to limit their reading to a brief as opposed to reading a full article. Even when reading a "full" article, users only read about 75% of the text." (Nielsen, 2000) Consequently, merely transferring word processed documents to the web would not be sufficient.

One of the purposes of assigning these papers was to encourage reflection on the part of the students regarding to their view of the learner and of curriculum. We did not want to lose that important piece of our curriculum, nor did we want our students to present themselves in their portfolio with the equivalent of sound bites. Our dilemma was how to allow our students to present thoughtful reflections in the context of a medium which seems to exist in contrast to such presentations.

To address this issue we asked our students to do two things. First the students wrote the essays for our classes as they ordinarily would, going through a peer review before submission. After the instructors have graded and commented on the papers they were returned to the students who were then asked to revise them again before including them in their portfolios. Recognizing the way web documents are read, however, we also asked them to prepare a 200-word abstract of the essay that they could post on the site along with a link to the full essay. In this way we not only met our objectives but also gave those looking at the portfolio (both fellow students as well as potential employers) an opportunity to quickly assess the
views of the students while being able to look at a more complete treatment of the subject. We also encouraged them to make liberal use of headings and links.

Results

The results from our first attempt at web portfolios yielded mostly positive results. (Examples may be seen at http://www.calvin.edu/~black20/index.htm or at http://www.calvin.edu/~konin99/portf.htm) Many of our students created web portfolios that truly reflected the vision that we had for this assignment. One noteworthy result is that a few of the best portfolios came from students for whom work in web page authoring was a new and sometimes frustrating experience. These same students, who we would have expected to produce excellent notebook portfolios were able to produce excellent web portfolios in spite of their lack of experience. Conversely, some students who had exhibited proficiency with creating web documents prior to this assignment were able to produce good looking front pages but demonstrated the same lack of depth in their portfolios as they had shown in their papers and other assignments.

Even though all students were able to complete the assignment on time, there were a few concerns. This process required a lot more time on behalf of students unfamiliar with web page authoring than the traditional portfolio did. Much of this time was spent learning how to use Dreamweaver 3 and struggling with translating documents from Microsoft Word to html. We wondered if this was time well spent. In addition, despite attempts to get everything “just right”, some of the pages continued to have broken links and images that did not work properly.

We addressed these concerns in subsequent semesters primarily by creating a technology assignment that is given earlier in the semester that required more web authoring proficiency. By addressing the technical aspect of the project earlier, we believe we can help the students focus more clearly on the content of their portfolios at the end of the semester.

Questions

There are still some outstanding questions that we are considering as we continue to work with our students in this project. We continue to wonder about the issue of how to adjust for the way people read web content as opposed to paper documents. We are not fully convinced that an abstract is a sufficient remedy. We also wonder if students should prepare paper documents in addition to web documents. Are some employers still going to want to see a portfolio that they can carry with them and handle? Will a printout of the web site be sufficient or will the student need to reformat the entire portfolio for print? Is the web the proper place for the storage of these portfolios? Items stored on the web are available for everyone to see. Even though these are professional documents, students may not want to have them available to everyone. They may want potential employers to have to request them to have access to them. Are there other ways to store these documents (like CD-ROM or floppy disc) that would do as well and restrict access? Was our dismissal of the CD-ROM format premature?

In conclusion, reaction from our students, our colleagues at the college and the principals of schools in which our students work indicate that our preliminary efforts were successful. Students left our class with additional technological proficiency and with an artifact from the class that we could use as an assessment tool and that they could use in helping them in their search for employment.

References

This paper is a report on a pilot project undertaken by the authors. In the spring of 2000, 15 preservice teacher candidates from a Faculty of Education were placed with associate teachers in elementary classrooms in local schools for a four-week practice teaching block. In addition to the normal expectations of such a practice teaching experience, there was an additional expectation that there be an enhanced use of technology. Either the preservice student was identified as "relatively computer literate" or their associate was deemed to possess effective computer skills. In some cases, both the student and associate were competent in the use of the technology. The expectation was that both groups of subjects would derive benefit in their teaching practices and their personal use of Information and Communication Skills as a result of this pairing and this project.

RATIONALE:

Information and Communication technologies, in their various forms, are becoming the driving forces behind many of the changes that are occurring in education at the present time. Teachers are being asked to incorporate these technologies into their courses and lesson on a regular basis. Schools are spending millions of dollars each year on technology – including network backbone, hardware, software and related materials. Parents are supporting computer programs in their schools through fund-raising efforts. Students are coming to their classrooms much more technologically literate.

The speed with which innovation and change have been occurring in the classroom and society in general has been blamed for a perceived increase in the level of stress. It is difficult to manage the list of new devices that have been introduced and have become commonplace. Before one can gain sufficient expertise with these mechanisms, we are again beset with a whole range of new mechanisms. For example, Sony has recently made available an MP3 player that is the size of a marker pen, has 64 meg of memory and is capable of playing 2 hours of near CD quality music. This device has no moving parts and therefore never skips musical sections. The new Minister iRadio has the ability to group digital radio stations into genre so that your favorite rock music can be grouped on one screen and can be accessed right across the country. There is also a CD and a large built-in hard drive that allows you to store files and plays all types of music formats. Minolta-Jeans will be equipping some cars with DistriXecs, a Proximity-Controlled Cruise. A small grill-mounted radar sensor calculates the car's speed and distance from the car in front. In a fraction of a second it will automatically let off the gas and begin braking when it calculates that you are too close for speed. There is also the Global Position System (GPS) that is being installed in cars to track a vehicle's position, lock and unlock doors, provide precise direction, guide the driver to the nearest gas station and prepare other information that can assist the driving endeavour. These products and others like big screen TVs, HDTV, DVD, and surround-sound speakers are all part of the landscape for current automobiles. It is now or what does the future hold?

It does not seem possible to maintain a working knowledge of all of the contrivances even if one had many hours to dedicate to such a task or to mention an excessive amount of money. Therefore, it seems like an opportune time to ask if educators, who are responsible for the daily care of children and operations of classrooms, can be expected to remain abreast of these changes. Of course the logical following question is how could educators not only learn to use the new technologies but also devise ways to use them to enhance lesson delivery and management functions? With all of the constraints and additional demands that seem to be impinging on their time, is it any wonder that much computer equipment appears to be underused by dedicated teachers?

Although technology seems to be present in many locations in schools, the consistent integration of technology and related applications with classroom teaching practices is not occurring quickly or as systematically as it should be. Often, computers are found to be drastically understated, despite the fact that the students know what to do once they are in front of a keyboard. In its "Year 2 STaR Report" (1999), CEO Forum on Education and Technology, in the United States found that the single greatest barrier to this taking place is teacher attitude and / or lack of training. While 80% of schools have Internet connections and the number of schools effectively using technology is almost 13%, only 20% of teachers reported feeling very well prepared to integrate educational technology into classroom instruction. Unfortunately, when in-service training is provided, it is often ineffective. The quiet workshop that is delivered through PD days does not use best current practices in methodology to ensure that what is taught is relevant, reasoned, and used by teachers.

A discussion paper produced by the advisory panel on Creating an Innovation Culture sponsored by the Ontario Jobs and Investment Board had this to say about technology, education, and innovation proposal.

"Technology and technological change have defined the 20th century. And, the 21st century could witness an even faster pace of change. A key challenge will be to not merely adapt to change, but to anticipate it and to take the steps to stay ahead of change to make the most of it. The new jobs of the future will depend on innovation. Innovation can lead to vast improvements in the ways we learn, teach, and communicate..."

There have been many books, articles and discussion papers that focus on the nature of change in the classroom and all indicate that unless a culture of change exists, no meaningful change will occur.

Teachers are faced with a myriad of changes in their schools and may not always have the time to learn new technology and how to apply it. In many cases, instructional strategies have not been modified to take into account the many facets of the technology and how it should be used most effectively in the classroom. Teachers don't know how to use the technology or when to use it to its greatest advantage. However, it is a fact, often repeated, that the demographics of the teaching profession in the province of Ontario will change drastically in the next five years. These new teachers will not only replace those who are retiring, but they are expected to come to their classrooms much better prepared to integrate technology competently into their teaching practices.

Recently, there has been, in any number of professional journals, much written about the problem of ensuring that graduating preservice teachers possess the capability to successfully integrate the computer as a tool into their classroom programming. These several articles suggest that it is not merely enough to make sure that "computers" is being taught as a subject at the preservice level. There must also be some specific attempts to ensure that the skills being acquired during formal classes are being utilized during practice teaching placements and beyond. However, if they are not encouraged, by those already in the field, to use their technology skills in the delivery of program, then little change will occur. Since they really aren't too comfortable with the technology as professionals, if the culture of the staff room is to leave the technologies alone, then new rookie teachers will be reticent to break those taboos and forge new ground. The same CEO Forum report referred to above also points out that new teachers entering classrooms currently do not take advantage of the technology that is in place. Rather they adapt to the culture of the classroom already in place and leave the computers and peripherals alone.

There have also been published much about the same concerns for the regular in-service teacher. It seems that many are still finding it very difficult to integrate the use of the computer as a tool to enhance the delivery of lessons or to individualize instruction for their students. Often the reasons cited are lack of time, resources,
support to acquire the skills and the fact of not having the level of mastery that their students already possess. Workshops and in-service sessions outside of the time frame of the regular school day are increasingly seen as unsuitable and an intrusion on already overtaxed workloads. In-service that requires accountability is expensive for boards of education and once again strains overtaxed personnel and resources. However, alternative learning approaches, including the training of teachers in reciprocal teaching, peer-tutor and take-turns relationship can be effective.

Fullan & Hargreaves (1999), in their article, "Mentoring the New Millenium," point out that a paradigm shift is occurring in how new teachers should be seen as they enter the profession. Whereas, in the past, new teachers were seen as relatively unskilled and in need of support by the system, we should now see them as possessing competencies that those already in the classroom could benefit from. We know that classroom culture changes slowly but, might it not be possible to use these new teachers and their skills to speed up the use of technology by the system as a whole by providing them with opportunities to mentor those relatively unskilled in the use of technology? Such mentoring would be seen as a positive approach to the enhancement of technology skills in the experienced classroom teacher.

We, the researchers, believe that there was a need for a research study that would look at these concerns and issues surrounding the integration of technology into teacher preparation and practice, taking advantage of the concept of mentoring proposed by Fullan and Hargreaves. As outcomes of such a study, one might expect to:

- determine what technological competencies teachers need in order to effectively integrate information and communication technologies into their teaching practices and professional requirements;
- develop strategies to assist teachers to determine how, when and why to integrate technology into their program based upon the current Ontario Curriculum expectations, subject by subject;
- raise the comfort and confidence level of practicing teachers when using technology in the classroom;
- foster a culture of change in individual schools by encouraging a mentorship program that sees not only practicing teachers but preservice and newly appointed teachers as possessing skills that can make a positive contribution to the classroom and school environment.

**PROCEDURE:**

In the early fall of 1999, it was decided to identify by some means, students enrolled in the class of 1999-2000 at the Faculty of Education, who possess a higher than average level of computer expertise and literacy or were destined of becoming so. The authors of this study would also identify classroom teachers in the schools who would consider themselves similarly expert and literate and would be willing to serve as partners during one of the teaching blocks of the preservice students. They would match up these students and classroom teachers and ensure that one of the expectations of the teaching block in the schools would be to use the technology to its fullest in their teaching practicing lessons. It would be the responsibility of the Faculty representatives to ensure that lesson plans reflect this specific outcome.

Prior to the start of the teaching block, the researchers would administer an instrument to establish perceptions of professional competency specific to computers and information technologies. They would then track the success of these matches during the teaching block and track indicators of computer integration in the classroom. Following the end of the placement, the instrument would be administered a second time to measure change. The in-service teachers, preservice teachers and faculty advisors were to ensure that lesson plans reflect the specific expectation of computers in the classroom.

Support was solicited from faculty advisors in the Faculty of Education, as they would have to agree to involvement on the part of the authors in their ongoing work with students. Preservice students who were interested in the possibilities inherent in the project were encouraged to volunteer themselves as subjects. Principals in the schools were invited to volunteer to participate in the project with the intent that it would facilitate change in their staff around Information & Communication Technologies (ICT) competencies. Some 30 principals indicated a willingness to participate and from this list, sites were chosen based upon the requests of the students for placement.

Since one of the assumptions of the researchers was that both students and teachers would enhance their competency levels in ICT skills, it was agreed that some sort of rating scale had to be found to use as a measurement tool. After considerable searching, a suitable tool was found on the Internet at the International Society for Technology in Education (ISTE) website. These ISTE Foundation Standards were the result of a partnership between ISTE and the National Council for Accreditation of Teacher Education (NCATE) as both groups move towards some sort of permanent definition of what specific ICT skills new teachers should have as they enter the profession. It was agreed that we would adopt this tool, having been given permission in advance by one of the authors who previously worked at the ISTE Foundation which was underwriting the project, in part. (See article - "National Standards For Technology in Teacher Preparation" by ISTE Accreditation and Standards Committee in Connections, Vol. 15, No. 1; Fall, 1998.)

The "Recommended Foundation Competencies in Technology" checklist was given to the preservice teachers when they were gathered at a meeting. They were also supplied with the same form at the end of their teaching block when they had returned for classes. Similarly, a meeting was called of all the identified teachers in the field and the form was distributed to them then. The second copy of the form was distributed by interoffice mail after the teaching block was completed. At each meeting, both researchers outlined the major expectations for the four-week teaching block and answered any questions either the students or their associate teachers had.

There are a total of 61 competencies in the rating scale used in this study. These were divided into 9 categories. These are:

- 1.1 Basic Computer / Technology Operations & Concepts
- 1.2 Personnel & Professional Use of Technology
- 1.3 Application of Technology in Instruction
- 2.1 Social, Ethical & Human Issues
- 2.2 Productivity Tools
- 2.3 Telecommunications and Information Access
- 2.4 Research, Problem Solving and Product Development
- 3.1 Teaching Methodology
- 3.2 Hardware, Software Selection, Installation and Maintenance.

On each of the competencies, all respondents were asked to assess themselves as at the Entry, Adoption, Adaptation or Appropriation level. To arrive at a single numerical descriptor which could be used to assess change over time, the scoring of the competencies check list was done through a simple assignment of a value (1 for Entry - 4 for Appropriation) to each of the possible categories. A total for each category was arrived at, as well as a percentage representing how far below perfect (Appropriation) on all competencies combined the respondent perceived himself or herself to be.

At the meetings referred to above and through written communication, the pairs of preservice / associate teachers were asked to identify an area of ICT which both felt could benefit from collaboration. The assumption was that each dyad needed a focus for their collaboration and choosing one area upon which to focus would better
facilitate growth. The researchers assumed that, following the teaching block's conclusion, not only would participants rate themselves as higher in that one specific area, but that there would be generalized growth over all the competency categories.

Following the meetings with the two groups of participants, there were phone calls to those individual classroom teachers unable to make the whole group sessions. There were individual briefings for those students who missed their whole group session as well. There were visits to each of the sites during the four-week teaching block and time was found to interview each of the preservice candidates as well as their associates separately. These interviews took the form of informal discussions to elicit impressions and subjective feedback on the success of the placements, the pairings and the use of the technology.

OBSERVATIONS & FINDINGS:

Both the preservice and their designated associate teachers were anxious to become involved with the project. Both groups viewed this project as a way to gain experience with technology in an educational setting by collaborating with others who had similar interests and possibly who had superior expertise. They welcomed the chance to work with the technology in an environment where such experimentation was not only encouraged but also expected.

The students also viewed participation in the project as a possible venue to gain recognition for their desire to collaborate with practicing professionals and to gain experience working with the technology to improve their own teaching practice. Some even verbalized their expectations that participation in such a project might have positive effects on their future employment possibilities.

Teachers in the field perceived the project as a vehicle to advance their knowledge of technological applications in the classroom by working with preservice teachers who might have a higher level of expertise with the technology. Some also saw this as an opportunity to convey some of the ideas and skills that they had developed over the years as they advanced their knowledge of the teaching environment.

Principals were very anxious to volunteer their schools and nominate associates to become involved. In each case, they were very intrigued by the possibilities inherent in the situation and wanted to provide their staff member with an opportunity to become more computer-literate or technologically competent.

During the four-week teaching block which was the focus of this initiative, visits were paid to each of the sites where preservice student and associate teacher pairings occurred. Informal interviews were conducted on site with both preservice and practicing teachers to elicit feedback on the process and establish whether any further intervention was required or any additional resources needed in order to facilitate program planning. After the fact, the comments made in discussion were grouped according to similarity of statement and the number of similar responses tabulated. Table I below summarizes that information.

As can be seen from Table I, the subjective feedback from the respondents in this study reinforces the original assumption of success. Repeatedly, in one way or another, individual teachers and students commented on how much they were enjoying the partnership, how much they were learning, how much more competent they felt about the technology and its use in the classroom. One teacher even suggested that as a result of her experience as a result of the project, she would be hesitant to try and integrate ICT skills into the course in her first year of teaching. She revealed that, in the past, when she reflected upon the future and the use of the computer, she was sure she would be unable to manage teaching and the technology at the same time. However, her experiences within this study forced her to change her mind and lowered her fear level considerably.

It was very pleasing, as well, to go from school to school and find the associates so enthusiastic and devoted about the project. The comments in Table 2 and Table 3 reinforce the positive feedback elicited by classroom teachers. What was not entirely surprising was the fact that the younger preservice student became a resource for the whole staff. In two cases, specifically, a process had been worked out whereby the staff as a whole was working individually with the preservice candidate to enhance competencies in one area or another. In one situation, it was with presentation software, in another it was in the area of spreadsheets.

Originally there were 15 placement sites with one site having a preservice student working with two teachers. The results displayed and herein discussed represent feedback from all 16 associate teachers. Unfortunately, one of the weaknesses of the process lies in the return of the measurement instrument. It took several weeks and much repeated reminding to gather the instruments from the teachers who were associates. As of the writing of this paper, we never did get returned survey forms from only 8 of the preservice students. The graphs and tables included in this article represent data gathered and tabulated in the above-mentioned fashion.
As Table 2 and Table 3 indicate, the predicted outcomes were evidenced by the results. Both groups did, in fact, experience growth in their perceived competency levels over all the criteria. Using the same standard of measurement for perceived competency levels, associate teachers self-rated their own growth by 6% over all, while preservice student teachers saw their competency levels grow by 19%.

While it would be very interesting to analyze the results by category and perhaps speculate on why growth was greater in some categories than in others, this particular study was meant to focus on general perceived competency. The classroom teachers in this study did grow as much as was expected overall, perhaps due to the fact that they were chosen in most of the situations because of their leadership and proven ability in ICT skills. The exact opposite is borne out by the results of the group of preservice teachers. Growth was real and significant in each category and in general. This result supported the comments elicited during the interviews as indicated in Table 1.

In this section the results of the data analyses are presented. A profile of the sample has been presented earlier in the paper. Individual comparisons (t-tests) were calculated to identify significant differences between the pre-teaching block and post teaching block periods within the two groups (i.e., the teachers and the students).

Table 4 illustrates that there were no significant differences between the means for the teachers' pre teaching block and post teaching block for section 1.1 $t(15)$ = 0.262, $p >0.05$; for section 1.2 $t(15)$ = 0.141, $p >0.05$; for section 1.3 $t(15)$ = 0.255, $p >0.05$; for section 2.1 $t(15)$ = 0.245, $p >0.05$; for section 2.2 $t(15)$ = 0.052, $p >0.05$; for section 2.3 $t(15)$ = 0.112, $p >0.05$; for section 2.4 $t(15)$ = 0.071, $p >0.05$; for section 3.1 $t(15)$ = 0.112, $p >0.05$; or for section 3.2 $t(15)$ = 0.278, $p >0.05$.

Even though no significant differences were found, it should be noted that there was an increase for the means in all 9 sections from pre teaching block to post teaching block. Teachers also reported increases in their perceived skill levels and were positive about their gains. Further explanations for the statistical result with the teacher group are advanced below, as well.

DISCUSSION:

This project began with the assumption that there would be benefits in matching preservice students and master teachers and putting the development of ICT competencies in the forefront of their planning. The former perceived themselves to be technologically competent and wanted to put into practice these skills in their practice teaching blocks. The latter would be anxious to either further their skills or mentor a student to help him or her become similarly competent. The results of these pairings, while positive, should be viewed in light of several factors.

- The completion of the survey forms used was not done at the same time in the same circumstances by both groups, or even by individuals in each group. Some participants made their choices and returned them immediately. Others needed to be repeatedly reminded until they were returned. In the end, only 8 of 15 preservice students completed and returned both the pre and post surveys within the time constraints of the project.

- Often, respondents did not fully understand the terminology of the descriptors on the measurement instrument and questioned just exactly what each line was alluding to. There was also a great deal of reluctance to self-rate oneself at the higher end of the rating scale because they felt that next to a technician or technical support person, they had to be much lower down in their skill set. Teachers and students both had a tendency to under-appraise themselves in terms of their general levels of technical ability.

- Although the original items had been that each pair would identify a specific area that they intended to work at developing competency in, at no time were they asked to follow that up and identify the area they had agreed upon. It would have been much better for interpretation and generalization of the findings if there had been some indication of the area to be focused on so that the results for that one area might be compared to that of the other areas and ICT skills in general.

- Since this was a project that evolved over time and solidified its main outlines, the process of matching up preservice students and master placements was very happenstance. No criteria were defined to set parameters for the working environment of the teaching block.

- The matches made between students and their placements were in fact at all grade levels and therefore included rotary and non-rotary teaching situations. Indeed, one of the matches was made in a secondary school and because of its rotary nature, the expectations of both the associates and their single assigned student could not be easily compared to a situation in a primary classroom.

- Many of the results were significantly altered by problems with the technology itself. In several situations, major work being done on the networks and their infrastructure prevented access on a continuing basis by all concerned. In other situations, the demands upon the networked machines made it necessary for planning to take into account shared access rather than access upon demand.

This project documents the impact on practicing teachers and pre service students who participated in a program that was designed to increase their focus on the use of information technology in their teaching practices. It was found that an average of four weeks of focusing on the use of technology in classroom practice resulted in increases in perceived skill levels for:

1. Basic Computer / Technology Operations & Concepts
2. Personal & Professional Use of Technology
3. Application of Technology in Instruction
4. Telecommunications and Information Access
5. Research, Problem Solving and Product Development
6. Teaching Methodology

Moreover, participants in this program reported that they enjoyed the experience and the chance to pay particular attention to the technology. Additionally, statistical analysis demonstrate that student teachers had significant gains in 7 of the nine sections. Those areas of identified gains are:

1. Basic Computer / Technology Operations & Concepts
2. Personal & Professional Use of Technology
3. Application of Technology in Instruction
4. Telecommunications and Information Access
5. Research, Problem Solving and Product Development
6. Teaching Methodology

The measured increases are meaningful for the teachers who decide to use this mentorship approach for increasing their own technological skill and perhaps raising awareness of the technology at the school and board levels. It is important to recognize that this project described elsewhere in this study represents one component of the ongoing quest for expertise with technology and its use in an educational setting.

RECOMMENDATIONS:

As pointed out above, this project was very successful and fulfilled most of the expectations of the researchers who directed it. However, this was only a pilot. The authors look forward, next year, to broadening the scope of the process. They plan to oversee the mentorship pairings in both the second and the third teaching blocks. It is also expected that the study will include classroom sites in the conterminous Roman Catholic board. The researchers will make the following changes to the process:

- The survey instrument will be administered to everyone at the same time and collected immediately, both at the beginning and at the end of the teaching block.
Each pair of teachers will have to identify a competency skill set that they wish to work on to enhance so that the researchers will then be able to compare results between the specific competency and the general set of competencies.

There will be greater coordination between the placements and the students interested in being part of the project so that there are more schools to choose from for test sites.

We will begin the fall to involve our partners at the Catholic District School Board so that it can involve all Preservice students, regardless of practice teaching assignment location.

We will rework the wording of the Competency Measurement Instrument so that the individual items are self explanatory and easy for teachers to understand.

We acknowledge that there is much to work at to improve our project scope and process. However, we also are very pleased with the results it has yielded for us as researchers and for the implications of those findings.

CONCLUSIONS:

Teachers in classrooms around the world are struggling with how to keep up with the changes in technology that are brought into the school by students. They are grappling with the problem of how to deliver effective classroom program based upon the new curricula as it is centrally defined, while also finding the time to integrate skills that are required for success in the future, which are, by definition, in a constant state of flux. Professional educators work in an environment where the goals of the program are not matched by the level or state of the technology it depends upon for delivery. Finally, they are trying to implement new methods of program delivery, assessment and evaluation while being expected to become professionally developed in Information and Communication Technologies. All of these expectations add tremendous pressures on their day to day functioning.

Preservice teachers are coming to the Colleges of Education having many of the ICT competencies in place but unable to apply these to their developing teaching repertoires. They have been kept abreast of all the changes in the world of technology by definition of the culture they have grown up in and somehow expect to be able to use these in their classrooms. Instruction and the expectations of practice teaching do not purposefully include technology so newly hired teachers begin to become accustomed to an environment that does not place high value on the use of the hardware and software already in the schools.

When individuals from both groups are brought together to measure each other not just in sound professional teaching practice but also in the integration of the new technologies with the old, both gain immeasurably. Mentorship is a two way street in our classrooms and by purposefully including technology we provide in-service for our preservice teachers in ICT that is 'in time' and on demand. It provides support for the in-service teachers for risk-taking because they are involved in measuring students who are in a learning mode. It also provides chances for preservice teachers to use their ICT skills while learning how to apply them to their prospective careers, and modeling for both groups how to integrate technology in useful and productive ways.

Given that there is a paucity of research demonstrating educational projects that are of benefit to teachers who wish to use technology more effectively, the findings from this pilot study are indeed encouraging. Nevertheless, further research is warranted to establish the most efficacious balance between traditional classroom approaches and the use of computer based instructional methodologies. Since four weeks was the time allocated for this study, one might reasonably question whether an increase to 8 weeks of involvement with the program would result in an equal ratio of skills gains.

Technological Foundations: Integrating the Use of Technology in Teaching and Learning in an Educational Foundations Course

Clare Kilbane, Teacher Education and Curriculum Studies, University of Massachusetts, Amherst, Massachusetts kilbane@virginia.edu

Marsha Gartland, Educational Leadership, Foundations, and Policy, University of Virginia, Charlottesville, Virginia mag3y@virginia.edu

Abstract: This paper presents one example of how technology was integrated successfully into an existing educational foundations course. Preservice teachers at the University of Virginia acquired knowledge of educational technology and developed technological competencies while learning about their future profession in EDIS 201: Teaching as a Profession. Student feedback collected during and after the course suggests that the strategies for integrating technology were appropriate and enjoyable. Technology blended with constructivist teaching methods made learning more engaging, effective, and efficient.

Rationale for Technology Integration

This paper presents one example of how technology was integrated successfully into an existing educational foundations course. Preservice teachers at the University of Virginia acquired knowledge of educational technology and developed technological competencies while learning about their future profession in EDIS 201: Teaching as a Profession. Student feedback collected during and after the course suggests that the strategies for integrating technology were appropriate and enjoyable. Technology blended with constructivist teaching methods made learning more engaging, effective, and efficient.

In 1996, Willis and Mehlinger challenged teacher educators to consider the benefit of an integrated approach to technology in the professional preparation of teachers (1996). They suggested preservice teachers might benefit from exposure to technology beyond simple participation in stand-alone computer courses and called for integration of technology across all existing components of teacher education programs namely foundations courses, methods courses, content-area courses, and student teaching. In 1997, the National Council for Accreditation of Teacher Education [NCATE] seconded this idea of an integrated approach for technology in teacher education. NCATE called for schools of education to “create a vision of what their programs would be like if they took full advantage of information technology” (NCATE, 1997, p. 9). In July 2000, the International Society for Technology in Education released a comprehensive list of technology standards developed for NCATE. These new standards will be used to determine how schools of education prepare their graduates to use technology across all areas of professional preparation, including foundations courses.

Foundations courses are a standard component of most teacher education programs. They address a broad spectrum of contemporary issues in the profession, while also exploring the sociological, philosophical, and historical contexts of education. These courses serve an important role in prospective teachers’ introduction to the profession—often allowing preservice teachers to build frameworks for future understandings of the field. Most preservice teachers experience at least one of these courses during their first year of professional preparation. They are often a “common experience” in which preservice teachers across diverse programs share experiences, ideas, and beliefs with colleagues.

Proper preparation and support increase the likelihood that the integration of technology into the instruction of these courses will be successful. Technology, when blended with constructivist learning strategies, might create better instructional opportunities for students and revitalize teacher education faculty. Here, we illustrate one example of how two different teacher educators during two different semesters used technology to help students examine crucial course content in a more engaging and effective manner.
A Case Study
At the Curry School of Education, EDIS 201: Teaching as a Profession is an introductory course for students planning careers in education. In this survey course, students examine education history, philosophy in action in schools, student diversity, curriculum, effective teaching, school organization and governance, and other topics affecting the role of the teacher as professional. Approximately 35 students, most in their second-year of a five-year program, take the course each semester. During fall semester of 1998, 1999, and 2000, technology was used in a variety of ways to: 1) assist the instructors in more effectively communicating course content, 2) involve students actively in thinking about their future profession, 3) build community among students with diverse interests and backgrounds, 4) provide students opportunities to develop comfort and competence with technology applications, and 5) model effective and engaging instruction with technology. These techniques addressed new NCATE standards. (See http://www-unix.oit.umass.edu/~kilbane/ncate/matrix.html)

In EDIS 201, technology was used to allow instructors to “do things differently and to do different things (Riel & Fulton, 1998). Teaching during two separate semesters, each instructor found different methods for teaching a traditional course. Both used “The Foundations of Education” (McNergney & Herbert, 2000) as a course textbook and met with their students twice a week for an hour and fifteen minutes. But what happened during many of these class meetings and outside of class made education for students more efficient, more engaging, and more effective.

Doing Things Differently
Some basic uses of technology allowed the instructors to approach traditional activities differently—making course operations more efficient in some cases. The class webpage enabled the instructor to update assignments more easily, provided students with easy access to online resources (syllabus, readings, videos, multimedia case studies) used to enhance the use of the course textbook. Additionally, the course website allowed students to communicate with one another outside of class about issues of concern including their field experience placements. PowerPoint presentations took the place of traditional lectures providing instructors with an easier way to organize content and provide instruction for different learning styles. A Quicktime video of each student articulating her beliefs about teaching at the beginning and end of the semester allowed classmates to learn each others' names and faces and made it easy for virtual guest lecturers to "get a feel" for the students and their ideas about teaching and learning. Inspiration, a semantic mapping program, facilitated class brainstorming about various educational concepts.

Doing Different Things
Technology also allowed instructors to implement new kinds of activities that encouraged students to think critically about course content. The software program Excel supported a problem-based lesson on school budgets and finance. Students manipulated vast amounts of information on educational history using a database program. To integrate and personalize ideas from the text, students designed philosophy of teaching Web pages and learned to post them on the public server space provided by the University. They also participated in a forum on careers in education with the US Department of Education's Technology Teacher in Residence using iVisit, a desktop videoconferencing program.

Obstacles to Integration
Technological innovations will continue to influence the practice of education, though the combination of online technologies with current course content will not always be seamless. O'Bannon and Brownell (1999) suggest that faculty members prepare themselves for a fundamentally new way of conveying knowledge while ensuring that the requisite learning takes place. The authors will discuss the obstacles encountered as they integrated technology in EDIS 201, and suggest strategies to anticipate and address such problems.

Abstract: This study investigated the perceptions of the education community in the Phoenix, Arizona metropolitan area regarding technology competency skills for preservice and inservice teachers. Participants included 67 preservice teachers, 67 inservice teachers, 45 school principals, and 21 school district human resource directors. Two sets of survey instruments were used for this study. One survey containing 26 items of technology skills for preservice teachers was distributed to preservice teachers, inservice teachers, and principals. Mean scores were calculated to test for significant multivariate effects on items among three groups. Another survey regarding hiring decisions was distributed to principals and human resource directors. Frequency and percentage analysis were used for the second survey. The results showed that preservice teachers placed more emphasis on overall technology skills than inservice teachers and principals and there were significant differences by group in nine of 26 items. The opinions from principals and human resource directors regarding hiring decisions were also explored.

Introduction

There are growing demands and continuing needs to infuse instructional technology in all professional education programs to better prepare teachers and administrators to use computer technology in classroom learning (Hill & Somers, 1996, Northrup & Little, 1996). However, recent research studies indicate that teacher-preparation programs in most universities are not adequately preparing future teachers to teach with technology (Strudler & Wetzel, 1999). A report prepared by the National Commission on Teaching and America's Future (NCTAF, 1996) stated that teacher programs are described as "fragmented, superficial, and unconnected to real classroom experiences". Wetzel (1993) has suggested that the best way to meet the International Society for Technology in Education (ISTE) teacher technology standards is through the combination of a core computer literacy course model and an integration model with specific standards being met. Although many universities offer specific preparation programs in the area of educational technology for preservice teachers, most of them have not yet developed curriculum that meets the ISTE standards for basic skill. This is especially true in states that do not require evidence of computer competency for teacher certification. Preservice teachers do not routinely use technology while in the field or work with supervising teachers who model the integration of technology (Moursund & Bielefieldt, 1999). Therefore, many preservice teachers are still entering the classroom with minimum technology skills and feel incompetent to utilize technology effectively to support classroom activities. In Teacher's Tools for 21st Century: A Report on Teacher's Use of Technology (Smerdon & Cronen, 2000), only one-third of teachers in the U.S. reported feeling well prepared to use computers and the Internet for classroom instruction. Teachers with fewer years of teaching experience were more likely to use home computers and/or Internet for planning lessons and creating instructional materials. The lack of release time for teachers to learn how to use the computer and Internet was the biggest obstacle reported by 82% of U.S. teachers. This study investigated the perceptions of the importance of technology competency for preservice and inservice teachers and the results will be used to create a strong foundation for an effective technology training program for preservice teachers. With the input from the school system, we hope to
design training programs that meet the needs of the schools while developing technology competency skills for preservice teachers that meet or exceed the national standards set forth by ISTE. With these technology skills, preservice teachers will meet the hiring requirements of schools and will be competent to integrate technology appropriately in the classroom.

Research Questions

The following research questions were investigated in this study:
1. What are the preservice teachers’, inservice teachers’, and school principals’ perceptions toward the importance of teacher technology skills?
2. Are there any significant differences in the perceptions of preservice teachers, inservice teachers, and school principals toward the importance of technology skills?
3. What are the current professional development mechanisms and opportunities for developing inservice teacher technology skills?
4. What technology skills and competencies are currently being considered during the hiring process of teachers?

Method

Subjects

Participants were preservice teachers enrolled in technology courses at a university and inservice teachers and administrators in the public school system in Arizona. The subjects included 67 preservice teachers, 67 inservice teachers, 45 principals, and 21 human resource directors from public school districts in the Phoenix metropolitan area.

Materials

The first survey was based on the National Educational Technology Standards and the North Carolina Public Schools Technology Competencies for Educators. The survey questions focused on the basic technology skills and competencies defined in these documents. Researchers asked preservice teachers, inservice teachers, and principals to rate the importance of 26 items of basic technology skills for a teacher. In the second survey, school principals and human resource directors were asked whether basic technology competency skills were an important factor in the hiring process and determined their preferred forms of assessing technology skills for new graduates.

Procedures

The survey for preservice teachers was administered during their regular class meeting times at a university. The surveys for inservice teachers, principals, and human resource directors were distributed at several local conferences and workshops and mailed directly to randomly selected public schools in Arizona.

Criterion Measures

The rating scores on the first survey that range from not important to very important on the five-point agreement scale were converted by the researchers to their numerical equivalents (1 = not important to 5 = very important). Mean scores were calculated for each survey item by different groups of participants. A multivariate univariate analysis (MANOVA) was used to test for significant multivariate effects on items within different groups. Follow-up univariate analyses were performed on the individual items in each area for which a significant MANOVA was obtained. Frequency and percentage were tabulated and calculated for the second set of survey.
Results

Four hundred and ninety surveys were distributed. The return rate was 54% for preservice teachers, 34% for inservice teachers, 39% for principals, and 54% for human resource directors.

1. What are the preservice teachers', inservice teachers', and school principals' perceptions toward the importance of teacher technology skills?

The mean scores for each statement that assesses the importance of a preservice teacher's ability to perform specific technology skills were analyzed and are shown in Table 1 (http://www.public.asu.edu/~hengyuku/SITE.htm). The highest level of agreement on importance for the survey was with the statement "Basic computer operations - start up and shut down the computer and its peripherals, start an application" (Overall Mean = 4.82). Three other statements with high levels of agreement on importance (Overall Mean > 4.50) indicated that preservice teachers should be able to: (1) create a document; name, save, retrieve and revise a document and use printing options (M = 4.78), (2) use word processing/desktop publishing to create letters and instructional materials (M = 4.56), and (3) use the Internet to browse, search, and send e-mail (M = 4.53).

The lowest level of agreement on importance was with the statement "Developing web pages and/or sites for instructional use and relating information to parents" (Overall Mean = 3.17). Three other statements with low levels of agreement on importance (Overall Mean < 3.50) included (1) creating a database to manage information (M = 3.48), (2) setting up and operating a presentation system that works with a computer (M = 3.47), and (3) producing electronic slides/overheads (M = 3.40).

2. Are there any significant differences in the perceptions of preservice teachers, inservice teachers, and school principals toward the importance of technology skills?

The overall mean score for the 26-item survey was 4.03. Overall mean scores by respondent groups were 4.21 for preservice teachers, 3.98 for inservice teachers, and 3.80 for principals, F(2, 147) = 4.60, p < .05. The multivariate analysis of variance at p < .01, followed by the Tukey HSD on the overall means revealed statistical differences between preservice teachers and principals.

An ANOVA was performed on each of the 26 items and the results are shown here in Table 1A. Statistically significant differences occurred between the three respondent groups on nine of the 26 items. Preservice teachers agreed significantly more strongly than both inservice teachers and principals on six statements. These six statements were (1) setting up and operating a VCR and monitor/TV, F(2,172) = 10.17, p < .01, (2) creating spreadsheets to manage information, F(2,171) = 6.55, p < .01, (3) creating a database to manage information, F(2,172) = 8.45, p < .01, (4) setting up and operating a presentation system that works with a computer F(2,171) = 5.63, p < .01, (5) producing electronic slides/overheads, F(2,171) = 8.20, p < .01, and (6) developing web pages and/or sites for instructional use and relating information to parents F(2,174) = 6.71, p < .01.

Both preservice teachers and inservice teachers agreed significantly more strongly on three statements of the technology skills than principals. These statements were (1) create a document; name, save, retrieve and revise a document and use printing options, F(2,175) = 4.82, p < .01, (2) apply strategies for identifying and solving routine hardware and software problems that occur during everyday use, F(2,175) = 5.62, p < .01, and (3) evaluate software and technology for instructional use, F(2,172) = 6.00, p < .01, as part of a certification process.

3. What are the current professional development mechanisms and opportunities for developing inservice teacher technology skills used in schools today?

Inservice teachers and principals were asked about the use of technology in instruction at schools and the types of technology professional development opportunities that were available for inservice teachers. Their responses were analyzed and are reported in Table 2 (http://www.public.asu.edu/~hengyuku/SITE.htm).
Which of the following technology skills are important for a preservice teacher to be able to perform as part of a certification process?

Table 1A: Mean Ratings and Significant Differences by Group and Item Statement.
When researchers asked whether teachers are evaluated in their use of technology in instruction, the results revealed that only 10 inservice teachers (15%) and 11 principals (26%) indicated “Yes” while 55 inservice teachers (85%) and 32 principals (74%) responded “No.”

When researchers asked which areas inservice teachers and principals feel their faculty could improve their current skills a total of 83 respondents (74%) indicated “Computer use for instruction”, 80 respondents (71%) indicated “Use of Internet resources for instruction”, 77 respondents (69%) indicated “Multimedia – video and electronic slides”, 67 respondents (60%) indicated “Computer use for management – grades, lesson plans, and instructional materials”, and eight respondents (7%) indicated “Other”.

When researchers asked what types of technology training opportunities are available for inservice teachers a total of 93 responded (83%) “District workshops”, 71 (63%) responded “Pccr training”, 53 (47%) responded “Consultant training at school”, 31 (28%) indicated “University professional development or courses”, 24 (21%) indicated “Industry courses”, and 4 (4%) indicated “None”.

4. What technology skills and competencies are currently being considered during the hiring process of teachers?

The responses regarding hiring decisions for preservice teachers from both principals and human resource directors were analyzed and are shown in Table 3 (http://www.public.asu.edu/∼hengyuku/SITE.htm). The researchers asked whether they would rate a new or preservice teaching applicant with well-developed technology skills higher than an applicant with minimum technology skills. The results revealed that 35 principals (78%) and 12 human resource directors (57%) indicated “Yes” while 10 principals (22%) and 9 human resource directors (43%) responded “Not considered.”

Principals and human resource directors also were asked about how they currently assess an applicant’s skills to use technology as an instructional and management tool. A total of 41 respondents (62%) indicated “Application interview”, 28 respondents (42%) indicated “Portfolio”, 21 respondents (32%) indicated “Transcript”, 12 respondents (18%) indicated “Certificate of training”, six respondents (9%) indicated “District interview”, four respondents (6%) indicated “Not assessed”, and three respondents (5%) indicated “Other”.

For the question regarding what methods they would prefer to use to assess an applicant’s technology skills as an instructional and management tool in the future a total of 26 respondents (41%) indicated “Portfolio”, 26 respondents (39%) indicated “Application interview”, 17 respondents (26%) indicated “Certificate of training”, 16 respondents (24%) indicated “District interview”, eight respondents (12%) indicated “Transcript”, and four respondents (6%) indicated “Other”.

Conclusions

The results from this study can offer a foundation for developing a new model for technology courses for preservice teachers. This model can be implemented at universities and, in addition, provide guidelines for local community colleges and other educational facilities for the development of technology courses that cover the basic skills required by the National Educational Technology Standards. The results can also demonstrate to preservice teachers what technology skills that future employers are expecting from them and provide assistance to those employers in the correct assessment of a teacher’s technological skill.

Research has shown that the educator who has developed skills before entering the classroom will use technology more in instruction and will make more of an effort to continue acquiring new skills. Research has also shown that teachers with fewer years of teaching experience are more likely to use technology as a tool in instruction and planning. Our survey results corresponded with these findings. The preservice teachers placed more importance on many of the technology skills than inservice teachers or principals did, and we can assume that they will want to use these skills in the classroom. The inservice teachers surveyed agreed more than the principals did that many of the basic technology skills in the survey were important. This is an indication that they are finding opportunities to use these skills in the classroom and are convinced of their importance.

It is interesting to note that both principals and teachers found areas for improvement in the current technology skill sets of teachers and that those skills include computer use for instruction, using the
internet and multimedia for instruction, and using technology for grading and management tasks. Again, these are the basic skills determined by the ISTE standards. Schools are currently providing workshops and other forms of commercial training for teachers to improve technology skills, and 63% of the teachers reported learning technology skills from a peer trainer. These findings point out the need for universities and other educational institutions to provide technology training for preservice teachers.

Basic technology skills must be developed before integration into instruction can be achieved. Results from this survey are being used in dialogue with university professors and community colleges to develop computer courses that cover basic skills outlined in the National Educational Technology Standards. The goal is to develop classes that not only would benefit the professional educator, but skills that would be used by the paraprofessional in a school setting. Once a student has a foundation of basic skills, the university preservice courses can focus on the integration of technology as a teaching tool. The technology course would develop the pedagogy for integration and methods courses would model and require the application of technology in student projects. Modeling the integration of technology would not only be in methods courses, but also in field study placements. When possible, the education colleges can also look outside of their own curriculum and identify other coursework that will benefit educators as they develop their technology skills. For example, technical writing, graphic design, and multimedia development can all play major roles in instructional development.

Our survey results also indicated that administrators are looking for skilled applicants and assess technology skills in various ways. Current assessment of technology skills is done by an application interview (62%) and by portfolio (42%). The survey results for future assessment show that these two assessment tools remain the most important, but that portfolio is as preferred (41%) as the application interview (39%). Schools of Education can provide a great service to the educational community by creating a consistent portfolio mechanism that identifies those students who have achieved a high level of technology skill and who are prepared to integrate technology into their classrooms immediately.

If our children are to become technically literate, it falls to the university to produce well-trained teachers who can provide models of technology skill as well as instruction and practice opportunities for their students. We believe that technology training will never be a static process and there will always be new skills to be learned. It will be important for university teaching programs to be riding the leading edge of technology in the future.

Learning with Internet Resources:  
Task Structure and Group Collaboration

Yiping Lou and Kim S. MacGregor  
Louisiana State University  
United States  
Email: ylou@lsu.edu

Abstract: The purpose of this project was to study how task structure and group collaboration may influence the way children learn with Internet resources. A group of 27 elementary school children and two classes of pre-service teachers participated in this study during the summer 2000. The children were assigned to work on a WebQuest designed by the pre-service teachers either individually or in pairs. Data were collected through an observation scheme and journals. The results showed differential patterns of behaviors and emotions when children learned individually and in small groups. In addition, the differences were often related to the different characteristics of the learners and the task structure.

Introduction

The Internet, with its vast array of information, offers students opportunities for learning from rich, up-to-date and authentic resources and for developing information-seeking skills. On the other hand, complaints are often heard from students that it is time-consuming to find useful and relevant information on the Web. Although more expansive and up-to-date than any encyclopedia, the information on the Web is not organized and filtered as that in encyclopedia (March, 1998). A lot of valuable time can be wasted if students lack the necessary research skills and appropriate guidance is not provided to them.

WebQuests, an inquiry-oriented activity in which most or all of the information used by learners is drawn from the Web, were developed by Dodge (1995) to help educators design meaningful and structured learning activities for students. Since then, WebQuests have become increasingly popular as a component in teacher education courses and in the K-12 schools. However, few studies have been conducted to date investigating the effects of using WebQuests, the adequacy of the structures provided and the influence of social context. A recent meta-analysis (Lou, 1999; Lou et al., 1998) of 103 studies comparing small group and individual learning with technology indicated that the effects of social context appeared to be moderated by type of technology-mediated learning activities, task structures, and group or individual outcomes. The purpose of this project was, therefore, to study how task structure and group collaboration may influence the way children learn with Internet resources.

Method

A group of 27 elementary school children ranging from grade 2 to 7 participated in this study during the summer 2000. These children were brought in by two classes of pre-service teachers who were taking a technology literacy course learning to use various software and ways to facilitate children's learning with technology. One of the course components is to design a WebQuest. In order to make the activity more meaningful and to observe how children learn with technology individually and in small groups, we suggested to the pre-service teachers that they bring in one or two children for the WebQuest try-out. Thus, each pair of pre-service teachers designed their WebQuest specifically for the children they knew. Each WebQuest contained all the five essential components (i.e., introduction, task specification, detailed procedures, a list of resources, and some concluding remarks) as suggested by Dodge (2000).

In one class, the WebQuest try-out was conducted in two days. About half of the children participated on Day 1, where each child worked on the WebQuest individually. On Day 2, the other half of the children worked in pairs. In the other class, the activity was conducted in one day. About half of the children worked individually and half in pairs. At the beginning of the activities, the pre-service teachers provided a brief introduction to the WebQuest activity each child or each pair of children would work on. Then the children worked on their own while the pre-service teachers sat beside the child(ren) observing, taking notes, and answering children's questions when needed. For those working in pairs, they were instructed to share and help each other.
Data were collected using an observation scheme with broad questions on how children interacted with each other and with the learning activities. In addition to the observation notes, each pre-service teacher also wrote a journal after the study, reflecting on what they observed and learned from the study.

Findings

Differential patterns of behaviors and emotions were observed when children learned individually and in small groups. In general, children working alone asked more directional questions of the facilitators, whereas pairs appeared to rely more on each other than on the facilitators. When working in pairs, the children shared work, decisions, as well as excitement and they appeared to enjoy the tasks more than those working alone. However, some observers noticed that the learner in control of the mouse was often actively involved in making decisions, while the one not in control often struggled to keep up.

Type of tasks appeared to have differential effects on children. Tasks that combined information-seeking activities with multimedia design appeared to motivate the children more than the former alone. In many cases, both individuals and pairs became more engaged and motivated when they applied the information they gathered in some multimedia design activities.

Although each WebQuest designed was quite structured and contained all the five essential components, a few children, especially those that were at younger age and were working alone, felt somewhat at a loss as to what to do after reading through the package and listening to a brief oral introduction by the facilitator. In addition, a few children expressed some frustration having to weed through irrelevant information on some Web sites.

Implications of the Study

The results of this exploratory study contribute to the knowledge of how children at different grade levels learn with Internet resources in small groups and individually. Although WebQuests are intended to provide structure when children learn with internet resources, results of this study suggest that the effectiveness of WebQuests may vary based on the type of tasks designed, the age level and cognitive ability of the learners, and whether children learn with others or by themselves. However, more studies may be needed to replicate the results.

This study also indicates that incorporating observation studies in teacher technology training courses can be a valuable experience for pre-service teachers. Through close observation, the pre-service teachers involved in this study noticed both the strengths and limitations of their designed learning activities and realized the importance of effective instructional design in motivating the students and enhancing their learning. They also realized that both individual cognition and social interaction play an important role in children’s learning (Anderson et al., 2000). The activities designed have to be closely related to the children’s prior knowledge as well as interests. A few pre-service teachers were disappointed that the excitement and enthusiasm they expected of their learners were not exhibited. Through close observation and reflection, they found what was lacking in their designed activities and suggested ways that their activities and learning experiences may be improved.

References

Abstract: This paper examines the experiences of beginning teacher education students in an inquiry-based, technology rich course that has been designed to change the work that both teachers and students do as they explore contemporary issues in the profession of teaching. Analysis of these experiences is framed by concepts from cross-cultural psychology, often used to understand experiences of individuals who abruptly find themselves living in a different culture. The premise is that classrooms characterized by changed teaching and learning design and activity are, in fact, "new cultures" to those who participate in them.

Introduction

In 1994, responding to a State of Ohio initiative to replace its certification program with one that licensed its new teachers, faculty in the College of Education at Kent State University began the process of reevaluating its teacher education program. That reevaluation led to the completely redesigned program that has been in place since the fall of 1998. Central to the goals of the new program has been to change the work students and teachers do: to make course work more interactive, to engage students and teachers in inquiry-based research, and to demonstrate student outcomes, experience, and achievement in new ways. In all these areas, the integration of technology has been a major tool.

In all segments of the program, students and teachers have experienced major changes in the work they do, how that work is done, and with whom. As might be expected, the transition to the new program has not been easy and not least of the difficulties has been— for all of us—the necessity of learning new ways to "do school." The purpose of this essay is to focus on the experiences of students and teachers in one particular course—the initial core inquiry seminar in which students are introduced to three major ideas: contemporary changes in the profession of teaching, the impact of a diverse population on classroom cultures, and the integration of technology into instruction.

The Argument from Design

The physicist, Freeman Dyson, writes of cosmological theories of the development of the universe, one of which is called "the argument from design" [Dyson 1979]. In that theory, the thesis is that a single "designer" created the universe, thus ensuring at least some degree of coherence in the design. Our small universe did not have the benefit (and the costs) of a single designer. Rather, it had the costs (and the benefits) of many "designers." As is customary in an era suffused with the "argument for collaboration," the reevaluation of our teacher education program began with a relatively small and partially representative committee, expanded—like the universe—to a number of partially representative committees, expanded again to the full teacher education faculty, reduced itself on a number of occasions to other, still partially representative committees for further consideration, and was finally accepted in 1997 by a group called, in our College, the Teacher Education Council, which is fully representative of all program areas involved in the preparation of teachers.
Along the way, many ideas were put forth, rejected, brought back, altered, refined, discarded, brought back again, and altered again. In the end, our "universe" settled into the elements of design with which we are working today.

The first of these is that it is a four-year program. Students start in teacher education as freshmen, or as newly-converted upper-classmen, whichever comes first.

Second, the program is inquiry-based. That is, increasingly more responsibility is placed on students to engage with us in their own education. This means that, wherever possible, knowledge and skills are framed in terms of questions, not answers, and students are encouraged—one could say, "forced"—to begin to frame their educational experiences in terms of their own questions about the relation between school and society, about the profession, the classroom, their own future students, and about methods of instruction.

Third, the program has what we might call "strands of design." These include emphases on a community of inquiry, integrative studies, reflective practice, responsiveness to differences, and the integration of technology into instruction. Each of these strands, although in different degrees as appropriate, are woven throughout the program.

Fourth, students are assessed not only through investigation, projects, writing, and testing, but finally in terms of initially, student portfolios, and later, professional portfolios. Soon, all students will have electronic portfolios.

Fifth, the program enlists classroom teachers and agency professionals as partners in the education of pre-service teachers. This is done in a number of ways, beginning with placement in schools in the freshman year and extending through student teaching.

Finally, the program includes introduction to a variety of forms of research, culminating with a major action-research project associated with student teaching.

The Inquiry Seminars

A central feature of the new curriculum design is a series of four Inquiry Seminars. The first three of these seminars combine elements of sociocultural and psychological foundations, are thematic in nature, and are designed in a spiral, so that concepts and issues introduced initially are revisited repeatedly, each time from a different angle or in more depth, or both. The fourth seminar, "Inquiry Intro Professional Practice," is taught in the program areas in association with student teaching. In addition, a series of three inquiry-based seminars is offered in individual program areas, beginning in the sophomore year. Students thus have seven such seminars in their whole program, three in foundational areas and four in program or licensure areas.

The first, Inquiry I, is called "Inquiry Into the Profession." The focus of this course is on our own students and their development as beginning pre-service teachers. It has three major elements: 1) inquiry into the nature of the teaching profession, its history and its current status and requirements; 2) inquiry into the diverse nature of learners in the United States today; and 3) inquiry into the integration of technology into instruction. It is not only an introduction to the teacher education program; it is also an introduction to a new culture of teacher education. The challenges inherent in this course appear, in varying degrees in all of the Inquiry seminars, as well as in the program as a whole. But because this particular course is the first, the challenges of a new culture are more apparent here.

The New Culture of Teacher Education

The new culture that students find when they enter the Inquiry I course can be characterized in the following ways:
it is a shift from passive to active orientation;
it is a shift from "getting" answers to formulating questions;
it is a shift from "knowing" to reflection;
it is a shift from teaching to learning;
it is a shift from individual work to collaboration;
It is a shift from certainty to ambiguity; and, in our case,
It is a shift from paper (textbooks, articles) to electronics (browsers, web sites)

Positing a Culture-Clash in the New Program

While there has been a great deal of literature on student “resistance” to new kinds of classroom organization and instruction, I think it is more helpful to conceptualize the situation in terms of a clash of cultures. We are familiar, I imagine, with the concept of “culture clash,” as representing what happens when one suddenly finds oneself in a different cultural milieu. My observation is that much the same thing is happening to our students, and—to a large extent—to ourselves as we struggle to find new and better ways of educating teachers. Thus, I want to borrow a schema from cross-cultural psychology to describe what happens when students who have learned, for the most part, how to be effective students in traditional teaching and learning situations, react when they find themselves, with little preparation, in a very different kind of classroom culture.

The schema is adapted from Cushner and Brislin [Cushner & Brislin 1996] as one that may be useful in analyzing and understanding the challenge we face with our students. Briefly, the schema “illustrates three psychological stages through which individuals usually proceed when immersed in an intercultural encounter” [Cusher, McClelland, & Safford 1996]:

Stage One: Emotional Arousal
Stage Two: Understanding Unfamiliar Behavior
Stage Three: Personal Adjustment and Growth

Emotional Responses

Emotional responses arise quickly when one is confronted with unpredictable behavior on the part of others and when their own behavior does not produce expected results. Among the emotional responses are anxiety, ambiguity, disconfirmed expectations, a need to belong coupled with a certain fear of rejection, and unhappiness at having to examine their own preconceived notions.

These emotions are almost immediately aroused in our students by a number of activities in the class. They are anxious because we have them reading trade books with no bold-face headings that tell them what is “important to learn.” They are anxious because we give them “teaching opportunities” in the class almost right away. They are anxious because we require them to articulate their own judgments, based on their inquiries, and there is no right answer.

They quickly develop a sense of ambiguity about the class for a number of reasons. For example, at first it seems to them to be a kind of “easy” class, because much of it is discussion. But it soon occurs to them that “opinions” are not enough; they need not only to support their opinions but those opinions are subject to public scrutiny in the class.

Their expectations are disconfirmed rather quickly, as well. I cannot emphasize enough the degree to which most of them have learned to “do school” successfully—by taking good notes, by learning concepts helpfully bold-faced or underlined in a recognizable text book, by learning definitions, and by giving “right answers.” How, they say, can they take notes on a free-flowing discussion? What concepts and ideas should they “learn”? How can they define an idea like “cultural identity,” which, for our mostly white, middle-class
students, “belong” only to people of color? What if there are no right answers? Indeed, what if questions—
inquiry—are more important than answers? My, how the rules have changed!

Not “knowing the rules” of appropriate behavior in this new situation makes it difficult for many to
feel that they “belong” in this milieu. At the very least, they expect this course to help them “learn to teach,”
which they define primarily as exercising control of classrooms, imparting information that they know and their
students don’t, and generally being effectively “in charge.” And they say, to themselves and to their
instructions, many variations of “What is this, and what am I doing here, and how is this going to help me get a
job as a teacher.” Indeed, the students who most easily come to “belong” are often those who have never been
truly socialized to “doing school” in the traditional way. They are kind of “closet rebels,” and they ask
extremely interesting questions, which, of course, is what inquiry is all about.

Finally, they have a difficult time—and are generally driven crazy—by having to first, identify, and
then examine the development of their own cultural identity—particularly since most are completely unaware
that they have one. In the process, they must step out of their own cultural enclave and “see” it, when it is
perceived as all but invisible. To say that many are unhappy about this activity is something of an
understatement. To say they would really like a textbook and be left alone is something of an understatement as
well.

Understanding Unfamiliar Behavior

After about a month, most accept they are stuck in this all-too-required class, and begin to try to figure
out what this class is about, and why it’s important, and what reconstitution of their own mindset is necessary.
In short, they have to acquire knowledge about this classroom culture and they have to learn the new rules.
This, too, is something one has to do when one finds oneself in a new cultural milieu. There are several kinds
of knowledge that they are required to gain.

First, they must learn a new kind of communication, and, in part, a new language. They are very used
to one-way communication patterns in school—from the teacher to the student. They are also used, in
traditional classrooms, to speaking answers, not generating questions. They have been taught that the text, or
the teacher, or some expert of some kind “knows” the answer and they must “learn” it. They have a hard time
even thinking of questions—because, after all, who are they to question the text, or the teacher? Further, they
are not accustomed to having a question answered with another question—how frustrating is that?

The language, of course, is English—but we throw a great deal of educational jargon at them, and to
give them credit, they pick it up rather quickly, immersed in it as they are. Collaborative learning, the Praxis
Series, reflective teaching, AACTE, NCATE, state educational funding formulae, portfolio assessment, the
induction year—and on and on and on. Indeed, they are learning a “professional” language.

In addition, they must learn new values and new rituals. The chief difference, I think, in values lies in
the area of individual work: they come from a culture in which one must keep one’s eye on one’s own paper
and not talk with one’s neighbors, into a culture where helping one another, teaching one another, making sure
everyone learns, are the overriding values. While they do individual work—largely writing—they also work in
small groups a good deal—and are rewarded (with grades) on the basis of the effectiveness of the group, not the
individual. This is a rather different relationship to one another than they have come to expect.

There are new classroom rituals, as well. Look at each other, not just at the teacher; go to work on on-
going projects when first entering the room—not wait for the teacher to get you started; and, of course, a
whole lot of rituals involving the computers that are in the classrooms where these courses are taught.

Status and roles often change, too, in this kind of classroom, particularly those of the heretofore
“excellent student.” The most plaintive exclamation is often, “But I always get As on my papers!” after a
student who, using the rules she has learned well, writes a paper that merely paraphrases someone else—that
“expert” I mentioned earlier. And does not get an A. Another, nearly universal, status that they have acquired in school is the very status as “student”—one who listens but does not venture an original idea or a critique. “What do you want???” they ask me. “I want you to think?” I answer.

Finally, differences in time and space are hallmarks of different cultural milieux. Accustomed to 50-minute liberal arts classes at this stage of their college experience, they spend 2 ½ hours in this class—time to explore, to inquire, to discuss, to work on projects—and to get bored! And the space is also used differently; there are five computers for 20-25 students; there are tables and chairs on wheels; they never know when they come to class just how the place is going to look. Quite often, they are responsible for decided how it will look. Good grief!

Making Adjustments

By about two-thirds of the way through the 15-week class, most—but not all—students have become reasonably adept at the “new” culture of this classroom. They have accomplished what anyone dropped into a different culture must do—they have undergone some degree of personal change. They have adopted a different frame of reference for thinking about teaching—with new categories and new values (e.g., questions are good; answers are open for discussion). They have learned, more or less, to work effectively in small groups—and often take a good deal of pride in “their” group. They have begun to learn that, as teachers, they will be expected to be learners—a new concept for those for whom the teacher is the ultimate authority with the power of the grade. They have begun to sense the scope of this new culture inhabited by “professional” teachers; and they have begun to develop a healthy respect for that culture. They have some new ways to differentiate effective classrooms from ineffective ones, and have begun to refine their notions of “good teaching.”

They have also begun—only begun—to learn to integrate technology, especially computer technology, into instruction. Even those for whom a computer is a new and frightening thing in the classroom, the end of the semester finds them mostly comfortable with them, and talking to each other in a language they didn’t know before. “Well,” they say to one another, “a PowerPoint presentation is really just a fancy overhead; what about actually linking the kids to web sites or having in-class chat rooms or threaded discussions?” I’m amazed.

New Roles for Teacher Educators

Given the nature of our program, and the degree to which we are all—students and faculty alike—“strangers in a strange land,” I believe that the role of the instructor in these courses is many-layered. Of the greatest importance is understanding that we are, indeed, in a different culture, and being overt about it. That is, we must, all along the way, not only model this different pedagogy, but explain what we are doing, why it is different from what students are used to, and how it is different (as well as how it is the same as) what they are used to. We must also enable students to stand back from and reflect on their own experiences in these courses, and this program; we must listen to them and adjust accordingly; and we must give them—and ourselves—the time necessary to “play” with it.

Since many of the sections of Inquiry I are taught by graduate teaching fellows, this also means a significant investment in both initial and on-going education for instructors, which is difficult, inasmuch as we are inventing it as we go along. This means, of course, that we must share the development of this culture with them—not simply tell them what to do. They, too, have grown up in traditional schooling systems, and they, too, tend to “teach as they were taught.”

If this “new” culture is of intrinsic worth, it is worth our best and most creative efforts to understand it, and to pass it along to our students. In a society (and a University) that values high-stakes testing and accountability, and does not particularly value long-term solutions to immediate problems, that is not an easy
What is at stake, however, may very well be the ability of our students’ students to flourish in a century about whose requirements we can only guess.

Abstract: ISTE NETS for Students and the new NETS for Teachers raise expectations of what students and teachers should know and be able to do. Because of this, we sometimes assume that teacher candidates come with more technology experience than they actually do.

Focus groups with undergraduate Foundations of Technology classes indicate that students leaving high school have had little experience using technology in school. None had college professors who modeled technology use.

As teacher education programs are redesigned, stand alone technology classes are often eliminated. However, teacher education programs can not assume that students will come with extensive experience in technology. An Essential Technology Skills Assessment was developed to help students gain basic skills needed to be successful in technology rich classes.

This session will focus on the technology skills and experiences our students are bringing to teacher education programs and one evolving process for building their entry technology skills.

Introduction

Focus groups with undergraduate Foundations of Technology classes indicate that students leaving high school as well as those returning to college after an absence have had little experience using technology in school. Most had used word processors and some had used telecommunications applications. Only one had used technology to support project based learning. While there were pockets of students with more advanced skills, most were still at the novice level of use of other applications.

When asked how technology was included in college courses, most indicated they used word processing to complete assignments but the Foundations of Technology course was the first where professors modeled technology use. In a few classes, they used e-mail to communicate with the instructor. They used the Internet to find information. Most did not know how to search effectively or to evaluate the information they found.

ISTE NETS for Students and the new NETS for Teachers raise expectations of what students and teachers should know and be able to do. Because of these higher standards, we sometimes assume that teacher candidates come with more technology experience than they actually do. However studies continue to show that only about 25% of the teachers in the country feel comfortable enough to use technology in their classes. School districts and teacher education programs are working to improve the percentage of teachers who effectively use technology in the classroom.

Schools of Education are being asked to provide appropriate experiences in less time with fewer credits. This sometimes leads to the elimination of the stand-alone technology class. Many studies have shown that stand alone technology classes are not effective by themselves. Students need to use technology through out their program (ISTE). Others have found that foundation technology courses provide students with the skills they need to be able to use technology in their other classes. Some studies suggest that a combination of a foundations class and technology infusion in all other classes if the most appropriate way to prepare technology proficient teachers. Not all Schools of Education have been able to provide that.
Identifying and Assessing Pre-requisite Technology Skills

Through support from the federal Alaska Partnership for Teacher Enhancement (APTE) grant, our teacher education program is being redesigned to meet the needs of our state. The results of this partnership was a one year, post-graduate, intensive, internship model. One of the changes to the current program was students would no longer take a stand-alone technology course. Educational technology was being integrated throughout the program. However, we could not assume that students would come with extensive experience in technology. Students need alternatives methods of developing pre-requisite skills when there is no foundations technology class.

To ensure that students entering the new certification program would have the basic skills needed to be successful in their classes, an essential technology skills assessment was created as part of our PT3 grant. The technology assessment is based on the new ISTE National Educational Technology Standards (NETS) for Teachers (Level 1 performance indicators).

The Essential Skills Assessment (http://cwolf.uaa.alaska.edu/~afahrn/ ) was designed to show students what they already knew and fill in the gaps where there were missing skills. It assessed only the basic skills that we felt were essential for students to know to be able to use technology successfully in their classes. Many university education program web sites were surveyed to develop a common list of basic skills. We tell students the assessment helps them gain only enough skills to be able to keep their heads above water using technology in their courses.

The Essential Skills Technology Assessment is a performance based assessment that addresses 11 skill areas: 1. Personal History of Tech Use, 2. Internet tools (e-mail, listserv), 3. Search strategies, site evaluation, information literacy, 4. Simple Web Page & Bookmarks, 5. Word processing, 6. Spread sheet, 7. Data base, 8. Graphics (including, scanner, camera), 9. Non-linear hypermedia presentation, 10. Linear Slide Show, and 11. Basic computer operations and troubleshooting. There were three ways for students to demonstrate competence in each area of the Essential Technology Skills Assessment. Option A asked them to provide evidence of prior learning. Option B was an on-line tutorial that helped them gain the skill individually. Option C was an on-campus workshop where they learned the skill. Students were allowed to mix and match options to meet their needs and skills. One option, that was not considered as the during the development of the skills assessment, evolved during the assessment interviews. That option was tutoring by the Tech Assessor during the scheduled assessment interview time.

Students were instructed to visit the Essential Technology Skills Assessment web site where they could work on the skills in any order. They were given general instructions which included the expectations for each of the options.

Instructions for Options to Completing the Essential Technology Skills Assessment.

Option A: Evidence

1. Use a word processor to reflect on your skill. Describe what you know and how you learned it. Tell about the evidence you are submitting to show your competence.
2. Gather evidence that demonstrates you are proficient in the skill as described in the table.
3. Assemble the reflections and evidence on disk. Share the results with a Tech Skills Assessor.

Option B: Tutorial

1. Complete an online skills tutorial.
2. Save your work to disk.
3. Use a word processor to write about what you learned and how you learned it.
4. Bring the files on disk and share your results with a Tech Skills Assessor.

Option C: Workshop

1. Participate in an essential skills workshop on campus.
2. Workshops will be scheduled for each of the skills.
3. Check the class calendar for dates.
Graduate assistants and undergraduate School of Education computer lab aides were used as Tech Assessors. At the beginning of the program, Tech Assessors met and determined the criteria for successful completion of each task. As students completed tasks, they scheduled interviews with a Tech Assessor. If they successfully completed the task, they were checked off. If not, they were told what they still needed to do and asked to come back to be rechecked.

Findings

Twenty four students participated in the Essential Technology Skills Assessment. All students were asked to write a short, one to two page paper to complete Technology Skill 1. They generally chose Option A to complete Technology Skill 2. Internet tools (e-mail, listserv). While students felt they knew Technology Skill 3. Search strategies, site evaluation, information literacy, in reality the Tech Assessors found they needed assistance with this skill. This was one of the skills where the Tech Assessors tutored them during the assessment session. Some students already had their own web page and were able to use Option A for Technology Skill 4. Simple Web Page & Bookmarks. Most students did this learned this with the Tech Assessor. Almost all students chose Option A to demonstrate Technology Skill 5. Word processing. About half of the students chose Option A and the other half Option C for Technology Skill 6. Spread sheet. We decided to teach Technology Skill 7. Data base to the whole group when we introduced them to electronic portfolios. A majority of the students chose Option C for Technology Skill 8. Graphics (including, scanner, camera). Technology Skill 9. Non-linear hypermedia presentation, and Technology Skill 10. Linear Slide Show. We presented Technology Skill 11. Basic computer operations and troubleshooting to the whole group when we distributed the iBooks we were loaning them.

Another part of our PT3 grant provided leased iBooks for each of the students in the new program. This allowed them to take the technology from the university to their PDS site and to their homes. We are evaluating the effect of this access to technology on technology use by faculty and students.

Students completed additional technology activities in the Foundations Class. Those activities were also based on the new ISTE/NCATE NETS for teachers (Level 1). Students were instructed to keep electronic copies of all their work so it would be available for the electronic portfolio they were to compile by the end of the program.

Conclusions

As we were developing the new program, we recommended that basic technology skills be a prerequisite for entrance into the program. The Essential Technology Skills Assessment was designed to help students meet the prerequisite level of basic skills. The intent was for them to complete it prior to beginning the program. The fast timeline for development of the program did not allow that to occur with the first cohort. Students were notified of their acceptance into the program by early June. Almost immediately they started the program with an online experience in mid-June, followed by a 9 credit Foundations of Education class, which integrated technology, in July and August. So rather than coming with the basic skills, they were having to complete the technology assessment and develop the skills as they were taking classes.

While the Essential Technology Skills laid a foundation, completing it in conjunction with the foundations course was too intense to be effective. The students did not become comfortable with the technology before they were asked to use it for class. They did not have time to thoughtfully complete the foundations content assignments. In short, they were overwhelmed.

Faculty realized what was done with the first cohort did not work. Because timelines from acceptance to starting the program will continue to be short, it was difficult to require a technology prerequisite. However, the post baccalaureate certification program continues to evolve. Next summer we plan to split the foundations course into two sections. Technology skills will be taught in conjunction with
history of education in the first section. The second section will contain the other foundations content and will continue to develop technology skills and provide students with technology integration activities.

If the program had a technology prerequisite, an expanded Essential Technology Skills Assessment could be an appropriate method for students to demonstrate minimal technology competency.

Using Multimedia and Technology to Teach Mathematics and Science: Research-Based Professional Development Materials

Abstract

The ultimate goal of this project is to have a new crop of teacher candidates finish their undergraduate teacher education program with a full understanding of the interconnections between mathematical scientific principles. This project supplied preservice teachers with the equipment and knowledge of how to use the latest technology that makes real-life data collecting and computational explorations routine. This was done by incorporating the use of multimedia and technology in the classroom in an effort to actively involve students in an integrated, reformed, technology-based, visual instructional model. Through the use of mathematical modeling and scientific inquiry, the tendency to teach each of the disciplines in isolation will be removed.

Need For the Project

Recognition of the importance of technology in teacher certification is gaining momentum. According to Arthur Wise, president of NCATE (National Council for Accreditation of Teacher Education), “beginning October 1, 1995, accredited schools of education must meet NCATE’s new standards for technology in teacher education to become or remain accredited.” (Wise 1995) NCATE recommends that (1) K-12 staff and university educators must work together to integrate technology into curriculum and classroom practices, (2) teacher educator and K-12 staff must receive training and support, and (3) models must be developed with technology supporting content areas.

The Office of Technology Assessment issued a report entitled Teachers and Technology: Making the Connection (1995) which found the most technology instruction in colleges of education focuses on teaching about technology as a separate subject, not teaching with technology with technology across the curriculum. These institutions do not model use, nor do they teach pre-service teachers how to use information technology for instruction. Most new teachers graduate from teacher preparation institutions with limited knowledge of the ways technology can be used in their professional practice. Telling preservice teachers about what is possible is not enough; they must see their instructors use technology in their own learning, observe uses of technological tools in classrooms, and practice teaching with technologies themselves if they are to use these effectively in their own teaching. Curriculum integration is central if technology is to become a truly effective educational resources.

Preservice teachers need to understand the applicability of multimedia and technology to their teaching of mathematics and science. Using multimedia and technology to teach mathematics and science would change undergraduate teacher education for the preparation of middle school mathematics and science teachers. In addition, the methods courses and the materials would cut across disciplinary boundaries by integrating mathematics and science. By providing a solid foundation for the preservice teachers’ proficiencies with computer/calculator applications in mathematics and science, this project would become a model to support the preparation of mathematics and science preservice teachers in their content area.

Purpose

The project initiated reform in the mathematics and science preservice middle school teacher education on the campus of North Carolina State University. The preservice teachers were prepared for effective instruction in the scientific/information based twenty-first century. The objective of the project are:

1. to develop professional research-based materials for use in undergraduate teacher preparation courses which incorporate laboratory experiments and/or field experiences that actively engage students to use scientific process and explore concepts; these materials will reflect the necessary integration of mathematics, science, and technology into the preservice pedagogical content preparation of undergraduate students.
2. to use cooperative/collaborative learning, peer teaching, learning communities, and technology to improve pedagogical in methods courses.
3. develop a methods course that requires preservice teachers to use visual imagery, manipulatives, multimedia, and technology to enhance the learning and teaching of mathematics and science.
4. to encourage change by providing preservice teachers an opportunity to reflect about the use of technology and multimedia in teaching mathematics and science and the teaching strategies needed to fully integrate the mathematics and science curriculum.

Project

This project involved about 15 mathematics and science dually certified middle school preservice teachers per year. This curriculum reform focused on the use of graphing calculators, calculator-based laboratories, digital cameras, multimedia, and computers to collect and analyze real-time experimental data. The calculator-based laboratories facilitated the development of the students' understanding of instructional strategies that facilitate the integration of mathematics and science into the curriculum. Professional materials for use using technology to teach mathematics and science and integrating mathematics and science into other disciplines through the use of technology are in the process of being developed. Both students and teachers involved in the project created interactive, multimedia laboratory reports for presentation purposes.

In addition, the researcher required all the participants (preservice teachers, cooperating teachers, and students) complete a Teacher Technology Survey to determine their attitudes about the usefulness of the technology for selected activities designed to integrate the mathematics and science. The students were given a pre-assessment before selected activities and a post-assessment after completing the activities. Data was gathered and analyzed (results are not yet available) to determine the effect of the technology on the participants attitudes about the use of the technology on learning the concepts, and to determine the effect of the technology on their conceptual development of various scientific topics.

Preparing Teachers to Succeed in Online Professional Development Courses

Susan L. O'Rourke Ed.D.
Education Division
Carlow College
USA
sorourke@carlow.edu

Abstract Specific learner characteristics are apparent in students who successfully complete online professional development courses. Self-motivation, time management skills, field independence, and proficient technological skills have each been site as beneficial to the online learner. This paper reviews these characteristics and suggests changes that may contribute to preparing teachers to succeed in this learning environment.

Introduction

Colleges, Universities and other institutions currently offer a wide variety of courses online. Advancements in technology will allow for a greater number of these courses to be delivered in the future as more options, such as streaming audio and video, become widely available. Online courses addressing the professional development of teachers are part of this new trend. Many states are increasing requirements for continued certification by expecting their teachers to complete a specific number of professional development hours or credit each year. Teachers may choose to accomplish this in an online learning situation.

Studies indicate that specific learner characteristics are apparent in students that are more successful in this type of learning environment. These characteristics include self-motivation, time management skills, field independence, and proficient technological skills. Many undergraduate students have not mastered and do not possess these skills and subsequently, may fail to learn in this environment. For this reason these skills should be developed in the undergraduate pre-service teacher education program so those students may be successful in professional development courses offered in the online format.

Self-motivation

The development of self-motivated, life long learners is a common goal for most teacher preparation programs. Faculty recognizes the importance of fostering these ideals in future educators. Motivation has been linked to a student’s confidence in their ability to successfully complete a task. This confidence is developed over time through a variety of techniques such as descriptive feedback and frequent communication with faculty when needed.

Studies indicate that student motivation plays an important role in the successful completion of an online course. Confidence is necessary in the ability to grasp the content, and to complete the task. Although students usually graduate with a mastery of the content, they may lack the skills necessary to complete an online class.

Time management

Excellent teachers must manage the students’ class time efficiently and effectively. A well-prepared teacher competently plans the schedule and follows through on time lines with ease. Faculty foster these skills by providing guidance or structure for the completion of projects early in a students career and then systematically fading those structures to allow students to develop their own strategies.

Time management strategies are essential for success in an online classroom environment. Students report extreme difficulty in managing the time needed to complete an online class. Due to the flexibility, they often must be responsible for setting their own time schedules. Teachers should be well suited to planning their time.
Field dependence

Students who are field dependent will require a greater amount of structure throughout their educational career to complete specific tasks. Given this structure, they can successfully complete assignments. Careful planning of rubrics that outline expectations and specific learning outcomes are beneficial. Cooperative learning groups that include field independent students also assist the field dependent student. Students who are field independent can often provide the structure necessary for the field dependent learner. Strategies allowing students to develop a structure when none is apparent will provide the guidance necessary for these students to succeed.

Technological skills

Finally, technology skills must be developed and mastered to succeed in an online classroom environment. Technological proficiency is not obtained through an event such as a training session or even a computer course. It is a process. Mastery of the needed skills must be developed over years. Students need to learn about an application, have opportunities to practice the appropriate use of such a program, and then continue to develop their skills. This process must begin early in the student’s educational career. Currently, students enter into programs with diverse abilities in the area of technology. All students must be skilled in the basic computing skills. These include word processing, spreadsheet, presentation technologies, communication tools such as the use of E-mail, and electronic research techniques. One method to address this is to require a computing course in the first year or an introductory set of sessions for academic computing.

In addition, faculty in all disciplines throughout the institution should be encouraged to integrate technology into their own teaching, as appropriate, and particularly in assignments for students. For example:

- College writing courses may consider including writing E-mail and bulletin board exchanges as a separate method and style of communication.
- Public speaking courses may require the use of presentation software in one speech.
- Internet resources may be included in the compilation of research references.
- Web based bulletin boards may be utilized to share views and exchange ideas.
- Faculty may require some assignments to be submitted electronically.
- Course syllabi as well as other learning materials may be available through the class web site.
- Some communication to students may be provided through E-mail.
- All students should be expected to complete written assignments in a word processing program.

Summary

When students are required to utilize the technology throughout their educational experience, over time, they will master the technological skills needed to enable them to become competent self-directed learners in an online classroom environment.

The development of self-motivation, time management strategies, and technological proficiency will benefit all students whether or not they intend to complete professional development courses offered in an online format. The systematic development of these learner characteristics will ultimately promote student success and should be incorporated into programs initially and throughout the educational experience.
Empowering teachers through cognitive literacy skills development: Implications for restructuring teacher education programs through technology infusion

Joyce Pittman, Ph.D.
Teachers College of Education
University of Cincinnati
Cincinnati, OH
USA
joyce.pittman@uc.edu

Abstract
Technology has opened Pandora's Box in many respects. Perhaps one of the greatest challenges is building college students' advanced literacy and technical skills, especially preservice teachers. This aspect of technology in education is raising unprecedented levels of new concerns for educators. It has presented educators and policymakers with problematic decision-making about how to attract, sustain, and prepare students for careers and living in an increasingly technological education society (Prager, 1993). The Comprehensive Educational Restructuring and Technology Infusion Initiative Pt3 Project is addressing the problem (CERTI² 2000). Educators need direction for retooling to restructure instructional approaches to help entering students construct new knowledge and skills. A electronic portfolio and performance-based assessment may be the key to identifying new teacher competencies and instructional practices. A recap of how 11 partners joined hands at the University of Cincinnati to connect K-16 teacher education restructuring and technology infusion.

Keywords: advanced literacy, teacher preparation, technology and pedagogy

Overview
Today's students are faced with a great challenge as the first generation expected to have knowledge and skills to meet industry's demand for more high skilled and qualified workers (SCANS, 1991). In 1997 a report, Mathematics Equals Opportunity provides information about problems that college students face that do not take rigorous science and mathematics courses. Additionally, given the emphasis on advanced literacy skills in these courses and in technology pedagogy environments (teaching with technology), students without them may have serious gaps in advanced literacy and critical processing skills, especially preservice teachers (Riley, 1997). These students risk having doors to colleges and new career opportunities closed because they lack required advanced literacy and technical skills now in demand by our technological society. Advanced literacy skills are those that require students to demonstrate a high capacity to think, reason, solve complex problems, and communicate their ideas to others while continuing to learn basic skills. Ongoing support is especially important in environments where pedagogy and technology are being interconnected. National studies report that liberal arts, minority, and low-income students continue to be less likely to have challenging academic courses in their secondary education experience are most likely to need additional support to develop these skills (NAEP, 1996).

Defining Cognitive Literacy
Research on guidelines for preparing students to function in a 21st Century workforce indicates that literacy is being redefined by technology integration in education and this presents new instructional challenges to teacher educators (International Reading Association, 1997; National Council of Teachers of Mathematics, 1989). Because I believe the proposed new definition of literacy is rooted in cognitive science I will use the term cognitive literacy. Cognitive literacy defines the process of demonstrating a high capacity to think, reason, solve complex problems, and communicate ideas while continuing to learn new basic skills.

The Problem
The International Society for Technology in Education (ISTE) and the National Educational Technology Standards project (NETS) is leading the nation in making teachers and teacher educators more aware of the need for reskilling in basic computer and technical skills (ISTE & NETS, 2000). During the past few years reports from a number of experts on entering skills and competencies of entering college support findings that some college students may lack advanced literacy skills necessary to master more challenging subject matter have emerged (Levy & Murnane, 1996). Research shows the highest concentration of students lacking rigorous academic skills may be education majors or those planning to
enter the teaching profession (ETS Score Reports, 1990-1998). Too often it appears the problem may be deeply rooted in the definition of what it once meant to be literate than it does in students' ability to perform and learn challenging subject matter (National Assessment of Educational Progress Scales/NAEP, 1969-1998). As new technologies continue to transform education, the research suggests our understanding of literacy is being reconstructed by cognitive learning theory (CLT). Sticht and Armstrong (1994) in Adult Literacy in the United States: A Compendium of Quantitative Data and Interpretive Comments discuss concise and comprehensive research about literacy and assessment, which led me to reason cognitive literacy may be premised in cognitive science. These findings are reflected in my discussion about methods to instruct, assess, prepare, and improve students' cognitive literacy skills through new instructional strategies and ways of thinking from a more pragmatic view. A primary assumption in this paper is that learning takes the form of both knowledge- and skilled based domains in technology-pedagogy (teaching with technology) and that:

1. Human cognitive systems emphasize the role of knowledge in literacy along with the information processes involved in oral and written language use and reasoning with graphic tools of thought (flow charts, tables, etc.) and
2. Information processing views of learning emphasize the active, constructive nature of cognitive development (including literacy) in social contexts.

The connections between these two approaches may provide new information for policy makers and educators to develop guidelines about the extent of students' needs and how to best meet these needs with programs and new instructional approaches (Herman, Aschbacher & Winters, 1992).

Background

Our research at the University of Cincinnati revealed that the first years in college for new students can be the most critical years of their educational experience. The first years will no doubt be a primary determinant in whether they will remain or join the open-door generation [those who leave without their desired credentials] (U.S. Department of Education Longitudinal Study, Bachelors and Beyond, 1993-94). When we consider the shortages projected for teachers in the next century, the potential lack of early success is especially concerning. It becomes more concerning when we reflect on the number of potential teachers lost during the beginning years--the time when students are considering the teaching profession or some other direction.

There is a need to examine the definition of cognitive literacy through technology-pedagogy perspectives and the most effective approach (es) for infusing new instructional strategies into general and specialized academia. These skills are being called the “new basics” (Weitzel, 1999). More importantly to determine which comes first--the knowledge or the skills in connecting technology-pedagogy? or are the two increasingly dependent on the other in new learning environments? The review discusses five issues centered on educators helping college students develop cognitive literacy:

1. Cognitive Literacy in Education
2. Revisiting Literacy Through Cognitive Literacy Perspectives
3. Implications for Restructuring Pedagogy by Focusing on Cognitive Literacy
4. Software for Building Cognitive Literacy Skills

Professional Program in Education
University of Wisconsin-Green Bay
United States

Abstract: The collaborative exploration, development and implementation of the use of web technology in the UW-Green Bay Professional Program in Education for early childhood students is discussed. This paper begins with a discussion of the origins of this innovative response to the process of teacher preparation, beginning with the award of a 3-year FIPSE Grant to support the vision and ending with the incorporation of distance learning to deliver course content and class contact hours. An overview of the technological issues, problems and glitches is shared, from institutional resistance to software incompatibility to instructional design, as well as the solutions that were used to address them. A summary of what is working, what is not, and why is presented and recommendations for what needs to be done next are made.

Introduction

The University of Wisconsin-Green Bay is committed to providing students in the Education Program with relevant, best-practice environments in which to demonstrate a variety of competencies needed for certification. To achieve this goal, the Education Program is moving toward a teacher preparation model built on collaborative relationships with local school districts, to share and combine the experiences of pre-service students and seasoned practitioners, and to provide earlier, more extensive, and more relevant field experiences for students in preparation. One of the first initiatives to emerge was an innovative response to the national call to reform teacher preparation. The UW-Green Bay Professional Program in Education, in collaboration with public schools and private childcare and family resource programs, was awarded a 3-year FIPSE Grant for the development of an on-site Early Childhood Teacher Preparation Program that matches program competencies with PK-12 school and community needs in a technologically-relevant, community-based model. Pre-service teachers now engage in performance-based learning in community-based early childhood settings where they receive hands-on training in problem-solving, collaborative teaching, and competency-based performance and assessment strategies, learn to develop family-school-community partnerships to increase family involvement, and help provide greater continuity between the early childhood and elementary school years. The 22-credit program sequence was converted into competency-based outcomes and transformed into on-line “core” offerings. Students now access core content on-line while spending 4 to 6 hours a week in a series of clinical rotations that include infant/toddler sites, nonprofit childcare centers, inclusive childcare programs, public and private preschools, Head Start classrooms, and full-day kindergartens. Competency acquisition is supported by a field-based faculty mentor who models best practice and provides students with ongoing feedback and support. Seminars at the university give pre-service teachers an opportunity to critically reflect on their experiences and problem-solve issues of concern, and a variety of ongoing performance-based assessment tools and techniques are used to measure student learning outcomes as they are reflected in increased knowledge, relevant and appropriate application in real-life settings, and positive changes in learning in the young children they work with.

Technological Implementation
The provision of more intensive and extensive field experiences required the adoption of a web-based format for the delivery of course content. Several software packages written to take advantage of the hypermedia profile common to the World Wide Web were available. Among them, several were designed for general education purposes. From those options, one specific package, WebCT, was selected to translate course material to web-ready form. This initial move to introduce technology into teacher preparation served as a major catalyst for change, beginning a sequence of events that led the institution to create an environment supportive of technology. The University was running its computer operations under the Windows NT version 4 environment and at that time, would not support the Web-based software, WebCT. Working collaboratively with the computer science department, a powerful version of a Linux Operating system was installed on a medium duty desktop computer purchased with grant funds. As expected from typical Universities and IT departments, the non-windows operating system, Linux, was under tight scrutiny with regards to security, reliability, and performance, but the project was allowed to go forward. This computer operated solely as the server for WebCT. Later this server would be networked and accessed by all students registered in the first web-enhanced early childhood course. Two additional education-based courses would use WebCT, but only as a supplement to the traditional delivery of course content. Table 1 illustrates how WebCT was used in these courses.

Along with the university’s inability to support Web-based software, came issues dealing with the generation and management of simple web page development and the conversion of course documents to web page format. A standards-based curriculum, with clearly defined competencies was designed to ensure pre-service teacher proficiency in all applicable standards and content knowledge, but the instructional design of a web-based course differs substantially from that of a traditional course and campus-based expertise in instructional design did not exist. It became necessary for project faculty to join forces with an alternative degree program on campus with grant funding to begin distance learning for nontraditional learners. Resources were pooled to bring in an outside consultant to provide training in instructional design.

If hardware and software issues were not enough, the human side of technology made the transition of course delivery from traditional to electronic an almost insurmountable task. Educators at all levels, from university faculty to classroom teachers, were feeling national, state and local level pressure to implement newly designed rigorous standards in technology into district curriculums and classroom activities. Effective integration and implementation of technology within a classroom curriculum, however, demands that educators know and understand how to operate the technology effectively, efficiently, and productively. Knowing that proficiency in the use of WebCT should precede the facilitation of student learning using WebCT, and that there was no time to develop proficiency in the use of WebCT and meet grant timelines, it was decided to move ahead. The faculty motto became, "Risk takers initiate change, and we will learn from our failures as well as our successes."
All of these implementation issues—institutional resistance, lack of resources and support, and insufficient training in the use of the software—contributed to the later difficulties that were encountered during the setup, course conversion, maintenance, and delivery of web-based coursework.

Technological Conversion

The journey from traditional to Web-based learning was a rocky one, as faculty and students immersed themselves in the unfamiliar territory of on-line learning. Right from the start there were obstacles and challenges (sometimes referred to as bugs, glitches, software irregularities, lack of technology literacy, etc.) that required adaptation, improvisation, and problem solving to overcome. They too became part of the learning process for faculty and students alike.

An instructional technology specialist and member of the Education faculty was identified to take the lead with respect to technology issues and training. This faculty member had a solid foundation and background in technology literacy, taught a major instructional technology course that all education students were required to take, and had the expertise for software and hardware training. In addition to the teaching and learning components of web-based delivery were other critical areas in which he was highly competent: (a) troubleshooting, (b) testing that deals with the electronic transition of courses, and (c) maintaining and managing the computer server running WebCT.

The first major task of our WebCT Administrator was to develop a strategy to convert and deliver courses from a traditional to a web-based design. The first step was to do research into WebCT. This involved asking questions of people who had experience working with the program, gathering information about web-based learning from numerous resources on the Internet, and visiting the WebCT homepage. Feedback from experienced users was overwhelmingly positive and, as we later discovered, negativity usually stemmed from misunderstanding, lack of experience, or lack of vision. Surprisingly, WebCT could be downloaded from the website at no cost and installed on the computer server, where all of the WebCT elements could be explored by participating staff. Some of these elements included: (a) WebCT access from anywhere in the world using the internet browsers such as Netscape Navigator and Internet Explorer, (b) uploading of files of many types from remote computers, and (c) WebCT course maintenance from remote computers. Additionally, users had the ability to browse, download, and print assignments and other course material, submit electronic mail within WebCT to other members and instructor(s) of the course, and browse a calendar of events that they can edit for their own use. Students were also able to browse digital images, listen to audio clips, and even view video clips. WebCT more than satisfied the on-line learning strategies and outcomes needed to effectively teach course content online.

The next step was to thoroughly explore the operation and procedures within WebCT and form some type of logical process for the production of the on-line courses. After testing and analyzing the program, a list of tasks was generated that needed to be accomplished before and after an enhanced course was set into live status. Before the course goes live, electronic text files that were formatted for HTML (Hypertext Markup Language) file type needed to be created. These files included course syllabi, assignments, articles to read, lectures, and audio clips. Once formatted for Html, the files could then be loaded onto WebCT.

Throughout the process of preparing the courses for web-based delivery, obstacles were identified in three major areas: converting electronic course components from non-html form to html, converting hard copy course components to electronic html documents, and local and network file management. The pros and cons of these three areas are discussed below.

Converting Non-HTML Electronic Course Content to HTML (Hypertext Markup Language)

The course content for all three courses consisted of computer generated media such as documents created in word processing, spreadsheet, and presentation formats, as well as hard copy media such as copies of articles, worksheets, and “passed down” curricular material. The hard copy media required a much more difficult process of digital conversion and will be explained following this section.

Word Processing Documents: Most of the major “brand name” word processors could convert documents into html form but did so at a cost. At a minimum, they added “garbage or extra baggage consisting of html code and JavaScript to the main document code to increase document efficiency and cross platform and cross browser uniformity. In the case for the three courses, this “baggage was not necessary and tended to add potentially serious formatting problems within high-end web-based programs such as WebCT. If the word processing software had worked as intended, then the traditional course documents along with special formatting such as attributes like bold, text color, etc., along with
tables and graphics, would have transferred efficiently and in a seamless manner. This "easy" method was not the case for this project and would involve a little more work and some recreation of certain aspects within documents. Before the document conversion could occur, a suitable software application, which would not require a large learning curve, needed to be identified and taught to each WebCT instructor. Two designated software packages, Microsoft FrontPage and Netscape Composer were found to satisfy the requirements of only writing the necessary background html code that would be compatible with the two major browsers and system platforms. The first step was to save the original document as "text only" which would strip the document down to plain text with no attributes including no tables, tabs, or columns. The next step was copy the text into a blank html document. Once the text was within an html environment, the process of converting the document continued until all attributes were assigned including font type, size, color, indentation, etc. Tables and graphics were lost in the text translation and needed to be recreated and/or imported back into the html document. The number of columns, graphics, and tables corresponded directly with the amount of time and effort needed to convert a document.

**Spreadsheets:** Any documents created in a spreadsheet environment had to be recreated using tables within an html environment. Text and graphics needed to be added in the same manner as the document conversion for word processing.

**Presentation software:** The conversion to html for presentation software was the easiest and quickest to accomplish due to the unique and extremely powerful built-in html conversion feature. This feature simply created a graphic image of each entire page and created an multi-page html document complete with hyperlinks, JavaScript, and navigation buttons.

### Converting Hard Copy Course Components to Electronic HTML Documents

This process dealt with scanning hard copy documents and then utilizing an OCR (optical character recognition) process to covert the document to contain editable text. This process can prove to be a very time consuming process and required some considerable problem solving techniques to overcome. The main reason that we had to scan documents was because we did not have the original document in electronic form. Some of the trouble spots dealt with the original document to scan. If the document was in good condition, contained only 1-3 continuous columns, and no graphics, then the scanning and OCR process was efficient and effective. Unfortunately, most of the documents contained multiple, non-continuous columns with tables, graphs, and other graphic images. These presented major problems in the scanning and OCR process and created a very labor-intensive project. One solution was to scan an entire page as an image and then create links to the image or create image documents. While this proved to a viable and efficient option when the WebCT course was accessed on campus, it proved to be a frustratingly slow process from the students typical home computer where download speeds are extremely slow in comparison. It was decided not to use this option and were forced to succumb to the labor-intensive alternative of scanning and converting text, column by column, scanning graphics one at a time, and then literally cutting and pasting and recreating new documents that resembled the originals. It was realized that once a document was finished, it could be used again for future courses, but the overall choice was to keep non-electronic original documents to a minimum.

### File Management

File management deals with two areas, local on the users own workstation, and over a network either a LAN (local area network) or WAN (wide area network). Additionally, this topic was one of the most important elements for the conversion of course materials and working within the WebCT environment. In fact, file management turns out to be the single most important reason, both positively and negatively, why people and educators carry such a high level of anxiety about using technology. The project quickly made good file management practices relevant and necessary because of the potential loss of data, accidental overwritten files and "updated" versions of documents being mistaken for other documents. Strategies were quickly put into place to ensure that all converted documents and traditional course documents were kept separate. Additionally, the WebCT program required course instructors to upload all course material into a built in "file manager" where they would be linked to specific course areas within the WebCT course modules. The easiest and most efficient way to organize files and folders was to create and maintain duplicate file and folder structures on local workstations and within the WebCT "file manager" environment. Besides local (user workstation) file management, network file management became extremely important because not all software and
hardware was located locally, meaning that users were required to import and export files from non-local workstations to workstations used to upload files into the WebCT environment.

Technological Delivery

The WebCT project proved to be a success as educators took the challenge of converting traditional course content and documents into html documents that would serve in a web-based environment. Within the teaching realm, instructors and students faced numerous challenges throughout the first semester dealing with low student proficiency in technology, software incompatibility, problems with access to the internet, limited student contact time, perceptions of interaction or lack of it, lack of backup plans when the server went down, and frustration in learning a new mode of content delivery. Most of these challenges were minimized or eliminated after the first semester with university conversion to the NT system, university-wide support for WebCT, and increased faculty experience in managing a web-based course. Despite recurring obstacles, the long-term positive outcomes far outweighed these initial issues, and the project served as a major catalyst for change in the students level of technological proficiency, in the use of technology in the Education Unit and other units across campus, and in the level of support provided at the university level.

Results

Program effectiveness was assessed through survey data collected on: (a) the use of technology to deliver content; (b) student comfort level and perceptions of success; and (c) student and instructor evaluations. Student evaluations were completed after each “core” offering, and final program evaluations were sent to pre-service students near the end of their student teaching experience. Faculty evaluations were completed by all instructors at the end of the 3 year project.

The positive features identified by the faculty and students were substantial. Faculty believed that web-based course delivery has the potential for high-level interaction, with instructors having the opportunity to track the cognitive processing and conceptual development of all of their students and correct faulty inferences before they escalate. Student complaints of insufficient availability were accurate but stemmed from unaddressed issues of workload. A 3-credit online course requires substantially more time if it is to be sufficiently interactive than does a course delivered in the traditional manner.

Flexibility in delivery and access was viewed positively by faculty and students alike, but there were differing perspectives on the issue of self-responsibility for one’s learning. Students needed to complete weekly assignments within a designated timeline in order to participate in weekly chat or discussion groups. This requirement was a mismatch for the traditional “cramming before the test” model that many college students opt for. Faculty viewed this as an opportunity for students to develop or strengthen personal responsibility skills, but many students found it difficult to adapt. Faculty also noted that there were opportunities for frequent feedback and review via email, the bulletin board, chats, and quizzes. In addition, the model was seen to support the provision of more relevant performance-based settings with mentoring support.

In the area of technology use, information was gathered on the variety of technological components and strategies used within WebCT, flexibility in the use of the medium to adapt the delivery model to diverse student populations, and pre and post-survey data on technology knowledge, skills and attitudes. Pre and post-survey data on technology knowledge, skills and attitudes over the 3 years of the grant, reported significant gains for students across all areas, and by the third year, 67% of Education students reported having taken a web-based or web-enhanced course by the second semester of their professional studies. Student comfort levels with technology, as well as their perceptions of success, as measured by course evaluations, also increased significantly for all course offerings across the 3 years of the grant. All instructors reported trying all the components available within WebCT, and, except for issues of workload, found them all to support the learning process. No data was reported on adaptations because of the absence of student requests.

Most of the issues, obstacles, and concerns were addressed earlier in the article. Additional concerns expressed in faculty and student feedback included: (a) institutional, faculty and student resistance, (b) TIME, TIME, TIME (instructional design, student contact, backup plans, communication among partners), (c) a lack of models to assess pedagogy, (d) the difficulties involved in scheduling and communicating with students in the field, (e) the critical need for the mentor component and the lack of institutional support for the workload issues, (f) the provision of more training for faculty in how to facilitate and support interaction in a web-based course, and (g) the need for a multimedia lab in the education unit for training.
Conclusions

On the strength of our data, the following recommendations are made and have important implications for the future success of online learning and teacher preparation.

- Institutional resistance must be addressed and new faculty roles defined.
- Issues of workload must be reexamined within the existing “course-for-credit” structure of higher education.
- Universities must provide strong, ongoing training and support for online teaching.
- If student learning is to become performance-based in intensive field settings, a mentoring component must be established along with online course delivery. It is a critical component.
- A variety of “models” for providing mentoring support need to be explored, beginning with a redefinition of “teaching” across all educational systems.

Across the nation, the major force driving change in educational systems is technology. Distance learning is here to stay. In the area of early childhood, there is a national effort to increase both the quantity and quality of early childhood providers. Professional development continuums and articulation initiatives are being established at the state level to move this population into higher education. Early childhood staff and directors affiliated with the new apprenticeship programs, working in Head Start programs, or accessing scholarship funding with work requirements, will find online teacher education courses an attractive and accessible option for pursuit of a degree. In other areas of education, federal Title II guidelines for teacher preparation require more extensive and intensive field experiences, again making a web-based or web-enhanced model a desirable alternative for delivering course content. Institutions must create campus environments that attract and support technologically driven change in teacher preparation.

First Things First: Addressing Teacher Concerns Toward Technology

Glenda C. Rakes

edgrakes@ulm.edu
edcasey@ulm.edu

Abstract: Many teachers, especially more experienced teachers, have been unable to find effective ways to use technology in their classrooms. One possible explanation for this lack of success is that the use of technology in the classroom has been viewed in terms of simple skill acquisition instead of as a change process that affects the behavior of individuals on a very profound level. This study analyzed the concerns of PK-12 teachers (n=659) toward the use of instructional technology using the Stages of Concern Questionnaire. Results indicate that the highest two stages of concern for the respondents reflect intense, personal, lower level concerns along with a desire to learn from what other teachers know and are doing. The lowest stage of concern for the aggregate data indicates that the respondents have minimal to no concerns about the relationship of students to the use of technology.

Introduction

The ultimate goal of instructional technology integration into PK-12 education is improved student achievement, but teachers must view technology in a positive manner, be comfortable with the technology, and use it effectively before improved student achievement can occur. Teacher technology training frequently produces less than desirable effects for a number of reasons including lack of time, funds, and direct connection of the technology training to the curriculum. As a result, the effect of technology on classroom instruction frequently fails to live up to its potential.

Even teachers who hold positive attitudes toward technology may have difficulty transferring these attitudes into actions. Millions of dollars have placed technology in PK-12 classrooms, but there has been considerably less attention paid to helping teachers make the transition into a technology-rich learning environment which would, in turn, impact student learning (National Center for Education Statistics, 1999). As greater numbers of technology installations occur in schools, the demands on classroom teachers to integrate technology into instruction increase. Many teachers, especially more experienced teachers, have been unable to find effective ways to use technology in their classrooms (Smerdon, Cronen, Lanahan, Anderson, Iannotti, Angeles, & Greene, 2000). One possible explanation for this lack of success is that the use of technology in the classroom has been viewed in terms of simple skill acquisition instead of as a change process that affects the behavior of individuals on a very profound level.

Fuller (1969) and Hall (1978) conducted studies on teacher concerns toward innovation which resulted in the development of theories regarding change. Frances Fuller theorized that preservice teachers were preoccupied with concerns about self, task, and impact. Hall, Wallace, and Dossel (1973) discovered those three sequences of concern were present when inservice teachers faced implementation of innovations. Hall’s hypothesis specifies seven stages of concern through which individuals progress when something new is introduced into their environment. The stages of concern (from lowest to highest levels) include Awareness (0), Informational (1), Personal (2), Management (3), Consequence (4), Collaboration (5), and Refocusing (6).

Ultimately, the Concerns Based Adoption Model (CBAM) was developed and has become a change model widely used by those individuals planning for staff development accompanying any educational innovation. Hall and Hord (1987) stressed the relevance of information regarding individuals impacted by the
change. Personal comfort with instructional technology is essential to an individual’s concern with its implementation and impact (Martin, 1989). According to Hall (1976), an individual’s concerns directly affect performance; and since concern levels correspond with levels of performance, lower level concerns must be removed before higher level concerns can emerge.

The Study

The following research question was investigated: What are technology using teachers’ concerns about instructional technology as measured by the Stages of Concern Questionnaire? The question was answered using the theoretical basis of the Concerns Based Adoption Model (CBAM) (Hall, Wallace & Dorsett, 1973). CBAM is a research-based framework that explains the process individuals follow as they undergo the process of change. The Stages of Concern Questionnaire is designed to capture teachers’ current concerns about adopting such an innovation, in this case instructional technology.

Respondents (n=659) were PK-12 teachers, including at least two respondents from each of the 50 states, who currently use instructional technology in some form related to their teaching. All transactions were electronic. The survey was provided to respondents on the Internet; email was used to transmit the responses. The sample was purposively selected from PK-12 teachers who subscribe to four email lists. Demographic information is seen in Table 1 below.

The Stages of Concern Questionnaire (SoCQ) uses a Likert scale response format to measure seven hypothesized stages of concerns individuals have toward implementing change. The questionnaire contains 35 statements (five statements for each stage) that allow respondents to describe a concern they currently feel on a scale of 0 to 7. A response of 0 indicates a very low concern; a response of 7 indicates a very high concern.

The Stages of Concern Questionnaire was originally validated in 1979 (Hall, George, & Rutherford) and has been validated numerous times since its creation as it has been used in many studies over the past 20 years. Cronbach's alpha was used to establish the instrument's internal validity, with a sample (n=830) of teachers involved in team teaching and professors concerned about innovation. A sub sample (n=132) participated in a test-retest of the instrument over a 2 week period. Alpha coefficients ranged from .64 to .83, and the test-retest correlation ranged from .65 to .84, indicating the internal consistency and stability for each of the seven stages (Hall et al., 1979).

The Stages of Concern Questionnaire was converted to hypertext markup language and placed on the Internet. Email messages were sent to mailing list and listserv managers, asking them to share the URL for the
online instrument with their participants.

Findings

One way of looking at group concerns is to aggregate individual data by developing a profile that provides the average scores for each stage of the individuals in a group. Participant responses on the SoCQ were initially analyzed using SPSSX (Statistical Package for the Social Sciences). Mean scores were plotted following the procedures outlined by Hall, George, and Rutherford (1998) using the SoCQ Quick Scoring Device. Typically, the group averages reflect the dominant high and low Stages of Concern of the entire group. The highest two stages of concern were analyzed along with the lowest stage of concern.

The raw score for each of the seven scales is the sum of the responses to the five statements on that scale. The mean scores for each item were computed for each item. The mean scores were converted to percentile scores in order to interpret the results. The percentiles are represented graphically in Figure 1.

![SoCQ Graph](image)

**Figure 1:** Graph of the percentiles for each stage of concern.

Interpretation of the scores is based on guidelines contained in *Measuring stages of concern about the innovation: A manual for use of the SoC Questionnaire* (Hall, George, & Rutherford, 1998). The highest stage of concern for the aggregate data was Stage 2. A high Stage 2 indicates an intense personal concern about instructional technology and its consequences for the respondents on a personal level. Though these concerns reflect uneasiness regarding technology, they do not necessarily indicate resistance to technology. Personal concerns deal with what Fuller (1969) calls self concerns. A high Stage 2 score indicates ego-oriented questions and uncertainties about technology. Individuals at this stage reflect high concerns about the status, reward, and potential or real effects of technology. Individuals with intense personal concerns may, in effect, operationally block out more substantive concerns.

The second highest concern was Stage 5. This stage reflects strong concerns about working with colleagues in coordinating the use of technology. The high Stage 5 typically indicates great concern about coordination with others in relation to the innovation. Since Stage 1 is also moderately high, it may be that these respondents have concerns about looking for ideas from others, reflecting more of a desire to learn from what other teachers know and are doing. The low stage of concern for the aggregate data was Stage 4. A low Stage 4 indicates that the respondents have minimal to no concerns about the relationship of students to the use of the innovation.
Conclusions

These results indicate that the intense, personal concerns of teachers may have been sacrificed as emphasis has been placed on student achievement. If it is desirable for teachers to be concerned with the application and use of technology with and for students, teachers' personal concerns must be addressed first. Concerns about innovations appear to be developmental in that earlier concerns must first be resolved (lowered in intensity) before later concerns emerge (increase in intensity). If these early concerns toward technology remain intense, teachers may even attempt to discontinue its use, in order to reduce the intensity of these concerns.

Administrators and trainers hoping to positively impact student learning through use of instructional technology first need to provide a clear demonstration of how the use of instructional technology tools can address the personal concerns of teachers. Use of a concerns-based training model rather than a skills-based training model is one method for addressing attitudes and feelings that may be inhibiting teacher use of technology. This finding supports those of Fuller (2000) who found that teacher technology support is more critical to student use than direct student support in a school. She also found that teachers who receive adequate, personal support for the use of technology tend to have students who use technology more and use it more effectively.

It is critical to note that another person cannot simply manipulate higher level concerns development. Holding and changing concerns is an individual matter. However, timely provision of experiences and resources can assist with concerns arousal and resolution, encouraging the development of higher level concerns. Providing training or other interventions that are not aimed at the appropriate concerns (e.g., attempting to force high level concerns) is an almost certain way to increase the intensity of lower, less desirable stage concerns. Training must target the individual concerns of teachers before moving on to concerns of how others, even their own students, will use the available technology.

Results also indicate a strong curiosity for increased information as to how other teachers are using technology. Although the demographic data indicates that computers are readily available to the majority of the respondents and that a substantial number of hours have been spent in technology training efforts, about two-thirds (68%) of the respondents indicated they are given no time during the school day to practice what has been taught. McKenzie (2000) says that making solid change with regard to the use of instructional technology necessitates time away from the "daily press" of teaching. Providing additional professional development opportunities for technology training should enable sharing and interaction among peers, not just with a trainer.

Despite millions of dollars invested in hardware and software, many teachers are still very uncomfortable with the use of instructional technology in their classrooms. Administrators under pressure to improve student performance are frequently reluctant to address teacher concerns, thus thwarting efforts to accomplish their goals.

From the perspective of concerns based theory, institutionalization of an innovation only occurs when a majority of the individuals within the target group have resolved (lowered) their concerns on Stages 1, 2, and 3. In order for any innovation to become a vital, lasting part of that institution, high intensity Informational, Personal, and Management concerns must be resolved. (Hall, George, & Rutherford, 1978). The results of this study indicate that this institutionalization has not occurred. "If these early concerns remain intense, then the user is apt to modify the innovation or their use of the innovation, or perhaps discontinue use, in order to reduce the intensity of these concerns" (p. 13). Administrators and trainers seeking to make technology an integral part of teaching and learning first need to provide a clear demonstration of how the use of instructional technology tools can address the personal concerns of teachers.

Technological Tools and Mathematical Guided-Discovery

Olga M. Ramirez, Ph.D. and John E. Bernard, Ph.D.
Department of Mathematics
The University of Texas-Pan American
Edinburg, Texas (USA)
oram@panam.edu and bernardiet@panam.edu

Abstract: Using technological tools to guide mathematical discovery is a relatively new adventure. Graphing calculators, dynamic geometry software, and spreadsheets are powerful and adaptable technological tools to create engaging guided-discovery activities for diverse backgrounds of middle and secondary students whether the to-be-discovered objects are concepts, generalizations, algorithms, heuristic problem-solving strategies, or something else. This paper shows how to use these technological tools to manage mathematical guided discovery so that the intended learning takes place with relative certainty within an appropriate amount of instructional time. A final premise is that the process of discovery is at least as important as what is to be discovered, since learning by discovery promotes understanding, learning to discover, problem solving, independent thinking, and life-long learning.

Teaching by discovery is probably as old as formal education itself given that its origins can be traced as far back as 430-320 B.C. to Plato and Socrates. Nonetheless, discovery learning, guided or otherwise, using technological tools such as graphing calculators, spreadsheets, or dynamic computer software is a relatively new teaching adventure! Depending upon the age and mathematical background of the students engaged in selected guided-discovery activities, the objects to be discovered can vary - e.g., concepts, generalizations\(^1\), algorithms, heuristic problem-solving strategies\(^2\), or whatever. TI-83 graphing calculators (Texas Instruments, 1996), CABRI Geometry II software (Laborder, and Franck. (1994-1997), and Microsoft Excel spreadsheets, for example, are technological tools that can be used to create high fidelity mathematical settings in which students are able to discover enhanced significance for mathematical concepts such as - independent variable, dependent variable, function, regression line, expected value, residual, and symmetry of power functions.

The use of such tools is highly recommended since they facilitate discovery, managing it with relative certainty in estimable amounts of instructional time. This paper illustrates how to engage students in mathematical guided discovery activities with the use the tools and demonstrates the stages of discovery in technological setting which like those in other settings, and note that sensitivity to the learners' reactions, familiarity especially, is critical to producing positive results. This paper advocates appropriate infusions of emerging technology into mathematics instruction and offers its approach as an example of how it might be done\(^3\).

The events of guided discovery seem to fall into five sequential stages, not necessarily mutually exclusive, which we call: The Relax and Get Ready Stage; The Exploring Instances Stage; The Exchange Emerging Views Stage; The Information Gathering Stage; and The Review and Summary Stage\(^4\). These stages provide a guide for dialogue between teacher and learners that elicits genuine discoveries of mathematical concepts or generalizations as illustrated in the activities that follow. The first activity (refer to Activity 1) is entitled Why Worry About Spilled Ink? Measure It!. This activity

---

\(^2\) George Polya states, "Thus, a teacher of mathematics has a great opportunity. If he fills his allotted time with drilling his students in routine operations he kills their interest, hampers their intellectual development, and misuses his opportunity. But if he challenges the curiosity of his students by setting them problems proportionate to their knowledge, and helps them to solve their problems with stimulating questions, he may give them a taste for, and some means of, independent thinking." See page v in: Polya, George. How to Solve It. Princeton, New Jersey: Princeton University Press, 1945, 1957 (2nd Ed.), & 1973. ISBN: 0-691-02356-5

\(^3\) The National Council of Teachers of Mathematics has stated, "A study of algebra is bound to change dramatically with the infusion of currently available and emerging technology" (1996); this, indeed, is occurring more generally.

educates relatively young learners\(^5\) to face new situations with a spirit of inquiry that promotes exploration, collection of data, analyses of the data, and the use of technology to investigate relationships among objects. The second activity (refer to Activity 2), entitled Symmetry of Power Functions shows how technological tools might facilitate and simplify discovery. Both activities advance the idea that technological tools in guided discovery activities promote learning to discover.

In both activities, the initial stage calls for the teacher and students to engage in conversation and activity related to the ultimate intended discovery, but not necessarily work required for the discovery to occur. The work done here is simply for the purpose of having the learners Relax and Get Ready. It can be done in a playful, attention-getting manner, yet include low-stress discovery related work. The teacher’s solicitations for actions should help students relax and get ready for the process of discovery. In the Spilled Ink activity (refer to Activity 1), for example, the teacher might ask, “What is a blob?... The diameter of a blob?... The average diameter of a blob?” The teacher could direct students to practice making blobs with their medicine droppers. Then students may be asked to practice making a blob with one drop, then a blob with two drops. They could continue making blobs, for practice until the teacher notices that “blob-making” has been mastered!

In the second activity, the Symmetry of Power Functions, the teacher may simply ask the students to graph functions, not necessarily power functions, on a TI-83 graphing calculator. If necessary, however, the teacher might “talk students through” the graphing of functions such as \(y = (x+3)(x+2)\) or \(y = (x+3)(x-3)\) and invite individuals to graph derivations or variations of these. If opportunities arise naturally, leading questions may be introduced such as, “You noticed the graph shift, what type of shift did it make?... Can you make the function graph shift again?... Up?... Left?... Can you predict the shift?... Control it?”.

If symmetry is noted, “Is it line symmetry? With respect to which line? Which axis, the y-axis or x-axis?... Is there rotational symmetry? About which point?” The purpose of these instructional moves is twofold: (1) the teacher encourages the students to relax and to be cognitively ready with knowledge and skills required of the activity; and (2) the students accustom themselves to what direction further study will take. For Activity 1, although students can be asked to turn their graphing calculators on at this time if applicable to review certain procedures\(^7\), such can also be delayed until necessary.

During the second stage or The Emerging Views Stage, level-specific vocabulary related to the discovery objectives is introduced to the extent necessary as students explore characteristics of instances of data samples collected through materials that the teacher has carefully sequenced (e.g., diameter of circular blobs in the ink activity, or as they make graphs and explore characteristics (symmetries) for even and odd power functions in the Symmetry of Power Functions activity. The sequence of instructional moves\(^6\) becomes more focused and formal and should gradually reveal to the students that instances within the guided-discovery activities are leading towards stable, observable patterns (e.g., the number of drops used to form blobs influences the size of the diameter; the symmetry of specific even and odd functions are indicating particular types of symmetry). Thus, many of the activities during this phase will be organized as sequences of short tasks designed to elicit specific responses.

In stage three, the Exchange Emerging Views Stage, drawing from their mathematical backgrounds, students build upon previous experiences as well as on their explorations of instances that embody the relationship between the number of drops required to make a blob and its diameter in Activity 1, or the kinds of symmetry found in even or odd functions in Activity 2. Students should be permitted to express and exchange their emerging views about the structures or patterns that have been observed. Other than to assist students with use of appropriate and accurate language (Vygotsky, 1978), plus correct uses of the technological tools, the teacher’s role is minimal. It is during this phase that the notion of relations (e.g., independent variable, dependent variable, function, line symmetry, rotational symmetry) begins to become apparent.

Next, in phase four or The Information Gathering Stage, as information is gathered (e.g., varied and specific graphs) students encounter more complex tasks, possibly tasks with many steps (especially in using TI-83 graphing calculators), or tasks that can be completed in several ways, and they respond to convergent as well as open-ended questions.

---

\(^5\) Intended for grades 6 to 8.

\(^6\) Intended for grades 8 to 12.

\(^7\) Students may or may not have had previous experiences with graphing calculators in general, or TI-83’s in particular. Some assessment of students’ prerequisite technology related knowledge and skills is warranted.

\(^8\) Instructional moves include such things as: assertion, exemplification, non example, counterexample, comparison and contrast, characterization, motivation, instantiation, non instance, counter instance, analysis, interpretation, justification, review, paraphrasing, pattern generation, analogy, demonstration, practice, and so on. The Cooney, Davis, and Henderson text Dynamics of Teaching Secondary School Mathematics incorporates these and makes use of them in designing instructional, teaching-learning strategies.
By orienting themselves in the field of investigation, many relations between the objects of study become explicit to the students. Extensions might surface, as well as associations to other topics in mathematics.

In the fifth and last stage, The Review and Summary Stage, students review and summarize what they have learned with the goal of forming an overview of the new network of objects and relations. The teacher can assist in this synthesis "by furnishing global surveys" of what the students have learned. It is important, however, that these surveys not present anything new, the emphasis being on the attainment of psychological closure. The relations that have emerged would be summarized and their origins reviewed. At the end of this phase, students have attained a new level of thought. The new domain of thinking replaces the old, and students are more appreciative of learning via guided-discovery. Technological tools can structure and facilitate movement through these stages and the learning of the objects selected for discovery. Using such tools is thus highly recommended!

Activity 1: Why Worry About Spilled Ink? Measure It!

Introduction: In this activity, intended for 6th-8th grade students, the diameter of a blob is studied in relation to the number of drops. Collecting the data for this experiment works best if students use a double layer of paper towels. Using medicine droppers, they should try to make small "ink" drops of equal size in about the same location away from the edge of the towels and away from where the towels have creases. Blobs should be measured as soon as the "ink" finishes spreading. Some blobs will be somewhat elliptical but not circular; take an arithmetic average of the largest and smallest diameters to provide usable data. If the "ink" blobs are made and measured carefully, the data form a discoverable pattern. This activity lends itself very well to a mathematical guided discovery lesson given that students generate data physically, and probably have little reason to know what it will look like. The stages for mathematical guided-discovery have been laid out below, but recall that they are not necessarily mutually exclusive from one another. Nonetheless, the point to be made is that the technological tools play a key role in the discoveries that will be made, specifically in that the technological tools facilitate the discoveries, and even make them more explicit!

Equipment Needed: Ink or colored water, food coloring, paper towels (quality brown & smooth, not especially absorbent towels), one ruler per group of four, and one medicine dropper per group. A TI-83 Graphing Calculator or Excel spreadsheet.

Mathematical Guided-Discovery Stages

A. The Relax & Get Ready Stage

Have students practice making blobs using the medicine droppers.

B. The Exploring Instances Stage

Have students determine whether a blob is circular or non-circular elliptical. Have students determine when the average of the smallest and largest diameter should be determined. Have students measure the diameter of a blob made with one drop. Have students measure the diameter of a blob made with two drops. Continue until blobs have been made with six drops.

C. The Exchange Emerging Views Stage

Record the findings in a table in the respective rows and columns where the independent variable is the number of drops to make a blob and the dependent variable is the diameter of the blob.
Graph the data using the STAT function of a TI-83 graphing calculator or using an Excel spreadsheet.

D. The Information Gathering Stage

Graph the curve that best fits the data using technological tools.
Suppose 11 drops were to be used, what would be the diameter of the formed blob?
How many drops would be needed to form a blob with a diameter of 80 cm?
How many drops would be needed to form a blob with a diameter of 95 cm?
How would the graph change if larger drops were to be used?

E. The Review and Summary Stage

Have the students explain the process of discovery, their findings, and their conjectures regarding the relationship between the variables explored. Have the students write a generalization regarding the relationship between the number of drops needed to make a blob and the measure of its diameter, or the average of the smallest and largest diameters.

Activity 2: The Symmetry of Power Functions

Introduction: In this activity, intended for 8th-12th grade students, the symmetry of power functions is studied in relation to the exponent (even or odd) of a power function. Collecting data for this experiment works best by graphing functions in the order listed below using a TI-83 graphing calculator, then analyzing the graphs of the functions, and analyzing the TI-83 graphing calculator TABLE output when appropriate. The questions that follow direct students to arrive at discoveries regarding symmetries of power functions. By using the TI-83 graphing calculator as guided, the learners are able to focus on the varying characteristics between graphs without spending enormous time drawing less than “perfect” or “near perfect” graphs, specifically regarding symmetry (if any). The mathematical guided-discovery stages as depicted below purport to draw distinctions between stages of work and thought processes as also suggested by The Van Hiele Model of Thinking in Geometry Among Adolescents (NCTM, 1988). Again, the stages are not necessarily mutually exclusive, but do lead to psychological closure as per the discoveries.

Mathematical Guided-Discovery Stages

A. The Relax and Get Ready Stage

Have the students do some warm-up graphing (open-ended or structured, as appropriate); include such functions as $y = (x+3)(x+2)$ or $y = (x+3)(x-3)$, and others.
Keep relatively informal, yet interject leading questions, “What is line symmetry? What is the point symmetry? What is rotational symmetry?” should opportunities arise naturally.

B. The Exploring Instances Stage

---

Readers familiar with graphing calculator will note a multitude of details (window settings, connected or dot plotting modes, “square” axes, ...) associated with drawing and interpreting the graphs.
Graph the following functions: $y = x$, $y = x^2$, $y = x^3$, $y = x^4$, $y = x^5$, $y = x^6$, $y = x^7$

What patterns do you notice in the graphs?

Graph the following functions on a TI-83 Graphing Calculator, first, let $n = 2$, then 3, then 4, then 5, then 6, then 7.

<table>
<thead>
<tr>
<th>Function</th>
<th>Does it have line symmetry? If so, describe it.</th>
<th>Does it have point symmetry? If so, describe it.</th>
</tr>
</thead>
<tbody>
<tr>
<td>a) $y = x^n$</td>
<td></td>
<td></td>
</tr>
<tr>
<td>b) $y = (-x)^n$</td>
<td></td>
<td></td>
</tr>
<tr>
<td>c) $y = -(x^n)$</td>
<td></td>
<td></td>
</tr>
<tr>
<td>d) $y = -(-x^n)$</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The cases for $n = 2$ and $n = 5$ are done for you using the same window settings as above.

Which power functions $n = 2, 3, 4, 5, 6, 7, \ldots$ have line symmetry?

10 In each case, $y$ is a real-valued function of the real variable $x$. Thus, $\mathbb{R}$, the set of all real numbers, is the domain and an appropriate codomain for each function.

11 What happens when $n$ is equal to 1?
Which power functions \( n = 2, 3, 4, 5, 6, 7, \ldots \) have point symmetry?

C. The Exchange Emerging Views Stage

Look at the even power functions. What symmetry do they have?
Look at the odd power functions. What symmetry do they have?

D. The Information Gathering Stage

Suppose \( n \) is even. Is \( x^n = (-x)^n \)? What are the possible values for \( n \)?

Still supposing \( n \) is even. Is \( x^n = (-x)^n \)? Again, what are some possible values for \( n \)?

When \( n \) is even, what symmetry does the power function possess?

Now suppose \( n \) is odd. Is \( x^n = (-x)^n \)? What are the possible values for \( n \)?

Still supposing \( n \) is odd. Is \( x^n = (-x)^n \)? Again, what are some possible values for \( n \)?

When \( n \) is odd, what symmetry does the power function possess?

E. The Review and Summary Stage

Have students review the different explorations made, and have them write a generalization regarding even power functions and odd power functions. Students should be encouraged to make connections between the concepts of symmetry and the even and odd power functions and to express them in a generalization expressing their views. By doing this, students may be assessed regarding multidimensional aspects that are integral to instruction (NCTM, 1991).

References

\(^{12}\) The even natural, counting numbers 2, 4, 6, 8, 10, 12, \ldots \( n = 0 \) could also be considered, and one might possibly introduce some negative even integers, \(-2, -4, -6, \ldots\)

\(^{13}\) Here, we are helping the students inductively formulate the discovered generalization as a means of describing the observed/noted patterns. This also takes place in the next section.

\(^{14}\) The odd natural, counting numbers 3, 5, 7, 9, 11, 13, \ldots \( n = 1 \) could also be considered, and one might possibly introduce some negative odd integers, \(-1, -3, -5, -7, \ldots\)

\(^{15}\) Here we have "mathematics in the making." Their observations, speaking more formally, constitute mathematical conjectures and, once proved, theorems.
The R.O.A.D Learning System (Read, Own, Apply, Discuss)
An On-line Method for Enhancing Teacher Pre-service and In-service Professional Growth

Geoff Irvine
NEWTcom
Ottawa
Canada
Geoff@newtcom.com
www.NEWTcom.com

Abstract: We (NEWTcom: a non-profit organization) have been developing a state of the art, Web-based, interactive, multimedia enhanced web-service to support the training and on-going development of teachers. We aim to serve both in-service and pre-service educator needs. The service is being built in collaboration with the Ottawa Carleton District School Board, the Ottawa Center for Research and Innovation (OCRI) and the Communications Research Center of Canada (CRC). We would like to show the resource to staff-developers and teacher-trainers to get their feedback and advice for further development. The goal of this session is to introduce this type of training medium to leading educators.
This hour long interactive presentation will be of interest to education faculty staff, school district staff development officials and state educational officials concerned with the on-going professional development of teachers.

Introduction

R.O.A.D Learning™ has a central philosophy based on “professional growth” rather than the “improvement model”. What do we mean by that? One of the central problems with the “P.D.” process in teaching is that it historically proceeds from the “improvement model”. The idea is that, “you need professional development!” This conveys the subtle, but clear message that you need to improve because your skills are inadequate. This is poor starting point.

Looked at from another perspective, Dr. Wilder Penfield, a pioneer in the field of brain surgery, was not an inadequate doctor the day before he risked a new procedure, mapping the actual functions of the brain to help a patient. He was a darned good doctor. The point is that he chose to engage in “action research”. In the process, he extended his own capacities as a doctor, and pushed the envelope of his profession. He was not engaged in “professional development”, but professional and personal growth.

This is the mind-set that teachers must be given the opportunity to acquire. R.O.A.D™ rejects the “improvement model” and embraces the personal, professional growth model. We do so with our distinctive content, delivery model and features.

R.O.A.D. Learning™, therefore, fills a need that the World Wide Web has not met: the professional growth of teachers. Web sites that deal with teaching ideas for specific K-12 subjects are legion. There are, however, few that focus on the foundational best practices of the teaching profession.

None do it the way we do. We offer a World Wide Web site and service, supported by an Internet CD-ROM containing large movie examples of teacher behavior, delivered quickly to the end user’s computer, rather than slowly via the Internet.
The service presents practical, next-day usable strategies for enhancing success in the classroom for teachers. R.O.A.D™ is written in an engaging style and is supported by multimedia (images, animations and movies). R.O.A.D™ offers a safe, virtual environment in which practitioners can experiment with new methods, collaborate and share results with their peers, reach levels of scored mastery of knowledge, and skill sets, and have their professional development tracked for official purposes. No other web-sites offer this feature.

R.O.A.D™ offers a safe, virtual environment in which practitioners can experiment with new methods, collaborate and share results with their peers, reach levels of scored mastery of knowledge and skill sets, and have their professional development tracked for official purposes.

The service also "gets to know the user". Responding to user pre-test surveys of knowledge and skill, it suggests best starting points and next actions. Furthermore, the service allows the end user to acquire expert mentoring while engaged in learning. These mentors are automatically connected to the user via e-mail and thereafter by whatever means suit the mentor and user.

Finally, the service is self-perpetuating. We are a publisher of high quality, research supported strategies for teaching. New modules are constantly under production that must meet our exacting standards before they will be made available at our site.

Relationships and Community Building

R.O.A.D. supports and facilitates a number of critical relationships depending on how its users choose to deploy and implement it.

Peer to Peer

In this case, a teacher or teacher trainee is linked to others in the same course, school, school district, or work group. They can simultaneously be members of many groups over great distances. They can send email within the service (no need to exit to another system), publish their action in the classroom to the PUBLIC Journals for comment, and schedule and organize meetings that will be either face-to-face or via telephone or computer.

Learners can access modules that are engagingly presented and which demonstrate foundational teaching skills (some include movies from an accompanying Internet CD-ROM, or animations of sequenced actions). This content, written by experienced, Master teachers, can become the focus of inter-peer discussion and distributed action research.

R.O.A.D™ can also support collaborative, curriculum workgroups that are geographically dispersed. Communications are asynchronous, thus solving the common problem of the lack of discretionary and "flex' time amongst teacher. Peers interact when and where they wish or are able. All they need is a connection to the Internet. Very low connection speeds and modems will work just fine.

Instructor to Training Teacher

In this instance, a faculty member has a virtual office. There they can view their student role, a learning contract editor for the whole class and for individual students. They can also access each student's OFFICIAL Journal. The Journal results from items submitted from the student's PRIVATE Journal and successful completion of MASTERY EXAMS (an on-line database of questions tied to the behavioral learning objectives for each module). Students may take these exams as often as they wish (new questions are presented randomly, and old questions have the answers and foils scrambled) and are not said to have achieved Mastery until a grade of 90% is achieved. Attempts that fall short of this goal only appear in the student's PRIVATE Journal.

Furthermore, the Instructor can email through the service to individual students or to the entire class at once. Instructors may also change the order of presentation of modules and lessons within modules. They can also edit the master index, and insert new lesson pages with the a simple cut and paste, and a click of a button. This gives the faculty the ability to author existing content "on-the-fly" or to author new modules as they see fit.
Mentor to Student/Teacher In the Field

Training teachers can be supported while on their practice teaching rounds. They remain in contact through R.O.A.D™ to their peers and instructors. Meeting via conference call, real-time, or on-line chat can be organized to solve individual or shared problems.

Novice teachers can be specifically assigned to experienced ones who are anywhere in the world. Alternatively, such teachers can request mentors from a pool of mentors previously established. In this case, each mentor previously declares the number of people he or she is prepared to mentor. The novice simply requests a mentor. This triggers R.O.A.D™ to search for an available mentor. The available mentor is notified of the request for coaching. A message can then be sent by the mentor, either accepting or declining the invitation to mentor. From that point on, the nature of their relationship evolves to meet the needs of this new coaching pair.

Authoring New Content

One of the greatest barriers to Web publication of best practice for teachers is a lack of comfort or savvy with Web authoring tools. Web development houses routinely make a fortune from this discomfort. In a cash strapped system such as education, this is not acceptable. R.O.A.D™’s creators, therefore, developed a set of simple, on-line tools for putting useful content up on the Web. This new content is then automatically managed and delivered by the R.O.A.D™ software to learners. Thus, an author can publish important new information directly into R.O.A.D remotely, never leaving his or her office, with no greater skill than word processing. Our author’s tools are on-line and include:

- A form that orders the presentation of lessons, sets prerequisites and creates interactions (applications or reflections). This provides the end-user with all the navigation and tools the author wants them to have.
- A template form for creating and editing a pretest based in behaviorally stated objectives. This will permit the learner to focus his or her learning tasks to those topics and concepts with which each is least confident first.
- An editable form to create an author’s recommended "default learning contract". This can used 'as is' by an instructor or modified to meet local needs).
- A template form for creating and editing on-line Mastery exams.
- A template form for giving the new course/module a title and a descriptive overview of the general goals and specific content that will be covered in the content.
- A form that allows the author to choose the graphic themes, button styles and even the language of the navigation and link buttons: English, French, Spanish, whatever the language of delivery of the author.

Conclusions

Our purpose for presenting R.O.A.D™ at the S.I.T.E. conference is to get feedback from educational leaders. Since our system does not require the installation of any software (all anyone needs is a standard Web-browser), we can modify the delivery shell to address comments from the field, and have these upgrades available to all users within hours. We are certain that our presentation will result in useful dialogue as we strive to improve and extend our work for the educational community.
Preparing Pre-Service Teachers to Use Technology

Stephen A. Rose, Curriculum and Instruction, University of Wisconsin Oshkosh, USA, rose@uwosh.edu

Henry F. Winterfeldt, Human Services and Professional Leadership, University of Wisconsin Oshkosh, USA, winterfe@uwosh.edu

Abstract: This paper describes how the UW-Oshkosh Teacher Education Program prepares pre-service teachers to integrate technology into instruction. Specifically, how the social studies methods and instructional technology courses are: using a framework for authentic instruction and assessment to help students develop and refine their pedagogical knowledge; using interdisciplinary teams to help students reflect on content, teaching methodologies, and appropriate use of technology; and having students develop and demonstrate technology based teaching materials.

Peter Martorella, in 1997 called the use of technology in the social studies classroom a sleeping giant. While he made mention of periodic unconfirmed reports of the giant’s awakening, this does not appear to be a widespread phenomenon. This same “giant” slept in the secondary social studies methods course at the University of Wisconsin Oshkosh. While stirring occasionally, there seemed no way to sustain its consciousness, given the uneven computer knowledge among the preservice teachers taking social studies methods and a fragmented approach to teaching technology and then social studies methods.

Prior to 1997 social studies preservice teachers at University of Wisconsin Oshkosh did not have the opportunity to become part of a community of learners where they would learn about technology, become skillful in its use, and integrate it into their teaching experience via the construction of subject matter units to be taught in clinical experiences and student teaching. Yet research suggests that offering these experiences heightens students success with technology and helps to foster positive values towards its use during instruction (Kellenberger, 1996). Further, the social studies methods course and the educational technology courses were disconnected making it difficult to model how technology could be integrated with other forms of instruction to foster powerful teaching and learning. Regular modeling of integration of technology in teacher education courses has been shown to positively influence latter adoption of technology in the classroom according to Willis (1997) and Keper, Harwood, & Larson (2000). Our practical response to these ideas in the College of Education and Human Services at the University of Wisconsin Oshkosh was to create a learning community between three courses – Social Studies Methods, Instructional Technology, and Reading In the Content Area.

Why A Learning Community?

The research base about the effects of instruction assisted by technology in social studies is small but what does exists is encouraging. Richard Diem (2000) has suggested that technology is valuable and effective in problem based learning. He bases this observation on the research conducted by Eastmond and Gibbons (1998) and Stites (1999). Wenglinsky (1998) who studied mathematics achievement indicated that technology does make a difference in student achievement if computers are used to teach higher-order not lower-order thinking skills. Yet technology is
unlikely to be used effectively in classrooms unless teachers have an adequate pedagogical framework for authentic instruction, assessment, and student performance. Such a framework can serve as a lens from which to view content, pedagogy, and how technology can help achieve powerful teaching.

Fred M. Newmann, Walter G. Secada and Gary G. Wehlage, 1995 in *A Guide To Authentic Instruction and Assessment: Vision, Standards and Scoring*, offer a research based framework for thinking about the content and pedagogy. The book is a compilation of the findings of a national research study of teachers who practice authentic instruction, assessment, and student performances. Newmann et al. believe that a central purpose of schooling is to teach students to use their minds well. To achieve this end, lessons and the resulting assessment tasks and student performances must represent construction of knowledge, disciplined inquiry, and value beyond school (see figure 2). Construction of knowledge is a blend of the learner's prior knowledge of what others have produced about a topic or problem, how the learner organizes new information and considers alternatives to produce an original conversation, piece of writing, repairing or building physical objects, or through an artistic performance. Disciplined inquiry which requires the use of prior knowledge, in-depth understanding of the content topic or problem rather than superficial awareness, and an expression of conclusions through elaborate communication. Value beyond school is when the in-class accomplishments of the learner have value apart from documenting the competence of the learner. Learners make connections between substantive knowledge and either personal experience or public problems.

Social studies learning community students are required to use Newmann et al.'s conception of authentic pedagogy. Preservice teachers begin to design and organize instruction which promotes engaged learning, fosters critical thinking, and can take advantage of electronic resources for data collection, organization, and presentation. This type of instruction seeks to harness the power of technology to support powerful new forms of learning as opposed to focusing upon reiteration of facts, events, and causes as stated by others.

Another reason for establishing the learning community was to foster team work among the three courses in the learning community. To accomplish complex goals, organizations require teamwork. The reality of the workplace for most preservice teachers is that they will be working in teams, whether interdisciplinary middle school teams or single-discipline high school departments. In methods courses across the country, preservice teachers engage in cooperative learning, try out related teaching strategies, and develop instructional materials to support this approach.

Another rationale for creating our learning community was to allow students taking both courses to focus their energies on long-term collaborative projects. Moreover, allocating one section of Instructional Technology to social studies preservice teachers enables instructors to offer in-depth explanations related specifically to social studies. Unfortunately, the same kind of teamwork is not often modeled by faculty members, who treat each course as a separate entity. The development of a social studies/technology/reading learning community is an attempt to model collaboration and develop meaningful connections between courses.

The uneven computer skills displayed by our students and their weakness in designing instruction that utilizes technology to help achieve powerful teaching and learning goals during practice teaching was yet another reason to...
more fully integrate technology into the secondary education program. The learning community allowed us to become more authentic with assessment and student performance. Assignments are performance based, and students must demonstrate their understanding of how to integrate technology into social studies teaching. Previously, assignments in the technology course were perceived by some students as disconnected from their subject area, since a direct application was not necessarily evident.

Finally educational policymakers believe that technology is the answer to many issues associated with quality in education. Whether this is true is certainly debatable, but school policy is often based upon such perceptions. Schools are buying truckloads of computers. Preservice teachers who do not know how to use technology in instruction will not fit in well with schools of the 21st century.

Developing a Structure

Developing a learning community in social studies methods and technology required coordinating many elements. We needed to find instructors willing to work together and coordinate their schedules to allow for joint planning time. Syllabi, assignments, and timing of instructional segments had to be carefully arranged so that the courses built upon one another. Student schedules also required coordination for a specific section of the technology course to be allocated to the learning community. The result was nine hours of weekly instructional time-three hours each for Social Studies Methods, Instructional Technology, and Reading in the Content Area.

Within this community, students could choose either a disciplinary or an interdisciplinary team to work with during the semester. All major assignments in both courses were team efforts. A major semester-long project served as a "hub" to tie teams, courses, and learnings together. Each student team developed a 10 day resource and teaching unit about a significant historical or contemporary problem/issue based on authentic teaching, the use of technology, and reference to social studies standards. For each unit, teams developed comprehensive lesson plans, to develop a problem/issue statement, identified unit goals, and collected resources. In the technology course, teams consulted with the instructor to identify what types of technology could best achieve their instruction, knowledge, and skill goals.

One unit focused on the different factors that contributed to the North's victory in the Civil War. To introduce the problem, this team used PowerPoint to present data about railroad mileage and track-gauge, transportation networks, economic indicators, strength of armies, geographic factors, data on trade, and so forth. Then the team used web page development tools to develop a research web page with links to history-related websites, dealing with the quality of military leadership on each side. Another student design team applied their web page development skills to developing a WebQuest that had students determine whether America's "War on Drugs" will share the same fate as Prohibition. The enabling technology skills and competencies were developed in the instructional technology course.

While the unit project was the basic connective tissue for the two courses, other topics and assignments bound them together. For example, while working on the use of charts, graphs, and other forms of data organization in the methods course, students also learned how to use spreadsheets and the graphing capabilities of various computer programs. Electronic communication (e-mail) facilitated communication between design teams. Each team was required to plan five complete lessons that employed one of the following instructional strategies: case study, cooperative learning, introducing a problem or issue, teaching a concept, and value analysis. For each lesson, one team member assumed responsibility for authorship and the other two members served as evaluator/critic. Team members used e-mail to send draft lessons and critiques to each other and to the instructors. Finally, teams were asked to review a videodisc and use multimedia authoring programs to design a presentation for teaching about an issue or problem. For example one team used images, speech, and music from the ABC Interactive Series Powers of the Supreme Court laser disc to introduce the issue of freedom of expression in their unit.

Obstacles and Solutions
Several obstacles may present themselves before a learning community like this can become a reality. The instructors must have some knowledge of and skill in using technology. Although no one person has to know it all, it is helpful to have each professor's knowledge complement the other's. Collaborators also need time to coordinate topics, procedures, and student assignments.

Time for advising and scheduling students is also critical. We were fortunate in having a very supportive college advisor and a centralized scheduling system, but even so, scheduling was not without its difficulties.

Finally, successful collaboration between methods and technology courses requires sufficient infrastructure and resources. Our university provides each student with Internet access from any campus general access computer lab or residence hall. Students receive an e-mail account when they register for classes. Most computer labs have both Macintosh and Windows computers. All of the computers are on the campus electronic network "backbone" and therefore are connected to the Internet. We work in a technology classroom and an adjacent modernized multimedia lab.

A future obstacle will be having enough technology and workspace when other learning communities are brought online. One potential solution to this condition is our new travelling computer lab which consist of Apple iBook computers using wireless technology.

Evaluation and Refinements

From our perspective, while the learning community was successful as a first time offering, several refinements need to be made. First, the successes. Student enthusiasm and motivation were strong, as evidenced by the number of hours the teams spent working together outside of class and in the computer lab. Methods, content, and technology were addressed in a holistic manner, and the design of collaborative unit projects enabled students to make direct application of what they were learning.

From our perspective, the "hub" teaching unit that combined technology with social studies methods was far and away superior to our previous unilateral assignments in separate courses. The problem-oriented teaching units designed by students were rich in information and purposeful about its use. Students developed both skill and confidence in their use of technology that far exceeded what had been possible in the methods course alone.

In subsequent offers of the learning community we plan to make a number of revisions. First, we need to take better account of the range of student computer skills. We misjudged how much time we would have to spend developing the basics. This tended to push back the more technical, and sometimes complicated, aspects of using computer technology, and resulted in an end-of-the-semester crunch. We have, for example, modified what we want to accomplish in the areas of multimedia and web page development.

Will the giant awaken in the social studies? This is anybody's guess. We hope that our example of a learning community based on collaboration between social Studies Methods, Instructional Technology, and Reading in the Content Area courses may help to stir the giant in our college.

Abstract: This paper is a report of a newly-initiated project designed to connect preservice teachers, cooperating teachers, student teachers, and higher education faculty through the use of a world-wide-web site. Goals of the project were to enhance the teacher preparation program and curriculum, to provide professional development for P-12 faculty and mentoring support for novice P-12 faculty, to provide professional development opportunities for higher education faculty, to provide educational resources for web-users outside of the cyberspace community that was developed in the project and to form the basis for continual teacher education program input and assessment.

Introduction

Those familiar with the teacher accreditation guidelines of the National Council for the Accreditation of Teacher Education (NCATE) are very familiar with the concept of "professional community" as it relates to pre-service teacher education. This professional community encompasses all who play important roles in the development of preservice educators: education faculty, arts and sciences faculty, inservice mentor or "cooperating" teachers, P-12 students and their parents, the community, and preservice educators themselves. The NCATE 2000 Standards refer to the involvement of the "Professional Community" in developing an assessment system for the teacher education program and in designing, delivering and evaluating field experiences and clinical practices. Additionally, college faculty are expected to be "actively involved with the professional world of practice in P-12 schools," as well as to collaborate "regularly and systematically with colleagues in P-12 settings" and other members of the broader professional community "to improve teaching, candidate learning and the preparation of educators (NCATE, 2000).

Institutions of higher education have utilized the "learning community" approach since approximately 1927, when the first documented "learning community" was established by Alexander Meiklejohn at the Experimental College at the University of Wisconsin (Kellogg, 1999). While this learning community existed solely on one campus and encompassed only higher education faculty and their college students, the concept of a learning environment that will promote coherence and create a sense of common purpose and community can be expanded to include community members off-campus as well (Kellogg, 1999).

Technology has enhanced the opportunities for interaction among the members of a professional education community through e-mail and the Internet (web pages, bulletin boards, chat rooms, and other opportunities). Research on preservice student use of technology has indicated that student teachers often use technology in on-campus classes; however, their use of technology during the student teaching internship drops off sharply (Beck & Wynn, 1998). Robert Morris College has seized this opportunity to bridge the physical space between College faculty, inservice teachers, preservice teachers, and others through the development of a "professional cyberspace community" website. The interaction fostered by this professional community has the potential to empower teachers to become self-reflecting individuals who are willing to take charge of their own professional development and to encourage the effective utilization of technology in order to enhance learning for all community members.
Program Overview

At one time, much was written regarding the lack of hardware available to P-12 teachers, teacher education faculty, and preservice teachers. This is no longer a major concern as almost all schools and higher education institutions have numerous computers, internet access, and other multimedia resources. It is now possible to move beyond issues of acquisition to focus on the optimal usage of these resources for the enhancement of teacher preparation, P-12 faculty professional development, and higher education faculty professional development. The existing infrastructure provides the scaffolding for a professional cyberspace community. Robert Morris College has utilized existing resources to accomplish this goal. Using a web-based approach, it has been possible to develop an easily-accessible resource that provides general resource links for sites relating to these areas of interest to all members of the professional community: employment in education, lesson plans, national and state standards, professional organizations, on-line educational publications, and grant opportunities.

Utilization of the world wide web for this purpose is consistent with adult learning theory. In a learning environment in which technology is utilized, Imel (1998) has identified that adults want a place where learners can collect important ideas, express themselves, and feel some security that they are going in the right direction and to provide fast and productive access to help when it is needed. Similarly, the use of technology enhances adult learning because technology provides increased flexibility and access to expertise, and can reduce feelings of isolation often experienced by nontraditional learners (Imel, 1998).

In the Robert Morris project, the development of the professional cyberspace community has met established goals in the areas of teacher preparation program enhancement, professional development of preservice teachers, professional development of P-12 faculty, and professional development of higher education faculty.

Enhancement of the Teacher Preparation Program and Curriculum and Professional Development of Preservice Teachers

In teacher education, effective supervision of student teachers has often been hindered by factors such as a lack of communication and collaboration (Kauffman, 1992) which make it difficult for higher education faculty and P-12 faculty to provide a coherent and organized professional development program for preservice teachers.

Moon, Niemeyer, & Simmons (cited in Kauffman, 1992) reported that, as a result of this lack of communication and collaboration, "cooperating teachers and university supervisors often misunderstand each other, lack unity in front of the student teacher, and continue to teach and supervise the way they always have instead of working as a supervisory team." Facilitating communication and collaboration among higher education faculty, student teachers, and P-12 inservice teachers can serve to build cooperative and collaborative teams that can more effectively meet the needs of all participants.

Through the Professional Cyberspace Community website, access to the education unit's conceptual framework, assessments, curricula, long-range plans, and other information is provided to everyone in the professional community. This information exists as a resource and guide for teacher education majors at all stages in their programs, student teachers in the field, P-12 faculty working with education majors doing field experiences and/or student teaching, parents, community members, and higher education faculty in both arts and sciences as well as education programs. All constituents can comment on this information at any time, thereby providing continual feedback about the teacher education curriculum and programs. Student teachers can post messages and/or e-mail their peers, mentor cooperating teachers, and college supervisors. Lesson plans can be posted for review and constructive feedback, and requests for assistance and information can be posted. Students may access course descriptions, class schedules, and other program information.

P-12 Faculty Professional Development

According to Joyce, et al. (1990, p. 33-34): "Proposals both for the 'empowerment' of teachers and for an increase in the use of a knowledge base in education depend upon the realization of a radically revised workplace with very different relationships...and much greater attention to the application of professional
knowledge." It is precisely this shift in relationships that has become possible through the use of technology to provide a workplace that is "radically revised" due to the replacement of teachers' feelings of isolation with opportunities for professional connections with others in their field.

Articles related to mentoring, preservice teacher education, action research, and related topics are available on the professional cyberspace community website. Inservice faculty may also post requests for information, materials, ideas, or other educationally-related needs. Information on workshops and inservice credit courses of interest to inservice teachers is made available; teachers may also make requests for workshops or courses to meet their needs in particular areas. In Pennsylvania, all certified teachers are required to obtain a minimum of six credits or 180 hours of professional development every five years in order to maintain their certification. The professional cyberspace community website provides up-to-date information on these "Act 48" requirements, including links to appropriate state information and lists of available opportunities for inservice credit.

These aspects of the website also provide support for recent Robert Morris College graduates who are in their first few years of teaching, who may continue to utilize the services and interact with the other members of the professional cyberspace community. Support for this population is critical, as research has indicated that many first-year teachers "are frequently left in a 'sink or swim' position with little support from colleagues and few opportunities for professional development" (Darling-Hammond, 1997). First through third year teachers may voluntarily remain as part of the cyberspace community, continuing to receive support from higher education faculty and other inservice P-12 faculty. In addition, these novice professionals also provide support for the student teachers in the community, as they share their tips and suggestions for "surviving" the first few years of teaching. Research has indicated that those beginning teachers who are mentored are more effective teachers at the beginning of their careers, tend to focus more on student learning, and leave the profession at a lower rate than beginning teachers who are not mentored (National Commission on Teaching and America's Future, 1996).

Higher Education Faculty Professional Development

The learning community developed within this project can be viewed, in a sense, as a cyberspace professional development school—a "learner-centered environment...in which reflective practice and teacher decision-making are part of a school culture where new teachers are naturally expected to collaborate with more experienced university-and school-based colleagues" (Levine & Trachtman, 1997). Obviously, this approach holds benefits for the experienced veterans, who may also learn from the novice teachers.

According to Kellogg (1999), "faculty who teach in learning communities reveal that they become re-energized and feel empowered..." While the learning communities in Kellogg's report referred to those comprised of on-campus individuals, it is logical to assume that the expansion of the learning community to include those off-campus will have similar, if not enhanced, results.

In the professional cyberspace community, higher education faculty also access and utilize the bulletin boards, e-mail services, program information, and mentoring information available to other community members. In addition, College faculty use the resources and relationships developed through the on-line community to establish contacts for action research projects, locate sites for field experience placements, and to develop additional projects cooperatively with P-12 colleagues.

Summary

The professional cyberspace community developed through this project supports a system of "co-mentoring," defined by Bona, et al. (cited in Mullen, 1999) as a name for "supportive assistance provided by several connected individuals. Placing the prefix 'co' before 'mentoring' reconstructs the relationship as non-hierarchical; 'co' makes mentoring 'reciprocal and mutual'" (p. 119.) The public nature of the website allows co-mentoring to flourish; questions, ideas, and lesson plans become public and, therefore, open to constructive feedback from any and all members of the community.
According to Mullen (1999, p. 42), Synergistic co-mentoring groups require empowerment of the members, so that "each member feels that what s/he has to offer is important to the group and valuable." The professional cyberspace community allows everyone to participate on equal ground; the input and feedback provided by preservice teachers is valued as much as the input and feedback provided by others in the community. It may be that this feeling of empowerment will provide the basis for continued professional development of all members of the cyberspace community.

As a teacher preparation program working toward continuous assessment and improvement, enhanced P-12 student and teacher-candidate learning, and national accreditation, Robert Morris College has embraced technology as the infrastructure through which the scaffolding of our professional community can be strengthened and expanded. This is a model of an approach which can be replicated at any institution with a teacher preparation program.

Abstract: In this paper, we describe the technology integration efforts at Albion College over the past four years, with the hope of providing a vision to programs that are both similar and dissimilar to us. Of particular interest is our successful integration into methods courses, and the way that we used our diverse strengths and worked as a team to accomplish it.

Acknowledgements

We would like to applaud the efforts of the following current and former faculty and staff whose content area understanding, pedagogical practice, willingness to share ideas and "ownership" of courses, and sense of community have been instrumental in helping to thoughtfully integrate technology into the Education program at Albion. In alphabetical order, they are: Carrie Dale, Albion College; Kathleen Fear, Olivet College; Karin Hanke, Albion College; Corinna Hasbach, Escola Graduada de São Paolo; Dorothy Kammer, Albion College (retired); Michael Michell, Escola Graduada de São Paolo; Deborah Roose, Albion College; Nicole Schonemann, Albion College; Pamela Schwartz, Albion College.

Introduction

In a given teacher education curriculum, it is not at all unusual to find a course in educational technology offered as a "stand-alone." Students either opt for or are required to take this course in order to learn the effective theory and practice of integrating technology into their teaching. While these classes can make a measurable impact in a student's preparation, the concept itself contradicts much of what we now believe about training teachers. We describe the importance of helping students build pedagogical content knowledge, but we deny them the opportunity to learn to use technology tools in parallel with their learning about content and its pedagogy. We value the notion of students dealing with ill-defined and complex problem spaces, but we stratify the study of educational technology and diminish its importance relative to study about content and its pedagogy. To wit, we do a disservice to pre-service teacher training when we separate classes in technology from classes in subject-specific methods or pedagogy.

There is probably a majority of education faculty who would agree that technology should be integrated into methods and pedagogy classes, even if this is not the case at their home institution. There are many reasons why integration is not possible, such as constraint by available personnel, by program review cycle, by facilities, or by the need for vision. It is in this latter area, vision, that our experience at Albion College may be of service and interest. Albion College is a liberal arts college for undergraduate education, with an Education program that accounts for over 10% of the total enrollment. Each year, approximately 30-35 elementary and secondary education students graduate from the program. Four years ago, the Ferguson Center for Technology-Aided Teaching was created with the involvement of a prominent member of the Board of Trustees, the President of the College, and the Chair of the Education Department. The primary goal of the Center was to help faculty in the Department to integrate technology across most or all courses.
and to help students learn to effectively use technology in the service of teaching and learning (http://www.albion.edu/education/technology_integration.asp). In this paper, we describe the efforts of the past four years, with the hope of providing a vision to programs that are both similar and dissimilar to us.

Courses

We will briefly describe our technology integration efforts across several different courses over the past four years, identifying course goals, software and hardware used, and course projects which were abetted by technology. The courses are laid out chronologically. At the heart of these efforts is the manner in which we coalesced our diverse strengths as faculty to produce an integrated curriculum. Almost all of the faculty saw themselves as average or below average in their personal or pedagogical technological ability. However, their expertise in diverse content areas and in teaching allowed us to have fruitful discussions about integration. As an example of this, the voice later in the paper that speaks about the course in Literacy Pedagogy differs from that used throughout the rest of the paper to convey the personal aspect of the collaboration. Some efforts resulting from these discussions were short-lived but important to the success of later ones. It was clear from the beginning that the responsibility for success did not rest on the shoulders of any one person; rather, our success depended upon our ability to be creative, to take risks, and to be honest about failures and triumphs.

Effective Instruction and Effective Schools (Elementary)

Effective Instruction and Effective Schools is a general methods course that is set against a backdrop of teaching elementary science. The course has been team-taught more often than not, and has been a valuable training ground for helping faculty, who are unsure of their ability to incorporate technology, come up to speed. It meets two hours a week, twice weekly, and has a two hour per week practicum component alongside.

Students who take this course are sophomores, and are often unsure of their ability to either teach science or use technology. Technology integration occurs in four different ways. The most far ranging is pointed towards helping students develop skills and self-efficacy in their personal use of technology. The goal is to help them increase their information literacy, understand the process of investigating and writing a research paper on an unfamiliar subject, and think about how to write good hypertext. The details of this project are provided elsewhere (Rubio, Michell, Kondelik, Blackwell, & Albery, 2000).

For the practicum, students spend most of the semester actively involved in working with teacher and students; near the end of the semester, they team-teach a curriculum-appropriate science unit with a classmate. They use the PIViT software (http://www.umich.edu/~pbsgroup/PIViT.html), described in the section on the Pedagogy classes, to plan their teaching. This is their first opportunity to use technology to plan and manage teaching.

One of the course assignments is a software or Internet site assessment. The students propose to study a piece of software or an Internet site for its educational value in teaching elementary science. Their selection must be approved by the instructor to make sure that it has sufficient depth for a worthwhile investigation; since some sites are extremely large, sometimes students are asked to focus on a particular segment of the site. Once their selection is approved, they explore the site or software, and assess it along several dimensions. These include ease of use, requisite background knowledge, purported educational use, how well it supports a constructivist view of learning, and whether it has any bias or strength towards gender or ethnicity. They must also give some specific scenarios for how it could be used in a classroom setting. Finally, they write a recommendation, a paragraph which stands alone but would adequately convey their opinion about the educational value to a fellow teacher. In order to help students with this assessment, the instructor spends up to a full day in class looking at software and sites which have overall positive and negative value in teaching elementary science.
Students also participate in a local, electronic discussion forum with a web interface. Their experience here is similar to that described in the Secondary Methods class.

Secondary Methods (Secondary)

Secondary Methods is a general methods course which takes a special, in-depth look at multicultural education, particularly ethnicity. Otherwise, it resembles the Effective Instruction course, but without the emphasis on science. To date, we have experimented with several possible ways to integrate technology into this course, but have yet to settle on anything because a different instructor has taught it for three consecutive years. One early attempt involved having the students create interdisciplinary units utilizing PIViT, a piece of software designed specifically for unit or project planning. It was ultimately decided that this component should be moved to the subject-specific Pedagogy classes, to allow students to learn to do such planning in the context of their own subject area. PIViT will be described more fully later in this paper, in the section devoted to those courses.

Another attempt at technology integration parallels some of the efforts involved in the Effective Instruction course, namely a discussion forum. During this semester, the course met once a week for three hours, with the students committed to a structured service learning project for an extra hour per week. Throughout the semester, the students commented that the discussion forum was especially useful in helping build a classroom community. The forum centered upon a weekly requirement that the students post a journal entry and respond to the entries of two other students. There are no specific assessment criteria other than "done well" or "not done at all." However, the overall grade is analogous to a grade for participation, in that a student cannot receive a high grade without taking part. The discussion forum was managed with O'Reilly's WebBoard®. WebBoard is accessed through a student-generated id and password; the instructor then gives students access to a specific forum. WebBoard provides threaded, dated discussions. It automatically places forum participants on an email listserv. It allows the instructor to review the number of posts made by each student, but has no other capability for assessment. The instructor must manually search postings to determine whether any were made on a certain day. The College's Instructional Technology Division provides instruction on the use of WebBoard on an individual basis. Faculty at Albion who use the forums comprise the spectrum from neophytes to techies.

Pedagogy of the Humanities, Social Sciences, and Natural Sciences (Secondary)

As noted previously, the student experience of unit/lesson planning utilizing PIViT was ultimately placed in this class. PIViT (Project Integration and Visualization Tool) allows teachers to plan units or projects in any content domain. It consists of a project map which allows the teacher to visually organize in a manner similar to that afforded by Inspiration (http://www.inspiration.com) or other concept mapping software. It also has an integrated calendar, so that teachers can assign dates to different classroom activities, investigations, and assessments and readily view or change those dates. Finally, teachers may enter specific lesson plans from within the project map. Thus, students who use this tool may view their plans from three different representations: visual/conceptual, chronological, and textual/detailed. There is a practicum placement with this class that is similar but not quite as all-encompassing as with the Effective Instruction class; the lessons that students create with PIViT are taught during that practicum.

PIVI only runs effectively on Macintosh computers, meaning that the vast majority of our students have to familiarize themselves with a computer platform that is largely unsupported by the College. However, since a significant percentage of schools utilize Macs, it is in our students' best interests to "force" them to use these computers so that they are prepared for the realities of a dual-platform profession.

Students in these classes are also asked to do a software or Internet site assessment in their own subject area. The parameters of this assignment are similar to the one used in the Effective Instruction course. Some simple HTML editing has also been taught and utilized, on the same scope as that in Secondary Methods.
Literacy Pedagogy (Elementary): An Implementation Story

I teach the Literacy methods courses for our elementary students. When I started at Albion College a year ago, Reuben came to me and said he'd like to help develop a technology component in each of our classes. I was excited by this, although I had to strongly warn him that I was less technologically skilled than most of our students. For this reason, we began with a plan to first help me learn how to use HyperStudio (http://www.hyperstudio.com), and then we could teach my students together.

I began by doing the tutorial in the HyperStudio manual; I actually had my nine year old son do it with me! I found the manual very easy to follow and I also got many ideas as to how I could incorporate the technology into my already full course offering. Originally, Reuben and I had talked about just doing a board book, described to me as being like those children’s books with the buttons down the side of the text you push in conjunction with the rebus picture in the text to get “exciting” sound effects as they read. But as I learned from the tutorial how to make cards into stacks, my mind switched from envisioning a board book to thinking of this as more of a teaching or reinforcing program my students could use in their classrooms when they did their student teaching.

The next step in our journey was to have the students repeat my own experience: begin by taking the tutorial, and then determine the skill or genre they wanted to teach or reinforce. As my model, I chose to reinforce my teaching of quotation marks, and made a sample storyboard of my stack. I then began to generate my cards, and this, more than anything, allowed me to acquire a realistic idea about the amount of time needed to create an effective stack. It also gave me the confidence to try to answer my students’ questions during the two class work sessions (two hours each) in which we met in the computer lab for class.

On the day that the stacks were due, we asked the students present their programs to their peers. We had asked the students to self-evaluate their learning, as well as their product, before the presentations began. The students found the sharing very enlightening, and immediately asked to have their evaluations back so they could talk about the upgrades they wished they could make, now that they had seen what others had done. I found it helpful to hear from my students their explanations of the purpose of the stack and their intention for its use very helpful when we went back and individually evaluated each student’s work. I was dismayed that it took me approximately one hour per stack to evaluate. We found many things that we wanted to hold the students accountable for, and other things we thought the students should consider before using their stack with students.

Based on our previous experiences, we revamped our rubric and I structured the assignments differently this year. I began by taking my students through the process slower. I made certain that all students had taken the tutorial prior to drafting their initial plans. I also had them create a well-developed, sequential lesson plan which structured the learning and the practice, to assure there was appropriate student support and levels of practice. I passed out a rubric which, I thought, better reflected my needs for the instruction and practice as well as Reuben’s needs for effective use of technology. I did not have them create their initial storyboards until they had received back from me their lesson plans, complete with suggestions and considerations for thought. Once the storyboards were in place, we met together in the computer lab. As we expected from our experience last year, the first session was slow going, with most students only completing one or two cards. But during the second session in the lab, the students’ questions were more advanced, and their level of anxiety was greatly decreased.

I think the benefits of doing the HyperStudio in this course are two-fold. I have seen the tremendous increase in confidence in my students, now that the first group are student teaching, when incorporating technology into their teaching and in their own presentations (such as in the Teaching of Science, Social Studies, and Mathematics, or the Student Teaching Seminar). But what I appreciate most, from the perspective of a methods instructor, is the quality of the direct interaction with curriculum design and implementation. My students now have discussions amongst themselves about effective methods for teaching or reinforcing skills, appropriate language use for children with limited experience and lexicons,
and open analysis of the level of skill required by specific forms of practice. I have never been able to obtain similar levels of discussion regarding "paper and pencil" unit design.

Teaching of Science, Social Studies, and Mathematics (Secondary)

Elementary education students in this class have the privilege of conducting a summer day camp for local elementary children at the College's Nature Center. For part of the day, class is in session for the students as they learn to teach in an interdisciplinary, multiage, field-based setting; for the remainder of the day, the students actually run the camp. Students plan all of the lessons using either PIViT or any other piece of software that allows them to show their plans in all of the three representations described previously; they also aggregate their individual design/project maps into one big class map.

Different children in the camp focus on plant and animal biology, geology, environmental science, or the history and culture of historical and contemporary peoples. The environmental group that studies water quality makes use of computer-based laboratory probes which interface with a computer and provide real-time data. They use digital probes to measure the conductivity, dissolved oxygen, and temperature of a large river at disparate locations, and then report their findings on the health of the river to the camp. The college students spend some class time learning to use the equipment, and work with the campers to make the measurements and distill the data.

Students in the class also use HyperStudio to create a hypermedia anthology or retrospective of the camp, drawing on their experience of creating stacks in the Literacy Pedagogy course. Each content area group (biology, geology, etc.) develops a set of stacks that portray the camp experience from their own perspective, utilizing source or scanned digital images, digital video, and personal artwork. The class is responsible for creating a gateway stack and agreeing on a consistent navigational structure so that the stacks may be aggregated. Students then present their anthology in an Institute-wide colloquium.

Student Teaching Seminar (Elementary and Secondary)

In the first years of our efforts, we noted that during the student teaching semester, students had a tendency to fall back upon what they considered their "tried and true" techniques and degree of comfort, which generally had little to do with technology. While this was appropriate for those first years, we realized that we would have to build something substantive into the curriculum in order to help the students see their technological knowledge as a strength. Beginning last year, we asked students to create a digital presentation portfolio. Beginning this year, we asked them to implement a technology project.

We explain to the student teachers that they will compile a digital portfolio in order to convey the essence of "what they are all about" to a prospective employer. It is partly a focused presentation of their professional knowledge, experiences, and artifacts, containing such things as a statement of philosophy, resume, lesson plans from student teaching or practicum experiences, examples of work that their students have done, classroom video, or samples of their own academic work. They may also put in extracurricular or personal information about themselves which helps paint a holistic picture of their potential as a teacher. The portfolio will ultimately reside on a CD-ROM that they can loan or give out. As such, the CD-ROM should be wholly self-supporting in that every application or file that is needed is already loaded. All of the specialty software and hardware tools that they need to create a digital portfolio are maintained in the Ferguson Center computer lab. They can also access Microsoft FrontPage, the College's officially supported HTML editing software, in any campus computer lab.

The technology project represents a substantive effort by the student teacher to utilize available computer technology at their school in order to accomplish teaching and/or learning that could not be accomplished otherwise. The project is grade- and curriculum-appropriate and spread out over 7-10 hours of classroom time. This time span was chosen with the hope that it would strike a proper balance away from either a superficial or onerous attempt. Each student teacher writes a project proposal early in the semester in order
to receive feedback and the assent of the seminar instructor. They must then carry out the project at a point in the semester of their choosing, and then document their efforts in the digital portfolio.

The seminar meets for two hours, once a week. During half or more seminar class meetings of the semester, basic information is presented or question and answer sessions are held for up to an hour. Either a student lab assistant or myself hold set lab hours throughout the semester to help students with individual problems. The lab has four computers, two scanners, a digital video workstation, a CD-RW/CD-R burner, a color printer, and software for creating and editing graphics, web pages, and audio or video.

**Advanced/Directed Study (Elementary and Secondary)**

This study course had its origins with a group of elementary students during the first year of the digital portfolio effort. They student taught during the fall semester, and wished to devote extra time to creating a more polished portfolio. One student from the group was particularly interested in applying for the Michigan Certificate for Outstanding Achievement in Teaching with Technology (see http://www.coatt.org). The course was beefed up to be worthy of academic credit, and initiated. The quality of the portfolios by these students was sufficiently high that we decided to continue to offer the study each semester to seniors who are anticipating student teaching or have just completed it. Apart from portfolio work, this elective course would allow students to extend a technology project or begin a new one. For example, in the fall semester a group of elementary student teachers used the study to prepare some HyperStudio stacks intended to provide their students with understanding of certain concepts that are perennially troublesome. The project resembles what was done in the Literacy Pedagogy, but is more wide-ranging because it involves research into how children learn math as well as beta testing of the software. In the spring semester, the students use the stacks in their teaching. This design experience is a more substantive utilization of technology than for someone who uses something "off the shelf," because they can understand and describe how multiple representations of difficult concepts can improve understanding.

**Areas of Future Growth**

All of the prior and current Education faculty agree that having a resource like the Ferguson Center is crucial to the success of technology integration. A willingness by methods instructors to "own" the use of technology in their teaching rather than see it as someone else's domain is equally important. Ongoing and future efforts for our education program in technology-aided teaching and learning include the ongoing effective integration of technology into other education courses, support for the technology projects of practicing teachers within the local education community, and research into possible uses of Personal Digital Assistants by practicing teachers. Three education courses, Foundations of Education, Reading in the Content Area, and Exceptional Child, have yet to experience appropriate integration. Some discussions have pointed toward the use of software for concept mapping and speech-to-text recognition in the latter course. Teaching regarding the use of technology for assessment (e.g. spreadsheets and mail merge) also needs to be housed in some courses. Since Albion is a four-year undergraduate institution, it does not deal with in-service teachers in a graduate program. However, a College-wide impetus for collaboration with community institutions finds a ready application in ongoing work with local teachers to make better use of technology in their teaching.

Abstract: Technology impacts our professional lives in many ways. Instead of a disconnected voice over the PA system, our classrooms are now invaded by the sounds of “You’ve got mail.” Teachers record attendance and grades “on line.” We teach our students how to conduct Internet research. We send students on “virtual field trips” and plan simulations. Instead of asking students to supply home addresses, we ask for e-mail addresses. We have begun, albeit slowly in many cases, to integrate technology into our classrooms and profession. As a profession, we are learning to use technology to build a sense of community among our members. At Robert Morris College, we plan to concentrate on the ways in which a virtual community can be built using technology, specifically e-mail and electronic bulletin boards, might be used as a way to keep student teachers connected to one another in addition to providing information on current issues as they complete their field work.

Introduction

Technology impacts our professional lives in many ways. Instead of a disconnected voice over the PA system, our classrooms are now invaded by the sounds of “You’ve got mail.” Teachers record attendance and grades “on line.” We teach our students how to conduct Internet research and refer them to web sites. We send students on “virtual field trips” and plan simulations. Instead of asking students to supply home addresses, we ask for e-mail addresses. We have begun, albeit slowly in many cases, to integrate technology in our classrooms and in our profession. Professional organizations use technology to publicize conferences, list resources, and begin conversations about important issues. As a profession, we are learning to use technology to build a sense of community among our members.

Technology has expanded the resources available to pre-service teachers as well as in-service teachers. In teacher preparation institutions across the nation, pre-service teachers are given instruction and opportunities to integrate technology into daily lesson plans. They use technology to complete assignments, to present mini lessons, and to critique their own and others’ tape-recorded performances. Using video conferencing technology, pre-service teachers are able to “look” into classrooms and see the interaction between real teachers and real students. Pre-service teachers can now log on and in a few minutes download several different lesson plans on ways to teach a particular topic at a particular grade level. During content and methods courses, pre-service teachers are taught the importance of using technology as a teaching tool. Technology, however, can be much more than an instructional tool for our pre-service teachers. It can help pre-service teachers build their own community: their own support group.

There has been much research on the retention of teachers in the profession. The National Education Association (NEA) conducted a survey in 1982 and reported that less than 50% of the nation’s teachers plan to stay in the profession. Wolfe and Smith (1996) discovered that of the 32,000+ teachers who begin teaching each year half will leave the profession within the first five years. One of the reasons for leaving the profession as cited in Zepeda and
Ponticelli's (1996) study was the feelings of loneliness and isolation. The problems and concerns student teachers report has also been the subject of other research studies as well (Ball 1985, Grossman 1990, and Strickland 1987). All of these studies empathize the importance of maintaining a support system for student teachers and beginning teachers as they enter the profession.

At Robert Morris College, we plan to concentrate on the ways in which a virtual community can be build using technology, specifically e-mail and electronic bulletin boards, might be used as a way to keep student teachers connected to one another in addition to providing information on current issues as they complete their field work. We, therefore, are adding an additional requirement to the student teacher experience: our student teachers must read and respond to their e-mail messages and posted messages at least three times each week.

The familiarity our students have with technology, the availability of computers with Internet connections in the schools in which they are placed, and the ease of forming electronic groups through the college has led to the proposed implementation of this program requirement.

Overview of the Program

When our pre-service teachers begin their fieldwork, they are assigned to several different schools; we do not often cluster student teachers. This adds to the feeling of isolation that our pre-service teachers report. Our students tell us that they need someone who understands their situation and is at the same professional level to share the successes and failures they have in their classrooms. The distance between schools and the college makes it difficult for many of them to return to campus for a weekly seminar; therefore, we decided that an alternative to a face-to-face return seminar might be beneficial for our students. We began by evaluating the technology that our students would have some degree of expertise and familiarity.

Pre-service teachers at Robert Morris College complete many of their content courses in classrooms that are equipped with various types of technology. These rooms have document cameras, video cameras with voice tracking capability, VCR recorders, CD players, Internet access, and computers. Our students, therefore, are comfortable with using technology in their mini lessons and integrating technology into their instructional units. Additionally, many of their instructors post assignments and other information on line. Many instructors require students to e-mail draft copies of assignments to them or to evaluate specific web sites. All instructors at Robert Morris College have the capability of creating class groups by clicking a button on the electronic roster. Our system is designed to allow instructors to e-mail the entire group, select specific members, or to post messages. Our pre-service teachers, therefore, are familiar with electronic communication. We decided to utilize this type of technology to help our students maintain a connection with one another and with the college.

The Specifics of the Program

The first step in creating this component is to ensure that all pre-service teachers have current e-mail accounts. The next step is to explain the importance of building a community and operating within the community to all of our student teachers. In our program, all student teachers spend the first four weeks of the student teaching semester on campus. A portion of this time is spent in whole group seminars. Having the opportunity to explain the program to all the student teachers at the same time will ensure that all the student teachers have the same information. More importantly, bringing the student teachers together will allow us to begin to build the sense of community we want them to have as they are in the field.

required to visit. Then the conversations begin. After reading To ensure consistency in the program, each Monday education faculty will take turns posting a message about an educational issue or concern. For example, many of our student teachers have concerns about classroom management. One of the first messages they may receive is information about classroom management in general and two specific web sites that they will be the articles or evaluating the sites, student teachers are invited to share their reactions. We
require that they make at least one comment with specific references about the material. As student teachers log on and read each other’s comments, they are encouraged to respond in positive ways to comments. Other topics for discussion include: using technology effectively with real students, teacher parent conferences, managing the paper load, grading, and effective assignments. We will also use this forum to give our student teachers current information on educational issues such as the state requirements for inclusion, no tolerance policies, and testing.

Student teachers are encouraged to post concerns or issues that they may be having in their classrooms. For example, if a student teacher has a parent conference scheduled, the student teacher might post a message asking for ideas from peers about procedures, what to say and what not to say, or what might be necessary in terms of documentation. Other student teachers respond with their ideas; thus, a conversation among the student teachers begins and the community continues to grow.

Another expected advantage of this component is that it will encourage student teachers to reflect on their teaching: specifically, lesson plans, content, and delivery. Often when asked to reflect, student teachers merely give a short, general comment. They are reluctant to elaborate or explain alternatives, successes, and failures in their reflection. We require that each student teacher post at least one reflection during the week. We encourage other students to comment on the reflection, ask questions, and suggest alternatives, or use the reflection as a springboard for new ideas.

Program Assessment

Before implementing the program, it is necessary to decide how to assess its strengths and benefits. Initially, we have decided to post an issue or concern and then to monitor the conversations. As faculty, we do not intend on responding to our student teachers comments through e-mail. If a student teacher seems to be in danger of committing a serious error in judgment, we plan to intervene privately. Although, our student teachers know that we monitor and examine their individual responses, it is our belief that by remaining “silent” we will be able to blend into the background as many ethnographers do.

In essence, we plan to take turns posting a concern on Monday. Although any of the coordinators or the department chair might monitor the responses for any week, the coordinator responsible for posting the issue will be responsible for checking the responses during the week and making hard copies of the electronic responses for the others on the next Monday. Each of the content coordinators will be responsible for closely examining the responses from the student teachers in that discipline. To encourage student participation, coordinators will assign points to the student teachers for each contribution to the conversations that helps to move the conversation along. Comments like “I agree,” will not receive points. Coordinators will be responsible for recording the points for student teachers in the coordinator’s discipline. Although our intent is not to use the conversations as a way to evaluate student teachers as they practice, we believe that the transition from extrinsic to intrinsic motivation needs to be strengthened for our students. We also believe, based similar in class discussions, that once the discussion begins most of our student teachers will begin to “join in” without the extra motivation of “the grade” to do so.

In addition, coordinators will be responsible for noting trends in the conversations. At the monthly coordinators meetings, these trends will be discussed and plans for appropriate action will be made. By evaluating the comments for patterns of concerns and issues, we believe we can better service our students. The patterns that we discover in our students’ conversations will enable us to engage in a continuous evaluation of our total program from the content and education courses to the field experiences. Thus, we believe this community of professionals will continue to grow and expand. We further believe that this sense of community will strengthen the profession by helping to retain teachers.

Conclusion
It is hoped that requiring student teachers to stay connected to each other and to the college as they complete their fieldwork will instill a habit of sharing and learning together. By providing this type of support system, student teachers will be able to rely on peers rather than instructors as they make important curricular decisions. We are confident that helping them to establish a community will sustain them through student teaching and provide a model for them as they begin their careers in their classrooms.

Abstract: This descriptive case study explored both the implementation of an interactive web module in a teacher education course and the instruments used to assess the learner outcomes of that implementation. Data collection consisted of a pre-post critical thinking measurement, which was the foundation for the construct of higher order reasoning, an analysis of student-teacher discourse through electronic mail, and an interview with a student. The findings from this study have implied that: 1. an integrated approach of instructional technology must be carefully planned and implemented to reduce anxiety and increase the likelihood of student use; 2. there is a need for differentiating between the types of learning goals and outcomes in relationship to different instructional web module designs, and 3. there is a need for developing a blueprint of a variety of instruments that assess learner outcomes, both quantitative and qualitative in nature.

Introduction

The details of the theoretical application and implementation of the web module used in this study, as an instructional tool in a teacher education course, can be found in previous studies (Hazari & Schnorr, 1998, 1999; Schnorr, Bracken, & Hazari, 1999). The aforementioned web module design includes McKenzie's (1995) considerations that it is essential for technology to be implemented through careful planning, and the necessity that learning theory be used as a foundation for technology's integration within course instruction. However, little is known about the effect of technology on learner outcomes as measured by higher order reasoning skills (McKenzie, 1995; Riel, 1994). Furthermore, Reid (1997) indicates that the demand is high but the supply is low for methods of assessing the teaching and learning experience in online education.

Therefore, this case study was conducted to solidify a plan for assessing the teaching and learning experience while using an interactive web module in an educational psychology teacher education course, ESEC 443, at California State University, San Bernardino (CSUSB). The course instruction is designed to embed practical applications, such as teaching strategies and learning tools, within a theoretical framework. In this course, the World Wide Web (WWW) is employed as an educational device where it provides a variety of sources, thereby significantly broadening the spectrum of practical applications. For example, it is a source for finding innovative lesson plans and current educational research and practices (Hazari & Schnorr, 1999).
This case study observes the applicability of the interactive web module within the classroom from the standpoint of the module’s ability to be used in facilitating learner growth as defined by the construct of higher order reasoning.

Theoretical Foundations

The World Wide Web is ideal for teachers who wish to use interactive technology to enhance learning within their courses. Since the Web is a newer medium that requires its own presentation style, careful planning is required to building effective Web pages that use learning theory as their guide (McKenzie, 1995). Such learning theories include Constructivism, Cognitive Behaviorism, and Cognitive Social Learning. Bednar, Cunningham, Duffy, and Perry (1992) strongly recommend applying theories of instruction to learning. The Constructivist theory incorporates pedagogical goals for the process of constructing knowledge by providing appreciation for multiple perspectives, embedding learning in relevant contexts, encouraging ownership in the learning process, embedding learning in social experience, encouraging use of multiple modes of representation, and encouraging self-awareness of the knowledge construction process (Vygotsky, 1986; Bruner, 1990). By virtue of its interactive nature, the WWW is a complement for a Constructivist learning environment.

Additionally, Relan & Gillani (1997) define Web Based instruction as, “the application of a repertoire of cognitively oriented instructional strategies implemented within a constructivist and collaborative learning environment, utilizing the attributes and resources of the World Wide Web” (p. 43). Furthermore, effective Web Based Instruction promotes student centered cooperative learning (Johnson & Johnson, 1990), critical thinking (Beyer, 1988; Ennis, 1989), communication skills, reasoning power, in a non-discriminatory environment that takes into account student cognitive styles by offering a multi-sensory interface that supports interaction and contextual learning.

The Study

The participants in this study were thirty-two students in the Single Subject Credential Program (SSCP) in the College of Education at CSUSB. The focus of the SSCP is to prepare educators who will evaluate current school practices and imagine teaching and learning in new ways. This program is designed in three phases: foundations, pedagogy, and Praxis. The phases lead candidates through a process in which ideas, models, and skills are continually reexamined and expanded. The SSCP is based on the philosophy of education embodied in five intersecting themes: diversity, curriculum in social contexts, critical reflection, communication, and academic competence (Handbook for the Single Subject Credential Programs, 1999). CSUSB can be described as serving a diverse population with a significant ratio of minority students, specifically Latino and African-American. The students can also be described as a primarily commuter population. The average socioeconomic status of the surrounding community is lower to middle income. The majority of the participants of the study had little (less than 2 years) of teaching experience.

This case study observes students in an adolescent psychology class, which met once a week over ten weeks. The interactive web module was introduced in the first class, and each consecutive class involved integration and expansion upon the module’s uses in the course. All instructions relating to the use of the web module were given during the first session by the instructor. Supplementary instructions were given over the time of the course on a one-to-one basis and as a reminder within the class instruction. In the first session, the students were asked to complete an on-line questionnaire and to pay particular attention to the following components of the instructor designed web module at http://soe.csusb.edu/schnorr: 1. Informal assessment/critical thinking questions, 2. On-line practice quiz, 3. Links within each chapter that would provide lecture notes and alternative WWW resources, 4. Examples of former students’ projects.

The data collected in this study were 1. Student Interview, 2. Pre/Post test assessment: Principles of Learning and Teaching: Grades 7-12, 3. Summary of technology use as indicated by student/ teacher discourse, 4. Evaluation of the Cal Press rubric for the study’s critical thinking assessment needs. The collection took place over the ten-week quarter period.
Findings

Student Interview

The student interview was chosen as a data source because of its ability to provide the descriptive self-report of any perceived influence of the web module application on the outcome of the learning process from an end-user perspective. This report includes affective and intellectualized descriptions of the experience. This data source was analyzed for underlying themes relating to the web module's use by the student. The interview was conducted through electronic mail after verbal acceptance for participation was obtained. The student chosen was female, Caucasian and in her mid-forties. She was chosen because of her stated lack of experience with Internet technology use before the class. The question asked was open-ended and was administered and analyzed by the research assistant. The interview consisted of the following open-ended question: “Tell, in your own words, about using the technology in class. Please be as complete as possible by describing the process from beginning to end. If possible, please include your feelings and thoughts as they occurred throughout the class.” The interview response revealed several themes.

Theme 1: Use of the web page as an instructional tool allows the class experience to become relevant to the student's personal life.

The interviewee said, “Because Dr. Schnorr encouraged us to write our Learning Projects in an area where we felt strong in order to LEARN TECHNOLOGY, I now feel that I could move beyond this and use the same tools to learn about other topics and fields of study. One of the goals of learning is to keep learning outside of the classroom and continue to grow as a person in a more holistic approach to learning. In my Learning Project, I wanted to incorporate a broader base of cultural awareness as related to the arts. I did research and was able to connect to the Getty Museum discovering they had a vast amount of information on Cultural Context and Cooperative Learning among Students. I also became aware that I could research the art of many countries and museums all over the world.”

Theme 2: The interactive technology is seen as an unknown, which has negative implications for the user from the first day. The initial emotional reaction to the unknown was anxiety.

The interviewee said, “I am an artist; therefore, abstraction is difficult for me at times. The computer itself seemed so foreign. I had been using the computer basically in the WORD program to type reports and to keep records. I had never been on-line, surfed the Internet or used E-mail. My first reaction to Dr. Schnorr's expectations of integrating technology into the classroom experience was anxiety.”

Theme 3: The teacher/educator, over time, provides a non-threatening environment where the student can overcome initial anxieties.

The interviewee said, “She (Dr. Schnorr) had a web page with all other important information and went through it in class with us. This turned out to be very empowering. Dr. Schnorr was able to give us tremendous access to a rubric and exact requirements for each assignment. She also had several illustrations of other learning projects so that we could further understand what a successful project should look like. Dr. Schnorr was able to show us power point presentations on a large screen instead of using an overhead--modeling. I didn't even know what a Power Point presentation was! That isn't really even important--she exposed me to new information that became clearer later.”

Pre/Post Test Assessment

The pre/post test assessment instrument was used to observe if the web design had any influence on the students' critical thinking ability in relation to a standardized instrument. The instrument used was the Praxis Series On Line- Professional Assessments for Beginning Teachers. The Principles of Learning and Teaching: Grades 7-12 (0524)[www.teachingandlearning.org/licensure/praxis]. This instrument assesses the student's knowledge of educational psychology principles. This test was designed to assess beginning teacher's knowledge of a variety of job-related criteria. The exam assesses knowledge on human growth and development, classroom management, instructional design and delivery techniques, evaluation and assessment. There are fifteen (15) total questions with thirteen (13) multiple choice questions and two (2)
essay. The pre-test and post-tests were given to all thirty-two (32) students in the first session of class. The results for the pre and post-test were analyzed both quantitatively and qualitatively. The essays were quantitatively scored using the rubric provided in the Test at a Glance booklet produced by the Praxis. The possible essay scores ranged from 0-3. The essays were then qualitatively scored using the guidelines from the booklet that had been modified to allow for the student's application of practical knowledge. The results of this analysis revealed that this instrument was not appropriate for the purposes of assessing critical thinking within a constructivist context. The standardized appropriate answers as outlined in the rubric did not account for the unique experiences that face the teachers in this sample.

Summary of Technology Use

The electronic mail represents the discourse between the instructor and students. This discourse took place over the ten-week course span. The analysis consisted of reading for and finding common themes that existed within the messages. The instructor noted that throughout the course, the same students seemed to be taking advantage of such features as the informal assessment templates and e-mail use.

Rubric Suitability

The Holistic Critical Thinking Rubric was the device chosen to measure the student's level of critical thinking employed in the pre/post test and on the students' learning project. The Holistic Critical Thinking Rubric is constructed by the Cal Press and can be found at http://www.calpress.org. The rubric was found limited in its ability to score the level of applied critical and creative thinking skills of the student. This instrument requires the learner to analyze, among other cognitive skills, opposing arguments without bias. The Learning project reflects some level of creative thinking. The student has the potential to take from the educational psychology theories presented in class what is necessary and develop an applicable product to the student's own experience and, in doing so, that type of learning does not fit within the guidelines of this critical thinking rubric.

Conclusions

The objective of this study was: (a) to explore the role of technology as it relates to learner goals and learner outcomes as determined by the researcher's theoretical foundations for instruction, such as Constructivism and Cognitive Social Learning theories; and (b) to validate the choice of rubrics for quantifying learner outcomes in relation to higher order reasoning. The outcomes of this study can be described as falling within two categories: 1. necessary procedural modifications for the subsequent experimental research study (i.e. independent variable or treatment issues) and 2. modifications of the researcher's learning theory construct and ideals about use of the web-based technology in relation to higher order reasoning (i.e. dependent variable or measuring issues).

Treatment Issues

The data that resulted from student online correspondence with the instructor (e.g. e-mails, on line questions, and etc.) and the student interview, lead to the realization that procedural changes were needed for introducing and reinforcing the use of the internet within the course. The analysis of the online correspondence said that the use was minimal and, in fact, isolated to a minority number of students with definite trends within the correspondence (e.g. lack of understanding about an assignment, or request for additional information.). The only time that there was a guaranteed use of the technology was if it was required, as in the case of the Learning Project Contract. To compound this issue, the interview revealed that initial levels of anxiety are produced when being introduced to technology while also being introduced to another educational context such as educational psychology. There is inherently a level of anxiety that is attached to learning something new- educational psychology, and that anxiety could be increased with the introduction of technology. This led to the identification of procedural issues for the ensuing study that would need to be addressed.

The following question emerges from these results: “How can the instructor reduce anxieties toward
technology in the beginning of the course while increasing the likelihood that it is being used effectively?

First, the technology must be accessible. The researcher could not count on ongoing use outside of the classroom setting, therefore the class would be held in a computer laboratory or near one where the whole class could be transferred. Through integrating the technology more as an in-class activity, its use would be convenient and students' learning curve could be increased. The most promising aspect of the in-class use is the scaffolding that could be provided by both the instructor and the peers; this would encourage the technology use, specifically in required assignments such as the Interdisciplinary Group projects.

Secondly, a non-threatening task must be given in the first class that enables the instructor to diagnose the technology-related weaknesses and strengths of the students. After the first class, the instructor can give an outside class activity using the web module so that during the next class such problems as interface issues can be assessed.

Measuring Issues

The need for modifying the researcher's construct on learning theory foundations in relation to the web-based technology came from two different sources, one being the analysis of the scores from The PRAXIS Series: Principles of Learning and Teaching: Grades 7-12 Sample Exam used as the pre and post-test. During the attempts to score the tests as prescribed by the scoring guide given with the sample exam, a discrepancy was determined in what was believed to reflect higher-order answers for the essay questions yet would not have been considered as such by the instrument's scoring guidelines. According to the scoring guidelines, what could be expected to be a “correct” answer was a standardized answer based upon discrete theoretical origin to the exclusion of answers that include, and value, personal experience within the context asked. This led to the findings that the use of the Sample Test for the purposes of this study was an invalid assessment of what the researcher believed was the effect of the web-based module on critical thinking skills. This study also had an impact on questioning the suitability of the Cal Press rubric for assessment of the thinking levels that emerged from the learning project assignment within this research study which appeared to be more creative in nature. These findings also lead to the realization that clarification was needed between the constructs of critical thinking and creative thinking. Critical thinking is considered evaluative thinking that is logical and creative thinking is defined as the ability to deal with a problem in an original way (Wakefield, 1996).

Finally, the researcher discovered that in the same way that various instructional strategies and assignments within a course target varying levels of reasoning and cognition, so do varying elements of instructional Internet designs. Whereas this researcher thought that some of the Internet scaffolding techniques produced higher order reasoning, the questions and feedback from the instructor with student use of the on-line critical thinking template, in some cases, narrowed the students' thinking more closely to the instructor's desired response. In line with all of the findings outlined above, the researcher's construct of what constituted higher order reasoning skills (critical and creative thinking) was determined as requiring realignment, and in fact, a more solid definition. The following question emerges from these results: Are there valid quantitative measures for critical and creative thinking given the qualitative nature of these constructs? Secondly, how does the interplay between the expected outcomes of the assignment itself and the use of the Internet in relation to that assignment affect learner outcomes? Thirdly, do unique components within the instructional Internet design target differential learner outcomes?

Recommendations

The results from this study have provided us with a solid framework from which to approach the subsequent quasi-experimental and qualitative research design that is outlined at http://soc.csusb.edu/schnorr/matrix.htm. The most pragmatic result was the determination that the ideology of the expected learner outcomes based upon Constructivist and Cognitive Behavioralist constructs required redefinition and realignment and how the web module design effects those outcomes. This result has led to the creation of a checklist (http://soc.csusb.edu/schnorr/matrix.htm) that can be used to evaluate the following ideals in concert: 1. the learning theory that provides the purpose for the web module design, 2. the relationship between the learning theory and the web module design components that align with that theory, 3. learner outcome assessment tools that align with the goal of the web module design.

Student Teacher Educational Technology Use

Allen H. Seed, Ph.D.
School of Education
Northern Kentucky University
USA
seed@nku.edu

Abstract: This paper deals with the use of instructional technology by student teachers. According to the results of three years of surveys, student teachers at our university are reporting limited use of instructional technology during this experience. Data from the surveys illustrate the restricted use of instructional technology, which technologies are being utilized, and some of the causes for concern.

Introduction

While working with colleagues in the Chemistry Department at Northern Kentucky University to develop a chemistry class for pre-education majors, I arrived at the idea of surveying our student teachers to see if the course had any impact on their use of educational technology. The following paper discusses the results of the survey, some implications, and direction for further research.

The Study and Findings

The following data were gathered over a three year period in which student teachers from Northern Kentucky University in the Elementary and Middle Grades Education Programs were surveyed concerning their use of educational technology. Surveys were distributed each Spring Semester. One hundred three surveys were returned out of just over three hundred. The overwhelming majority of respondents were female (93.2%). Most (68.9%) were seeking elementary certification.

Only 60.2% reported that they used educational technology while student teaching. Mathematics was the subject area that rated the most use of educational technology (14.1%). English and other subjects each accounted for 7.7%, while science and social studies each rated 6.4%. Many respondents reported that they used technology for a combination of subject areas (57.7%).

The most frequently used hardware was the CD ROM (48.5%). Second was LCD projectors (18%). That was followed by laser disc players (15.6%) and computer interfaced probes (1.7%). Results were consistent for the use of software with CD ROM’s being the most used form of software (54%). Floppy discs were second with 37.7%. Laser discs were used by 21.8% of the respondents and 11.3% reported using simulations. Just over half (51.5%) of the student teachers stated that they or their students used Internet resources.

Student teachers were asked to rate the impact two courses that were specifically designed to promote and model educational technology usage had on their use of technology. The first course was CHE 105: Chemistry and Society. The second course was EDU 313: Computer Applications for Teachers. CHE 105 was rated by 23.1% of the respondents as having impact or the highest impact on their use of educational technology. 48.1% rated EDU 313 as having impact or the highest impact on their use of technology.
while student teaching. Several student teachers rated other courses as having greater impact, but these were courses that few in the program had taken.

Respondents were also asked to answer essay type questions to explain some of their responses to the other questions. The first essay asked, "Why haven't you used educational technology for instructional use?"
The following are quotes from the student teachers:
"Because they were not readily available to me."
"During the first eight weeks of student teaching I was told what and how to teach. During the second eight weeks, we have been covering materials to prepare for [state] testing."
"Technology was not readily available."
"In my classroom, technology is not available. I would like to use it if it would come available."
"The classroom has a few computers but are not set up to teach a whole class. In addition, I don't feel ready to use this technology to teach yet- maybe when I have more experience in the classroom."
"Would love to use computers if available and current teacher supervisors in the school district felt confident with them."

Recommendations

These responses indicate a direction the university and cooperating schools must take to improve the use of instructional technology by student teachers. Professors must model the use of technology in teacher preparation programs, especially those teaching courses in the content areas. University supervisors must encourage and support cooperating teachers to obtain and use educational technology.

Further Research

Interviews and focus groups will be conducted in the spring of 2001 to explore further the data resulting form the surveys and to identify ways universities and cooperating schools can improve student teacher use of educational technology.

The following is a quote from a student teacher you wanted to write his/her own essay:
"I feel like my education I received here at NKU prepared me for my career somewhat. I do not feel as if my computer knowledge or use of technology was enhanced at all. With our growing and changing society NKU should have smothered me with computer work and technological advances."

Acknowledgements

Thank you to the Department of Energy (DOE) and the Kentucky Experimental Program to Stimulate Competitive Research (KyEPSCoR), and Northern Kentucky University for their support of this instructional research project. I also want to express my gratitude to my colleagues in Northern Kentucky University's Chemistry Department: Vinay Kumar, Julia Bedell, and Vernon Hicks.
Project Sun: Teacher Preparation at Brevard Community College

kruppl@brevard.cc.fl.us

Abstract: Brevard Community College (BCC), in partnership with the Florida Solar Energy Center (FSEC), the School District of Brevard County, the Astronauts Memorial Foundation (AMF), and the University of Central Florida (UCF), has submitted a proposal to the National Science Foundation, Advanced Technological Education Program called Project Sun to provide pre-service (BCC teacher education students) and in-service (Brevard County certified) teachers an exciting array of curriculum opportunities and technical experiences to enhance their scientific and technical instructional skills. Project Sun is a comprehensive plan that addresses an ATE project in the Technical Experiences program track with objectives that will provide 1) technical experiences for pre-service (PS) and in-service (IS) teachers, 2) a thematic approach to science instruction, 3) a method of scientific investigation, scientific practice, and thought, 4) exposure to working scientists and educators, 5) recruitment and articulation activities between all institutions involved, and 6) business partnership connections.

Introduction

The educational community does not fully realize and recognize the essential role of two-year colleges in teacher preparation. Nationwide, more than 40 percent of teachers complete a portion of their science and mathematics course work at two-year colleges, with most of the elementary and middle school teachers completing all of their college-level work at these institutions (NSF, 1998). Thus, for most public colleges, opting out of providing teacher education, especially in science, mathematics, and technology, is not a choice. Pursuing a concentrated effort to improve teacher education is both practical and moral (Gonzalez 1999). According to an industry task force, many teachers are teaching "rain forest mathematics" curricula that are light on the tools tomorrow's high-tech workers will need (Leopold 2000).

The solar curriculum and experiments will give impetus for teachers, both PS and IS, to expand their personal and academic capabilities in science, mathematics, and technology education. The four Solar Energy curriculum units ("Solar Matters," "Alternative Fuel Matters," "Solar Wonders," "Building Performance Matters") provide an exciting thematic approach to scientific and mathematical study through a myriad of topics, experiments, and activities. Each of the curriculum units and activities are adaptable and versatile, allowing them to be adjusted up or down to fit any academic level. Common materials and supplies are used in the experiments and activities so that they can be conducted in or outside the classroom. Most importantly, they use a renewable and readily available energy source - the Sun.

The project outcomes will enable educators to integrate creative and intriguing science and mathematic activities into their daily instruction, provide "hands-on" experiences to increase the PS and the IS teachers' scientific and technologic capacities and skills, increase their interest in teaching science and math, connect mentoring teachers with students, and engage educators, scientists, and industry in supporting teacher preparation. In addition, PS teachers will gain a clearer understanding of the career opportunities, roles of responsibility, and challenges of the teaching occupation. They will also be better prepared to continue their
teacher preparation at the university level and be aware of occupations using science, mathematics, and technology skills. The dissemination activities, video, and the community forum will heighten the community’s awareness and sense of stewardship of renewable energy, the importance of quality teacher preparation, and the role of the community in the education efforts.

The Project

The content focus of Project Sun are the solar energy curriculum units developed by the Florida Solar Energy Center, a nationally recognized research institute of the University of Central Florida. The curriculum units are aligned to the national science standards and the Florida Sunshine State Standards.

Summer Sun Academy, a five-day workshop for 25 PS and 25 IS teachers, will be conducted. Subsequent mentorships will be created at this time, which will continue throughout the year as PS teachers complete their field experiences, internships, and curriculum projects. All participants will receive support from each other.

The Project Sun partnership was formed among BCC, UCF, FSEC, AMF and Brevard Public Schools so that each entity would provide resources toward the success of the project. Objectives regarding teacher preparation, enrollment, and articulation are focused on students at Brevard Community College. Founded in 1960, BCC is a comprehensive, public two-year community college in east central Florida, home of the nation’s space program. In 1999, BCC enrolled over 14,000 students in degree and vocational courses. In 1997, Forbes Magazine listed BCC as one of America’s top 20 “CyberU’s”—the only community college to receive the distinction. In addition, The Association of Community College Trustees has recognized BCC as one of the two most outstanding community colleges in America in terms of equal opportunities for women and minorities. The primary target population for the project participants is BCC students who have completed or intend to soon enroll for an education course. The secondary target population is in-service elementary school teachers in Brevard County, particularly those from schools with the highest percentages of children from low-income families. Participants should already have introductory computer skills. Before Sun Academy, participants will complete a technology self-evaluation rubric; they will also be encouraged to visit Web sites such as Computers for Lunch as a learning-readiness activity.

Designed for future and current elementary teachers, Project Sun’s content of instruction focuses on the top three most requested training needs: Internet, PowerPoint, and Web design. This training will not duplicate existing training already provided by BCC or Brevard Public Schools, but rather complement and support other technology training. Project Sun consists of a summer workshop and school year activities. Project activities directly address the project objectives.

a. Sun Academy. The Sun Academy is an intensive, five-day workshop for 25 in-service and 25 pre-service teachers per year with a dual purpose of increasing technological literacy and science/math preparation. Sun Academy was developed in direct response to surveys which documented needs of elementary school teachers in Brevard County for integration of technology into the curriculum and specific technology applications. Pre-service teachers will choose to receive either a stipend or a fourth credit hour to the EME 2040 Teaching with Technology course; in-service teachers will receive 35 in-service points and a stipend. This Academy will unleash the technical potential of the participants, giving them practical experience in using the tools of technology, expose them to a thematic curriculum approach, and give them confidence in their own potential for teaching science, math, and technology. Participants receive a Project Sun notebook and are encouraged to keep a journal of their progress.

The Project Sun’s PI and Co-PI will supervise. During Sun Academy, activities are performed in teams that contain both in-service and pre-service teachers in order to build group problem-solving skills and develop mentoring relationships. The following is a schedule of activities for Year 1. Years 2 and 3 are similar except that 1) previous Project Sun participants will make presentations at Sun Academy about their experience, and 2) instruction will change according to what is most suitable and requested in the yearly survey of technology training needs in Brevard County.
Activities

The project activities during the academic year will directly address the objectives for technical experiences, preparation of teachers, recruitment, and partnerships. Providing experiential and hands-on activities with technologies and applications to PS teachers is a primary objective. PS teachers enrolled (approximately 300) in the BCC "Technology for Educators" course will learn to use and understand technology tools of the classroom teachers by engaging in the improvement of the existing solar energy posted on the FSEC website (www.fsec.ucf.edu/ed/teachers). Under the instruction of key faculty, students will develop, create, and integrate interactive components, a FAQ section, animation, video, and other activities for the text-based curriculum, making them livelier, real, and more interesting to teachers and students.

DAYS 1 – 2: Instruction for Sun Academy will be delivered by BCC technology and education faculty and Florida Solar Energy Center (FSEC) staff on Days 1 to 4. Participants will work in teams to evaluate "Solar Matters," a solar energy curriculum unit that includes 25 inquiry-based, cooperative learning projects for upper elementary school/early middle school students. Currently posted on the FSEC Teacher Web site (www.fsec.ucf.edu/ed/teachers), "Solar Matters" is one of four Solar Energy curriculum units developed by FSEC, a nationally recognized center of UCF. "Solar Matters" is aligned to the national science standards from the National Research Council, and the Florida State Sunshine Standards for science and math in Grades 4-8.

Currently, "Solar Matters" is pages of static text; participants will develop ways to improve the curriculum, based on current research they have just reviewed on effective educational technology strategies. Teams will develop, create, and integrate interactive components, a Frequently Asked Question (FAQ) section, word problems, and activities to the text-based curriculum to make it more learner-centered, interesting, and user-friendly for teachers and students. Participants will also learn how to make Web sites accessible for all students, such as creating audio files for blind students, or ensuring that all cultures are represented in graphics of students and teachers.

Participants will learn how to use software programs such as QuizPlease or Hot Potatoes, which are user-friendly ways to add interactive quizzes to the Web sites. They will be instructed in using presentation software (such as PowerPoint and Kid Pix) which allows you to draw and animate models, and to add slides to Web sites. They will also gain experience in searching the Web for the many freeware/shareware resources available to enhance Web sites (such as clip art graphics, sign-in guest books, counters, puzzles, chat areas, bulletin boards, and more).

In addition to advancing their knowledge of technology and science, participants will increase their math skills as they create original math word problems for "Solar Matters" which includes integrated curriculum that aligns with state math standards. They will also perform math while working with "Solar Matters" activities that require calculations of time, temperature, angles, and population demographics.

DAY 3: Participants will develop a Sun Kids Web site, appealing to all levels from elementary to secondary. Participants will learn to use Microsoft FrontPage or Publisher for Web site creation, which are ideal for beginning Web authors. (They are also the two Web design programs that come with versions of Microsoft Office 2000, which was one of the top programs Brevard elementary schools requested training in). Web site highlights will include a Guest Scientist section, FAQ's, Learning Centers, a Discussion Forum for students to exchange ideas with others around the world, an Ask Professor Soleil column, solar experiments, and activities for home or school use.

DAY 4: This instruction is at The Astronauts Memorial Foundation. Participants will choose a solar energy activity/experiment from "Solar Matters" to perform. Having participants perform the experiments they will teach their students is crucial to their development as teachers. One study notes that 19% of third graders never perform experiments in science class; that many pre-service elementary teachers have misconceptions about science; and that many elementary are reluctant to teach science due to an inadequate science background (Sutton). Teachers who model scientific inquiry and technology use are more effective in the classroom.

Participants will rehearse and then videotape each other's presentations using digitized video cameras, or they will take a series of still photographs with Mavica digital cameras. (98% of elementary schools in Brevard County have digital cameras and/or video editing equipment). (They are also the two Web design programs that come with versions of Microsoft Office 2000, which was one of the top programs Brevard elementary schools requested training in).

DAY 5: At AMF, participants edit their videos on iMac computers (Macintosh computers outnumber PC computers at Brevard elementary schools 2 to 1). Participants will use iMovies digital editing software, which turns the series of digital still photographs into a motion picture. Final presentations will have participants exhibit their movie and then burn it onto a CD for use in a resource library. At the end of Day 5, there will be a "graduation" ceremony where participants receive a Certificate of Completion and a Sun Academy T-shirt. Each school represented at the Academy will receive a curriculum unit and a "Solar Matters"
Kit composed of enough materials and supplies to recreate Academy experiments.

b. Follow-Up Activities During the School Year. Learning is more meaningful when placed in a context with practical applications; learning technology is no exception. Once participants have completed the summer academy, they are Sun Academy graduates. It is expected that 90% of graduates will continue with follow-up activities throughout the following school year; several will continue to be involved with Project Sun for the full three years of the project. They will remain involved in Project Sun due to a comprehensive plan of project retention, which includes academic support, mentoring relationships, electronic conferencing, and workshop opportunities. The project expects to compensate for the estimated 10% of Sun Academy graduates (five) a year who choose not to follow up. Five pre- and in-service teachers a year who are interested in participating in some of the school-year activities may do so with a colleague who attended Sun Academy; they will be recruited for the next Sun Academy.

All education, math, science, and technology faculty at BCC will be involved in helping Sun Academy graduates who are BCC students to build on the knowledge gained at Sun Academy. Education students at BCC take the core courses Introduction to Education, Teaching Diverse Populations, Teaching with Technology, and Introduction to Special Education—all of which are available as distance education online as well as in a traditional classroom. Particularly in the EME 2040 Teaching with Technology course, students will reinforce the technology skills learned at Sun Academy. Specifically, they have assignments that require them to make PowerPoint presentations, practice with digital cameras and digital video cameras, use the Internet extensively, and evaluate educational Web sites.

Participants are encouraged during Sun Academy to find a mentor and also be one themselves throughout the school year. Mentoring relationships do not necessarily have an in-service teacher as mentor and pre-service teacher as protégé. A pre-service teacher needs an in-service teacher as a role model for pedagogy, but may be more technologically literate and can act as a mentor as well. A national study found that teachers with three or fewer years of experience were more likely to feel well-prepared to use computers than teachers with 20 or more years of experience (Rowand 1999).

BCC education students are required to go into the schools for classroom observations. In the past, this has been simply observing pedagogy. Project Sun participants, with the cooperation of the supervisor teacher, will do their observations in classrooms supervised by in-service teachers who allow the student take a more active role. During their in-school time, participants will use technology to support innovative assessment of students, as described by Sheingold and Frederiksen (91-108). Participants will use An Educator's Guide to Evaluating Use of Technology in Schools and Classrooms (Quiñones et al. 1998), which describes benchmarks, indicators, and methods of collecting information with nine worksheets that cover topics such as “Why am I evaluating?” “What questions should I ask?” and “How do I communicate my results?” Participants will fill out these worksheets as they observe students going through Solar Matters and Sun Kids. To develop reflection on their progress, participants will add to the journals they began at Sun Academy. Participants can decide to keep the journal private, submit it to project directors, or post it on the Web site.

To promote awareness of technologies and the teaching career, participants will create an Inquiry Group among themselves, with support from project directors and education faculty. The Glenn Commission recommends Inquiry Groups because “however well they may have been prepared to teach, and whatever knowledge they may have gained in Summer Institutes, all teachers need continuing, collegial contact, peer reinforcement, and input from experts to sharpen their skills and deepen their subject knowledge.” Participants will make a field trip to the Instructional Technology Resource Center at UCF in Orlando to increase their knowledge of current teaching technologies. They will also visit FSEC to learn about the origins of the solar energy curriculum, and to meet scientists who are conducting research on renewable energy for commercial and non-commercial use globally.

The Inquiry Group will set up an electronic discussion group (also known as a listserv), develop their mentoring relationships by E-mail, arrange real-time chat sessions to discuss a variety of topics, take electronic field trips, and post lessons (in-service teachers) or notes from their observations (pre-service teachers) on the Web site. The listserv and chat sessions will help participants organize a Renewable Energy Community Forum featuring a variety of guest speakers. This will be an opportunity for Project Sun participants to gain experience organizing and disseminating results of an educational forum, increase their knowledge of solar energy, and meet working scientists, government representatives, business and industry leaders, and other educators.

c. Increasing Enrollment and Diversity. Increasing the number and diversity of prospective K-12 teachers at BCC is a key concern of Project Sun (Objective 3). It is crucial to the future of teaching to be more inclusive,
and teachers should reflect the diversity of the students they teach. While minorities comprise only 13% of our
teachers, almost 30% of our students are from minority populations (NCTAF, 1996). The Project Sun Director
(Principal Investigator), Dr. Krupp, will create recruitment materials that explain the AA degree and how to
make a smooth transition to UCF. Other materials will be created for BCC students in math, engineering,
science, and technology classes, encouraging them to consider a career in teaching. This effort is aided by a new
incentive by Brevard Public Schools to give teachers in math, science, and special education $1,000 sign-on
bonuses. Participants from Sun Academy who want to expand their experience producing and editing video
will make a video of Brevard Public School teachers describing the rewards of a teaching career, and current
BCC and UCF education students talking about how much they enjoy their major.

In addition, the PI will work with BCC Minority Recruitment and Retention and the Office for
Students with Disabilities to create materials to encourage the enrollment of those traditionally under-
represented in elementary education, such as males (only one out of ten elementary school majors is male), and
those from minority, low-income, and disabled populations. As role models are an important factor in deciding
da college major, BCC elementary education students who are from an under-represented population will be
available at career fairs and on the video discussing their background and why they chose to pursue a teaching
career. This effort will work hand-in-hand with Brevard Public School’s recent efforts to increase minority
teaching candidates. The Project Director will also work closely with the local One-Stop Center to develop
materials to specifically target career changers. Materials will show, among other information, that the Brevard
average teacher’s salary is above the Florida average (Gonzalez, 2000).

The Project Sun PI will also visit high schools to talk about the education major, to promote Project
Sun, and to encourage seniors to attend Sun Academy when they graduate. At Rockledge High School, students
are enrolled in a new “Exploratory Education” course where they get training and then teach children at Hoover
Middle School with reading. The 30 students in the program will be the focus of recruiting efforts. Retention of
current students in the BCC education program will be improved by Project Sun as well as by the establishment
of a Future Teachers of America chapter at BCC.

Pre-service teachers will be tracked through the duration of the project to determine their progress
toward graduation, certification, employment, and preparation. Project directors will cooperate with longitudinal
studies to track students beyond the grant period, in order to follow them through their first year of teaching
(which may be five years after entering the project) and see that they demonstrate successful performance in the
classroom.

d. Articulation Partnerships. Currently in Florida, students who are awarded an Associate of Arts degree are
guaranteed complete acceptance of the community college credits toward their Bachelor’s degree. Articulation
agreements exist between BCC and UCF on the prerequisites necessary for a teacher education degree program.
The Articulation Committee, consisting of administrators and instructors from BCC and UCF, will be
responsible for reviewing the current articulation agreements and course requirements to determine what
modifications are necessary to ensure that: 1) courses are aligned with state and national requirements; and 2)
students have a smooth transition into an upper-division teacher education program. The Committee will survey
UCF students who transferred from BCC to determine their satisfaction with the information, academic
counseling, and services received during their transfer. The survey will elicit suggestions for improvement from
students, and use the results to improve the transfer process.

Conclusion
Project Sun intends to be a statewide and nationwide model for improving teacher preparation. The results of
the project will advance knowledge in the fields of technological literacy for teachers, theme-based science
teaching, alternative energy education, mentor relationships between pre-service and in-service teachers, and the
transfer process from a two-year college to a four-year university.

Abstract: The expansion of educational technologies in the College of Education at the University of Florida has resulted in three interrelated phenomena: (1) the development of educational technology support throughout the College, (2) the integration of technology within our teacher education program and other programs throughout the College, and (3) the expansion and revision of our Educational Technology degree program. This paper explores these three interrelated phenomena in detail.

Introduction

A metamorphosis has been occurring in the College of Education at the University of Florida in recent years. In increasing numbers, faculty and students alike are using technology to create and provide meaningful and engaging learning environments. The expansion of educational technologies in the College of Education has resulted in three interrelated phenomena: (1) the development of educational technology support throughout the College, (2) the integration of technology within our teacher education program (ProTeach) and other programs throughout the College (i.e. educational technology for non-majors) and (3) the expansion and revision of our Educational Technology degree program. Figure 1 illustrates these three interrelated phenomena and the rest of this paper further explains each in detail. Please see our web page for more information: http://www.coe.ufl.edu/Courses/EdTech/ET.html
Support Structure

The importance of having a support structure for students and faculty cannot be overlooked when infusing educational technologies into the College of Education. Without a robust and changing support system, many, if not all, of the technologies will be underutilized in this learning environment. It is critical that all members of the College of Education community learn not only fundamental skills for using educational technologies but also to develop strategies for seamlessly integrating these educational technologies into the daily learning environment. Currently, the College of Education has four areas of support dealing with access, skill acquisition, and professional development.

CIRCA labs and Equipment
Students have access to the university supported computing labs (CIRCA labs). Located within the College of Education are two labs of 25 G4 Macintosh computers. These labs provide students access to scanners, printers, and numerous specialized application packages. In addition, there is at least one computer consultant on duty in the College of Education labs.

College of Education computer lab and Equipment
The College of Education computer lab is primarily used by the Educational Technology program and for college-wide faculty development. This lab has 15 G4 Macintosh computers, digital video cameras, scanners, video acquisition machines, video editing software, high-level production packages, laser disc players, and a CD ROM burner. Students work in the lab on class projects when the lab is not being used for classes. With the abundance of classes and the popularity of the lab, it is rare to find a time when the G518 lab is not being used. This lab allows students to have access to equipment and also provides a place for skill acquisition and professional development. Educational technology faculty offices are located within this lab so there are always graduate students and faculty around the lab to provide assistance.

Faculty Development Workshops
The Office of Educational Technology, an academic computing group of staff and graduate students, has recently been established in the College of Education to support faculty in the integration of technology into all curricular areas. New faculty meet with the Director of the Office of Educational Technology to determine technological fluency and to provide suggestions for integrating technology into the classroom.
and work environment. Faculty new to using technology are building skills in workshops and gaining insight on strategies for using technology in their courses. In addition, graduate students serve as mentors/coaches for new faculty members. More experienced computer-using faculty receive instruction in advanced computer applications as well as learning strategies for effectively using technology in the curriculum.

Educational Technology Online Support Center

In 1994, we decided that many of the support documents we were creating for our courses transcended an individual course. As a result, the web-based Educational Technology Support Center was developed. It has undergone several transformations as different groups of students worked on its evolution. We now offer support to new students, school children, teachers, and those interested in developing technological skills. The existence of the support center has had an impact on K-12 schools, where students often use our reference pages to learn how to build web pages, and on our own courses, where we no longer teach web page development directly. Although the Educational Technology web suite is now extensive, we envision a time when institutional resources will be directed at our web presence, allowing us to build a more robust virtual "knowledge community". Since our students are both producers and consumers of information, our web suite should become an interface between the global infosphere and our particular corner of it.

Non-majors in the Educational Technology program

The faculty, staff, and students in the College of Education recognize the need for technological fluency for success in the 21st century classroom. Teachers at all levels must be able to appropriately utilize educational technologies in their learning environments. This thrust in the College of Education has prompted the development of several courses and an alternative certification program. Described below are only a few of the courses and programs available for different audiences within the College of Education.

EME 2040: Introduction to Educational Technology

EME 2040 is an introductory technology course mandated by the state for all declared education majors. With the organizational structure of the teacher education program, this class primarily contains elementary education students. (Secondary education students obtain a baccalaureate degree in their field and declare majors in their area of specialization.) This course is designed to introduce students to current and emerging educational technologies, and frameworks for critical assessment of the changing nature of humankind's relationship to information and knowledge. By examining the influence of specific technologies on education, society, culture, economics, politics and history, the course analyzes human to human communication and our expanding knowledge base. By comparing and contrasting research and instructional models the course addresses innovation diffusion, paradigm shift, and the nature of change at a local, regional, and global level. Simultaneously, students are required to engage in laboratory activities designed to expand their personal horizons with respect to technology. Further information can be found at http://www.coe.ufl.edu/courses/EME2040/2040.htm.

EME 4406: Integrating Technology into the Curriculum (Secondary Sections)

EME 4406 is one of the required courses in the education minor for students in the College of Liberal Arts and Sciences. This is frequently the first computing course that students encounter in their educational experiences. Integrating Technology into the Curriculum is a hands-on and discussion/lecture/group-based course designed to give students experience with the infusion of computers into curricula. Students engage in activities that are based on the idea that a learning concept involves viewing it from multiple perspectives to accommodate different types of learners. Students also gain first hand experience in creating activities that span academic disciplines and address a wide variety of learners. Additional information can be found at http://www.coe.ufl.edu/Courses/EME4406Sec/4406.htm.
EME 4406: Integrating Technology into the Curriculum (Elementary Sections)

EME 4406 is designed to help students think about how technology may be used to enhance and extend elementary teaching. While students learn many technology skills during the semester, the primary emphasis of this class is on teaching and learning in the elementary school. Two very basic questions about how and when to use technology guide the class (Harris, 1998): (1) Will the technology enable us to do things we couldn't do before? (2) Will the technology enable us to do things better than we could before? Other fundamental principles that guide the class include the use of technology to promote content area learning and constructivist teaching principles, alternative assessment strategies, reflection and integration of state-mandated standards. More details are available on the class website: http://www.coe.ufl.edu/Courses/EME4406elem/home.htm.

Content Integration Course for Secondary ProTeach

Students in Secondary ProTeach have classes to learn strategies of using technology in their area of specialization (mathematics, science, and social studies). In this setting, students gain experience in using specialized software for their field and in creating technology-rich learning environments. For example, mathematics students learn methods for using software packages such as Cabri Geometry and the Geometer's Sketchpad as well as various Internet sites to enhance student learning opportunities. Students in the science and social studies classes also learn to use specialized software packages and technology integration strategies for their field.

Electronic Portfolios

In the fall semester of 1999 the Proteach students at the University of Florida began creating electronic portfolios as a way to demonstrate proficiency in the state of Florida's 12 accomplished practices. These are process portfolios which evolve throughout the student's education in the College of Education. Through the development of electronic portfolios students will understand and operationalize an evolving relationship with the accomplished practices. All students in teacher education certification programs create and maintain an electronic portfolio. An extensive support system is currently being created to assist students and faculty in this endeavor. Additional information can be found at http://www.coe.ufl.edu/school/portfolio/index.htm.

Project SITE

Project SITE (Site-based Implementation of Teacher Education) allows students to earn a Master of Education degree in Elementary Education and be eligible for certification. This project is offered jointly by the University of Florida’s College of Education and the School Board of Alachua County. The site-based program is an intense 4-semester sequence that includes 48 credit hours of study and classroom teaching under excellent supervision.

This alternative to traditional teacher preparation provides a learning environment in which the graduate student's previous careers and volunteer experiences supplement their classroom instruction. This results in new teachers whose rich experiential backgrounds enable them to relate well to a wide variety of students.

Formal course work is taught at both the University of Florida’s College of Education and the Alachua County Schools. Instructional strategies and methods are taught by practicing classroom teachers, administrators, and University of Florida faculty. The theory learned in course work is applied through daily classroom apprenticeship, with the intern working under the guidance of a mentor teacher.
Educational Technology Majors

The Educational Technology program accommodates students with a wide variety of interests and career goals. Although most of our students find positions in K-16 educational settings, some are employed in the private sector as instructional designers, multimedia developers, and content providers. In order to meet the particular needs of our students, we have developed four areas of study or tracks. The delineation of the program areas helps students decide which courses are appropriate for their career goals. The four program areas are Information/Media Specialists, Instructional Design, Production, and Teaching and Teacher Education. Following their interests, students often take courses outside of their specified track. Descriptions of the areas of study follow:

Information/Media Specialists

The information/media specialist track is intended to prepare students for service in preK-12 school media centers. Successful completion of courses in this track leads to qualification for Florida certification as a school media specialist. Students in this track take core library/media courses as well as courses in communication theory, video production, and computer applications.

Instructional Design

Students in the instructional design track desire to become instructional developers in various settings including government, business, health, industry, and post-secondary environments. Students focus on topics such as the various perspectives of instructional design and message design.

Production

Students enrolled in the production track investigate the dovetail between theory and practice in instructional technology. They develop a theoretical framework which includes conceptualizations of interactivity, graphical design, animation, video communication, audio communication and new media. While developing software, they gain production and programming skills in a collaborative, situated learning environment. Recent projects may be found at http://www.coe.ufl.edu/webtech/index.htm

Teaching and Teacher Education

Students in this track are interested in ways technology can advance student learning in K-12 and/or post-secondary environments. These students desire to become K-12 teachers, K-12 school technology administrators, K-12 computer resource teachers or teacher educators. Most importantly, teaching and teacher education students are preparing to become educational technology leaders in their respective educational environment. Students enrolled in the teaching and teacher education track focus on topics such as designing technology rich curriculum, communicating using the Internet, and distance teaching and learning.

Conclusion

In conclusion, the College of Education at the University of Florida continues to change and development with respect to the use of educational technologies. This metamorphosis can be seen in all areas of the College: students, faculty and staff, and the support structures. Students and faculty alike are benefiting from the infusion of educational technologies into our learning and working environment. These changes are also allowing students majoring in Educational Technology to gain more breadth and depth in our areas.
of specialization. We encourage you to watch us as we grow and change to meet the various changes needed in education for the 21st century.
Work-in-progress project aiming at assessing the Faculty Attitudes Toward Information Technology of Universidade Paulista (UNIP) Post Graduation Course in Brazil

Sandra Mônica Szwarc
Mestrado em Comunicação
Universidade Paulista
São Paulo – Brazil
smszwarc@netscape.net

Abstract: This small paper is a report of the work-in-progress project aiming at assessing the Faculty Attitudes Toward Information Technology of Universidade Paulista – Post Graduation Course in Brazil leading to tailor-made training suggestion at identified areas in order to promote inquiry-based learning and effectively integrate the use of technology into existing curriculum thus increasing teacher-student learning and achievements. Assessment will follow Project for the Longitudinal Assessment of New Information Technologies in Education coordinated by Professors Gerald Knezek and Rhonda Christensen of University of Texas- TECET translated into Portuguese.

Introduction

Universidade Paulista is the biggest private university of Brazil, with over 50,000 undergraduate students nationwide and 3,000 on post graduation courses. Being a private school, the vast majority of their campus possess technology infrastructure although other than for the specific courses in which it is integrated into the curriculum, such as Engineering and Computer Sciences, there is little use of technology in class related activities. The Master in Communications course has plans to implement and increase the use of technology in their courses mostly because one of the areas of concentration of the course is on New Technologies and Education. Nonetheless, there is still no formal body responsible for the dissemination of technical assistance nor a milestone plan to be implemented towards this dissemination and relatively few educators know how to use technology in their classes. The level of current faculty is equivalent to those of the best universities worldwide, all 10 teachers are PhDs, over 50% with Post PHD qualifications (Livre Docencia) and awarded several prizes for their academic production.

The Study

The importance of technological literacy is acknowledged by the teachers and is encouraged through students and social pressures. Technological advances are viewed as powerful agents of change and these educators were used to being agents of change themselves. Not so long ago they knew, each in their specific field of expertise, what was the state-of-the-art in terms of teaching and learning. They are now faced with the challenge of reevaluating their modus-operandi and access the implications of using and recommending technology. However beneficial and cost-effective new technologies may be, they are also viewed a potential threat to universities and faculties, once these so called “new technologies” makes the dispersal of universities students possible (Young, 2000).

In accessing these faculty attitudes toward Information technology and computers in general, we aim at gathering all the necessary data in identified areas of need and in compiling these enable a pre-service and in-
service taylor made course to effectively integrate the use of technology into existing curriculum and increase teacher - student learning and achievements (Knezek et ali,1998).

Project Goals and Aims

1. Assess trends in faculty attitudes toward information technology in UNIP SP – Masters in Communication Course , using FAIT (TECET, 99) as the assessment instrument
2. Suggest taylor-made pre-service and in-service training for in-house faculty
3. Enable effective use of technology in the classroom
4. Enhancement of learning and teaching through research, communication, and productivity strategies
5. Emphasis on hands-on approaches in alignment with local and international standards
6. Encouragement of teamwork, problem-solving, and peer review
7. Provide the grounds for an in-service and post-service training assessment of faculty and students

Plan of Operation

1. Baseline data will be gathered in Brazil from faculty between 2000 and 2001
2. Post status reports and findings will be placed on our local web site.
3. Plan to present a joint project summary report at WCCE '2001 in Copenhagen with PLANIT Panel (Project for Longitudinal Assessment of New Information Technology Attitudes in Education) from the Texas Center for Educational Technology Telecommunications and Informatics Laboratory .

Recommended Instrument

For College/University Faculty: FAIT - 5-point Likert questionnaire (Knezek et ali,1998) courteously authorized for use in this study by Texas Center for Educational Technology .

Abstract: The current focus on technology and Information Literacy (IL) represents an important shift in preservice teacher education from basic skills, which are necessary but not sufficient for students today, toward evaluation, analysis, synthesis, and production. The National Council for Accreditation of Teacher Education (NCATE) recommends infusing IL requirements into undergraduate and graduate programs in teacher education. The NCATE 2000 standards specify that candidates preparing to work in schools must be able to integrate technology appropriately and effectively with IL to support student learning and recognize the importance of using research in teaching. The intent of this study is to observe the complexity of preservice IL processes as they occur in one teacher education program and to describe how one education resource librarian and two professors of education collaborated to provide IL instruction to preservice educators that went beyond the traditional bibliographic instruction lecture format, using active learning methods and constructivist principles to encourage lifelong information literacy.

Introduction

The current focus on technology and Information Literacy (IL) represents an important shift in preservice teacher education. The American Library Association (ALA) defines Information Literacy as the ability to recognize when information is needed and to identify, evaluate, and use information effectively (ALA, 1989; 1998). New knowledge about teaching and learning supports the idea that even though basic skills are necessary, they are no longer sufficient for students today. Schools are now being asked to prepare students who can demonstrate understanding as well as knowledge and skill (Lieberman & Miller, 2000). Because Information Literacy can be transferred across subject areas, improve research, writing, and critical thinking, it helps students interpret and understand the world (Soucek & Meir, 1997).

National education associations are recognizing the need to educate students for lifelong learning in a time of exponential growth of information. In January 2000, the Association of College and Research Libraries (ACRL) adopted new standards for college libraries specifying that librarians collaborate frequently with classroom faculty to integrate Information Literacy into appropriate courses. The National Education Association (NEA) recently introduced Information Literacy into the Teacher Education Initiative Program. The American Association for Higher Education (AAHE) created an action committee to incorporate Information Literacy into their programming. The National Association of Secondary School Principals (NASSP) devoted the March 1998 issue of the NAASP Bulletin to a discussion of Information Literacy.
When reporting on the progress of modifying teacher education to include Information Literacy in March 1998, the American Library Association Presidential Committee on Information Literacy reported that no progress had been made (Progress Report on Information Literacy, March 1998). Their recommendations included developing plans for working with teacher education programs and the National Council for Accreditation of Teacher Education (NCATE) "to infuse information literacy requirements into undergraduate and graduate programs in teacher education." Newly revised NCATE standards reflect this recommendation specifying that candidates preparing to work in schools must be "able to appropriately and effectively integrate technology and information literacy in instruction to support student learning" and "understand the importance of using research in teaching...." (NCATE 2000 Standards).

The Ohio Library Report recommends that library and information literacy instruction be included in the revision of teacher education curricula in order to "ensure that school teachers have the skills needed for effective incorporation of information literacy instruction into the elementary and secondary curriculum" (Jacobsen, 1988, p. 52). In her U.S. Department of Education brochure, Barbara Humes (1999), sites a 1995 study conducted by Rader, listing the following factors as necessary for successful integration into the academic curriculum:

- The institution has a strong commitment to excellent educational outcomes for the students in the areas of critical thinking, problem solving, and information skills;
- Library administrators have long-term commitments to integrate library instruction into the curriculum and;
- Faculty and librarians work together on curriculum development

Purpose

The intent of this study is to observe the complexity of preservice Information Literacy (IL) processes as they occur in one teacher education program. The study describes how one education resource librarian and two professors of education collaborated to provide information literacy instruction to preservice educators that went beyond the traditional bibliographic instruction lecture format, employing active learning methods and constructivist principles (Brooks and Brooks, 1999) to encourage lifelong information literacy skills.

Theoretical Framework

A review of the IL literature provides the theoretical foundation for the study. The areas to be described are IL roles and definitions and critical thinking skill development. Scriven and Paul (1992), define critical thinking as "the intellectually disciplined process of actively and skillfully conceptualizing, applying, analyzing, synthesizing, and/or evaluating information gathered...as a guide to belief and action." Rasool, et al. (1996), point out that an essential element of critical thinking is creative thinking. Learning is an active process in which learners construct new ideas or concepts based on their past knowledge and construct cognitive structures (i.e., schema, mental models) that provide meaning and organization to experiences and allow the individual to "go beyond the information given" (Bruner, 1973). Bloom's Taxonomy (1956) identifies a hierarchy of levels of thinking that increasingly challenge the student to higher order thinking skills.

This study goes beyond the conventional definitions of IL to point out the influence of contemporary learning theory on IL when engaging student teachers in an authentic learning environment. In contemporary learning theory the student is seen as an actively engaged information user, underscoring the importance of developing information expertise. Learning is defined as the active knowledge building through dynamic interaction with information and experience. The information search process mirrors this description of the learning process when students "actively seek to construct meaning from the sources they encounter and to create products that shape and communicate that meaning effectively" (ALA, 1998).

Constructivism is a philosophy of learning founded on the premise that, by reflecting on our experiences, we construct our own understanding of the world we live in. In a constructivist learning environment, students are encouraged to refine or revise their understanding. Five overarching principles are evident in constructivist classrooms: (1) teachers seek and value their students' point of view; (2) classroom activities challenge students' suppositions; (3) teachers pose problems of emerging relevance; (4) teachers build lessons around primary concept and "big" ideas; (5) teachers assess student learning in the context of daily teaching (Brooks & Brooks, 1999).
Modes of Inquiry

A case study research design (Merriam, 1998), based on the qualitative paradigm is used. Through surveys, stories, and an examination of documents, researchers examined the nature of the preservice IL process with an in-depth look at preservice IL during prepracticum methods courses within one teacher education program. Using qualitative methodology, elements found within this case study contributed to the development of an active learning model of IL at the preservice level. The main questions that guide this inquiry are:

1. How does the Information Literacy (IL) program contribute to education courses of one teacher education program?
2. What do student teachers identify as the key influences of IL in the teacher education program?
3. What are the attitudes and expectations of education faculty toward student IL competency?

The participants are two preservice teacher educators, one education resource librarian, and 200 students enrolled in required education courses over a period of two academic years. Contrary to current practice as noted by Collis (1994), that "much computer related teacher education is stimulated and delivered by persons without an academic background in teacher education," the education resource librarian has tenure and is a former classroom teacher. The setting is a state college of 4000 students in the northeast region of the United States, one of nine in the state college system. The Education Resource Center is housed on the mezzanine floor of the college library directly above the main library reference and circulation areas. A collection of over 12,000 items includes children's literature, curriculum guides, textbooks, tests, children's software, compact disks, magazines, kits, posters, games and other multimedia resources. A viewing room for previewing videos and CDs is located at one end of the Education Resource Center. At the opposite end of the Education Resource Center is an electronic instruction classroom used for library instruction classes. Computers on one side of the mezzanine area provide access to the Internet and over 350 electronic databases. Located on the adjacent wall are workstations with children's educational software programs. A number of institutions of higher education maintain similar curriculum libraries to support teacher education programs. The Directory of Curriculum Materials Centers, Fourth Edition, edited by Beth Anderson (1996), describes our center along with 277 other curriculum materials centers in the United States and Canada.

Data Sources

Faculty and student survey data, syllabi, reflective journals, prepracticum field experience manuals, integrated thematic units, reflections on the unitary process and cooperating teacher evaluations were all used to examine the nature of the IL process. These extracted materials are the basis for categories and themes drawn from the data.

Preservice Information Literacy Model

The Preservice Information Literacy Model provides opportunities for students to develop critical thinking skills in the context of active research connecting course work and student practicum experiences with hands-on information literacy exercises. The collaborative nature of the model with on-going consultation between faculty and librarian ensures that IL objectives are consistent with course assignments and requirements of the student practicum experience.

After initial discussion and demonstrations of Internet web sites and search techniques in an electronic classroom, students are given opportunities to explore and evaluate resources that are directly connected to their required course work and field work. Information is gathered, analyzed, synthesized, and evaluated and combined in new ways and eventually applied in the prepracticum teaching site by the student in consultation with the cooperating teacher. Lesson plans designed and implemented by students are assessed by the cooperating teacher and teacher educators.

Outreach into the community to facilitate Information Literacy skills for kindergarten through college has been one of the long term goals of this collaborative project. In the spring of 1998, the Education Resource Librarian conducted a series of three (3) full day workshops for twenty-two (22) librarians from the public schools of a nearby large urban district. In September 2000, workshops were offered at elementary school libraries in the local professional development school network for all the public school librarians. The workshops focused on
guidelines for library media facilities and personnel, current research on effective use of the Internet, and strategies for assisting student teachers with school-based library resources for lesson plans and integrated unit preparation.

Results/Conclusions

A total of 34 survey forms, based on a questionnaire developed by O'Hanlon (1988), were distributed to education faculty and 21 were returned for a 62% rate of return. Eighty-five per cent of the faculty responding to the survey required their students to conduct research for one or more assigned projects. Lesson plans were the most frequently assigned research project, closely followed by research papers and then book or journal article reviews. Interdisciplinary curriculum units and literature reviews constituted the next most frequently ranked categories. Over half of the education faculty responding to the survey listed the first priority of the teacher education curriculum to be teach students life-long or independent learning skills as opposed to teaching specific facts, concepts, and methods. When asked which research skills were essential for future teachers, the ability to synthesize information gathered from many sources received unanimous support. There was consensus that students will need to be prepared to teach Information Literacy in Pre-K-12 classrooms and that instruction be shared between the classroom teacher and the librarian. Nearly all faculty surveyed agreed that elementary and secondary teachers are in a better position to help their students become information literate when they receive formal instruction themselves during their teacher education program.

Analysis of the preservice students' course documents and practicum field experience manuals revealed that the preservice student teachers had successfully integrated many of the objectives of the IL instructional process. The individually designed and implemented interdisciplinary curriculum units provided a rich source of data demonstrating the effectiveness of library research and technology skills as a result of the active learning Information Literacy model. Some students utilized resources available in the Education Resource Center to a greater extent than others. Students enrolled in methods classes used children's literature, curriculum guides, and electronic databases that could be directly linked to the materials and technology available in the Education Resource Center. The quality of these units created by students who utilized various types of media and technology available in the Education Resource Center was judged to be superior by the education professor and the cooperating teachers. Internet sites identified by students in their bibliographies could be traced to their active learning experiences in the IL program. The cooperating teacher evaluations highlighted the research aspect of the preservice student's work.

Educational Importance of the Study

A Nation at Risk (U.S. National Commission on Excellence in Education, 1983), emphasizes the need to develop critical thinking skills to evaluate the plethora of data produced by the information explosion. Since then, learning how to locate, access, and evaluate information in a variety of formats has become an even greater challenge. The Education Resource Center environment helps students and faculty move beyond the textbook to support critical thinking and inquiry-based learning. Education faculty collaborate with the librarian to ensure access to primary sources and developmentally appropriate materials. The library becomes a research center for students engaged in project- and inquiry-based learning.

The flexible Preservice Information Literacy Model provides opportunities for students to develop critical thinking skills in the context of active research connecting course work and student practicum experiences with hands-on information literacy exercises. The collaborative nature of the model with ongoing consultation between faculty and librarian ensures that IL objectives are consistent with course assignments and requirements of the student practicum experience.

The qualitative paradigm further provides the latitude needed to study IL from the participants' perspectives within the context in which this takes place. Information Literacy Programs help to bridge the gap between theory and practice (Furlong & Roberts, 1998). Teacher educators could benefit from this study because there are universal elements which contribute to a systematic integrated model of IL at the preservice level.
References

Introduction

More than 20 preservice methods courses are currently taught in the College of Education at the University of North Texas. Prior to 1999, fewer than half of these courses made extensive use of information technology, and fewer than one-fourth involved active modeling technology-infusion teaching and learning techniques. Utilizing Funding from a Department of Education, Preparing Tomorrow’s Teachers to Use Technology (PT3), the College of Education at the University of North Texas is producing technology enhanced teachers for the 21st century. The preservice teacher initiatives of the PT3 grant have provided:

- Technology mentoring programs for senior faculty members
- An opportunity for credentialing of technology competent paraprofessionals
- An infusion of technology enriched experiences within the preservice teacher education curriculum

The current paper seeks to outline four of the activities sponsored by the PT3 program.

Infusing Technology into Reading/Language Arts Teacher Preparation Programs

Technology is often taught as a separate subject in order for students to learn the basic use of computers. However, preservice teachers’ knowledge of technology use should not end with their own achievement of computer literacy (Vannatta & Reinhart, 1999). Even after reaching the point of literacy in technology, students often do not transfer what they have learned to other situations or subject areas (Kinzer and Leu, 1997). In order for preservice teachers to become effective integrators of technology and language arts, it is essential that its uses be modeled for them (Vannatta & Reinhart, 1999) and they must be provided with opportunities to practice what they have learned, as well as develop their own ideas for weaving technology into the language arts curriculum.

In the spring of 1999, two doctoral candidates majoring in reading education worked collaboratively to integrate the use of technology into two reading methods courses for preservice teachers. Planning for the spring semester began in the fall of 1999 with searches for meaningful activities that could be easily implemented to enrich the reading courses. A web site was constructed for each reading course that consisted of the course syllabus, schedule and resources for preservice teachers (see http://www.people.unt.edu/~mlm0012 and http://courseweb.tac.coe.unt.edu/dana). These resources included links to World Wide Web sites pertaining to language arts such as book award sites, professional organizations, lesson plans, government agencies and reading initiatives, ERIC Online, online language arts journals, web publishing for children, web sites belonging to authors of children’s books, and a site that created puzzles that could be used in vocabulary activities.

Modeling the use of PowerPoint presentations required hardware in the form of computers and LCD panels for whole class viewing. While these items were routinely used in computer education courses, they were not used at that time for courses in the department of teacher education. Faculty members from the future Institute of the Integration of Technology into Teaching and Learning (IITTL) loaned laptops and LCD panels to the reading instructors for use in the
presentations throughout the semester, as well as provided space on a server that enabled the instructors to post materials related to the courses and student work on the World Wide Web.

The curriculum for the reading courses was already in place. No assignments or expectations were changed due to the addition of the technology component. The instructors were in agreement with Niess (1990), who believed that computers must be fitted to the curriculum rather than the curriculum to computers. The intent of the instructors was not to change the reading courses to accommodate the technology, but to infuse technology into the courses to enhance the preservice teachers’ experiences and to help them become aware of the exciting possibilities for technology use in the area of language arts.

The technology infused course was an introductory reading course that is required of all students in the college of education at the university. It covers a variety of topics that include knowledge of the reading process, stages of reading and writing development, techniques for teaching reading skills, an overview of reading assessment, and an introduction to various types of reading programs currently in use today. This course was taught on campus at the university, where the students had easy access to computer laboratories and the class was able to meet in a computer education classroom on several occasions. The technology infused course is a prerequisite to the technology enhanced course involved in this study.

Two sections of another reading course, one of which was technology enhanced, participated in this study. It is required for all preservice teachers specializing in elementary education. This course is designed to teach students how to perform reading assessments, conduct evaluations, and provide remedial assistance for elementary level students. Students are required to perform assessments and tutor one child throughout the semester.

The amount of technology present in the three courses varied. Preservice teachers in the technology infused class had a course web site where they could access the syllabus, course schedule, PowerPoints from previous lectures, and many resources. PowerPoint presentations were modeled for them throughout the course. Toward the end of the semester, the students created their own presentations using PowerPoint and presented them to their classmates. They received instruction in web searching early in the semester. Some students indicated an interest in learning to design their web pages as an addition to the required course project. The instructor met with them several times out of class and the students spent many hours on their own time developing the web pages. The preservice teachers in this course participated in an email exchange that focused on reading assessment with students in the technology enhanced course.

Due to the limitations in availability of on-site technology equipment for the students in the technology enhanced course, those preservice teachers were unable to participate in all the activities experienced by the students in the technology infused course. A course web site was provided, the instructor modeled PowerPoint usage each week, and they engaged in an email exchange with the preservice teachers in the technology infused course.

The technology teaching tools offered to the students enrolled in the traditional methods course were limited to an overhead projector and transparencies. No course web site or PowerPoint presentations were provided and they did not participate in the email exchange.

The preservice teachers enrolled in the three courses were surveyed on the first and last day of class. According to survey results, students in the technology infused reading methods course believed they were better prepared (P < .01) to integrate technology into the language arts curriculum in their future classroom than did students in the traditional methods class. Students in the technology enhanced course rated their capabilities as somewhere in between those of students enrolled in the technology enhanced class and the traditional class.

**Technology Integration Mentoring**

CECS 4800, Technology Integration Mentoring was a new course introduced as part of the PT3 Capacity Building plan, during the spring of 2000. The course was designed to allow students who had completed CECS 4100, Computers in the Classroom, to continue to advance in their technology integration abilities. The purpose of this course was to provide an extension of CECS 4100 which would enable preservice educators to focus on technology integration in an authentic classroom environments.

**Course Description**

Students met together three times during the semester but communicated frequently via a class listserv. The remainder of the class time was spent in a working classroom where they were paired with a classroom teacher. The students were also required to submit assignments such as answering weekly questions via the listserv, finding and turning in the Acceptable Use Policy for the school in which they were working, filling out a technology survey (which required them to find out what hardware and software were available to them in the school/classroom), as well as writing and implementing a plan of action. The students were observed onsite by their instructor, Rhonda Christensen and her team teacher, Theresa Overall.

The Plan of Action differed according to the needs of the classroom teacher, but all of the plans were required to have certain components such as Texas Essential Knowledge and Skills (TEKS) and International Society for Technology in Education (ISTE) technology standards, a rubric for evaluating their plan, and other standard components of an effective unit or lesson.

Distribution of materials for the course was carried out at the first class meeting. These included a handbook for the cooperating classroom teacher, examples of technology integrated units, rubrics and other resources. A class website was developed with links to other technology and curriculum resources. Students' digital pictures were taken and placed on the course website so that when they were communicating with each other via the listserv, they could view the photos to recall the faces of fellow classmates.
Students had the option of selecting their own teacher or being placed in a classroom arranged by the instructor. This resulted in a wide geographic distribution for the students in the course. Two 4800 students were placed in the same school in special instances. This seemed to be very helpful to the students for peer support.

The second face-to-face meeting included a follow up of placement, as well as interaction on how things were going for the students in the course. A model activity of collaborative learning using technology, in which the 4800 students were participants, also took place at the second face to face meeting.

The final face-to-face meeting focused on presentations of student plans of action. This was an impressive display of wonderful work with classrooms of students and their teachers.

**Assessment/Evaluation**

An anonymous course evaluation was given to the students at the end of the semester. On a scale from 1 to 5 (awful to excellent), all students rated it as a 5.

Open-ended questions included: Please list two stars and a wish. What was the best aspect of the course (two stars) and I *wish* the following would have been different. There was also a place for additional comments.

The cooperating teachers also filled out a more extensive evaluation of both the student and the program.

Overall the comments were wonderful. The teachers seemed to think this was a useful course that benefited both the university students and the classroom teachers.

**Observation/Discussion**

One nice benefit of this type of course is the two-way mentoring that occurs. The undergraduate students were the “technology integration experts” to help the classroom teachers. However these preservice students learned a great deal from these “expert classroom teachers” about classroom management and curriculum.

While there is currently much emphasis on the preservice teacher education technology integration in colleges of education, there isn’t a precise plan for how to best improve preservice students’ technology integration. In this course, placing preservice students in a real teaching environment was a rich and rewarding experience for both the students as well as the cooperating classroom teachers. **Infusing Technology in Preservice Teacher Preparation in Special Education**

The State of Texas lists Special Education as an area with a critical teacher shortage. Interestingly enough, there is not a shortage of Special Education teachers in Texas. Basically, a large number of certified teachers choose not to teach or have left the teaching field for other occupations. The "burn-out" rate for a Special Education teacher in the field is typically four years (Cunningham, 1989). Two of the most common reasons for leaving the field involve discipline problems and the abundance of paperwork required of Special Education teachers. The paperwork problem is often more pronounced for Special Education teachers in testing and administrative position such as the Educational Diagnostician. Although a number of initiatives and incentives have been implemented to attract and keep more teachers in the field of Special Education the critical shortage of teachers remains. It is most important to alleviate areas that contribute to “burn-out.” The College of Education at the University of North Texas has attempted to provide strategies to assist teachers with their paperwork and discipline problems through the use of technology. Instructors in the Special Education Program have developed a plan to infuse appropriate technology into teacher preparation courses. Instructors model the use of technology through class lectures and assignments. Instructors also develop a fluency with the aspects of technology which can help teachers reduce paperwork in the field. Instructors expose students to time saving technology such as:

- Computer Generated Individual Educational Plans
- Interactive CD's depicting students with special needs
- Test Scoring Programs
- Report Writing Programs
- Grade Books
- Effective Remedial Software
- Computer Generated Behavioral Plans

The goal of the Special Education Program is to not merely produce teachers, but to produce teachers who have the technology skills to facilitate their timely and successful completion of job requirements. Surveys indicate that teachers completing the Special Education preservice sequence of courses improve their technology skills as they progress through the undergraduate sequence of courses. It will be important to monitor these technology proficient special educators to determine if technology training plays a role in classroom success.

**Web Based 2 + 2 Articulation**

During 1999, Dr. Jeff Allen created a web-based 2 + 2 articulation web page for students transferring from six North Texas community colleges AAS programs to the University of North Texas BAAS program. This site can be accessed at: (http://www.attd.unt.edu/Articulation/Index.html).

The State of Texas has a strong community college system that is willing and able to prepare students in their first two years of college. Community college students are representative of their local community populations (urban, rural, religion, race, national origin, gender, age, and disabilities). Eighty-five percent of students in the Bachelors of Applied Arts and Science (BAAS) program at the University of North Texas (UNT) have transferred from a community college Associate of Applied Arts and Science (AAS) program, thus allowing the BAAS program to better represent community populations Central and North Texas.

Utilizing funding provided by the Department of Education, UNT developed computerized (web-based) degree plan templates for all of the AAS programs offered at the following six community colleges:
Collin County Community College, Dallas County Community College, Grayson County Community College, McLennan County Community College, Navarro Community College, North Central Texas College, and Tarrant County College.

<table>
<thead>

<tr>
<td><strong>Total</strong></td>
<td><strong>233</strong></td>
</tr>
</tbody>
</table>

Dallas County Community College, the largest of these districts, pilot tested the pages during the Spring 2000 semester. This website was fully published during summer 2000 for the remaining districts. In addition, during Fall 2000, Hill College, McLennan Community College, Texas State Technical College and Weatherford Community College will be added to the web-based articulation/advising program. These 11 community college districts serve rural and urban populations in approximately twenty-nine counties of Central and North Texas.

The web-based Program articulation is a difficult and time-consuming effort involving many levels of cooperation and discussions. This web-based articulation/advising program provides greater opportunities for community college counselors and faculty to advise their students of UNT technology-based program. Through this local advising process, UNT faculty and staff can act in a resource and support role rather than a marketer for students exploring degree plan pathways options from community college programs. This program provides students a two-tier support/advising system to finish their four year degree program at the University of North Texas.

It's a Small University After All - Reducing Distances Between Colleges Via Web CT

Karen W. Verkler, Ph.D.
Coordinator, Foreign Language Education Program
College of Education
University of Central Florida
Orlando, Florida USA
kverkler@mail.ucf.edu

Abstract

This paper describes a Web-CT based project between foreign language education majors in the College of Education and foreign language students in the College of Arts and Sciences at a large metropolitan university. Thousand-level Spanish and French students responded weekly in the target language to instructors' queries posted on Web CT class accounts. Foreign language education majors, as a form of formative assessment, provided constructive feedback to these students by means of comments posted to them on WebCT. At the end of the semester, student reactions to this project were obtained via surveys. Education majors responded favorably to the assignment. Reactions of the language students, however, were mixed. Many of these students, most of whom were taking the course to simply fulfill a graduation requirement and were resentful of this requirement, expressed negativity toward the WebCT assignment. Others appreciated being able to correspond with a peer.

At a large metropolitan Central Florida university, the Foreign Language Department and the Foreign Language Education Program are housed in different colleges. The Foreign Language Department is contained within the College of Arts and Sciences, while the Foreign Language Education Program is part of the College of Education. As interdisciplinary projects are growing in prominence nationally, colleges are seeking ways by which to integrate curricula cross-college.

Last year, a collaborative relationship was established between the Foreign Language Department and the Foreign Language Education Program by means of a WebCT assignment. The author, Coordinator of the Foreign Language Education Program, had recently developed a course entitled “Technology in the Foreign Language Classroom” and sought a way by which to tie in course requirements with those in foreign language classes. During course development, the author participated in a summer faculty institute in which additional stipends were awarded for interdisciplinary project development and implementation. It was during this institute that foreign language faculty and the author met frequently to share syllabi and brainstorm ways to integrate assignments in their respective courses.

Foreign language faculty decided to begin cross-college collaboration within the context of their 1000-level Spanish and French classes since those classes already had a WebCT assignment in place. Students in these classes were required to respond on a weekly basis to questions posed by their instructor on WebCT. The questions necessitated student response in the target language and provided the students with additional practice in reading comprehension and writing. Questions typically asked the students to elaborate on topics that had been discussed in class, thus providing further reinforcement of the material as well as additional communicative opportunities. An example of a question is the following: “Tell me about yourself. What is your name? How old are you? Where do you live?” Instructors then commented on the students’ responses by providing linguistic extensions, contributing constructive grammatical feedback, and/or continuing the conversation in a natural way. Given the large number of students in these introductory level classes, which are a requirement for graduation, provision of this feedback became very time-consuming.

Students in Technology in the Foreign Language Classroom were education majors who needed as much exposure as possible to the different areas of competency required in the field of education. One such competency is in the area of assessment. Upon comparing course syllabi for the entry level foreign language courses and Technology in the Foreign Language Classroom, faculty found a natural fit between the need for the provision of feedback to the language students’ written productions and the need for practice in different modes of assessment for the foreign language education students. Thus a collaborative relationship was formed between both sets of students and their respective faculty. Thousand-level students would continue to respond to queries posed by their instructors. However, instead of the foreign language instructors addressing the written productions, students in Technology in the Foreign Language Classroom
replied to them weekly. This afforded a number of different opportunities: language students communicated with peers in another class and received prompt feedback, education students received practical experience in a very different mode of assessment, and instructors were relieved of the time constraints of responding to their large numbers of students. In order to monitor their students and the education students' continuance of their respective roles in this assignment, faculty from both programs accessed the Website weekly to determine the frequency and quality of the students' writings and feedback.

This assignment ran the course of the entire semester. At the end of the semester, both sets of students completed surveys that were geared toward their particular group. In other words, education majors were provided with a survey that addressed their observations/concerns from an educator's standpoint. The survey administered to the language students queried them from a student viewpoint. Overall, education majors' responses were overwhelmingly positive, although they did express a desire to have some face-to-face interaction with the language students. They found the unique mode of assessment to be challenging, yet intriguing. They also appreciated being given the opportunity to become familiar with the typical types of errors they will encounter in second language learners progressing through the natural stages of language acquisition.

To the contrary, language students' reactions to the collaborative assignment were very mixed. A number of the foreign language students appreciated feedback from a peer. However, several students expressed the preference for one-on-one interaction rather than asynchronous written communication. A number of students resented the entire university foreign language requirement; the overall negative evaluation they accorded the assignment may have been a generalization of this resentment.

Faculty in the Foreign Language Department and the Foreign Language Education Program at the University of Central Florida plan to further analyze the responses of the two groups of students to determine means by which to enhance the experience so that both groups realize equal benefits from the collaborative assignment. They also intend to develop other intercollegiate projects that will strengthen the growing relationship between the respective faculties and students.
Technology and Problem-Based Learning: 
Connecting Students, Teachers, and Student Teachers

Abstract: The investigation reported in this paper strives to bring technology and problem-based learning into the student teaching experience through an integrated, collaborative mathematics task. The project presented is based in data collection and analysis. It supports the National Educational Technology Standards (International Society for Technology in Education [ISTE], 2000) and the latest standards for school mathematics (National Council of Teachers of Mathematics [NCTM], 2000). Students from several schools collected and analyzed data for a task on an 2000 Summer Olympic project. Technology was vital to data collection, data sharing among schools, and data analysis. This project served as a stimulus and prototype for projects for the 2002 Winter Olympics. Presenters

Introduction

Tom Carroll of the United States Department of Education states that technology has the potential to be a tool in the re-invention of education (1999). If this re-invention is to occur in ways that are meaningful to students, preservice teachers need to experience innovative uses of technology in their instructions. Integrating technology into teaching can be enhanced when problem-based learning is used (Albion 1999). Hannum (1999) describes the ways in which technology can be implemented into the Seven Principles of Good Practice in Undergraduate Education (Chickering & Gamso, 1991). The technology Hannum recommends includes but is not limited to listservs as a tools for communication between several students and the instructor, email for student-to-student collaboration, websites as a source for data, and hyperlinks for students to access webdata efficiently. The investigation reported in this paper strives to bring technology into the student teaching experience in innovative ways through a problem-based learning task. This task helps student teachers understand and attend to relevant technology and mathematics standards as they plan and implement lessons. The lessons support the National Educational Technology Standards (International Society for Technology in Education [ISTE], 2000) and the latest standards for school mathematics (National Council of Teachers of Mathematics [NCTM], 2000).

The Olympic Task

This investigation has as its context an event that is both rich in content and likely to be of high interest to elementary, middle, and high school students—the 2002 Olympic Games. During the 2000
Summer Olympics several teachers were invited to begin a 2-year problem-based project that would continue through the 2002 Winter Olympics in Utah. They defined several problems or questions that would require students to gather data before, during, and after the games. They set up listservs to share data among schools. Their students used Internet sites to explore both the 2000 and the 2002 Olympic Games. They gathered data about medals, participants, viewers’ preferences, and TV scheduling. They used spreadsheets to analyze their data. They created WebPages at their schools to display their data analyses. Student teachers participated in these projects and reported their experiences in their electronic portfolios.

The first activity completed during the 2000 Games was to plan a schedule for prime time Olympic coverage for the 2002 games. Students posed relevant questions regarding scheduling, then engage in collecting, organizing, representing, and interpreting data from the 2000 games to build their 2002 schedules. They plan to compare their completed schedules with the schedules actually followed by major channels during the Olympics 2002 games. The following is an outline of the first problem-based task presented to the students:

**Student Assignment**

Plan a schedule for prime time Olympic coverage during the 2002 Games. Discuss population, sample, and sampling methods. Discuss data collection procedures, e.g., surveys. Generate questions that you might need to investigate to complete the task.

- What kinds of coverage do most people like to watch?
- What age levels watch the Olympics the most?
- How are the 2000 games covered by the TV networks?
- What other kinds of information will be needed?

**Data organization**

What will your categories of information be? How many categories will you need? Will you need to design a chart or some other recording device to organize the information you collect?

**Data representation**

What ways of summarizing and representing your data will help you make sense of your information? Possible strategy: Using a spreadsheet program such as Excel, students compile the data collected by their class. They represent the data with percentages and a circle graph.

**Data interpretation**

What do the data show regarding the most popular events? Based on the data, how much time each evening should be devoted to each event? Possible product: Students generate a prime time television schedule for a week of the Olympics using the data they have studied.

**Technology Standards**

The International Society for Technology in Education (ISTE) National Educational Technology Standards (NETS) (2000) defined technology competencies for teachers and students. The standards for teachers include (1) operations and concepts, (2) planning and designing learning environments and experiences, (3) teaching, learning, and the curriculum, (4) assessment and evaluation, (5) productivity and professional practice, and (6) social, ethical, legal, and human issues. Standards for students include (1)
basic operations and concepts, (2) social, ethical and human issues, (3) technology productivity tools, (4) technology communication tools, (5) technology research tools, and (6) technology problem-solving and decision making tools.

These standards support the development of new learning environments for students. Classrooms using technology appropriately are less teacher-centered and more student-centered. Instruction moves from single sense stimulation to multi-sensory stimulation. Students progress through multiple paths rather than single paths to the completion of their learning goal. Instruction utilizes multimedia not single media. Students work collaboratively, not in isolation. Students and teachers engage in information exchange, not just information delivery by the teacher. Learning is more active, exploratory, and inquiry-based, less passive. Students do not learn facts through literal thinking. They use critical thinking to make informed decisions. Their work is authentic based in real world context.

Content Area Standards

The National Council of Teachers of Mathematics (NCTM) has defined several principles and standards for the teaching of mathematics (2000). The principles are equity, curriculum, learning, teaching, assessment, and technology. The technology principle states that “technology is essential in teaching and learning” and that “technology influences the mathematics that is taught and enhances students’ learning” (p.24). The project described in this paper requires data collection and analysis that would not be feasible without the use of technology. Student learning was enhanced through use of real world data collection that led to an authentic understanding of graphing, charting, and decision making.

The NCTM standards include both content and process standards. The content standards are (1) number and operations, (2) algebra, (3) geometry, (4) measurement, and (5) data analysis and probability. The process standards include (1) problem solving, (2) reasoning and proof, (3) communication, (4) connections, and (5) representation. This project addresses content standard (5) data analysis and probability and all five of the process standards. The project involves problem solving and reasoning by asking students to develop and use a variety of strategies in their mathematical thinking. Students are asked to communicate their analysis of data with other students. The project requires students to make connections among several mathematical concepts and learn about mathematics from real-world contexts. Finally the Olympic project requires students to create representations of data collected, primarily in the form of charts and graphs.

Student Work

Students, teachers, and student teachers from across the state participated in this project. They collected data on the television coverage of the Sydney Summer Games for information to help them create the schedule for the Salt Lake City Winter Games. Data was entered into a spreadsheet. Students at different schools represented their data in various ways. As they shared their data and analyses with each other, their range of strategies for creating a TV schedule increased. Table 1 shows the data collection sheet and sample data summaries. Figure 1 and Figure 2 show two different data representation, one as a bar chart and the other as a pie chart. Figure 3 shows a minute-by-minute summary of the events during one hour of TV coverage. This was used as a model of minute-by-minute coverage for the TV schedule for the Winter Games.

Total Minutes for Three Different Hours

Figure 1: Data Representation of total minutes for three different TV hours.

Total Percentages

Figure 2: Data representation of the percent totals for all TV coverage.
Figure 3: Data representation of minute-by-minute TV coverage.

Data from Figure 3 allowed students to think about how to plan TV coverage for the 2002 Winter Games. Students visited the www.saltlake2002.org/sloc/event_schedule/index.htm Internet site to choose a day to schedule. The students were directed to have some coverage of every event, but to strive to have the most time allocated for the most popular events. They wrote a survey asking classmates to indicate which event from the assigned day they would be interested in viewing. The survey results were used to determine how much time each event should be given during 4 hours of prime time TV coverage. The scheduled amount of time for each event matched the percents of popularity from the student survey. Table 2 is a summary of one survey for a day of the 2002 Winter Games. Students were asked if they were VERY LIKELY (3), SOMEWHAT LIKELY (2), or UNLIKELY (1) to watch the event on TV. The tallies were averaged to determine how much time to schedule for each event during the prime time TV coverage. As of the date of this paper submission, the students were still building their final TV coverage.

Future Work

Preservice teachers who will be student teaching during the 2002 Winter Games are preparing learning activities in current methods courses. Teachers from across the state are planning additional problems for the months before, during, and after the 2002 Winter Games. These problems include a study of restaurant prices during the games, cost of planning a trip to the games from several places around the world, housing and food costs for the athletes while at the games, transportation issues to and from venue sites, etc. Participating schools are working to design the projects and share information electronically with each other. Comparisons will be made of results in different areas based on distance from venue sites. We are hoping to invite schools from across the country to have electronic pen pals with students in venue sites. Student teachers from this year’s project will be teachers around the country next year and can continue in the project with their students.

Graduate School of Education
George Mason University
USA
dsprague1@gmu.edu

Abstract: Changes in State regulations and National Standards have resulted in Colleges of Education redesigning their teacher preparation programs. During this redesign, many programs are eliminating their “technology course” in favor of integrating technology throughout all teacher preparation courses. This redesign has often resulted in concerns that many teacher education faculty are not well prepared to provide teacher candidates with the technology skills and knowledge needed to insure the effective integration of technology into K-12 curriculum. This paper focuses on one teacher preparation program’s efforts to address this concern. Faculty members at George Mason University in the Elementary and Instructional Technology Programs paired up and team-taught an Introductory to Elementary Curriculum course, providing students with the needed foundational knowledge and technology skills.

Overview and Background

The inclusion of technology into elementary teacher preparation programs has become a necessary and important component in most, if not all, teacher education programs. In the past five years the integration of technology into teaching methods courses has been suggested as an effective model for helping teacher education candidates develop a vision of the role of computers in an integrated curriculum (Willis, 1997). Typical models for integrating technology into teacher preparation courses include the use of e-mail, on-line databases, WebQuests, software, spreadsheets, and word processing (Maeers & Brown, 1999; Willis, 1997). Other technology uses typically found in coursework include the incorporation of electronic portfolios and the creation of video presentations with film clips from CD-ROM encyclopedias (Kovalchik, 1997; Willis, 1997). Specific barriers to successful integration of technology into teacher preparation courses have also been identified in the literature. These barriers include limited access to technology resources, technical problems, and time to experiment and learn (Falba et al., 1999). In addition, Roberts and Ferris (1994) indicate that faculty who teach the courses may not see technology as important, may believe that there are too many course changes required at one time, may be unfamiliar with available hardware and software or find that it is hard to take risks using technology. Robert and Ferris (1994) recommend that a team teaching model be used to successfully integrate technology into teacher preparation courses.

The purpose of this paper is to describe teacher education faculty efforts to develop and implement an introductory and foundations course in elementary education that integrates technology into the course content. During the 1998-99 academic year, George Mason University redesigned its teacher preparation programs in response to changes in State Licensure requirements. During this redesign, the
Elementary Program faculty decided to eliminate the Introduction to Educational Technology course, the only course in the teacher education program that focused on technology, and integrate technology throughout all courses. The faculty expressed the belief that technology should be infused into the program and were committed to modeling the effective use of technology to support teaching and learning. To help the faculty accomplish this goal a member of the Instructional Technology Program (Dr. S) accepted an affiliation with the Elementary Program. Dr. S had expertise in integrating technology in the K-12 curriculum and was responsible for the Introduction to Educational Technology course that was being eliminated.

An immediate concern the faculty faced was to ensure that the Introduction to Elementary Curriculum course (the first course in the program sequence) provided students with the technology skills needed to complete assignments across the other teaching methods courses. The faculty spent time examining each of the methods courses and determined that the preservice teacher candidates would need to learn the following technology skills: how to use e-mail, how to evaluate websites, how to conduct Internet and ERIC searches, how to use the university’s threaded discussions tool (TownHall), and how to use Microsoft’s PowerPoint software for presentations. In addition, students needed to understand the basic tenets of elementary curriculum and a variety of instructional strategies and related topics (i.e. direct instruction, cooperative learning, authentic assessment, and inclusion). Students also needed to develop an understanding of historical influences and school laws in elementary schools.

The merging of introductory technology skills and a foundational knowledge base presented a challenge for the Elementary Program faculty. Two sections of this course were to be taught in the spring of 2000 for the first time. It became apparent that none of the faculty members had expertise in both of these areas. It was decided that the best way to handle this was for the technology faculty member (Dr. S) and the foundation faculty member (Dr. W) to team-teach the two sections together. To accomplish this the two sections were scheduled to meet at the same time in two adjacent computer labs.

Preparing the Course

During the semester prior to the spring 2000 semester, Dr. S and Dr. W met weekly to co-design the course. The two faculty members collaborated on choosing the textbooks and materials and on developing the class assignments. As the course was developed Dr. S spent time determining the best way to integrate the technology skills into the course. For example, when students were ready to begin working on their research paper, they needed to learn how to conduct an ERIC Search and develop search strategies for finding resources on the Internet. The use of e-mail and TownHall should be presented the first and second week of classes.

Several issues and questions related to course design and scheduling emerged. It became apparent that the integration of some of the technology skills required creative thinking and problem solving. For example, while learning foundation topics, should students learn how to evaluate websites and also perform Internet searches? Trying to cover three topics at once could be too much for the students. Teaching PowerPoint should be included when students were required to do a presentation, but what were they going to present? To solve these problems, it was decided that Dr. S would create a WebQuest as a way to integrate content about U.S. laws and how they influence elementary teachers in schools (see http://mason.gmu.edu/~dspragu1/lawquest.html). The WebQuest would include the evaluation of websites and result in the students preparing a presentation using PowerPoint software.

Several other topics addressed in the course allowed the introduction of software programs not typically included in an introductory elementary education foundations course. For example, when the class discussed direct instruction, students could spend time previewing some drill-and-practice programs. When the class discussed cooperative learning, students could spend time using one of Tom Snyder's Decisions, Decisions programs. Exposing students to software popular in K-6 classrooms provided an opportunity for meaningful integration of technology into course content. The course syllabus can be found at http://mason.gmu.edu/~dspragu1/educ542.html.

The other major decision that had to be made was how the team-teaching would be accomplished. Since the two sections were scheduled at the same time and were in adjoining rooms, it
was possible for Dr. S and Dr. W to move back and forth between the classes. It was also possible for the students in the two sections to collaborate with each other on assignments. It was determined that Dr. S and Dr. W would switch mid-way through each class session. Dr. S would ensure the students had the technology skills needed for the methods courses while Dr. W would provide students with the content knowledge. Students would be provided with opportunities to collaborate on the completion of the WebQuest and the resulting presentations.

Implementing the Course

During the first few weeks of the course the instructors became aware of four issues that needed to be addressed. These four issues were time, communication, consistency, and instructor expertise. In terms of time, the instructors realized that switching mid-way through each class session took additional time and it was often difficult to coordinate the timing of the activities each instructor was responsible for. For example, when the lesson on PowerPoint took longer than predicted, Dr. W had to extend a discussion on significant individuals in educational history with the group he was teaching. Consequently, the second part of the class session was shorter for both instructors when they had to modify the planned experiences for their second group.

In the team teaching model used, each instructor was responsible for evaluating and assigning grades for a particular group of students. Consequently, communication between instructors and between students and instructors emerged as an issue. Students from one group would periodically ask the instructor of the other group questions about an assignment he or she had not originally explained. For example, Dr. W had to discuss and clarify particular details of the WebQuest assignment with Dr. S so that he then could discuss it with students in both groups. Similarly, the importance of consistency in communication between the two instructors emerged as a critical issue. The teacher education students in both groups frequently discussed assignments and expectations with each other. If any inconsistencies in expectations or grading criteria were apparent to the students, they would ask both of the instructors for clarification.

The two instructors met weekly to review and discuss the content to be taught in the next class session. These meetings served as an opportunity for the instructors to “mentor” each other on specific aspects of the content that was to be taught. For example, since Dr. S was more of an expert in technology, she explained the concepts and procedures involved in the WebQuest so that Dr. W could address any questions that students might have while working on that assignment. Similarly, in an activity on instructional strategies, Dr. W assumed responsibility for explaining how to conduct a cooperative learning strategy used to teach concepts underlying Direct Instruction.

Student comments in a formative evaluation conducted in the middle of the semester reflected the issues identified by the instructors. Students indicated through their comments that 1) they felt certain activities were rushed because there was not enough time, 2) one class may get more information on a particular topic than the other class, and 3) at times the classes seemed to be disorganized. The student feedback also indicated that students had varying comfort levels with technology. For example, one student stated, “I don’t always feel comfortable with the technology section of the class. Many times I find myself behind the rest of the class”. In contrast, another student stated, “too much time was spent on PowerPoint, I already knew how to use it.” After reviewing the student feedback in the middle of the semester the instructors decided to change the way they moved back and forth between the two classes. Rather than move back and forth during each class session, the instructors tried to work with one group for an entire class period as much as possible. In addition, both instructors worked on communicating the same expectations for the remaining assignments.

Course Evaluation and Conclusions

The formative evaluation administered at the end of the course and shared reflections by both instructors served as the basis for course evaluation. The student feedback indicated that the change in the organization of each class session (one instructor teaching one group for an entire session) was more effective than constantly switching back and forth. Student feedback indicated that most students
perceived the course to be a “little disorganized at the beginning.” In addition, student feedback indicated that: 1) the students would like more discussion on technology; 2) there were specific technology activities that were valued while others were not (for example a specific videotape on the uses of technology was not valued); and 3) there was not enough time to cover all of the material (the foundations content as well as technology applications).

Instructor reflections focused on how to effectively integrate technology into the foundations content in practical ways while still including the key content components of the course. The instructors have also worked on how to accommodate students with varying levels of previous experience with technology. The instructors decided to continue to work together in planning and preparing specific activities. However, for the next course implementation in 2001 both instructors will teach all of the content. That is, each instructor will be responsible for the technology and elementary foundations content. This change will require more mentoring for Dr. W who is not an expert with technology. Since the elementary program is currently involved in a Preparing Tomorrow’s Teachers for Technology (PT3) grant, Dr. W will be working with both Dr. S and a mentor from the public schools who is considered to be an expert in technology use in elementary classrooms (Sprague and White, 2001).

Based on our experiences with integrating technology into an elementary education introductory/foundations course we pose the following recommendations: 1) organize each class session so that there is enough time for the technology experiences; 2) infuse technology into the program gradually and incorporate technology into assignments that are relevant to realistic education settings (Siegel, Good, & Morre, 1996); 3) seek student feedback through formative and summative evaluations as well as weekly reflections on both the class experiences and understanding of the technology applications and related course content; and 4) emphasize how technology can be used in every day classroom settings.

Effectiveness of an Exemption Exam for an Introductory Educational Technology Course

William R. Wiencke, Assistant Professor
Media & Instructional Technology
College of Education
State University of West Georgia
United States
wwiencne@westga.edu

Abstract: The need for teachers who are proficient in the use of technology in the classroom has increased dramatically over the past few years. Professional and regulatory organizations with direct and indirect influence on teacher education programs have issued reports, recommendations, standards, and accreditation criteria all aimed at increasing the technology competencies of beginning teachers. The College of Education at the State University of West Georgia established an introductory technology course for all teacher education majors to meet this demand. This survey course provides students with a background in various instructional technologies as well as classroom integration strategies. At the time the course was created, many of the faculty involved believed that many students entering the program would be sufficiently competent in technology to enable them to exempt the course. Those exempting the course would be able to take an additional class in their content area. This presentation will provide an overview on how the exemption exam was created and implemented, as well as a measure of its effectiveness in identifying technology competent students. Additionally, the results of the exam will be viewed in relation to the students beginning the course perceived level of technology expertise.

Introduction

The need for teachers who are proficient in the use of technology in the classroom has increased dramatically over the past few years. Professional and regulatory organizations with direct and indirect influence on teacher education programs have issued reports, recommendations, and standards all aimed at increasing the technology competencies of beginning teachers (CEO Forum on Education & Technology, 2000; ISTE, 2000; Solomon, 1998).

The College of Education at the State University of West Georgia established an introductory technology course for all teacher education majors to meet this demand. This survey course provides students with a background in various instructional technologies as well as classroom integration strategies.

At the time the course was created, many of the faculty involved believed that many students entering the program would be sufficiently competent in technology to enable them to exempt the course. Those exempting the course would be able to take an additional class in their content area. This presentation will provide an overview on how the exemption exam was created and implemented, as well as a measure of its effectiveness in identifying technology competent students. Additionally, the results of the exam will be viewed in relation to the students beginning the course perceived level of technology expertise.

Why the Exam Was Created

The College of Education at the State University of West Georgia had felt the pressure, as many institutions have, to both reduce the total number of semester credit hours to 120 while also being required by the Board of Regents to increase the number of content courses in its various programs. The Introduction to
Instructional Technology course was developed by merging two existing courses in an attempt to reduce the total credit hour load.

Although deemed a very necessary component of the curriculum, many faculty believed that students entering the college would possess many of the technology skills covered in the course. It was decided to create an exam that would evaluate a student’s technology competencies. If the students met the basic criterion of the test, they would be exempted from taking the course. However, they would not be given the credit hours so that they could be required to take a different course in its place. The faculty wanted to utilize the opened space in the program created when the technology course requirements were satisfied.

How the Exam Was Developed

Media and instructional technology faculty teaching the technology courses were asked to develop the new introductory course and the exemption test. Meetings were held to review the new course objectives and content based on the ISTE technology standards. It was agreed that the knowledge, skills, and attitudes to be conveyed in such a course were not only to help the students to succeed in their future profession, but also to provide support in their other courses in their teacher training program. This would be particularly important since it would provide a base level of understanding that would enhance the ability of the students to understand the integration of technology infused in their advanced content and methods courses. The test, consisting primarily of performance and some written test items, would evaluate the students’ mastery of the objectives set by the course.

The test covered the same topic areas as the course. These are operating systems, email, list servers, on-line resources, word processing, data base development, spreadsheets, presentation software, and technology integration. Test items are designed to emulate projects assigned in the course that require the students to create a product (e.g. newsletter, budget, presentation, etc). The final draft of the exemption test was reviewed by the dean of the College of Education, selected CoE chairs and faculty, adjunct instructors teaching the course, and a business education professor to insure face validly.

How the Exam is Administered

The exam is offered twice a semester during the Fall, Spring, and once in the Summer terms. The selection of the dates corresponds with advisement periods to allow students to use the results in planning their schedules. It is always given on a Saturday to avoid conflicts with students’ classes and courses that use the college’s computer lab. The exam is widely publicized by posted flyers, recommended by student’s advisors and announced in classrooms. In addition, criteria for each section of the test is made available to potential test takers in the college’s resource library.

Students are given four hours to complete the exam to allow enough time to complete the various projects. All necessary materials are provided including two disks on which to save the exam’s projects. One disk is used while working on the exam and the second is used to create a final back-up, a requirement under the operating system section.

Since the exam is entirely performance based, the number of students who can sit for the exam is limed by the number of computer stations in the lab. To insure that all examinees will have a workstation, students are required to register for the test with the Media & Instructional Technology department. Contact information is used to remind prospective test takers of the date, time, and location of the exam.

How the Exam is Graded

The exam was designed to follow as closely as possible the projects assigned in the course. Each section is evaluated as a separate project and assigned a grade based on the number of correct responses and/or actions. Because each individual project must be evaluated on its own merits, each exam requires approximately 20 to 30 minutes to grade. Although this requires a large investment in time, it is deemed
necessary to effectively evaluate the student’s capabilities in using the technology. The section grades are then averaged to establish a final grade.

A measure of reliability has not been established primarily due to the four hour length of the test. Since the exam is not in multiple choice format, common statistical methods for calculating reliability are not appropriate. A test-retest or multiple forms method would suffice but the small number of participants as well as the length of the test has prevented their use.

The passing score for the exam was originally set at 85%. The rationale for this decision was that students needed more than a minimal score to show enough competence to exempt the course. After administering the exam twice, this minimal score was lowered to 80% to better reflect the passing rate of students in the course.

Outcomes

At the outset, it was anticipated that a large number of students would take advantage of exempting the course. However, this has been far from the case. Although the test is well publicized, few sign up to sit for it, and of those that do, only a small percentage actually show up.

Feedback from those who failed to participate revealed that some, after reviewing the published criteria, decided that they did not have the necessary knowledge to pass the test. This is supported by the results of a survey given to 259 students enrolled in the introductory course on the first day of class. The students had a high to moderate perceived knowledge level of the Windows operating system, word processing, web searching, email and the GALILEO online library catalogue system. However, perceived knowledge level of spreadsheets, data base development, presentation and multimedia software, and technology integration was dramatically lower (see Table 1). Results of a similar study at Appalachian State University were consistent with these findings (Green & Zimmerman, 1999).

Table 1: Response to a survey on perceived level of technology knowledge at the beginning of the course. Shaded areas illustrate the higher percentage of responses.

Another important factor seems to be the requirement that the students take an additional course to replace the credit. They feel that knowledge of technology will be beneficial and if they have to take a course anyway, it should probably be in instructional technology.
To date, 33 students have taken the exam, twenty undergraduate and thirteen graduate. The overall passing rate is 48% with 55% of the undergraduates passing and only 38% of the graduates. An examination of the passing rates by topic shows results similar to the perceived ability level of the students enrolled in the course. Scores are higher on operating systems, word processing, on-line resources, and email and lower on spreadsheets and data base development (see Table 2).

![Exemption Exam Results by Program Level & Technology Area](image)

Table 2: Exam results by program level and technology area.

**Conclusions**

At the time the course and exam was created it was anticipated that a large number of students would attempt to exempt the course. To date, 942 students have enrolled in the course since its inception in the Fall of 1998, while only 33 have taken the exam. This low participation rate (3.5%) can be attributed primarily to the requirement that students who pass the exam must still make up the credit hours by taking an additional course. If students have fundamental skills in technology, it is a more attractive option to take a course in which they have some knowledge than one that would require additional effort and a possible lower grade. The exam is not providing the anticipated option for students to open their class schedule to take additional subject area courses.

The review of the perceived level of technology knowledge from the students beginning the course does show that many have an introductory skill level in the basic use of computers and associated communication software (e.g. email and word processing.) They do not have knowledge of the more advanced analysis, presentation, or multimedia software. Although this knowledge level may have prevented them from passing the test, there is an apparent sufficient level of knowledge that there should have been a greater number attempting the exam.

The 48% overall passing rate indicates that the exam is sufficiently difficult to insure that those passing have an understanding of the subject matter and skills covered in the course. Inspection of the passing rate by technology area supports the data on the perceived level of technology knowledge of students beginning the course. The passing rate is higher for use of the operating system and communication technologies and lower for the more advanced programs. The only exception to this is the passing rate for presentation software (e.g. PowerPoint) which is higher than word processing at the undergraduate level but was rated low for students beginning the course.

The higher passing rate for undergraduate students over graduates tends to support the perception that students entering college are beginning to bring in a higher level of technology skills. Information on the number of years since the graduate students had been awarded their undergraduate degrees was not available so that it is difficult to conclude that the lower passing rate is related to them not having access to
technology while they were in secondary and post-secondary programs. However, graduate students are only required to enroll in the introductory course if there is no indication that they have completed a technology course in their undergraduate studies.

The data also tends to support those advocating the continued use of an introductory course in the curriculum. Although education programs are quickly moving toward the incorporation of technology into content and methods courses it is questionable whether it is a best use of time in these courses to teach technology fundamentals. For the immediate future, it would be more expedient to provide students with a strong technology base so that content and methods courses could focus on integration strategies and not the upgrading of basic skills.

References

Abstract: Educators in northeastern Oklahoma have collaborated on a special three-year project entitled "Tomorrow's Teachers and Tomorrow's Technology (T4) Project". The focus of the project will be to deliver a three-year comprehensive professional preparation program for prospective teachers from the northeastern region of Oklahoma for the purpose of empowering these future educators with the technological skills necessary for effectively teaching in twenty-first century schools. The purpose of this paper is to document the goals and objectives of the T4 Project, the elements involved in Phase I, and detail the benefits of this project to Langston University / Tulsa elementary education majors.

The overall goals and objectives to support the full-scale implementation of a comprehensive program to development technology-proficient prospective teachers includes the following:

1. Implement a comprehensive professional development program in the use of technology for prospective pre-service teachers;
2. Implement a sustained service learning component for prospective teachers that focuses on technology connections and applications;
3. Implement a coherent professional development program focuses on the use of technology for higher education and teacher education faculty who will be active in the preparation of prospective teachers; and
4. Implement a rigorous evaluation plan for assessing program effectiveness and technology-proficiency levels of pre-service educators.

5. Implement a comprehensive professional development program in the use of technology for prospective pre-service teachers.
6. Implement a sustained service learning component for prospective teachers that focuses on technology connections and applications.
7. Implement a sustained service learning component for prospective teachers that focuses on technology connections and applications.
8. Implement a coherent professional development program focuses on the use of technology for higher education and teacher education faculty who will be active in the preparation of prospective teachers.
9. Implement a rigorous evaluation plan for assessing program effectiveness and technology-proficiency levels of pre-service educators.
10. Implement a follow-up consultative support network and listserve for pre-service educators to access as a resource in sustaining their professional technology-proficient careers.

The primary prohibitive factor for the full development of technology-rich instructional environments in American schools is the lack of teachers prepared in the use of technology. The need for technology-proficient educators entering the teaching profession is paramount. Employable teachers for the 21st century will be those graduates who display technology-proficient portfolios. The T4 Project
attends to this need by incorporating specific tools and strategies in the preparation of prospective teachers via technology-rich portfolios, presentations, and lesson plans.

Members of this partnership consortium include Tulsa Community College, Langston University / Tulsa, Tulsa Public Schools, the Tulsa Chamber of Commerce, Oklahoma State Department of Education, Tulsa area school districts, and local businesses in the Tulsa, Oklahoma area. This project is an alliance, which includes a wide variety of interest groups all focusing on common goals to help benefit future teachers.

Tulsa Community College (TCC) and Langston University / Tulsa are the primary institutions involved in the T4 Project. TCC is a "feeder" college, transferring students on to Langston University / Tulsa to receive a Bachelor's Degree in Elementary Education. Just as TCC is the "feeder" institution, Langston University / Tulsa is the "receiving" institution. Many of the students at Langston University / Tulsa take courses at both LU / Tulsa and TCC concurrently in order to complete general requirements.

In Oklahoma almost two-thirds of the education majors begin their study at community colleges. TCC (Tulsa Community College) is the largest two-year college in Oklahoma and the second largest college in the state with an enrollment in excess of 20,000 students located on five campus sites within Tulsa County. TCC serves over 1,000 pre-service education majors each semester.

Langston University / Tulsa serves only upper division undergraduate education majors and has been the primary receiving institution of TCC education associate degree students for the past ten years. The commitment of Langston University / Tulsa to the development of a seamless program for the technology preparation of prospective teachers is evidenced in the willingness of LU / Tulsa to utilize the TCC campus sites, to request professional development programs for LU / Tulsa teacher education faculty via TCC course offerings and faculty expertise, and by the LU / Tulsa expressed need for education majors to have more extensive experiences with technology before entering teacher education programs.

The three-year project has been divided into the following components: (1) Phase I: Participant Recruitment and Curriculum Restructuring; (2) Phase II: Implementation and Evaluation; and (3) Phase III: Follow-up and Consultative Support. Phase I project milestones included the following: (a) conduct participant recruitment activities, (b) provide incentives for education majors, (c) provide incentives for increased enrollments in technology education courses, and (d) provide incentives for higher education faculty professional development, (e) upgrade and modify existing general education curriculum, (f) upgrade and modify existing teacher education curriculum, (g) restructure education curricula to include a greater focus on technology, and (h) select sample pre-service education students for evaluation focus.

Teacher Education faculty at Langston University / Tulsa have participated in the areas of recruitment, higher education faculty professional development, upgrading the teacher education curriculum to include technology use for both the students and the professor. Teacher Education faculty also have been able to participate in a Faculty Grants for Technology Innovation program. Two Langston University / Tulsa faculty members have received grant funding for the Spring semester of 2000.

In conclusion, educators in northeastern Oklahoma have collaborated on a special project benefiting prospective teachers from the region. The purpose is to empower these future educators with the technological skills necessary for effectively teaching in the twenty-first century schools.
The Computer Endorsement Program: Examining Expectations as a Catalyst for Change

Linda Young
School of Education
Indiana University South Bend
United States
lyoung@iusb.edu

Abstract: This paper examines attitudes and perceptions associated with instructional technology programs offered by the School of Education at Indiana University South Bend. I chose to examine instructional technology programs offered by the School of Education. The School of Education currently offers a computer endorsement, which may be added to an initial area of certification. It is expected that teachers holding this endorsement will be sufficiently competent to incorporate computers into instruction in various contexts. It was therefore my intent to determine the level to which our students are meeting school expectations. An appropriate instrument was developed to investigate prevailing attitudes and expectations, and the survey was conducted. While technological skill expectations of the School of Education and P-12 schools were similar, disparity was observed in two areas. The results of this survey will be used as a catalyst for change in the School of Education's instructional technology programs.

Introduction

Changing state and national standards as well as the changing needs of schools served by the School of Education at Indiana University South Bend (IUSB), have made it necessary to examine the instructional technology programs offered by the School of Education. The School of Education at IUSB currently offers a computer endorsement, which may be added to an initial area of certification. It is expected that teachers holding this endorsement will be sufficiently competent to incorporate computers into instruction in a variety of contexts. The IUSB computer endorsement program has been in existence for six (6) years, and has produced approximately twelve (12) graduates with a computer endorsement. There are currently a number of students pursuing this endorsement as well. As these graduates enter the workforce they hope that the endorsement will qualify them for a broader range of positions than they would have been qualified for without the endorsement. Through discussions with these graduates it has come to our attention that human resource personnel and school administrators may be uncertain about the computer endorsement, and its implications. While the number of computer endorsees is not large, it was decided that this matter warranted further investigation. It was therefore my intent to conduct a survey of school corporations in the IUSB service area to determine the level to which our students are meeting school expectations.

Context

Created in 1820 by an Act of the General Assembly, Indiana University is one of the oldest state universities in the Midwest, and with more than 97,000 students on eight campuses, one of the largest institutions of higher education in the United States. The campus of Indiana University South Bend (IUSB) serves the greater Michiana area (northwest Indiana southwest lower Michigan.) IUSB strives to meet the needs of local employers by educating potential future employees in the region. The social environment of the School of Education at IUSB consists of one thousand three hundred seventy-eight (1378) students. This number includes undergraduate, graduate, certification and degree seeking students. Traditional and non-traditional students are represented in equal proportions. The School of Education places approximately two hundred (200) student teachers in area school corporations each year. In addition to student teachers IUSB's School of Education assigns two hundred fifty five (255) students in field experience placements in area schools as well. The relationship between the IUSB School of Education and area schools continues to be one of shared responsibility and respect.
School corporations in the IUSB service area were surveyed to discover attitudes and expectations relating to instructional technology in general, and the School of Education’s Computer endorsement specifically. Schools participating in the survey represent a wide range of size, settings, socioeconomic status and financial resources. All school corporations represent P-12 schools. An appropriate instrument was developed to investigate prevailing attitudes and expectations.

The Survey

Forty-one (41) school corporations were contacted for the survey. Forty-six percent (46%) of school corporations contacted answered the survey. The survey was administered in two formats. All school corporations served by IUSB were placed on a contact list. All school corporations on the contact list were initially contacted by telephone. Some of these contacts resulted in telephone interviews. In school corporations where the appropriate contact person was unavailable, surveys were mailed. Respondents include superintendents, technology coordinators, principals and human resource personnel. The survey was conducted in early August of 2000, with mailed responses arriving intermittently through the early fall. The survey is comprised of six open-ended questions. The open-ended format provides respondents freedom in answering the questions as well as allowing for a varied depth of response.

The first area addressed was skills and abilities in instructional technology. School corporations in the IUSB service area vary greatly in the degree to which technology is utilized, and technological expertise is expected of teachers. Some schools in the IUSB service area include a technological skill component as part of the hiring process. This survey item addressed educational technology expectations for any beginning teacher. Respondents were to address four categories: general, software, peripherals, and platform. In the general category respondents indicated that the use of the Internet and integrating technology into the curriculum were key issues. The Internet has emerged as an invaluable source of information for classroom teachers as well as an essential research tool for students and teachers alike. Knowledge of Internet technology and proficiency in its use are crucial for the classroom teacher. Proficiency with basic applications such as personal productivity software was stressed by survey participants. Expertise with productivity applications enables the teacher to be more efficient in the management of data related to students as well as the planning and implementation of learning opportunities. When asked about peripherals, respondents indicated that scanners, digital cameras and printers were the essential items with which beginning teachers needed to be familiar. Respondents also indicated that familiarity with Zip® drives and the use of video projectors was an asset for a beginning teacher. The reduced cost and widespread availability of a variety of peripherals, enables schools and teachers to access a greater amount of technology. This provides an increased application of technology across the curriculum.

When asked which platform our students and beginning teachers should be comfortable in, the majority indicated that their computer applications operated in the Windows platform. The remaining respondents said that it would be beneficial for beginning teachers to be equally comfortable in the Mac and Windows platform. Elementary schools in the IUSB service area operate mainly on the Mac platform, while high schools operate in Windows. Middle schools in the area however, typically use both platforms. IUSB School of Education students interested in middle school teaching are encouraged to become familiar with both platforms. All students in the School of Education at IUSB are required to take a course that serves as an introduction to microcomputers in education. This course addresses all software, peripheral and platform issues considered essential by respondents, with the exception of digital imaging and the use of video projectors.

While the debate concerning the standards movement is ongoing, standards are currently a reality that many teacher preparation programs must face. Technology standards have been set at national and state levels for P-12 education. These new standards create a need for teacher education programs to provide students with skills that will allow them to integrate technology throughout the classroom curriculum. The Indiana University South Bend School of Education is accredited by the National Council for Accreditation of Teacher Education (NCATE). NCATE standards now expect accredited schools of education to provide adequate access to computers and other technologies, and expect faculty and students to be able to use it successfully. Programs offered by the School of Education must also meet the standards developed by the Interstate New Teacher Assessment and Support Consortium (INTASC), as these standards have been adopted by the state of Indiana. According to the Indiana Academic Standards for P-12 schools each student who participates in technology education will acquire an understanding of technology as a component of the global context. Teachers must be prepared to provide students with instruction that will accomplish this goal. Survey participants were asked to address future directions for instructional technology delivered by the IUSB School of Education in light of changing standards. Participants indicated that the IUSB School of Education should offer instruction in the use
of technology as a tool for curriculum integration to all education students in the future. It was suggested that this offering begin as soon as possible. The integration of technology into and across the curriculum is vital. Many teachers feel unprepared to face the challenges this integration presents. Participants strongly felt that the School of Education should offer instruction in routine cleaning, maintenance and repair (Fig. 1). While some schools employ individuals whose central responsibility is to maintain, clean and repair technological equipment, often these responsibilities fall upon school personnel who are ill prepared for the task. Providing basic instruction in these areas would be beneficial. It was also suggested that the ability to communicate technological knowledge and act as staff developers be encouraged in our students. In addition, instruction in the use of the Internet as a research tool was stressed. Aligning curriculum, instruction and assessment with the use of technology was stressed as well; as was the use of technology to align school curricula with various standards. Alignment of curriculum, instruction and assessment helps to ensure equal access to an educational experience of high standards for all students. This process is also a crucial step in fulfilling requirements of various state and national standards.

**Figure 1: Future Directions for School of Education Instructional Technology**

In an effort to examine existing notions, survey participants were asked to describe their expectations of potential employees who have a computer endorsement. Respondents expressed the expectation that students with a computer endorsement should be prepared to assume a leadership role in technology. It was also expected that these individuals would lead staff development sessions on the use of technology in educational settings. It was further revealed that the ability to integrate technology into the classroom and teach others to do so was expected of individuals holding a computer endorsement. In the area of technological skills, expectations of the School of Education and P-12 schools were quite similar. Disparity was found to exist between the expectations of P-12 schools and the IUSB School of Education in two areas. One area of disparity is that some respondents have expectations that an individual with a computer endorsement should be able to maintain and repair computer equipment. At the present time this is not an element in either the School of Education’s instructional technology course, or the computer endorsement program. Changes are underway that would incorporate more hands-on experience in this area into existing courses. Another area of inconsistency is the issue of computer endorsement holders as staff developers. The intended purpose of providing a computer endorsement option is to provide added levels of knowledge and experience with educational applications of technology to enhance a teacher’s performance in the classroom. School of Education students are given instruction in, and opportunities to practice, the teaching of computer applications but emphasis has not been placed on large-scale staff development.

As the instructional technology offerings of the School of Education were examined, respondents proposed possible additions to existing course offerings. It was again suggested that there should be instruction on routine maintenance cleaning and repair of common hardware. This issue has been raised throughout the course of this study. Respondents suggested that instruction in web page design be included in required technology courses for IUSB School of Education students. The introduction to microcomputers course mentioned earlier does not contain a web page design component, while the computer endorsement program includes web page design. Respondents also stressed that the average teacher should possess the ability to
troubleshoot classroom technology and common software applications. While troubleshooting has been included in the introductory course, it has not been emphasized. It was again stressed that students should be provided instruction in the integration of technology into the curriculum. Some respondents indicated that instruction in networking be a priority.

To conclude, survey participants were asked if there were any other issues that needed to be addressed. Most respondents replied that there were not. One issue that did arise was concern on the part of schools concerning teachers who have been in the classroom for a number of years. School administrators are searching for ways to get more experienced teachers to become enthusiastic about technology. The possibilities technology presents for teachers are limitless. Sadly, either lack of knowledge or fear of technology causes many teachers to avoid using the valuable resources available. Many teachers lack confidence in their ability to teach their students how to use technology, or to use it themselves.

Christopher Moersch has constructed a conceptual framework that measures the level of technology implementation or LoTi™. Moersch asserts that there are “seven discrete implementation levels teachers can demonstrate, ranging from nonuse (Level 0) to refinement (Level 6). As teachers move from one level to the next, a series of changes to the instructional curriculum are observed” (Moersch, 1995, p41.) The challenge faced by schools is to move teachers from the level of nonuse along the continuum towards refinement. In an effort to bring this about, many schools have attempted to provide technological training with limited success. Many staff development programs are based on the assumption that participants in such sessions are easily able to make the connections between the technology available and their instructional curricula; as well as the assumption that the individuals are ready and willing to initiate changes in their instructional practices. Frequently neither assumption is valid, and staff development sessions result in nonuse or low levels of technology use by classroom teachers (Moersch, 1994). “The use of technology does not guarantee a fundamental change in the teaching-learning process and consequently in learning outcomes” (Dwyer, 1991). In order for schools to successfully move reluctant teachers along the technological continuum, emphasis must be placed on linking technological gains with long-term instructional objectives.

Conclusions and Implications

In keeping with the School of Education’s commitment to continuous program improvement, the IUSB School of Education has initiated the process of changing the instructional technology program, and the computer endorsement program to more accurately address the needs of the P-12 schools in our service area. It is intended that more hands-on opportunities be available to our students, to learn routine maintenance and repair procedures. The process of change presents many challenges. One such challenge is formulating a plan to add requirements to a program that is already very rigorous. Some School of Education students at IUSB, depending on the specifics of their program of study, require five years to obtain a bachelors degree. Another challenge is the time factor. IUSB is one campus in a very large university system. Even though the changes are to be made only on the South Bend campus, certain changes will require not only campus-wide but perhaps system-wide approval. This requires more time. Currently in the Indiana University system, it takes one to two years to change requirements for an existing program of study on a single campus.

The issue of computer endorsement holders as staff development leaders will be examined in further detail. Although there are some components of staff development in the computer endorsement program, at this time, it is not intended to provide P-12 schools with staff developers, but rather teachers with an above average level of technological expertise. Efforts will be concentrated at this time to ensure that instructional technology offerings by the Indiana University South Bend School of Education are as effective as possible in meeting the needs of the P-12 schools, which we serve.

It is the intent of the Indiana University South Bend School of Education to prepare students to serve as effective teachers. It is our belief that the effective teacher must master both a significant body of content knowledge, as well as demonstrate myriad effective teaching skills, one of which is proficiency with instructional technology. Instructional technology goes beyond any single media, or device, the classroom computer for example. It is a systematic way of planning, implementing and evaluating the entire teaching-learning process. It is a way of combining human and non human resources to bring about more effective instruction. In order to ensure that the instructional technology offerings of the IUSB School of Education meet the needs of students who will in turn meet the personnel needs of area schools, it is necessary to periodically examine those needs as well as prevailing attitudes and expectations and make appropriate changes.
The results of this study will be used as a valuable source of data as well as a catalyst for change in the School of Education's required instructional technology courses, as well as the computer endorsement program. It is possible to bring about change in existing courses with relative ease, in a short amount of time; changes such as incorporating experiences in routine maintenance for example. Program changes, however, require more time. This process may be expedited by the fact that precedent exists in the Indiana University system to support the proposed changes to be made on the South Bend campus. Bringing about change in a program, which is part of a large university system requires time and documentation. The need for change as well as the potential benefits of such a change must be carefully and thoroughly examined. Only through periodic examination and evaluation of changing needs, can the Indiana University South Bend School of Education continue its proud tradition of excellence in teacher preparation.

2. (for HR people) When an applicant comes to you with a computer endorsement, what positions do you consider them qualified for?

3. Given the changing standards, where do you feel we need to be taking our students 3 or 4 years from now?

4. When an IUSB graduate comes to you with a computer endorsement, what does that mean to you? What skills and abilities do you expect that student to possess?

5. What do we need to offer in the area of instructional technology?

6. Is there a question that we should have asked, but did not?
Abstract: The purpose of this paper is to highlight technology infusion within a unique professional development school (PDS) context. Emphasis is placed on teaching interns (preservice elementary teachers in their final year of preparation) who were introduced to applications of technology through their university coursework. Opportunities to explore technology use in the classroom were afforded through a year-long and school based internship. These preservice teachers experienced multiple ways integrate a wide range of technologies that were designed to enhance and support student learning. The following aspects are highlighted in this paper: program context, approach to technology integration in university coursework, five case studies of technology infusion in the context of elementary classrooms, and implications for learning to teach with technology. The case studies include: Grade 1 – Prehistoric Life with the Dinosaurs using Kid Pix; Grade 2 – Exploring the Seasons; Grade 3 – Where do Insects go during the Winter? Grade 4 – Representing Nutritional Information through Electronic Graphing; and last, Grade 5 – How can the Internet be used effectively to enhance Human Body instruction for Fifth Grade Students?

In their review of literature on information technology and teacher education, Willis and Mehlinger (1996) purport that, “most preservice teachers know very little about effective use of technology in education and leaders believe there is a pressing need to increase substantially the amount and quality of instruction teachers receive about technology” (p. 978). This is not surprising given the United States Office of Technology Assessment (U.S. Congress, 1995) report that found technology was not a central component of teacher preparation programs in most colleges of education. A summary of the key findings states, “Most technology instruction in colleges of education is teaching about technology as a separate subject, not teaching with technology across the curriculum. Seldom are students asked to create lessons using technologies or practice teaching with technological tools” (p. 165). Clearly there is a need to integrate technology into teacher preparation.

Attention to technology integration alone, however, may be insufficient for assisting preservice teachers in learning how to effectively infuse technology into their classroom teaching practice. A common problem reported in the literature is the decontextualization of elements of teacher education (Zeichner, 1992). In light of the potential to provide unique opportunities to integrate university coursework and field experiences (Darling-Hammond, 1994, Levine & Trachtman, 1997), professional development schools (PDSs) offer a possible means of addressing this issue. Some of the underlying elements of PDSs include developing collaborative relationships between members of the school-university partnership, engaging in authentic problem-solving in light of a shared vision, and nurturing a common vocabulary and knowledge base (Rosaen & Hoekwater, 1990). School-university partnerships foster contexts in which school-wide and classroom-based environments offer preservice teachers multiple opportunities to develop skills and understandings to effectively use instructional technology. Technology infusion in such settings stands to be a powerful approach to fostering changes with respect to instructional technology in preservice teacher preparation.
The purpose of this paper is to highlight technology infusion in the context of a particular PDS, the school-university partnership between The Pennsylvania State University and the State College Area School District (PSU-SCASD PDS program).

Program Context

Based on the definition and historical development of the PDS movement nationwide, the State College Area School District and The Pennsylvania State University joined in partnership to create four Professional Development Schools. These four schools are a result of a six-year effort to collaboratively plan and open Professional Development Schools that achieve three goals. The first goal is to enhance the educational experiences of all children. The second goal focuses on ensuring high quality field experiences for prospective teachers. The third and final goal is to engage in furthering the professional growth of school and university based teachers and teacher educators (Dana, Silva, & Colangelo, 1999).

Today, Penn State students are selected to complete the yearlong internship program through an extensive application and interview process in which mentor teachers play a major role. The students begin the experience during the second week in August with an intensive two-week campus-based preparation experience, termed "Jump Start." Interns then join their mentors for orientation, classroom preparation for the school year, and district meetings. At this point, interns abandon the university calendar to teach alongside their mentors.

Through seminar and teaching alongside a mentor each day of the school year, interns earn 30 credits, the equivalent of the Penn State’s Elementary Education Discipline Inquiry Block Courses (three credits each in math methods, science methods, social studies methods, classroom management, and clinical experience) and Student Teaching. Teams constituted by mentor teachers and Penn State teacher educators structure the experience to ensure that course objectives are met, within the rich context of spending a full school year in the field.

Technology infusion in university coursework and the PDS classroom

Identified as a goal of the PSU-SCASD PDS program is to find ways to support the development of interns' skills and understandings of ways to effectively use technology to enhance and support children's learning. To achieve this goal, interns are given initial experiences that are supported by the university method instructors. During the first phase, interns experience activities that are designed to help them explore and make sense of teaching with technology. Individually, interns are asked to reflect on these experiences. Class and on-line discussions (using CourseInfo through the website www.blackboard.com) focus on the students' emerging ideas about teaching with technology.

In the second phase, the interns engage in additional scientific investigations using the technology tool. As some of the instructor support is removed, interns experience setting up the technological tool. For example, they explore how to use individually selected software such as Tom Snyder's Graph Club, Claris Home-page for designing web pages, and Kid Pix for presentations. Interns practice with such technological equipment as heart monitors, and electronic microscopes. While they 'played' with digital cameras, scanners, and video equipment for recording and digitizing, interns explored technological tools that were available for teacher use in their schools. In conjunction with their mentor teachers, interns figured ways to have the hardware available for daily use in their classrooms. They negotiated some of the practical dilemmas that arise when trying to make technology effectively usable in a classroom.

During the third phase, PDS interns examine and modify existing exemplary curricula to effectively infuse technological tools. Interns consider in-depth the plausibility of using a particular piece/s of technology. Mentor teachers, interns, and university faculty are involved in discussions that help the intern to conceptualize what the process of technology infusion might look like in the classroom. The goal is to integrate technology into planning classroom activities that support and enhance children's learning, rather than designing and implementing some 'cute' motivational activity. Consequently, the children's experiences with technology fosters further learning experiences that are open-ended.
In the last phase of the technology infusion process, interns move from the role of learner about technology to that of teacher with technology. Interns write and enact technology-enhanced lesson plans. Lesson may be co-planned and co-taught with other interns and mentor teachers, and the process is supported by university faculty. The interns reflect on these individually, and are asked to post their lesson plans and reflections on their web pages. The latter two phases emphasize the planning and teaching aspects of learning to teach with technology. Further, central to this process, is the building of interns' confidence as they learn about technology and how to use it, and how to be a teacher who can effectively infuse technological tools to enhance the curriculum and support student learning.

Case Studies in the Elementary PDS Classrooms

Five case studies are described as examples of technological infusion in the context of PDS elementary classrooms.

Grade 1 – Prehistoric Life with the Dinosaurs using Kid Pix Studio

In designing a culmination activity for a first grade science unit, Prehistoric Life, a team of two interns and two mentor teachers brainstormed ideas that integrated technology. They sought ways to construct a report-writing task as the final activity. Such a task would allow children an opportunity to present gathered information in a way that was supported by technology. Creating a slide show using Kid Pix Studio to highlight the children’s experiences with discovering their mystery dinosaurs was the agreed upon task for each group of children. Support was offered by university faculty members in the PDS community to facilitate this process in conjunction with the teachers, parent helpers, and the first graders.

A planning time was organized to familiarize the children with Kid Pix Studio. Digital photographs were taken throughout the unit as the children engaged in activities that sought to identify their mystery dinosaurs. Each child selected the background for at least one slide, the transition from slide to slide, and the appropriate photograph. In order to access enough computers to allow 46 children to work in groups to construct a slide show, five computers were relocated into one of the first grade rooms for one day. Teams of children, each facilitated by an adult, worked over a four-hour period to complete the slide shows. Every child wrote and recorded (using a microphone device) reflections underneath the photograph on the slide.

Parents were invited to attend the Slide Show presentations on the final day of the unit. Teachers, university faculty, parents, and other audience members were very impressed with the children's explanations that highlighted how they designed their slide shows. Shared comments from the witnessing adults expressed surprise that first grades were capable of using such technology to create slide shows.

Grade 2 – Exploring the Seasons at Acorn Pond

The software program, Sammy's Science House was integrated into a second grade science unit that facilitated student understanding of the weather characteristics of the four seasons. The objectives of the unit focused on how students identified the four seasons, and explained the effects of each season on people, plants, and animals. The instructional plan was framed.

Before: The station area was arranged to accommodate a computer work area. The computer software Sammy's Science House was installed. Construction paper was prepared for students' drawings.

During: The computer software Sammy's Science House was explained and demonstrated to the children. The children were instructed to go to Acorn Pond. In this area the children rotated through the seasons at Acorn Pond. First, they folded their paper into four sections. In each section, they drew and labeled each scene at Acorn Pond. Second, they explained what was occurring to the plants and animals at Acorn Pond. They included in their picture what happened to the pond, the tree, and the animals each season. Third, the children included the temperature at Acorn Pond during each season. Last, they clicked on the animals and
listened to what the animal was doing to prepare for life at Acorn Pond. This interactive activity focused the children's learning on this ecosystem and its inhabitants throughout each season.

After: The children discussed what they saw occurring at Acorn Pond. Ask volunteers described their drawings. Questions were pondered: What happened to the tree, the animals, and the pond during each season? What were some of the animals you learned about during each season?

Closure: The children identified how they relate to each season. How do they change throughout the seasons? What in their lives changes? What are some real life problems that they encounter within each season?

Assessment: The assessment for each child's work was based on the drawing completed and the explanations given about Acorn Pond's adaptations for each season. The children included the changes occurring to the tree, pond, and animals at Acorn Pond; the temperature averages at Acorn Pond; an explanation about the weather characteristics of each season; and labeling of each season.

Reflection: The children depicted through drawings and text the effects of the seasons on plants and animals. They also learned the attributes of each season. The computer program was very effective in helping the children understand the concepts. The students were excited about the computer software. The students arrived at the station in groups of 4 to 5. They cooperatively shared two computers with their partners. Conversation and discussions were held around the computers about the animals and scenes at Acorn Pond. The children liked the interaction of the computer. This allowed the children the freedom to converse and make decisions on their own about what they wanted to depict in their illustrations of each season. Throughout the lesson the children verbalized their findings to the adults and their peers.

Grade 3 – Where do Insects go during the Winter?

In Andrea's third grade classroom, there were a number of students who demonstrated an interest in the outdoors. Considering the constraints of curriculum and the interests of these students, Andrea lead a small group of children into the woods for a science investigation. She chose to use a guided type of inquiry and framed the investigation with the question: Where do insects go during the winter?

As she searched for books on insects in the school library, and browsed the net for sites (Topics in insect ecology, and Insects Winter) on insect galls and over-wintering, Andrea realized how important it is for a teacher to have a good understanding of content before trying to teach it to children.

After venturing into the woods the previous day, Andrea led a class discussion that focused on what the students had observed on their field trip. She asked the students why they had not found any insects in the woods. One suggested it was too cold. Some students indicated that the insects were buried deep under the ground, and we didn't dig far enough.

At this point the intern stopped the discussion and introduced a plant gall that her mentor teacher had brought in. Andrea let them look at it with microscopes and make conjectures as to what it could be. Some students thought it might be a cocoon that hardened on a seed pod from a tree. At this point, Andrea divided the group in half. Three children found a seat around a computer with her, and the other half of the group wrote further question down in their journals. Books on insects were available for the students to browse after they finished writing. This part of my lesson was aimed at showing the students sources of information about insects in particular, and science in general.

Andrea shared a series of web sites (Insect Galls, Butterfly Farm, and Ants) that included pictures of galls, information about various insects, and pictures of the insects in their many habitats. The students analyzed the detailed images of the galls. They identified galls that they had seen in their yards or on pine trees as well as maple and oak trees.

This intern concluded that finding ways to infuse technology with scientific inquiry is an important process for supporting children's learning. In particular, guided researching of the Internet provides information that children can use to expand their knowledge and generate further questions for scientific inquiry.

Grade 4 – Representing Nutritional Information through Electronic Graphing

In his efforts to familiarize students with constructing graphs using technology and connect these with the Pennsylvania Science Standards, an intern facilitated fourth graders exploration of foods on the
basis of protein content. In searching for a developmentally appropriate task, students were given opportunities to explore and implement the Graph Club software, designed by Tom Snyder. Initially, the workings of the Graph Club were explained to groups of students. Time was given for these groups to investigate the software and explore its capabilities. The task was outlined to each group, and roles were set for each member of the team. Two students spent some time exploring the program, while the other two identified information from the labels of the two foods to be compared, and recorded this onto a worksheet. The information was used to construct the graphs.

The task was designed to provide the four students with a job each: one at the keyboard, one at the mouse, one providing the information from the worksheet, and one student to serve as a "proofreader"—assessing the group's progress, making sure that the information was assigned correctly to the graph's columns. The roles of the students were exchanged. In this context, student learning was assessed as they constructed the graphs. Focus questions were provided by the intern to guide the students in a comparison of the content of two different foods. For example, How are the axes to be labeled?

Questions were asked that promoted student involvement in predicting and comparing. For example, In what ways are these foods different? How do you know? Students were asked to make predictions, using their current experiences with their knowledge about their foods and the graphs they designed. For example, If we graphed information using Graph Club, what foods are similar in content? Students asked insightful questions. For example, How can two apple sauces contain such different amounts of sodium? Printed graphs indicated the graph's accuracy in comparison to the recorded information on the worksheet, and each group's progress with the task.

Grade 5 – How can the Internet be used effectively to enhance Human Body Instruction for Fifth Grade Students?

As she became more responsible for planning lessons, an intern explored ways she could use technology to support instruction in her fifth grade classroom. With all the information allowed by the Internet, this intern felt that there must be useful ways to incorporate this technology into more of the instruction, particularly to give students access to artifacts and images that they would not normally have the opportunity to see firsthand.

As they embarked on the science unit, The Human Body, Sara figured ways she could present an explanation of the human cell. She contemplated an in-depth analysis of a cell model, showing different organelles to the students and explaining the functions of each. As she did not feel particularly comfortable using a photocopied image of a cell, Sara searched the Internet for a suitable website. As part of an introductory lesson, Sara used the site: http://www.cellsalive.com that featured many actual microscope images of various types of cells. There was an option to watch a real time video of cells undergoing mitosis. In her exploration of this site, Sara found a model of a cell – a detailed, color representation that allowed the user to click on a desired organelle. It linked to a page that gave a more in-depth explanation of the organelle along with more photographs and a few animations that simulated various functions. Sara showed these pages to the students and talked through the important points. The students were instructed to draw a model of the cell, and list the names and functions of the organelles in a chart format.

From earlier experiences using the Internet as part of instructional practice, Sara anticipated the students' many questions about spellings. Although the organelle names were on the web pages, these were only legible for the students nearest the television monitor. Sara used the computer as a chalkboard by taking advantage of its multitasking capabilities. As she used Netscape to navigate through the cellsalive page, Sara opened two windows within AppleWorks – one was for word processing and the other for painting. From here she dragged these windows into positions that would allow her to click on the edges of the windows and easily switch applications. After introducing a new organelle, Sara clicked on the word processing window and typed its name in a font which was large enough for the students furthest from the monitor to read and copy. Once the students had an opportunity to copy this information, she clicked on the painting window and drew an example of a model cell, adding organelles to the drawing. This reinforced what the students were learning – first, students looked at the web page and discussed the organelle, then they saw the words and copied them down, and finally they labeled their drawings of the cell.

The next computer-based lesson focused on the skeletal system. Sara located a web page through the Penn State biology department that showed a full skeleton alongside the names of all the bones. When
the user clicked on a bone name or part of the body, a real picture of that bone was seen. Sara's intent was to use this as a guide to talk through the parts of the skeleton and look at the different features of bones and joints by examining individual bones.

The final Internet based body lesson related to the muscular system. Sara located two sites with short movies about types of muscles and their functions. Since the first animated movie had a pause button, Sara was able to stop it at certain points to reinforce, question, or check for understanding. After the introductory movies, Sara moved to another site that had a large diagram of the muscles of the human body. Here, a user can move the pointer over a muscle and the muscle name popped up. Sara worked through this from the head to the toes, highlighting important muscles, while the students recorded these on their own diagrams. Again, the words on the screen were small and unfamiliar, Sara used a large font on AppleWorks to ensure that students recorded the information accurately.

Conclusion

As we figure ways to facilitate the development of preservice teachers' skills and understandings about how to use and infuse technology into curriculum, teacher educators are faced with 'better problems.' Negotiating our better dilemmas leads us to ask questions such as: How do our philosophies of teaching and learning with technology impact the way preservice teachers understand using technology? How do we keep up with the changing technology? How can we further evolve our own understanding and skills about using technology? In what ways can we sustain classroom learning environments that facilitate preservice teachers understandings of technology? How do we support and enhance inservice teachers in their efforts to model the effective use of technology in classrooms?

References

Almquist, Corinne. (2000). http://www.personal.psu.edu/users/c/m/cma137/

Snyder, Amy. (2000). http://www.personal.psu.edu/users/a/m/ams361/

The year 2000 continued the unprecedented trend toward stakeholders from PreK-16 education, the community, business, and government joining forces to reconfigure teacher education to include the intelligent use of technology by our future teachers. Sparked in large part by the Preparing Tomorrow's Teachers to Use Technology (PT3) grants awarded by the Department of Education, this trend was additionally supported by national initiatives in standards, reform, and research with an eye toward sustained change through the use of technology in teaching and learning. Traditional educational methods and structures are being challenged: past era practice is not sufficient for 21st century learners.

In the first two years, the PT3 program awarded over 250 grants to consortia nationwide. Along with the groundbreaking innovations and organizational changes that grantees undertake, they are further charged to disseminate findings and practices to fellow grantees, peer institutions, and the general public. A dedicated PT3 section in these SITE Proceedings, representing over 60 institutions, is a testament to the diligence of these consortia to share their knowledge, successes, and challenges so that others may learn.

The initiatives highlighted in this section describe more than successful courses or innovative individuals. Experience has shown that such isolated change will wither in the long term without transformed assumptions about learning, shared visions of success, and committed wholes, from the top administrator to the novice student. Due to the exceptional volume of entries in this section, individual papers will not be introduced; rather, general trends have been used to organize the selections into categories: Design of Model Programs, Restructuring Existing Technology Courses, Faculty Professional Development, K12/University Partnerships, Electronic Portfolios, Online Tools, and Video-Based Resources.

Design of Model Programs
A great number of the PT3 grantees are progressing through their first year of funding, while the rest are well into their second year. Not only are the authors of these papers able to describe the components of their model designs, but many can now also give advice on early implementation. One project, for example, details a training model for preservice teachers. Another utilizes the three components of faculty development, technology-enabled field experiences, and a digital portfolio system. A third makes use of four tools: classroom mentoring, mini-grants and stipends, innovative training formats, and K-6 to university modeling. A field-based model that provides preservice teachers with supported opportunities to use instructional technology in authentic classroom settings is detailed. At least one paper focuses on efforts to incorporate technology proficiency into teacher preparation, and two in particular describe the elements of systemic change spurred by their projects. Other grantees present strategies of modeling and mentoring for effective technology use. A final paper in this section comments on the larger implications for such program improvements in teacher education programs across the country.

Second-year projects have submitted papers that address their first-year evaluation results. Authors describe faculty attitudes toward the inclusion of technology within teacher education courses, qualitative and quantitative results demonstrating positive results gained over the first year, the components of program implementation, including pre-planning, roles and responsibilities, and management tools, and the processes, instruments, data collected, and lessons learned on the way toward a technology-rich and sustainable teacher education program. Clear in many of the papers in this section is an honest appraisal of the
difficulties inherent in the technology training process, with practical suggestions for project implementation in other settings.

**Restructuring Existing Technology Courses**

How to best prepare preservice teachers to meet the challenges of technology-integrated learning stands as one of the major concerns within the PT3 grant program. Many grant recipients have agreed that the traditional educational computing course seems to no longer suffice. Accordingly, universities have developed innovative approaches to restructuring the traditional course format. New models, successes, and student responses to these changes are shared in these papers.

**Faculty Professional Development**

A clear theme emerging from this selection of writing is the focus on developing the technology skills integration abilities of faculty, although the strategies for faculty development are broad in range. The four broad categories of faculty support cited in one report are reflected throughout this section: faculty release time, frequent meeting to share successes and challenges, workshops and training sessions, and ongoing support. One project used data from a questionnaire to design and evaluate computer support services and training workshops, as well as to help individual professors to design professional development plans. Another provided resources for methods faculty to devise courses and model technology integration, while a third used a mini-grant process to enable faculty to change syllabi, take training courses, and collaborate with technology-trained K-12 faculty. Supporting faculty for the long term in their efforts to experiment with ways to use technology to change and enhance their teaching was key in the majority of papers.

The methods of instructing faculty on technology skills described in these papers come in all forms, from a three-day technology camp for faculty, K-12 teachers and teacher education students to a week-long “technology chalkboard” program within a smart classroom to four month intensive faculty training period to develop technology-enhanced lessons. Faculty work with technology fellows or coaches in two projects to provide “just-in-time” instruction, and even taught one another technology skills in another.

**PreK-12/University Partnerships**

The end result of all PT3 efforts is to see technology being successfully integrated in schools. To further this effort, many universities have used their grant monies to fund partnerships with school districts. Benefits are reaped by all participants; preservice teachers have the opportunity to implement their technology skills in a real world environment, school districts receive equipment, training, and other resources from universities, and in-service teachers have access to the latest technologies and teaching strategies for their classrooms. The main benefactors, however, are the students whose needs are met by the collaboration and cooperation of so many on their behalf.

**Electronic Portfolios**

As artists use portfolios to select and demonstrate the best products of their craft, teachers can use electronic portfolios to demonstrate their proficiency to a far greater degree than is allowed by a single observation. In addition to being used as evaluation tools for pre-service and in-service teachers, portfolios are also used as a self-assessment tool. Reaping the greatest benefits from this powerful technology requires intense planning and learning from others’ experience. Provided within these papers are discussions of necessary technologies, advantages and disadvantages, and various models of portfolio implementation which will guide the broader application of these tools.

**Online Tools**

The projects described in this section not only position technology as the focus of instruction for their preservice teachers, but also utilize technology tools for data management, communication, and curriculum design. A university-based project using an online data collection system reports on the pros and cons of the system. Another partnership tells of the use of a technology-based curriculum design software used by faculty and teachers to quickly align curriculum with state accountability guidelines. Two groups describe online communication tools, one using course-related online discussions to gauge students’ learning and disciplinary thinking, and another building community and facilitating group problem solving among preservice teachers and faculty through participation in online discussions. The development of an interactive website for faculty and teacher education students is the focus of one paper, although the majority of papers in this section describe some extent of web presence.

**Video-Based Resources**

Advanced technologies such as streaming video are being developed to bring authentic classroom experiences into the college methods course and serving as the instructional medium for students at a distance. Visual communications artifacts for teacher education are detailed in one paper. Another project discusses the challenges of developing a streamed video collection of teachers using technology to be used online by teacher education students as examples of technology incorporation into content areas. Other papers in this section also make mention of efforts to develop video-based materials.

As evidenced by the variety of topics addressed in these papers, the PT3 grants have engendered innovative
plans and creative responses from universities and organizations across the country. A forum such as SITE 2001 allows solutions to be shared, ingenuity to be recognized and partnerships to be formed. Recognizing that we stand at the threshold of promising developments and understandings within a complex topic, the papers contained in this section serve as foundations upon which the larger goal of technology integration will be based.
Modeling Instruction with Modern Information and Communications Technology: the MIMIC Project

Abstract: This paper describes the MIMIC Project a U. S. Department of Education Preparing Tomorrow's Teachers to Use Technology implementation grant. In this project colleges of education at five Ohio universities are collaborating to increase the modeling of technology in pre-service teacher education. The underlying premise of the partnership is that teachers teach as they were taught. As such, the partner institutions have developed a variety of processes where technology proficient educators mentor university faculty on the integration of technology into undergraduate teaching. The faculty in turn model best practice with technology in pre-service teacher education programs. Students enrolled in the pre-service teacher education programs encounter further technology modeling from cooperating teachers who have received technology training and the pre-service students are provided with opportunities to implement technology in field placements and student teaching.

Introduction

Teachers who integrate technology into their K-12 teaching on a regular basis are still in the minority (OTA, 1995). Despite considerable cost and effort the potential of technology remains unfulfilled in the classroom. This unfulfilled potential is a major concern as questions regarding the efficacy of educational technology intensify (Stoll, 1995). What makes the current situation increasingly untenable is that twenty years of inquiry into the barriers to technology use in K-12 classrooms have led to an understanding of many of the key obstacles. Dias (1999) has identified resources, teacher time, training, and support as critical to technology integration. As more school districts equip facilities with computers, software, and Internet access, issues regarding resources (hardware, software, and accessibility to technology) have given way to questions regarding the nature and quality of professional development (teacher time, training, and support) (Ohio SchoolNet, 1999).

Recent research has identified attitudinal impediments to technology implementation in K-12 classrooms. Prominent among these are teacher beliefs (Ertmer, Addison, Land, Ross & Woods, 1999), and their relation to the adoption of instructional reforms (Neiderhauser, Salem, & Fields, 1999). Technology
integration as a component of instructional reform requires that teachers change beliefs and practices. Neiderhauser et al concluded that traditional beliefs about schooling remain strong and stable. The question remains whether many classroom teachers are experienced enough with educational technology to alter their beliefs, and embrace the potential for technology in the classroom.

Historically, the call for higher education reform related to technology has emphasized the need for hardware and software, the development of basic technology skills, the creation of instructional materials and, more recently, connectivity to online resources. Indeed considerable funds have been expended in these arenas. However, the sufficiency of this approach to impact overall change is open to question as the teaching methods modeled in typical teacher preparation programs have changed little over the years. Faculty modeling of technology integration is crucial, but the probability of increasing technology modeling is low as incentives to reexamine methods of instruction are haphazard and resistance to change in higher education is extensive.

Why has teacher education reform been so difficult when the investment in and promotion of technology integration has increased dramatically? In part, it is because prior reforms discount the importance of what Lortie (1975) documented twenty-five years ago, “that teachers teach as they were taught.” Despite the addition of equipment, instructional materials and basic skill development, novice teachers do not use technology appropriately because informed models of technology use are lacking or absent in their learning experiences. At best, there is little within teacher preparation programs to systematically encourage novice teachers to embrace technological innovations. More often, the unknowns associated with technology use discourage novice teachers from integrating technology into their teaching repertoires.

Possession of technological skills though necessary does not guarantee technology integration. Novice teachers must also have appropriate experiences and instruction throughout their pre-service preparation (Thompson, Hansen, & Reinhart, 1996). Teachers must also understand how to apply technological skills in a pedagogically sound manner. This pedagogical capability is a key premise for integration. According to Handler (1992) teachers must observe the use of technology in the instruction they experience if they are to perceive technology as an instructional tool.

The current task is to provide instruction in pre-service teacher education that models the integration of technology. With this approach novice teachers will have experiences that will encourage them to effectively integrate technology into their teaching – to teach as they were taught. To this end, the MIMIC project is based on the premise that faculty mentored in the use of technology will be more likely to demonstrate the integration of technology to their students.

Prior Efforts

There was a precedent set at Cleveland State University (CSU) for mentoring faculty during the 1980s when the College of Education (COE) initiated the Visiting Instructor Program (VIP), a practitioner guided mentoring program. This popular and successful program recruited master teachers from area schools. The teachers were afforded COE faculty status during a one-year appointment and team-taught methods courses with COE faculty. The unanticipated consequence of this mentoring program was that the COE faculty was led to reevaluate the teacher education program and to revise it to reflect the realities of the classroom of the 1980s. Co-mentoring associations developed during the VIP program are still in existence today.

Design of the MIMIC Implementation project was also influenced by experiences gained from a one year Capacity Building grant (Abate, 2000). Practices that proved successful during the Capacity Building year were continued in the Implementation project. Primary among the successful practices were the use of classroom professionals as mentors for higher education faculty, the involvement of both College of Education and College of Arts and Sciences faculty, local decision making, and the application of standard evaluation materials.

Five Cleveland area colleges of education (Cleveland State, Baldwin-Wallace College, John Carroll University, Notre Dame College of Ohio, and Ursuline College) participated in the Capacity Building project. Acknowledging that each of the participating teacher preparation programs faced different technology integration challenges, the partners developed a plan to facilitate autonomous and flexible local management by each institution while promoting an exchange of ideas and solutions across institutions. Despite programmatic differences, all of the partner institutions were guided by a commitment to prepare education students to integrate technology in K-12 teaching.
As a result of the partnership plan, each institution recruited individuals best suited to meet its specific educational technology challenges. The majority of recruits were classroom teachers, but some were retired classroom teachers, school administrators, and even pre-service teachers with technology backgrounds, to mentor their higher education faculty and cooperating teachers. All mentors were designated Master Classroom Teachers (MCTs). They held Ohio SchoolNet training certification, or the equivalent, and were regarded as outstanding classroom teachers or potential teachers. They provided the higher education faculty with a host of technology integration experiences through one-on-one personalized mentoring. The influence of such able mentors in educational methods and selected Arts and Sciences courses increased pre-service teachers’ awareness and understanding of technology use in the context of their teacher preparation courses. Technological solutions were modeled that reflected the kinds of technology problems faced by teachers in today’s classrooms. Furthermore, in their role as mentors to the faculty, the MCTs had direct input into the ongoing shape of the courses and related field experiences. Several of the MCTs participating as mentors have indicated a willingness to serve as cooperating teachers for pre-service teacher field experiences, thus extending the impact of the project to future students.

Having someone to interact with that successfully uses technology in the classroom proved advantageous to both higher education faculty and the pre-service teachers. The curricular modifications and the development of technology-infused teaching strategies that the MCTs sparked during the Capacity Building year led to major modifications in higher education classroom instruction.

We just burned a CD-ROM of pictures I had from Antarctica and tropical rain forests for my Geology 101 class. I can now present to the whole class without having to deal with slide trays and projectors. My mentor is encouraging me to make duplicate copies of the CD-ROM so we can make them available for student use. (Heather Gallacher, The College of Arts and Sciences, Cleveland State University)

The benefits of course modifications will remain on the campuses for future student populations. As such, even in the Capacity Building year the MIMIC Project was institutionalizing the integration of technology into teacher preparation courses. Applying the ISTE standards the MCTs were encouraging the higher education faculty and pre-service teachers to model learning strategies that involve more student interaction, more connections among schools, more collaboration among teachers, and more emphasis on technology as a learning tool.

My MCT teaches English/language arts in an urban setting. We view technology as a means for supporting best practice in integrated English/language arts methods. Careful revision of my syllabus has resulted in technology-supported assignments including use of the Internet for exchanging teaching ideas and establishing local and national professional collaborations via learned society Teacher Exchanges. I consider my MCT a teaching partner, and with her support I am changing my vision of meaningful technology implementation in integrated English/language arts. (Kathleen Benghiat, The College of Education, Cleveland State University)

In addition to the work of the higher education faculty and their MCTs, assistance provided by the MIMIC educational technologists helped teachers implement technology in their classrooms. This mentoring and support had a profound impact.

This year, our pilot program is bringing technology assistance to 14 teachers at St. Thomas Elementary School, an urban, Catholic school in the Hough area. Without the support of the capacity grant, the faculty would not have the ability to prepare the classroom teachers to model technology for their students. (Jennifer Merritt, The College of Education, John Carroll University)

Overall the Capacity project provided a foundation for a full implementation. Students at all levels benefited from the effective modeling of technology in the classroom.

Implementation Project Design

A consortium consisting of faculty from Cleveland area colleges of education including Cleveland State University, Baldwin Wallace College, John Carroll University, Notre Dame College of Ohio, and Ursuline College, developed the MIMIC implementation model. Three interrelated activities serve as the foundation for this model:

- Higher education faculty members are mentored in the meaningful integration of technology into their teaching. The higher education faculty in turn model this instruction for pre-service teachers;
• Professional development in basic technology integration in specific content areas is provided to K-12 schools identified by partner institutions. In particular, schools which routinely accept and support pre-service teacher field placements receive support; and
• Materials produced by the project are disseminated to local, regional, and national audiences.

Implementation Mentor and Faculty Format

As in the Capacity Building project, each of the MIMIC partners is recruiting the assistance of technology proficient MCTs. Local needs at each partner site, including the individual needs of each faculty member being mentored, dictate the recruitment of MCTs. The goal remains the same at each site: to mentor higher education faculty and advance practical insight into the integration of technology in pre-service courses. The mentoring relationships are markedly different from traditional training in educational technology. In MIMIC mentoring, each faculty member has a partner to interact with on specific needs and areas of interest. The mentor, who is typically a classroom professional, affords a bridge between theory and practice. The MCTs bring authenticity to pre-service programs by introducing solutions to “real world” technology problems faced in today’s classrooms.

In their role as mentors to faculty, the MCTs have direct input into the ongoing shape of the courses and clinical supervision of related field experiences for teacher preparation. The curricular revision and the development of technology-infused teaching strategies that the MCTs introduce lead to modifications in university classroom instruction. The benefits of those modifications remain on campus for future student populations. As such, the influence of the Implementation Project extends beyond the individual mentor pairs.

The MCTs apply ISTE standards to further what research supports about how students learn best. The MCTs encourage the higher education faculty and pre-service teachers to model learning strategies that involve more student interaction, more connections among schools, more collaboration among teachers, and more emphasis on technology as a tool for learning. On their return to their classrooms, these teachers provide the project with a unique pool of educators who will then participate on a continuing basis as supervising teachers.

Faculty Participants

Across the five participating campuses there are many college of education faculty members interested in augmenting their teaching repertoire with the integration of technology. Since the inception of the Capacity Building grant, numerous faculty members have become involved in the project. Recruiting college of education faculty is a straightforward task as the number of volunteers exceeds the number of available openings. One limiting condition for selection is that college of education participants must be responsible for teaching pre-service methods or foundation courses. In addition, a limited number of positions are reserved for faculty indicating a desire to participate for more than one year of the project. The logistics of recruiting Arts and Sciences faculty is more complicated. In order to have the greatest impact on pre-service teachers, only faculty members responsible for teaching Arts and Sciences courses required within general pre-service programs are recruited for the MIMIC implementation project. Target numbers for Arts and Sciences faculty involvement are set by each institution.

Together with the MCTs the Faculty assume the following responsibilities:
• Review best practice with technology in their content area with the educational technologists;
• Examine the syllabi of courses to detail technological activities suitable for inclusion;
• Work with MCT mentors to integrate technology into the identified courses;
• Review the ISTE NETS with educational technology faculty;
• View videotaped technology-rich lessons for use in methods courses;
• Where necessary learn the basic use of specific technologies;
• Team teach in undergraduate courses;
• Participate in the development of instructional resources; and
• Develop descriptive accounts of processes for dissemination.
Cooperating Teachers

Every year hundreds of northeast Ohio K-12 teachers serve as cooperating teachers, opening their classrooms and providing guidance to pre-service teachers fulfilling their field experience requirements. In the Capacity building MIMIC Project, educational technology faculty from the participating institutions mentored small numbers of cooperating teachers to assist them in the development and implementation of technology in their teaching. Creating a widespread impact on teacher modeling with technology via this approach, though successful, is not feasible. For example, even though these cooperating teachers may receive student teachers, practicum placements, and field observations, the total number of students they will encounter is very low when compared with the time and effort expended in mentoring. In addition, all of the cooperating teachers who were mentored across all of the institutions entered the mentoring activity at a very basic technology skill level. The majority of the time spent mentoring was geared to developing basic technology skills. More traditional inservice workshops can achieve the same results with a greater number of cooperating teachers serviced. For this reason, the Implementation project replaced mentoring with cooperating teachers with professional development workshops. The professional development differs slightly from traditional educational technology training in that it is offered to content based teams rather than school based teams. As content based technology training it focuses on Implementation details as well as basic skill development.

Project Evaluation

Implementation project evaluation activities address both formative and summative evaluation questions that examine the validity and impact of the project. A comprehensive sequence of evaluation activities is implemented to insure that the goals proposed by the MIMIC Project are addressed satisfactorily. A monthly review is used to track project activities and to verify that planned activities occur as scheduled. Progress notes are recorded and used to modify planned activities. Surveys are administered to identify the technology proficiency of higher education faculty and supervising teachers. Information collected from the survey is used to tailor mentoring and instructional activities. End of the year surveys comparable to previously mentioned surveys will be administered to furnish a pre-post picture of faculty and supervising teacher skill development.

Mentors prepare an implementation plan for each faculty member and maintain notes on support provided. This qualitative data is used to modify mentoring plans. A pre-post review of syllabi developed by participating faculty members and supervising teacher logs of technology activities implemented offers qualitative data that will document technology use by participants.

Dissemination

A prototype web site (http://mimic.ed.csuohio.edu) dedicated exclusively to the implementation of technology by novice level technology using teacher educators was developed in the Capacity Building year. Content on this site is revised periodically, and selected outside reviewers are currently testing the site.

One of the primary roles of the MIMIC project coordinator is to increase dissemination of the MIMIC Project by reporting project efforts, editing papers for submission, and assisting in the development of faculty presentations. This added attention and support by the project coordinator dramatically increase the availability of information on modeling technology in teacher education programs.

To encourage involvement in the project faculty participants are provided travel funds to report on lessons learned the MIMIC Project at regional and national conferences. During the spring of each year the MIMIC project will host an Urban Colleges of Education Technology Summit. The focus of the summit is on preparing pre-service teachers who will teach in urban settings to integrate technology into their teaching. Proceedings from this summit will be disseminated through the Internet and traditional publication sources.

Conclusion

The MIMIC Project began in the fall of 1999. To date the project has recruited Master Classroom Teachers, paired these MCT's with university faculty, and together they have developed individual mentoring
plans. Monitoring and evaluation of participant interactions is ongoing and feedback has been provided to participants. E-mail has been used extensively to promote community and to serve as an example of modeling of technology integration. A web site designed by the MIMIC team and local classroom teachers is currently under development. K-12 teachers who model technology in their classes have been recruited for the purpose of developing videos that exemplify the integration of technology in the classroom. The long-term success of the MIMIC project is dependent on the active participation of the mentor-faculty dyads. As such, emphasis has been placed on supporting participant control over project activities and minimizing administrative requirements. To this end, the project team has simplified recorded keeping, provided technical support, and kept physical meeting to a minimum.

As participant interactions increase, the mentor-faculty dyads will document the successes and failures of the school-based learning, work-based learning, and connecting activities implemented. Management of the project will be revised based on this documentation. Finally, indications at this point are that both classroom teachers and university faculty are reacting favorably to the mentoring arrangement and more importantly that the university faculty are starting to integrate technology into their teaching.

Abstract: Prior to Fall 2000, the College of Education at the University of Houston, required its undergraduate education majors to enroll in a three-hour course, CUIN 3312, “Information Technology for Young Children.” The original one semester course was divided into three one-hour courses spanning three semesters. The elimination of prescribed assignments is a major change in the requirements for the newly structured technology course. In the new model, technology assignments support required education course activities, thereby demonstrating through practical applications how technology should be integrated into classrooms. Education professors are beginning to restructure their course requirements to allow for increased technological use. Students are searching out ways to meet course requirements using technology even when they are not specifically required to do so by their professors. Early indications arc that this model may in fact fulfill the intent of the restructuring effort.

Like most universities, prior to Fall 2000, the College of Education at the University of Houston, required its undergraduate education majors to enroll in a three-hour course, CUIN 3312, “Information Technology for Young Children.” This class taught instructional technology applications through predetermined assignments that focused on learning basic computer applications. This course was generally effective; however, some faculty perceived a need for the technology course to be integrated with the students' required education courses. Handler and Strudler (1997, p.16) assert that pre-service teachers “often do not have the opportunities to apply what they have learned in their other classes and field experiences.” There was a shared value among our faculty that the classroom training of pre-service teachers should use technology that was aligned with methods instruction and include active self-directed learning experiences. The vision was for students to learn technological skills and apply to the assignments required in their education classes. It was thought that this approach would better prepare them to use technology both in the performance of professional tasks and as a teaching and learning tool in their future classrooms. The faculty in the Instructional Technology program applied for and received a grant through the "Preparing Tomorrow's Teachers to use Technology" (PT3) program. The grant provided funds for changing the way technology was taught and applied in the undergraduate education program at the University of Houston.

Following the proposed project design, the original one semester course was divided into three one-hour courses spanning three semesters. This provides students with technological support throughout their upper-level coursework and student teaching experience. The new model allows for a continuous
learning process over a longer period of time, intended to result in students developing stronger skills and having more opportunities to apply those skills in real world scenarios.

The elimination of prescribed assignments is a major change in the requirements for the newly structured technology course. In the new model, technology assignments support required education course activities, thereby demonstrating through practical applications how technology should be integrated into classrooms. Objectives for the new technology course are based upon the International Society for Technology in Education (ISTE) National Educational Technology Standards (NETS). Course objectives require that students demonstrate mastery of at least eight of the twenty-four ISTE indicators during each of the three semesters. Grading criteria for the new course includes attendance, demonstration of at least eight ISTE indicators, and participation both in class and in regular on-line discussions. In order to implement these revisions to the technology course format, lab instructors meet with education professors to learn about their course assignments and investigate how those requirements can be met through the use of technology.

On the first class day, the new course model was introduced to the pre-service teachers, and they began brainstorming class assignments that could satisfy ISTE indicators. The students also recognized how course assignments using technology would enhance their teaching portfolios, a requirement for graduation and an important asset during interviews. Supported by the findings of Hirumi and Grau (1995, p.14) that “teacher education programs that cover a limited number of prescribed computer proficiencies at a set pace and sequence may leave many educators unsatisfied and frustrated with their training,” the new class format is driven by students needs and is based on individualized learning activities. The technology instructors pre-assess students on their basic computer and Internet skills in order to plan effectively. Currently, instructional formats include large group presentations, small group workshops, and independent learning activities. Participating pre-service teachers have collaboratively developed a reflection format that accompanies their individual projects and allows them to articulate their mastery of ISTE indicators. In addition, students have developed a grading rubric that instructors use to assess the reflections and finished projects. Lab instructors have provided assistance to students in locating resources necessary to meet those ISTE standards that are not evident through part of required tasks in their education classes. These include the investigation of such materials as online grade books, forms of assistive technology, and information on copyright issues and acceptable use policies.

During the first semester, stakeholders have responded favorably to the changes in the course. Education professors are beginning to restructure their course requirements to allow for increased technological use. Some professors have actually changed their syllabi to incorporate more technologically based assignments. Lab instructors are developing workshops to strengthen application skills for both students and professors. Students are searching out ways to meet course requirements using technology even when they are not specifically required to do so by their professors. The online hypergroup, a format for ongoing communication and collaboration, is supporting the evolution of a learning community among the participating pre-service teachers. Through this medium, students share ideas regarding their course assignments and research efforts. While applying new technological skills in their class presentations, students inspire their peers to learn new applications. Early indications are that this model may in fact fulfill the intent of the restructuring effort. Future study of implementation and outcomes will continue to better determine the impact on the skills of pre-service teachers in the use of technology as an integrated instructional tool.

Trek 21: A PT3 Project to Facilitate Teachers' Design of Engaging Learning Environments

Laura Adams Advanced Educational Studies, West Virginia University, USA, ladams3@wvu.edu
Trey Dunham Advanced Educational Studies, West Virginia University, USA, pdunham@wvu.edu
John Wells Advanced Educational Studies, West Virginia University, USA, jwells3@wvu.edu
Neal Shambaugh Advanced Educational Studies, West Virginia University, USA, nshamba@wvu.edu

Abstract: The goal of Trek 21 is to prepare educators to use and integrate instructional technologies (IT) for teaching and learning. This paper reports on outcomes resulting from the first-year implementation of a 3-year model of IT integration – a collaborative process for developing sustained, systemic changes in teaching, using a year-long cycle of on-going professional development and analyses of data designed to inform these changes. Baseline findings profiled K-12 participants as preferring a teacher-centered approach, providing minimal written details in lesson plans, and depicting themselves with a low level of computer use, and low use and integration levels of instructional technology. Teacher change from 3-week summer institutes included (1) improvements in skill, comfort, and confidence with ITs; (2) increased awareness on how IT use changes student and teacher participation; and (3) increased motivation in IT integration after seeing improvements in students' own motivation to a different teaching approach and involvement.

Introduction

Current instructional technologies afford student and teacher access to information and multiple modes of knowledge construction. By design, these new technologies make this method of knowledge construction largely individualistic and demand changes in the teaching and learning environments where they are truly integrated into the instructional process. New teachers (pre-service) cannot develop new perspectives on instructional design and new instructional technology skills outside of settings and environments in which these approaches are modeled. Students exiting teacher preparation programs must include experiences to integrate new and future instructional technologies and develop the skills necessary develop appropriate teaching environments where limited technology infrastructure and capacity exists.

Recent recommendations by the National Commission on Teaching and America's Future claim that the single greatest likelihood of impact on student learning is the education and professional development of pre-service teachers. The report's assertion that pre-service teacher education has the potential for the greatest influence in enhancing the learning opportunities of children requires bringing together the contexts of schools with the preparation of teachers. This preparation must be adequate and sustained in the professional practice of teachers such that schools become the leader of this transformation rather than merely a participant, or worse a trailing, incidental, disaffected subject of the transformation.

Technology integration must be embedded in the work of teachers and in the preparation of teachers (Darling-Hammond, 1994). Technology becomes not just a tool, but an engine in the transformation of schools. To insuresuch transformation, teachers must be the agents, not the recipients, of the technological shift. The integration of teacher education must be an endeavor located in the complete system that affects the quality of teacher preparation. This partnership requires that we view teacher education as more than a linkage of partners who use technology in isolation. Teacher education would be a “place” that engages all contexts vital to successful teachers in one shared, professional culture. Public school and university professionals at the in-service and pre-service levels would provide the knowledge base for technology integration critical to successful teacher practice and the highest quality learning for children. The goal is not just a set of experiences, but rather the creation of a professional culture where pre-service students are engaged in settings at the university and in schools where the best integration of technology in teaching practice is modeled systemically.
Teacher Preparation Program

The Benedum Collaborative at West Virginia University is a 5-year teacher education Professional Development School-based program that is attempting to build a professional culture in a partnership. This partnership includes 5 West Virginia school districts, University partners and 21 Professional Development Schools in an effort to renew public schools and teacher education. A core element of the new program is a technology strand, developed to help university faculty and PDS faculty in the integration of instructional technology as they participate in the pre-service teacher education process. These teaching and learning environments engaged in instructional technology provide pre-service teachers opportunities to experiment with technology integration and to re-examine their roles as teachers in a technologically enhanced classroom.

Project Design

The Trek 21 model of teacher preparation and professional development includes Host Teachers in West Virginia's statewide Professional Development Schools (PDS), faculty from the College of Human Resources and Education (HR&E), and student interns in their 5th year of WVU's teacher preparation program. Trek 21 looks to impart lasting change in the culture of teacher practice. When effective modeling and integration of instructional technologies occur, new teachers entering the profession meet with success. To accomplish this, the design of the Trek 21 model includes the following series of professional development events.

Summer Institute: Three-week technology integration summer institutes for PDS Host Teachers and a two-week technology integration summer institute for university faculty initiate each year of the Trek 21 project cycle. These institutes address genres of instructional technology applications (Harris, 1998), targeted technical training, and the preparation of instructional technology materials and resources necessary for immediate integration into classroom instruction. Teachers develop a web-based instructional unit, which they implement in the fall with the pre-service student intern.

Continuity Meetings/Site Visits: Following the summer institutes, Trek 21 holds site-based continuity meetings with PDS faculty each semester to address issues related to the successful integration of instructional technologies at their location. Site visits occur throughout the year to provide continued support.

Semi-annual Mini Conferences: Each semester a mini-conference is held in partnership with the West Virginia "Technology, Teacher Education, Tomorrow" (T3) non-profit organization to share best practices, receive technology enhancement training, and to deliver presentations of activities related to the integration of instructional technologies.

Assessment

Project assessment uses multiple forms of data, multiple roles and levels of participants, and at developmental stages that assess the impact of technology integration during and after project completion. This assessment strategy also provides formative assessment information to help the teacher education partnership meet national standards for teacher preparation and practice, including NCATE, INTASC, and the National Board for Professional Teaching Standards. Both quantitative and qualitative methods of data collection are used for assessment, and serve as the foundation for evaluating the impact of this initiative to integrate technology into teacher education. All instruments and assessment of knowledge products are thematically consistent in evaluating the changing nature technology integration within classrooms, across schools, across faculty groups, and within the outcomes of the teacher education students' learning experiences and teaching practices.

Findings

The baseline assessment of this project incorporates multiple instruments that will assess the impact of technology integration after the project has completed. These instruments along with others described below will serve as the foundation for assessing the impact of this initiative to integrate technology into teacher education. All of these instruments are thematically consistent in assessing the changing nature of how technology is integrated within classrooms, across schools, across faculty groups and within the outcomes of the teacher education students' learning experiences and teaching practices.
Schools Climate Education Survey: This survey assesses four factors of change in school climate related to national standards and shared partnership beliefs. Two of these factors, “Professional Development Activities” and “Classroom Teaching/Learning Activities”, are critical to our assessment strategy and will reflect the use of technology in PDS classrooms. Data gathering for this assessment is scheduled for May, 2001.

Pre-Service Teacher Survey: This survey assesses three factors of student teaching and other clinical experiences with reference to partnership standards and beliefs. Quantitative results from the instruments administered indicate K-12 and Higher Education faculty alike are predominantly at low use and low integration levels (42% and 47% respectively). Approximately 30% of faculty in each group could be categorized as intermediate, and the remaining split fairly equally between experienced or beginner stages. As these are pre-training assessments, effectiveness of training will not be available until the September of 2000 following evaluation of Trek 21 summer institutes.

Concerns-Based Adoption Model: This instrument (Hall & Louck, 1978) describes and assesses teachers’ transition through 7 levels of concern that they may experience as they implement a change or innovation in teaching. The survey tracks their levels as they adopt and/or implement the new practice. Findings indicate that the PDS Institutes were effective in addressing participants’ internal concerns as reflected in decreases in eight of twelve pre/post-test I comparisons. The Institutes had limited impact on any external stages of concern.

Learning Strategies Survey: The Learning Strategies Survey contains items that assess teachers’ perceptions of practice in their own classrooms. The Likert-scale ranges from “always” to “never” and applies to questions that ask teachers to reflect on the nature of their teaching practices. PDS participants preferred a teacher-centered approach. Looking at individual factor scores, a small number of participants’ scores slightly exceeded the mean norm. For Learner Centered Activities, four respondents exceeded the group mean; for Assessing Student Needs and Climate Building, seven respondents exceeded the group mean; and for Participation in the Learning Process, two respondents exceeded the group mean.

Self-Evaluation of Basic Computer Use: This rubric assesses the level of achievement that teachers self-report according to a set of computer competencies. Teachers are asked to rate themselves across three rubrics of computer use: 1) basic computer use; 2) advanced computer use; 3) teacher Internet use. Each of the rubrics has four levels; Beginner, Low Level User, Intermediate Level User, or Experienced User. A total of 44 teachers responded across all three Institutes and rated their level of computer use; 6% (3) of the 44 teachers related their ability to be an Experienced User, 30% (13) rated their ability as Intermediate Level User, 50% (22) rated their ability as a Low Level User, and 14% (6) rated their ability as Beginners.

Lesson Plan Assessment: Teachers submitted paper-based lessons for IT integration. Complete lesson plans included learning outcomes, state standards, materials, procedures, and assessment. Analysis of these lessons revealed that 38% (18) of the 47 teachers did not submit a lesson plan, 32% (15) submissions included some features of a lesson plan, and 30% (14) of the teachers submitted a complete lesson plan.

PDS Summer Institutes

During each summer institute teachers were asked to respond daily to questions regarding the content and quality of training. Two batteries of questions were asked: Likert-scale, forced choice and open-ended response.

Likert-Scale Items: Overall the summer institute training had a positive impact on understandings of the project, the process of planning for IT integration and the use of the ITs used in the training agenda. The training also had a positive impact on participants’ level of confidence that they would use the skills and the ITs would be included in future training. Faculty members from the Professional Development Schools were less likely to be familiar with storyboarding than were faculty from the College. Overall, the impact of the training on the HR&E faculty was less. Sessions where only ITs were introduced without hands-on application did not exhibit significant impact. Participants indicated that they were less confident in using ITs in their units.

Open-Ended Questions: Responses to open-ended questions were categorized as opportunities, expectations and engagement, impacts on intern, and impacts on students.

Teachers stated that it was nice to have time set aside to develop and work on units, as schedules during the school year were often prohibitive to the opportunities afforded by the Summer Institute. Similarly, teachers noted that traditional technology training focused on the development of skills, but the Institute provided strategies and support for integration of the technology into actual units. The majority of teachers mentioned the opportunity for one-on-one assistance and hands-on application.
Most teachers stated that expectations for the Summer Institute needed to be made clear from the outset. How the Institute was to be organized, the level and duration of commitment expected of teachers and what the teachers were to produce were areas the teachers stated needed clarification.

Several teachers emphasized that use of language was a source of confusion with regard to expectations. Teacher and trainer understandings of what constitutes a “unit” and what is a “lesson” appeared to teachers to be different. The use of vocabulary surrounding the technology (lingo and jargon) by trainers raised levels of expectation of computer literacy.

Many teachers commented that their skill and comfort levels with technology and integration had increased throughout the Institute. Teachers noted that the kinds of technology presented were pertinent to their teaching situations in the classroom and therefore the training was motivating. Several teachers also mentioned that the increased integration of technology into units would increase student motivation and engagement. They stated that engagement, not just increased learning opportunities was a worthwhile goal.

A majority of teachers were excited to share with their interns what they had learned. They saw themselves as able to model IT and to “encourage them to use technology as a teaching tool.” Citing increased comfort levels with technology teachers also planned to help the interns develop their own units and lessons.

Teachers also stated that they felt “ready” to teach their units and “excited” about what their students will learn. Some said that students would be exposed to new things, motivated and “will definitely benefit” from the IT units. Increased opportunities to use the computer and technology were other impacts that teachers cited.

Overall, teachers felt that the Summer Institute was a positive though “exhausting” experience. Several teachers stated that they were thankful to have the laptop, the training, the one-on-one help and the time to develop the units. “This [was] an intense 3-week institute, with additional work at home. However, the experience [was] really great! And rewarding. I really [appreciated] having this opportunity!”

PDS Site Visits

Generally, teachers reported that the implementation of the units was proceeding as planned, but that modifications based on time, content and student skill level were often needed. Some teachers stated that most difficulties arose from problems with equipment, especially hardware. Most teacher reported that, although more time-consuming, the IT unit had given them an alternative teaching strategy and had increased their own interest and motivation. Nearly all teachers said that students were more engaged, interested and motivated as a result of the technology integration. Other impacts were an increase of collaboration between students, “asking good questions,” interest in doing relevant searches at home and increased satisfaction in “the finished product.” Some teachers also noted the many new learning opportunities technology afforded students while a few regarded the computer as “managerial and teacher-focused; not items that related specifically to teaching.” Teachers stated that intern involvement ranged from complete implementation (in the case of a sick teacher) to “secretarial duties” (e.g., entering rosters into Blackboard.com. Nearly all teachers expressed frustration at the delay of interns receiving laptops. One teacher allowed her intern to take her laptop home every night to work on a new unit while another intern was not afforded any type of “collaborative experience with the computer.”

Continuity Meeting

Modifications. Teachers reported that they either had or planned to make modifications to their units (21/34) such as the following:

- Expand or add features
- Need to “fine tune” their units
- Forced to modify the timeline for their unit
- Make their unit more “student-centered”
- Change the types of technologies used
- Modifications based on students’ abilities or needs
- Modifications based on “technical difficulties”

A few teachers (3/34) explained that they had not yet run their units and so were unsure if changes would be needed. In addition, several teachers (8/34) shared that they were satisfied with their units and had no immediate plans for modification. A few teachers (3/34) planned to amend other units or classroom activities by integrating technology.
Intern Involvement: Teachers reported that intern involvement (unit modifications and unit implementation) was often dictated by the timing of placements. Several teachers (8/34) reported that their intern had either not arrived, had completed placement before the unit was implemented, or had not been in the classroom long enough to participate. Teachers (5/34) also cited the delay in obtaining laptops for intern use as a barrier to involvement. Some (12/34) indicated a high level of intern involvement in unit development and implementation. Others (7/34) described a less active intern role—observing the host teacher integrating technology or providing one-on-one assistance as students interacted with technology, but not “teaching” with technology. Some teachers (20/34) indicated that interns developed and integrated technologies at fairly high levels when they arrived for their placements. “My intern used some parts of the unit, but had designed her own to use prior to starting this year.” Teachers (7/34) described instances where they felt interns had inadequate training or where interns were not familiar with integration in the classroom.

Impact on Students: The majority of teachers (26/34) described increased student engagement as a result of unit implementation, particularly where students had “hands-on” opportunities: Teachers (13/34) described an increase in learning as an outcome of technology-supported instruction. In addition the “fit” between content and technology enhanced student opportunities to learn. Several teachers (4/34) commented on the proficiency and ability of their students to learn to use technology. However, teachers (5/34) also indicated that the impact would have been greater but for the barriers of lack of access to equipment and their own abilities to provide technology training for students.

Impact on Teachers: Increased confidence and comfort related to using technology personally and professionally was the most often cited (17/31) change when teachers were asked to “describe the impact you think the experience of developing and running your unit has had on you.” Related to their increased comfort was a perceived impact on their teaching:

- Change in the activities they use
- Improvement in the quality of instruction
- Change in their role in the teaching process
- Increased their own engagement
- Awareness of other IT possibilities
- Increased motivation to learn
- More efficient communication and management
- Sense of themselves as resources

Teacher Units

The PI, IDT specialist and Special Education Specialist evaluated a total of 43 units (Table 1). The PI and IDT specialist passed a similar number of units, while the Special Education specialist assigned a passing score to a higher number of units, but identified only one exemplar unit. The PI and IDT specialist identified nearly the same number of exemplar units, but passed fewer units than the Special Education specialist. Jurors agreed on eight passing units, four failed units, and one exemplar unit.

<tr>
<td></td>
<td>Internet searches (6)</td>
</tr>
</tbody>
</table>

Table 2: Juror ratings of teacher-developed web-based and IT-integrated units.
To support problem-solving teachers primarily used information retrieval activities and desktop publishing. Concept scaffolding was supported by the teachers' use of presentations and information retrieval activities. Discovery learning was supported by information retrieval activities and Internet searches. IT applications most utilized by teachers were presentations (32 activities), information retrieval (29), and Internet searches (17).

The most important IDT issue was lack of identifying the purpose and learning outcomes for each lesson on the unit home page. The web-based units were typically structured as teacher sites with a limited number distinguishing between teacher and student activity. Rich learning activities were frequently depicted in those lessons using traditional teacher-centered approaches; this was generally not true of IT-integrated student-focused activities. Some IT-based activities, such as chat rooms and web boards, lacked procedural details.

Web design issues identified included the following:

- Restructuring home page to communicate intent
- Descriptive titles for individual lessons
- A home page to structure the learning activities
- Less scrollable text or separate lessons pages

Conclusions

Baseline findings profiled K-12 participants as preferring a teacher-centered approach, providing minimal written details in lesson plans, and depicting themselves with a low level of computer use, and low use and integration levels of instructional technology.

Results from 3-week summer institutes improved teachers' internal concerns with instructional technology. Limited impact on the external stages of concern may reflect the limitations of a three-week experience and the lack of opportunity for teachers to apply new skills and knowledge in their teaching. Teachers valued the time made available to concentrate on skill development and unit development. Teacher change can be cited as (1) improvements in skill, comfort, and confidence with instructional technology; (2) increased awareness on how IT use changes student and teacher participation; and (3) increased motivation in IT integration after seeing improvements in students' own motivation to a different teaching approach and involvement. Exactly how to design or orchestrate these changes in student engagement within the web-based units was tentative on the part of many teachers, which could have been partly due to learning how to use the software and laptop. Also, teachers' use of ITs were devoted to teacher-based presentations and Internet-based search and information retrieval activities. However, an important finding for this project was the majority of teachers (26/34) who were interviewed after implementation of their units reported that student engagement increased, particularly when hands-on opportunities were provided.

A major deficiency of our design was not being clear as to what we wanted them to bring to the institute, in terms of a "lesson," learning instead that a "unit" made more sense to them. We also learned that we need to be more clear of their role in their own professional development, not only what was expected of them during the institutes but afterwards. This was due to field-testing a new approach and the logistical learning we did during the planning and running of the Institutes as well as what it meant to assist teachers in changing their teaching.

Contextual Levers: An Embedded Approach to Faculty Technology Development

Peter Adamy
School of Education
University of Rhode Island
United States
adamy@uri.edu

Ted Kellogg
School of Education
University of Rhode Island
United States
tmk@uri.edu

Abstract: While much has been written about the potential benefits of technology integration for teacher education, not all university faculty members embrace the process willingly. This paper describes efforts at the University of Rhode Island to create a unified approach to teacher education across disciplines that incorporates faculty technology development in routine practice. Through the use of standards of practice, an electronic student portfolio system, and the support of innovative practices through a PT3 implementation grant, the School of Education is attempting to integrate faculty technology training into the key aspects of regular operating procedures.

The School of Education (SOE) at the University of Rhode Island (URI), in conjunction with recent major efforts at the university level, is committed to the exploration of ways in which technology can change the nature of teacher education and classroom instruction. The discovery of potential benefits and innovative practices made possible by new technologies has become an integral part of the URI teacher-training program. While the standards to which teacher education programs are held include some acknowledgement of the potential benefits of educational technology, they focus much more on sound pedagogy and what could be termed the traditional aspects of teacher education. This has presented the faculty with the challenge of integrating technology to enhance the teacher education process while maintaining its more conventional elements.

Several authors (ISTE 1999; Wetzel 1993; Willis and Mehlinger 1996) raise questions about the value of the traditional “introduction to technology” course that is the hallmark of many efforts to include technology in teacher education. In such courses, technological tools are taught out of context. The instruction is skills-based, and is focused on the technology instead of curriculum content. To this end, URI faculty and students in the SOE are not trained specifically on the use of basic technologies in isolation from the teacher education curriculum. Instead, efforts are being made to encourage and support the use of technology by all stakeholders in their administrative, educational, and practicum experiences. The goal is to motivate faculty members to maintain a consistent effort to be knowledgeable about new technologies, as well as practical ways these technologies can be used to make the teacher education process more efficient and effective.

Faculty Participation

It is perhaps no surprise that not all of the members of the SOE faculty have embraced technology integration efforts at URI. Like faculty at many universities, they do not see the necessity of incorporating technology into both institutional and personal instructional systems that have worked for years without it. The focus of efforts to change faculty practice is on the development of a shared vision of how to move forward with the school’s instructional program. Gaining group consensus in the process of technology
integration is consistent with much of the literature on the adoption of technology in higher education. One basic conclusion of this research is that people are the key to success; both the faculty and the administration must support the integration efforts in order for them to work (Anandam & Kelly 1981; Armstrong 1996).

Higher education faculty members are accustomed to functioning as experts in their particular fields, which can make it difficult for them to accept the role of learner that is often required when approaching new technologies (Brunner 1992). At the same time, forced acceptance of technology is ineffective (Bull & Cooper 1997). A shared vision (Falba 1997) of the role that technology plays in the mission of preparing teachers is crucial to success, and is key to the approach being used to move URI faculty forward in their use of technology. In agreement with Heuer, et al. (1996) and Kozma (1985), the faculty members have played an ongoing and vital role in the development of a revised program of study that embeds technology as an integral part of the teacher education process. This active role is not only key in ensuring that these efforts are more successful and long-lasting than individual labors, but also serves as a point of leverage for convincing professors and adjunct faculty of the importance of learning to use and integrate technology into their teaching and supervision.

Contextual Levers

URI’s integrated approach to faculty development combines three elements to address the task from three different perspectives:

Beginning Teacher Standards

In recent years, the state of Rhode Island has moved to increase the rigor of its teacher education programs through the use of standards for all new teachers. The Rhode Island Beginning Teacher Standards (BTS) cover eleven areas of professional practice that one would expect to find as part of standard operating procedure for high-quality teachers (e.g., solid content and pedagogical knowledge, ability to foster critical thinking, classroom management skills, effective communication skills, etc.). In part, the BTS also serve as a quality control mechanism for the state. Institutions such as URI have an agreement with the Department of Education that allows the SOE to indicate when a student has met all eleven standards, at which point the state assumes that he or she is eligible for certification.

The SOE at URI has adopted these standards as a primary guide for the organization and implementation of its teacher education programs. The focus on the BTS has facilitated the coming together of all departments that train teachers under a set of common purposes, tasks, and evaluation criteria. The traditional resistance that is encountered when trying to achieve this kind of group consensus on curriculum (typically dressed in the guise of “academic freedom”) represents something of a victory - a confluence that was previously unknown at this institution.

The standards themselves have provided a common element across disciplines and the various tasks that are part of teacher training, which has increased consistency in the way teachers are trained. However, the BTS does not stress technology directly, but implicitly. For example, the standard:

"Teachers create learning experiences that reflect an understanding of central concepts, structures, and tools of inquiry of the disciplines they teach..."

Includes the following sub-standards with implications for being able to use technology:

2.3 select instructional materials and resources based on their comprehensiveness, accuracy, and usefulness for representing particular ideas and concepts.
2.4 incorporate appropriate technological resources to explore student exploration of the disciplines.
2.5 use a variety of explanations and multiple representations of concepts including analogies, metaphors, experiments, demonstrations, and illustrations, that help students develop conceptual understanding.
Prospective teachers at URI are required to complete a portfolio at three separate stages in their program: Prior to admission, prior to commencing their student teaching, and upon completion of all program requirements. The first portfolio is basically a compilation of evidence that candidates are qualified for admission. The second is designed to provide evidence that students have acquired an appropriate understanding of pedagogy through their methods courses. The third contains evidence that they have met all eleven BTS, and are thus qualified for certification. This evidence is compiled on an ongoing basis as they proceed through the program, and culminates as their final task at the end of student teaching.

Electronic Portfolio System

Until recently, the compilation, storage, and organization of this material have been isolated efforts for each student. As part of the technology integration endeavor at URI, this process has been redesigned to allow students to do these tasks electronically. This system is designed with a database structure that allows students to store and organize their evidence for each standard on a server that allows web-based access. Students can view and update their portfolio at any time from any location.

Faculty also have access to communicate with students about their progress, to view work that has been completed, and to grade each element of their students' portfolios. The online nature of this process changes the role of individual instructors to the extent that this interaction that is so vital to new teachers' growth now takes place within a paperless format. Typically, this type of change is one that could be expected to meet resistance, since the move to grading work online is not essential in a paper-based system.

Searching capabilities built into the database also allow outside reviewers and program accreditors to view evidence of the effectiveness of the teacher training programs at the university. This fact has also increased the level of buy-in from both the tenure-track and adjunct faculty, as they are forced to address an increased level of accountability for the program. Accrediting bodies are now requiring specific alignment of tasks and syllabi with standards, as well as more standardized methods for determining whether students have met the requirements and achieved the competencies outlined in the standards. As described above, the online portfolio system has been designed to align SOE curricula with the BTS. This provides a specific and consistent way for the program to address these issues of accountability, and is a powerful lever for motivating faculty to change and to buy in to new procedures.

The process of compiling and reviewing electronic portfolios provides one avenue for enhancing the technological capabilities of both faculty and students. For both groups, the portfolios represent a critically relevant task that requires the use of technologies such as text manipulation, digital storage, digital photography, video, and sound editing. Tying these technologies to one of the core tasks in the credential programs has significantly increased motivation to learn these technologies. The portfolio development process requires each program to carefully reflect on the essential elements of its curriculum and the pieces of evidence to be considered as indicators of the standards. Attainment of any standard requires satisfactory completion of multiple core projects, each of which may provide evidence to more than one standard. Careful planning of these projects and the nature of the technology used is required to assist faculty in planning assignments in specific courses.

In its effort to bring together all departments responsible for training teachers, the SOE is in the process of expanding the training in and use of this portfolio system to all relevant faculty and students. This in turn is helping to expand technology training beyond the teacher education faculty in a way that is consistent with the goal of integration versus isolated skill development. Traditionally, those departments outside the SOE that train teachers (e.g., music, art, foreign language, etc.) maintain a certain level of independence and isolation from the SOE. Accrediting bodies are now requiring the SOE to be responsible for any students who gets their teaching credential from any program within the university. This has created a substantial increase in the desire to work with those programs more closely, in order to help ensure the quality of training their students receive. The electronic portfolio system is serving as a way to bring all departments that train teachers under the SOE umbrella. They are required to meet similar standards of accountability, and the portfolio system will help make that job easier and more consistent for all programs involved.
Preparing Tomorrow's Teachers for Technology (PT3)

While the electronic portfolio system is helping to increase faculty motivation for technology use, it does not specifically address ways that technology can be used to change the nature of their instruction and training of teachers. This is currently being accomplished through the SOE's PT3 implementation grant. This initiative supports Education and Arts & Sciences faculty members in their efforts to experiment with ways to use technology to change and/or enhance what they do at the university. This represents an opportunity to increase the use of technology in content area courses that student teachers encounter in their Arts and Sciences majors (see Bull and Cooper 1997).

Regular meetings between faculty members from multiple departments and K-12 classroom teachers facilitate discussion of innovative technologies and techniques for using them in the classroom. This forum creates an opportunity to increase faculty self-efficacy with technology through the sharing of effective uses that are already in place (Faseyitan, et al. 1996). These meetings have also helped in the formation of partnerships across disciplines that have increased participants' exposure to other methods, issues, and concerns about using technology in education.

While most of the efforts that have been described in this paper are focused on group processes and outcomes, the PT3 project provides the most support for individual endeavors to integrate technology into practice. Technical support is provided for the entire SOE through the grant in the form of knowledgeable faculty and student employees. Individual faculty members are also being encouraged to experiment with technology to change the ways in which they conduct instruction and supervision in the teacher education process. This experimentation is encouraged and supported through the availability of funds for hardware and software, and through individual mentoring and support.

Conclusion

The process of change within any university is unpredictable, given the traditional freedom that is expected by faculty members in their role as experts within their disciplines. Most attempts to mandate change in practice are met with resistance due to a perception of infringement of this freedom. The School of Education at URI has approached the task of changing practice through technology integration as a group process. By achieving consensus on curricular changes that must be made in order to satisfy more rigorous demands from accrediting bodies, the SOE has taken a significant first step in changing teacher training to align the curriculum with state standards for beginning teachers. In addition, the SOE has increased faculty acceptance of the potential that technology holds for enhancing practice by creating a process of teacher education that fully integrates technology into the key steps of that process. Faculty get meaningful, hands-on experience with technology in teacher education, because it is required to complete key components of the mission of the SOE.

This group process is simultaneously supplemented by support for individual efforts to use technology to enhance practice. Through a PT3 implementation grant, the SOE is encouraging faculty to engage in dialogue across programs and departments, and in experimentation with the ways in which they have traditionally functioned as teacher educators. Through these combined group and individual processes, URI is attempting to get faculty to examine and explore the potential that technology holds for enhancing teacher education and individual practice.

Teaching, Learning and Technology: Providing for Higher Education Faculty Professional Development

Valeria Amburgey, Ed.D.
School of Education
Northern Kentucky University
United States
amburgey@nku.edu

Abstract: Recognizing the need to better prepare teachers in the appropriate and effective instructional applications of technology has not been a difficult task for the faculty at Northern Kentucky University (NKU). The adoption of the ISTE Recommended Foundations for Teachers and a five-year Technology Plan for the School of Education in 1998 set the stage for increased emphasis on technology education at NKU. While the faculty supported these initiatives, there were many concerns about how best to accomplish these tasks. One of the critical needs identified by faculty in their ability to infuse technology into the teacher education program involved their own technological skills and abilities. Professional Development of faculty became a high priority issue. This paper describes the professional development component of NKU’s Teaching, Learning and Technology (TLT) Project.

Introduction

Schools and Colleges of Education must review and revise their teacher education program as needed in an effort to prepare teachers to meet the challenges of current school and classroom environments. As society changes, the educational needs of students change. Technology, today, is a primary problem-solving tool in many aspects of society. Schools must prepare students to use technology effectively, which means that teachers must also know how to use technology effectively. Institutions of Higher Education who do not address the technological needs of P-12 teachers will be unable to provide society with the best teachers.

Robinson (2000) states that changes in the use of technology in the classroom necessitate strategic planning and forethought. He emphasizes the importance in the planning and preparation of the institution’s most valuable asset --- people. Hixson and Tinzmann (1990) describe institutional change as both a people and a policy process. They continue to point out that professional development is the primary vehicle through which important educational changes are implemented as one of four overriding principles. Northern Kentucky University (NKU) recognizes the importance of the people within the institution as the developers and implementers of any institutional change.

NKU’s School of Education uses a continuous review and assessment model for both student and program evaluation. Strategic planning is an on-going and reflective process. Standing committees make recommendations to the faculty for consideration in revising, refining and updating the teacher education program. Committee recommendations are often based upon standards from learned societies, accrediting agencies, student performance measures or other available data. In 1998, the Technology Committee recommended to the faculty the adoption of the ISTE Recommended Foundations for Teachers. Once approved, these standards became the basis of the technology-training component of NKU’s teacher education program. With these standards in mind, the faculty approved a five-year Technology Plan for the School of Education which included four major goals to help provide better technology preparation of teachers: (1) to provide the students and faculty in the School of Education with the most advanced multimedia teaching and learning environments, (2) to assist faculty in becoming fully competent in using multimedia in their teaching, (3) to develop a plan for maintenance and regular software and hardware upgrades of the faculty and staff computers within the School of Education, and (4) to revise the manner in which the School of Education ensures and verifies that undergraduate and graduate students completing a degree or certification program at NKU have the necessary skills in using technology in the classroom.
Setting the Context

The importance of having teachers within the state of Kentucky who are more technology literate has been supported by several key initiatives. Increased emphasis on the use of technology in P-12 schools began with the implementation of the Kentucky Education Technology System (KETS) during the early 1990s. And, in May 1999, the Education Professional Standards Board in the state of Kentucky implemented a new technology standard for both new and experienced teachers. The statewide technology standard is based upon the ISTE technology standards for teachers.

Many teachers, however, do not feel prepared to use technology effectively. The Kentucky Institute for Education Research (KIER) stated in their January 1999 report that 26% of all new teachers in the state of Kentucky felt moderately/very poorly prepared to "use technology as an integral part of instruction". A principal survey conducted by Northern Kentucky University in 1999 found that 25% of area principals felt that their teachers were moderately/very poorly prepared. A 1999 business and education study (Forward Quest) in Northern Kentucky called for effective implementation of technology in our schools and the Northern Kentucky Cooperative for Education Services (NKCES, 1999) Professional Development Needs Assessment found that 12 of the 25 priority needs of area educators involved one or more areas of technology.

NKU's faculty addressed the need to better prepare teachers to use technology with the adoption of the Technology Plan for the School of Education. Technology standards were already beginning to be included within the teacher education program. However, concerns existed about how to meet these goals and fully implement the new technology standards. An outside consultant interviewed faculty during the 1999-2000 academic year and identified three main concerns in their ability to integrate technology into their classroom: (1) convenient access to the technology, (2) training on how to use technology and (3) time to experiment and redesign their classes to include more technology.

The TLT Project

During the 1999-2000 academic year, NKU was able to begin to build capacity for technology training of new teachers with the award of a one-year PT3 grant from the United States Department of Education (U.S. DOE). This grant allowed NKU to accomplish major beginning steps in the implementation of the five-year technology plan. The next step to be able to fully implement all components of the technology plan became possible with the award of a three-year PT3 implementation grant from the U.S. DOE.

The goals for NKU's Teaching, Learning and Technology (TLT) Project are based upon three of the four goals outlined in the Technology Plan for the School of Education. The goals for this three-year project are to continue to build upon the successful integration of technology into the teacher preparation curriculum by providing:

- **TECHNOLOGY-RICH ENVIRONMENTS**: providing technology-rich environments for students and faculty, both on-campus and in field placements.
- **FACULTY PROFESSIONAL DEVELOPMENT**: designing and implementing professional development for NKU faculty.
- **STUDENT PROFESSIONAL DEVELOPMENT**: ensuring that students seeking initial teacher certification have the necessary skills and resources to use technology in their teaching and learning.

The professional development of NKU's faculty is a crucial component to the successful implementation of this project. Classrooms can be equipped with state of the art technology. However, if faculty do not know how to use the technology in their classroom, then technology will once again be lost to the students.

Teacher education students are required to provide evidence of their knowledge and skills with technology. However, they will be unable to demonstrate effective and appropriate uses of technology to support instruction if
they have not observed these best practices. It might be possible for teacher education students to become familiar
with effective instructional practices with technology if their field placements provide these models. There is no
guarantee that this will happen as evidenced by the reports noted above that in-service teachers do not feel prepared
to use technology effectively. It is imperative, then, that our faculty model best practices with technology just as
they do with instructional strategies, classroom management, evaluation and assessment.

Providing for Professional Development

At NKU, the teacher education program includes faculty from most disciplines across campus. NKU’s faculty have
a wide variety of technology concepts and skills — ranging from leaders in technology use and innovation to those
who have yet to turn on a computer or use email. As part of the TLT Project, professional development is provided
to our faculty through formal or informal venues. The School of Education’s Technology Coordinator works as a
“technology mentor” to faculty providing not only professional development but also continuing support for faculty
who are working to infuse technology into the teacher education program.

Formal professional development

Each semester, a select group of faculty receives three semester hours of reassigned time for professional
development in the area of technology. This reassigned time allows faculty to participate in structured technology
training. It also provides the time for restructuring or redesigning their individual courses to include technology.

At the beginning of each semester, the Technology Coordinator meets with the group of faculty who are receiving
reassigned time for technology training. During this meeting, each faculty member identifies a list of personal
goals/objectives they wish to accomplish in order to infuse technology into their classes. This is similar to a
professional growth plan that P-12 teachers may develop as part of their professional development. Faculty also
provide “before” samples of course syllabi or other course materials that they expect will be revised/updated as a
result of their technology professional development. With the goals of each faculty member in mind, the
Technology Coordinator assists in the development of a plan for accomplishing these goals.

A time and location are identified for regular meetings with the faculty technology group. Based upon the skills and
knowledge of the faculty for that semester, the formal meeting times may be weekly or biweekly. Each meeting will
focus on one of the goals/objectives of the faculty group. Development of web pages and/or use of the Internet to
enhance their classes has been the most requested formal training request. Additional requests have included
technology standards, presentation software (such as PowerPoint), spreadsheets, educational software, and
technology resources along with individual requests for training with basic computer skills.

Many of the structured training sessions are conducted with the entire group of faculty who has received the
reassigned time. One or more faculty members may have specialized or individual needs that others in the group
may not require. To accomplish these individualized needs, the Technology Coordinator may work one-on-one with
the individual faculty member. In the case where the needs are outside of the Technology Coordinator’s realm, the
faculty member may work with someone else or do independent research that is later shared with the group. Two
examples that reflect this individualized approach: (1) the science and math education faculty wanted structured
training on the use of CBL’s and their use with graphing calculators. This was provided by a Chemistry professor
from the College of Arts and Sciences on campus who had extensive experience with this technology. (2) one
faculty member was so new to technology and did not feel comfortable with turning on the computer or using email.
The Technology Coordinator met once a week with this faculty member and provided very individualized
instruction on basic computer use.

Informal Professional Development

Changes and issues related to technology in the instructional setting are on-going. Even the most proficient
technology-using teacher has to participate in some form of professional development just to keep up with the
technology revolution. And, often the time within a particular class or single training session is not adequate to
explore a technology topic in depth or to expand upon the basic training provided.
Technology seminars are regularly scheduled to provide opportunities for both faculty and students within the teacher education program to learn new technologies or explore beyond the basics of specific technology skills. These seminars are conducted by NKU students, faculty or area educators. Faculty who participated in formal professional development training during the previous year have provided seminars on their current projects or use of technology in their classes. Area educators have provided updates on statewide initiatives in technology education or shared projects from their schools or districts in technology.

As noted above, these seminars are open to all NKU faculty, teacher education students and area educators. One interesting outcome of our project is the interest of the teacher education program staff in these seminars. The staff is invited to these seminars and the Technology Coordinator is working with them to develop seminars specially designed for their needs. The staff serves as an important support system for our faculty and students. A strong technology foundation for our staff will provide our faculty and students with additional resources for technology issues.

On-going Support

Providing faculty with reassigned time and formal professional development for one semester will not ensure that technology will continue to be infused into their classes. Changes in technology, standards in teacher preparation and needs of area schools will require faculty to continually review, revise and update their classes for the current demands. The role of the Technology Coordinator will be to provide regular updates and maintenance of faculty skills and knowledge long after the formal technology training period. Technology seminars will be an important means of providing new and current information to all faculty and students. NKU will also be providing a central location for faculty development of professional materials. Student technology leaders are also being trained to provide technical support to students and faculty in the development of instructional materials.

Concluding Remarks

Faculty who feel comfortable with technology are more likely to infuse technology into their courses. The professional development opportunities provided to NKU’s faculty often begin with learning the technology. But, an important component of the training also includes best practices with the technology. As each semester progresses, faculty are becoming more familiar with technology and beginning to use some level of technology in their teacher education courses. Other faculty members are able to find models and ideas from their colleagues about possible uses of technology in their classes. The “after” training samples of course syllabi, web pages and other course materials are already beginning to reflect the increased infusion of technology into NKU’s teacher preparation program. The true test will be the long-term evaluation of course materials and the quality of student assessment measures related to technology skills and knowledge.

Infusing Authentic, Content-Based Technology During Teacher Preparation: A Team Approach

Steven Barnhart, Ph.D.
Rutgers, the State University Of New Jersey
Graduate School of Education
United States
barnhart@rci.rutgers.edu

Abstract: Focused teams of professors, K-12 teachers, graduate students and educational technology staff help faculty and teacher candidates infuse technology into academic activities. The faculty integrate technology into instruction, use technology in mentoring candidates in their disciplines, and collaborate with K-12 teachers in technology rich schools. A team is assigned to each certification subject area and has as a high priority the development of interdisciplinary partnerships among faculty in teacher preparation programs and the faculty of arts and sciences. Candidates collaborate with teachers in public and private schools who have been identified for skills in integrating technology into learning. The goal is to ensure that all candidates graduate with a demonstrated ability to provide innovative and authentic technological support for learning. A 3-year cross sequential design has been implemented to evaluate the influence of the project on the abilities and attitudes of teaching candidates.

Introduction

A major theme of current research and of the New Jersey Core Curriculum standards is that students learn from thinking, and thinking is engaged by activities - solving a problem, writing a melody, arguing a point (Jonassen, Peck and Wilson, 1999, p.1). Students gain disciplinary knowledge when they are engaged in problems meaningful to those disciplines, rather than in the more synthetic activity common in school (Brown, Collins, and Duguid, 1989). Students learn any content area best by doing it. Since the process of learning is enhanced through authentic, thoughtful activity, integration of technology within the curriculum should itself be active and authentic. Students make the best use of technology when they use it as a tool for thinking, to learn something they want to know, prompted by a problem that is significant to them. Learning is further enhanced when students collaborate to solve problems or accomplish goals, and share memories and strategies (Perkins, 1991). It is important for teachers to be able to understand and use technologies that enhance conversation and collaboration.

Rutgers, the State University of New Jersey, has redesigned its teacher preparation programs as five-year experiences culminating in a baccalaureate degree in an academic content area and a masters degree in education. This reflects the aim that candidates become qualified teachers who are subject area experts, adept at scaffolding learning within their disciplines. The current project is key to the redesign. It originates, implements and evaluates infusions of technology in each discipline. The goal is to ensure that all candidates graduate with a demonstrated ability to provide innovative and authentic technological support for learning.

With initial funding from Johnson & Johnson Corporation, the project worked with academic leaders and educators in the university and school districts to (1) evaluate current use of technology in Rutgers teacher preparation programs, and (2) design system wide changes in the way Rutgers goes about preparing teachers to use technology. During the first semester, the project piloted three specific strategies in literacy, science and mathematics. With additional support through the U.S. Department of Education grant program Preparing Tomorrow's Teachers to use Technology, the project is now implementing a plan across all teacher preparation programs.
Weaknesses Identified in the Current Program

A survey of university professors and school district personnel administered at the onset of the project showed weaknesses in the existing program that limit the exposure of teaching candidates to modern technology, and limit their practice of technology-supported learning in academic work and school placements. Professors made modest use of technology in their class presentations and interactions with students. Only a few modeled constructive uses of technology in learning or research. Some assigned students to investigate drills or tutorials available in the school’s software collections, reflecting efforts to understand how technology can be used as a teacher substitute, rather than as a tool for investigation and collaboration. Many professors admitted a lack of conceptual and practical knowledge of relatively standard technologies, such as the web, discussion groups, chat, and listservs. They had not used computers extensively in their own academic preparation, and had not yet begun to use them productively in their research and teaching. Some faculty reported they did not have clearly articulated ideas on how they could use technology and wanted guidance from more experienced faculty and staff. Others had some ideas but required additional support to implement them. They asked for educationally grounded technologists who could help them frame issues and design approaches, not pure technicians.

An examination of the existing courses of study revealed a structural weakness. Teaching candidates were intended to gain technology expertise through a technology requirement in their programs, but most students fulfilled it by taking a basic programming class with little regard to pedagogical issues, and no connection to the subject area classes. There was no coordination of assignments between the classes that would, for example, encourage elementary science students to develop web sites with links to important, reliable resources for areas of science poorly represented in their texts. As a result, many candidates in the existing program got little or no systematic exposure to educational technology.

These shortcomings in preparation were reflected in the candidate’s skills at infusing technology into learning. Superintendents in school districts agreed that most of the new teachers they hired from Rutgers or other institutions needed significant training before they could use technology meaningfully in their work. Though the new teachers had basic technical skills, they were not equipped to provide leadership in how to incorporate modern technology into the classroom. The districts and professors agreed that there was little collaboration and coordination among cooperating teachers in districts and professors in the university regarding technology. The use of technology by candidates in different academic areas was not compared or coordinated to ensure that it was meaningful, or to exchange ideas about how technology might be used. These and other weaknesses identified through the survey drove the development of the project design.

Project Design

The central feature of the project is the development of focused subject-area teams of professors, K-12 teachers, graduate students and educational technology staff. The teams help faculty and candidates infuse technology into academic activities. They have as a high priority the continuing development of interdisciplinary partnerships between the teacher preparation programs and the arts and sciences faculty. Each team is led by a professor who is committed to the goals of the project.

A team is assigned to each certification subject area and has two responsibilities: (1) to continually evaluate the experiences candidates have with technology throughout their time in the program to ensure that they develop effective skills; and (2) to design meaningful infusions of technology into learning appropriate for that subject area. The teams assist faculty to more fully integrate technology into learning and help them guide candidates as they complete mentored projects. In the process, candidates collaborate with teachers in public and private schools who have been identified for their skill at integrating technology into learning. The teams support the school teachers as they infuse technology into the experience of candidates during their teaching placements. Elementary and high school students participate in these activities. The technology-rich districts that participate in the program have close ties to the university and have well equipped classrooms with good opportunities for hands-on training of candidates. As the teams work with professors who teach the subject area courses and support the cooperating teachers in the districts, they provide curriculum and faculty development on an ongoing basis. The project is continuously assessed to inform future work. The primary objectives are to:
1. Engage teacher candidates in activities during subject area classes and teacher placements that develop the skills they need to use technology effectively in their future classrooms.
2. Provide technical support, instructional support, incentives, and faculty development for subject area professors to help them effectively practice and model technology integration.
3. Develop collaborations among Rutgers professors, teaching candidates, and teachers in technology-rich school districts.
4. Encourage faculty within and between disciplines to collaborate on meaningful instructional uses of technology and to share problems, strategies and solutions.
5. Use assessment information developed throughout the experience to continuously correct flaws, redesign, and replicate successful activities.

A Project Team Example: Encouraging Apprenticeship and Mentored Research

Students learn content areas best when they are engaged in meaningful problems within the discipline, when they are doing the discipline in apprenticeship with a mentor (Palincsar and Brown, 1984). When teacher preparation students are in a mentoring relationship with an experienced researcher they can begin to understand contemporary approaches and thought in their field. Science professors in the Graduate School of Education have partnered with professors in the science departments to support teacher preparation students in substantive work in contemporary science. In the summer before science candidates enter their fifth year, they attend either the Rutgers Waksman Student Scholars Summer Institute or the Rutgers Astrophysics Institute for an intensive study in their chosen field. They work with current teachers and high school students, and with Rutgers faculty from the Graduate School of Education and the departments of Genetics, Physics, and Chemistry. In the process of doing real science, candidates learn about emerging technologies, experimental design, research methodology, laboratory procedures, data collection and analysis, and scientific reporting. The science support team guides the candidates using constructivist instructional methodologies that can be incorporated in classroom practice.

As part of the Astrophysics Institute, for example, students use the internet to examine NASA’s X-ray photon counts collected by satellites orbiting the earth and perform quantitative analysis of the data using software tools. They construct models of objects that emit photons in an attempt to identify them as white dwarfs, neutron stars, binary stars or other phenomena. During the summer they learn the physics and data analysis techniques needed to conduct research. During the following year they are challenged to solve problems posted on the web and to report their findings there. One important aspect of this program is that the candidates get raw data as quickly as any researchers in the world and do real investigative science. As they use live data, they become part of the internet-based scientific community.

The development of a collaborative relationship between the GSE and the three major science departments in the education of science teachers has been critical to the program’s success. All four units have come together to implement an integrated approach to the education of science teachers. A similar model is followed for other disciplines, including literature, history, world languages, and social sciences. The History team, for example, is making good use of the Valley of the Shadow web site developed at the University of Virginia (Ayers, 1999). The site provides rich primary sources from two communities during the civil war, including letters, diaries, newspaper articles, soldier dossiers, and battle plans. The candidates learn history by doing it. They perform historical research from primary sources and practice techniques to scaffold their own student’s learning of history.

Criteria for Evaluating Instructional Activities that Infuse Technology

Instructional activities are being assessed according to the criteria shown in Table 1 (adapted from Jonassen, Peck and Wilson, 1999, page 227-231) to evaluate how meaningfully they are embedded in each discipline and teaching placement. The criteria are being further refined for specific content areas.

Table 1. Criteria for Instructional Activities Infusing Technology

1. To what extent is the activity naturally complex and embedded in a real world context?
2. To what extent do candidates observe and reflect upon their actions?
3. To what extent is technology contributing to the attainment of specific goals?
4. Do candidates engage in this because it is required or because it is of intrinsic interest?
5. Do candidates wrestle with new experiences and become expert at identifying problems?
6. To what extent do candidates spend time engaged with other learners?
7. To what extent do candidates improve in their ability to negotiate with other learners?
8. Do candidates simply memorize or do they generate hypotheses, evaluate, assess, predict?
9. To what extent is there one 'right' answer, or does the activity foster generation of multiple complex solutions of varying quality that can be analyzed and evaluated?

The Study

A 3-year cross-sequential (longitudinal and cross-sectional) design has been implemented to evaluate the influence of the project on the abilities and attitudes of the teaching candidates in the program. Data was collected in the first semester of the project from teaching candidates in the junior, senior, and fifth year in the teacher preparation program, and from all post-baccalaureate students in the program. The initial data was collected through a paper and pencil instrument. Performance-based evaluations of abilities will be made later in the year. The paper and pencil instrument was used to collect two types of information: student attitudes about the importance of specific internet and productivity technologies, and student abilities to infuse technology into learning. Students self-rated their competence with various technologies and their ability to develop meaningful learning activities that involve technologies. They also proposed specific ways that technology can be meaningfully used to support learning. Data will be collected each semester over the next three years as students are tracked through their programs.

A total of 458 students were assessed this year, approximately 96% of those in the program. A preliminary analysis has been conducted. While most students rated themselves as competent using email and searching the internet, they assigned themselves lower ratings at using other internet applications such as listservs, chat rooms, and online discussion groups - most rated themselves as not familiar at all with web-based distance education or with interactive TV. Similarly, students rated themselves as competent using word processing software, but assigned themselves lower ratings at using other productivity software, such as presentation packages, databases and spreadsheets. The majority rated themselves as not familiar at all with modeling and simulation software or with data analysis tools. Almost half indicated they had never attempted to develop meaningful learning activities involving technology or could do so only with assistance. This held across program and year. More than half indicated they had a similar weakness in applying current instructional principles, research and assessment practices to the use of computers and technologies. Finally, across program and year, most students were unable to propose specific ways that technology can be meaningfully used to support learning. There were some differences by year: post-baccalaureate students rated themselves as less competent with certain technologies, such as listservs, chat, and online discussion groups than did the students in the five-year program. All groups, however, gave similar high ratings to the level of importance that teachers should hold for internet technologies.

Conclusions

Current and emerging technologies include powerful tools that can be used to spur thoughtful, authentic activities within content areas. Yet professors tend not to model constructive uses of technology in learning or research, and school districts find that the new teachers coming out of teacher preparation programs are not equipped to provide leadership in how to incorporate modern technology into the classroom. Initial assessments from the project study reveal striking weaknesses in the ability of teacher preparation students to apply instructional principles, research and assessment practices to the use of technologies in their disciplines. Students are unable to propose specific and meaningful ways to infuse technology into learning activities, though they recognize their weaknesses and assign a high level of importance to technologies in teaching and learning.

The main goal of the current project is to help students learn to develop meaningful infusions of technology in support of learning. A key element has been the development of focused subject-area teams of professors, K-12 teachers, graduate students and educational technology staff to help faculty and candidates
infuse technology into academic activities. It is anticipated that student attitudes and abilities will develop over the life of the project. By engaging students in meaningful technology-enhanced activities during subject area classes and teacher placements, and by providing significant technical and instructional support for faculty who practice and model technology integration, it is hoped that teaching candidates will graduate with a demonstrated ability to provide innovative and authentic technological support for learning.

Abstract: Technology provides opportunities to link students, faculty, partners in education, and the wider communities together to expand, improve, develop, and enhance the learning experience for all. It is this challenge that has led California Lutheran University’s (CLU) School of Education to conceive and implement Project MAGNETIC CONNECTIONS. Progress on the project can be measured through five major activities. These activities include development of a teacher/scholar in residence program, use of an electronic portfolio system and other distance learning technologies, faculty development workshops, and revision of the Teacher Preparation Program curriculum. Results indicate that CLU is better preparing preservice teachers to use technology in teaching and learning and they are provided with better models and mentors for integrating technology into the curriculum. As well, preservice teachers are held accountable for meeting state and CLU standards for beginning teachers through the use of a web-based electronic portfolio system and distance learning technologies.

Introduction

The nation’s teaching force faces a critical challenge as a record number of students enter our schools. By 2008, schools will need to hire more than 2.2 million teachers to serve growing student enrollments and to replace the considerable number of current teachers expected to retire in the coming years. In California, shortages are particularly acute. Educating nearly 11% of the nation’s student population, California’s school enrollment is at about five million and growing by more than 100,000...
students per year. California will need to hire more than a quarter of a million teachers over the next decade. (Haselkorn & Harris, 1998).

This extraordinary need for teachers comes at a time in which the demands placed on teachers, particularly in California, has never been greater. Already serving the nation’s most diverse population, California provides a look ahead to many of the educational and demographic challenges facing the nation in the 21\textsuperscript{st} century. Like many other states, California has embraced the “standards movement” calling for more accountability for teachers, students, and schools. Therefore, at the very time we are asked to produce more teachers through a greater variety of teacher preparation routes, we are also being called upon to prepare a more capable workforce that is well prepared for the challenges and complexities of the next century.

Technology offers promise as a tool and a resource for those of us who prepare teachers, and for teachers themselves who are challenged to provide more and better services and educational opportunities for students. It challenges us to think about new ways to link our students, our faculty, our educational partners, and our wider communities together to expand, improve, develop, and enhance the learning experience for all. It is this challenge that has led the faculty in the School of Education at California Lutheran University to conceive the plan for Project MAGNETIC CONNECTIONS.

California Lutheran University and its school partners have already committed significant resources to developing and supporting our technology capabilities. Yet, technology itself is not pursued as an end in itself but as a vehicle and medium for teaching and learning. The Information Systems and Services unit of our university has articulated a vision statement that reads: “We build community by providing solution oriented, integrated information resources and services. Our graduates are technologically competent and competitive in a global market.”

The School of Education has embraced this vision in our own strategic plan, which calls for us to infuse technology throughout all of our programs. Nowhere is this challenge more important than in teacher education.

Teacher education does not occur in isolated classrooms that are disconnected from practice. We believe that making, building, and strengthening connections are vital to the future of teacher education. CONNECTIONS between content and pedagogy, CONNECTIONS between theory and practice, CONNECTIONS across the curriculum, CONNECTIONS between the university and the schools, and CONNECTIONS between teachers and students are only some of the most crucial linkages that must be made. Technology holds promise of being a tool and a resource for making these CONNECTIONS.

There is a natural affinity and powerful draw among the participants in this project; they have common goals and purposes to improve teaching and learning for all. They have already committed to the use of technology as a vehicle for improved instruction. These common purposes serve as a MAGNET, drawing together all of the players and the resources they bring to the table. In this project, a primary resource for linking with the real world of practice is three MAGNET schools—schools with a special focus on technology. Therefore, we have entitled this Project MAGNETIC CONNECTIONS, in anticipation that we will build on this natural affinity to strengthen these powerful connections through the use of technology.

Many have predicted that technology has the potential to change education in dramatic ways. (Hertzke & Olson, 1994; Kent & McNergney, 1998). However, teachers often report that they are not well prepared to use even the limited technology available in school classrooms. Even though they may know how to use the computer-based technology they find in their classrooms, they may not know how to use it for effective instructional purposes. This is not surprising, considering the history of teacher preparation program practices. Arthur Wise, President of NCATE (1998) suggests that the models provided for preservice teachers are inadequate for today's technological demands on the teaching profession.

Despite the technology changes in society, being a teacher in American schools too often consists of helping children and youth acquire information from textbooks and acting as an additional source of expertise. Teachers are provided role models of this approach to teaching from kindergarten through graduate school; their teacher education courses provide hints for making textbook-oriented instruction interesting and productive, and as teaching interns, they both observe and practice instruction based upon mastering information found in books. Teachers may be forgiven if they cling to old models of teaching that have served them well in the past. All of their formal instruction and role models were driven by traditional teaching practices. (p.5)
If teachers in elementary and secondary schools are to use technology well, they must experience its use in their own learning. Sandholtz, Ringstaff & Dwyer (1997) indicate that students learn best about the appropriate use of technology in the classroom when they are provided with models of good practice.

As we take the necessary steps to achieve our vision for teacher preparation in the twenty-first century, our faculty identified five areas related to our human and technological resources that need to be addressed. These areas are:

- providing better teacher training in the selection, access and use of technology in teaching and learning;
- providing better mentors and models for preservice teachers in the form of university faculty, K-12 master teachers, and university supervisors, who integrate and appropriately use technology in their own teaching and learning;
- expanding the Teacher Preparation Program to reach more preservice teachers;
- developing and using new assessment models that incorporate the use of an electronic portfolio system; and
- building better linkages between subject matter and professional preparation and K-12 schools.

The Project MAGNETIC CONNECTIONS

Although prior to beginning this project, many School of Education faculty members already used technology to deliver and enhance instructional opportunities, conduct research, and communicate with students outside of class, our own studies indicated that this use was highly idiosyncratic, largely dependent upon the interests and inclinations of the individual faculty member, course specific, and not well connected to any overall programmatic vision or initiatives. We were poised to take the next step to fully integrate technology into our program and to utilize its power to significantly change the way we prepare teachers for their work in contemporary schools when presented with the opportunity to apply for external funding to help accomplish our goals.

Project MAGNETIC CONNECTIONS is strengthening the links between teacher preparation programs and K-12 schools through live, real-time connections and shared learning opportunities between the partners. The three technology-rich schools have become "laboratories for learning" for CLU students and faculty and are connected via distance learning capabilities to CLU students on the Thousand Oaks campus and to its graduate centers in Woodland Hills and Ventura. All CLU students are developing a web-based electronic portfolio, documenting their progress and accomplishments as they advance through the "benchmarks" of the teacher preparation program. They are taught and mentored in their use of technology by highly trained teacher education faculty and two visiting teacher/scholars (clinical faculty) in residence for the duration of the three-year program.

The project includes conferences and workshops to redesign the teacher preparation curriculum at California Lutheran University to infuse technology into the teaching and learning process. We are developing and implementing an electronic portfolio system that is linked to the six domains of the California Standards for the Teaching Profession. Preservice teachers and education faculty are utilizing the new electronic portfolio system to enhance communication regarding professional expectations and preservice teacher accountability for meeting those standards.

In July 1997 The California Commission of Teacher Credentialing and the California Department of Education adopted the California Standards for the Teaching Profession (CSTP). The standards were jointly developed by the two agencies to facilitate induction of beginning teachers into professional roles and responsibilities. The standards provide teachers and teacher educators a common language and structure to describe the complexity of teaching and are intended to guide teachers as they develop their professional practice.

The standards are organized around six interrelated categories of teaching practice. In summary, they are, 1) Engaging and supporting all students in learning, 2) Creating and maintaining effective environments for student learning, 3) Understanding and organizing subject matter for student learning, 4) Planning instruction and designing learning experiences for all students, 5) Assessing student learning, and 6) Developing as a professional educator. The list is not intended to be sequential, and does not indicate priority or value, but is merely numbered to facilitate identification and discussion. The 6th standard does
not describe specific classroom conduct but is more a reminder of the need for ongoing professional development and relationships.

The six categories provide a developmental, holistic view of teaching intended to serve the needs of the diverse student and teacher populations in this State. The overlap that is evident among the standards communicates the interrelationships and complexities of teaching that require continued development of professional judgement. The standards are designed to support work in diverse classrooms in a variety of ways, and not to force a single approach on all practitioners. Use of the standards is intended to stimulate reflection on practice, formulation of goals, and assessment of growth. Therefore the use of these criteria is flexible.

The Department of Teacher Education in the School of Education at California Lutheran University adopted the CSTP’s as an organizing principle for its teacher credential programs. Curriculum and assessment approaches are now based on the standards, with an emphasis of providing evidence of progress on the first five. Preservice teachers are held accountable for these standards through the use of a web-based electronic portfolio system. This web-based system allows students, faculty, educational partners, and education employers to expand, improve, develop, and enhance the learning experience for preservice teachers. However, reliable identification and description of student work for purposes of formative growth remains the primary purpose for the use of the state standards and the electronic portfolio system at CLU.

Implementation of a web-based electronic portfolio system throughout the teacher preparation program complements the student-centered approach CLU takes to preparing teachers for the classrooms of tomorrow. The portfolio system is analogous to a relational database that is cooperatively developed by faculty, students, cooperating teachers, supervisors and employers. It enables a grand conversation between these parties, focusing around the student’s professional development. The state standards (CSTP’s and technology) and the School of Education’s conceptual framework of reflective, principled practice serve as a scaffold around which teacher educators and preservice teachers weave their dialog. This dialog is enhanced through the use of other distance learning technologies, namely Tapped In (a Multi-object Orientation [MOO] for educators) and ClearPhone (an Internet video-phone). These two technologies are used mainly in real-time as teacher educators meet in virtual classrooms with preservice teachers, or preservice teachers tutor k-12 students through video conferencing. The electronic portfolio system tends to be used asynchronously as students respond to teacher educators’ assignments and deposit artifacts supporting their growth and accomplishments as a beginning teacher. Only recently have the two technologies merged, where teacher educators are able to converse in real-time with students about artifacts in their electronic portfolio, either in the MOO or through video conferencing. There is much potential for mentoring preservice teachers online while holding them accountable for the standards through demonstrations and artifacts deposited in their electronic portfolio.

In order to meet the new performance standards and to integrate these technologies throughout the program, the teacher preparation program curriculum needed to be revised. This revision is ongoing and over a three-year period, the goal is to modify course goals, objectives, and assignments to reflect the vision of our teacher preparation program and ensure that all beginning teachers have met rigorous state standards for teaching and technology. Faculty curriculum revision efforts identified four major considerations that will shape the revised program. These include the School of Education’s conceptual framework, the state standards for the teaching profession (CSTP’s), the state technology standards and the cross-cultural and language development (CLAD) foci. Any curriculum revision must include, address and hold students accountable for meeting these state standards as well as realizing the School of Education’s vision that strives to prepare principled, reflective educators. Hence, faculty and administration expect that the final revision will articulate the relationship between course goals and objectives, the School of Education’s conceptual framework and the other program and state standards for teaching and technology.

Evaluation Design:

The MAGNETIC CONNECTIONS Project uses a participatory evaluation design. This evaluation model, described by Cousins and Whitmore (1998) and Rossi, Freeman and Lipsay (1999) views program participant stakeholders as partners in the evaluation process. The stakeholders define the evaluation purpose, create research questions, design instruments, collect data and interpret and report findings. Cousins and Whitmore (1998) and Greene (1988) suggest that such participation keeps the evaluation relevant and increases utilization of findings without sacrificing technical quality or credibility.
As a result, the evaluation seeks to change the organization or solve a problem, rather than simply collect programmatic information.

At CLU, the participatory evaluation used a formative/summative design recommended by Stevens, Lawrenz, Sharp and Freehling (1997), examining five formative and one summative goal. Participants included a sample of 17 full and part-time higher education faculty, all preservice teachers and K-12 teachers at three technology-rich partner schools. Instruments included document analysis of course syllabi, portfolio contents and training materials; pre-post technology use surveys of faculty and preservice teachers; observation of faculty and preservice teachers, focus groups conducted with faculty and preservice teachers and analysis on online transcripts. Each goal was examined with at least two data collection techniques, allowing for triangulation of findings.

Initial Results:

Preservice teachers, K-12 partners, and education faculty are conducting action research on the implementation strategies and distance learning ideas embedded in the project. The action research findings identify and amplify successful strategies for curriculum development, implementation and assessment.

Progress on the project has been achieved within five major activities:

- Teacher/scholars hired in January 2000. These teacher/scholars support the implementation of the project objectives and support preservice teacher education within the School of Education and K-12 partner schools.
- Electronic portfolio system implemented throughout the teacher preparation program. The system is based on the State standards for professional teacher development and provides a self-assessment tool for students as well as an opportunity for K-12 teachers and higher education faculty to mentor and advise preservice teachers throughout their teacher preparation program.
- Higher education and K-12 faculty workshops. Various sessions conducted in 1999-2000. Two 3-day and numerous 2-hour workshops. Topics include curriculum revision, web page construction; use of chat room software "Tapped In," using Internet search resources; electronic portfolios; technology to connect schools; program evaluation and technology tools.
- Initiated use of distance learning technologies, including the use of "Tapped In" for teacher preparation methods block seminar discussions and "ClearPhone" videoconferencing through the Internet.
- Curriculum revision of Teacher Preparation program. Established curriculum revision teams consisting of School of Education faculty, K-12 teachers, undergraduate faculty and administrative support personnel.

All indicators suggest that California Lutheran University is:

- better preparing preservice teachers to use technology in teaching and learning.
- providing preservice teachers with better models and mentors for integrating technology into teaching and learning.
- maintaining State and School of Education standards for preservice teachers through the use of a web-based electronic portfolio system and distance learning technologies.

References

Abstract: Preservice teachers graduating from education programs feel unprepared to integrate technology into their classrooms due to lack of modeling by university faculty and limited opportunities for observation of exemplary technology practices in internship classrooms. The Arizona State University West faculty, through a PT³ Grant, is addressing this issue by providing workshops on integration of technology in instructional planning for cohort teams of ASUW preservice teachers and inservice mentor teachers. During the workshops, teams collaborated on developing Units of Practice integrating technology, which were jointly implemented in field placement classrooms. Workshops provided teams a variety of technology and technology resources that could be incorporated into unit and lesson planning including the Internet, digital cameras, Inspiration software and PowerPoint applications. Results indicated participants benefited greatly from the information and practical applications of the workshops. Teams demonstrated considerable skill growth for using various applications and substantial success in developing Internet skills.
Introduction

Many colleges and universities are attempting to improve teaching and learning with technology throughout their colleges of education. Nationwide, most recent teacher education graduates do not feel prepared to integrate technology in their curriculum (U.S. OTA, 1995). Arizona State University West students report that, despite taking a course about using technology in the classroom, they do not feel prepared to teach effectively with technology (Wetzel, Buss, Zambo & Arbaugh, 1996; Chisholm, Carey, & Hernandez, 1998). This lack of preparation is due to two major factors that we are addressing in a Preparing Tomorrow’s Teachers to Use Technology Implementation Project. First, our students do not see consistent or extensive modeling of the use of technology by our faculty in their preservice classes (Chisholm, Carey & Hernandez, 1998). Second, we lack school sites for field placements where preservice teachers can observe exemplary technology practices in K-8 classrooms (Carlile, 1998).

In this paper, we evaluated our Practicum Plus Program that directly influences field placements for our preservice teachers in required practicum experiences. In the Practicum Plus program, preservice teachers and their K-8 mentor teachers received training together in technology integration just prior to and during the practicum experience. This is a critical intervention because practicum students are often most influenced by what they observe their mentor teachers do, or by their own school memories (Darling-Hammond & Ball, 1998). Further, cohorts of beginning teachers receive a richer, more coherent learning experience when they are organized in teams to study and practice with veteran teachers and with one another (Darling-Hammond, 1995). The PT³ Practicum Plus Program provides technology integration workshops for preservice teachers and their mentors. During the workshops the preservice-teacher-mentor-teacher pair developed a curricular Unit of Practice (UOP), which they implemented in the K-8 practicum classroom.

Overview of the Program

The Practicum Plus Program offered collaborative, hands-on training in technology to K-8 preservice teachers and their mentor teachers to prepare them to integrate appropriate technology with grade level curriculum, incorporate state and national standards into their lessons, and practice new technologies and instructional strategies. The preservice teacher-mentor teacher teams attended workshops together prior to and during the semester. These workshops were offered at each of six partner school districts and at the Child Development Center at Arizona State University West. Each workshop was geared to a specific program area: Elementary Education, ESL Education, Bilingual Education, and Early Childhood Education. Preservice teachers were recruited during class at the end of their junior year. Summer workshops lasted 6.5 hours per day over a 6 day period; the three Fall workshops were 2 hours each.

Mentor teachers were recruited through their districts and invited to apply for the Practicum Plus program. Both the preservice teachers and the mentor teachers received three graduate credits at no cost for attending the summer and fall workshops. A total of eighty-two mentor teacher and sixty-eight preservice teachers participated in the seven cohort groups. Additionally, fifteen ASU West faculty assigned to the site-based district locations attended the Practicum Plus training with participants. ASU West faculty played a key role in defining the particular curriculum for each major program.

The workshops provided each preservice teacher-mentor teacher team the opportunity to assess the available technology at their school and district, explore and evaluate various hardware and software, locate relevant Internet sites and bookmark them, evaluate websites, use a listserv to share ideas, strategies, resources, and develop two Units of Practice (UOP) that address state and national standards. In addition, teachers presented technology-integrated activities that they have used successfully in their own classrooms. Invited speakers also introduced district standards, local technology resources for teachers and examples of their own UOPs. One of the intangible benefits of these workshops was the opportunity for preservice teachers and mentor teachers to get acquainted before the beginning of the school year and to work collaboratively as a team in developing technology-integrated UOPs that they would jointly implement in the K-8 classroom.
On the first day of the workshops, the participants were introduced to the UOP and its seven components: Standards, Invitation, Tasks, Situations, Interactions, Tools, and Assessment. On subsequent days, participants deepened their understanding of one or more components per day identifying the standards they would incorporate in their unit, developing the Invitation, and collecting on-line resources for their UOP. As pairs worked together, mentor teachers and preservice teachers became equal partners in the endeavor and learned from each other. Additionally each preservice teacher-mentor teacher cohort was introduced to the listserv that serves as a vehicle for collegial sharing.

The Study
The investigators sought answers to the following research questions. Question 1--How effective was the Practicum Plus program in preparing mentor teachers and their university practicum students to create a curriculum unit of practice in their K-8 classrooms? Question 2--How did the mentor teachers and practicum students use the cohort listserv to support the community of learners?

Method
Multiple measures were used to examine the research questions. In each of the following sections, the instruments employed and the procedures used to gather data are presented briefly.

Faculty Reflections
Faculty attended the Practicum Plus Program summer classes from each program area along with mentor teachers and preservice teachers. Twelve faculty members attended the 3 credit hour classes while four attended the 1 credit hour classes. At the end of the intensive classes faculty were asked to reflect and provide the program staff with written comments. Eight faculty members completed a reflection providing program staff with written comments. Faculty members were also invited to discuss the written reports and provide additional feedback to the program staff at a later meeting.

Daily Participant Exit Tickets
At the end of each workshop day, participants completed an Exit Ticket consisting of five prompts: One thing you learned or relearned today; one positive comment about today's activities; one idea you learned or saw today that you can use with your students; suggestions for improvement; and general comments and questions about today's topic. Content analysis procedures were applied to responses and themes were extracted.

Technology Checklist
Preservice teachers' and mentor teachers' technology skills were evaluated using a Technology Skills Inventory that assessed skills in eight areas. The eight skill areas were: General computer, equipment, Internet, HyperStudio, Inspiration, PowerPoint, Claris Works/Apple Works Slide Show; and Netscape Composer. Example skills from the Internet list included: Subscribe to a listserv; send and reply to a listserv; send an e-mail attachment; create, organize and save bookmarks; and use a search engine to conduct research. Participants had to actually demonstrate proficiency on skills in these areas.

Unit of Practice
A rubric was used to identify proficiency levels for each category of the UOP, Standards, Invitation, Tasks, Situations, Interactions, Tools, and Assessment. Each was evaluated on a scale of Accomplished, Developing, or Emerging (http://www.asu/pt3).

Listserv

The seven cohorts in the Practicum Plus workshops enrolled in listservs. The purpose of the listservs was threefold: To provide the participants with skills of electronic communication; to encourage collegial sharing, and to create a community of learners who could interact beyond the time and place of the actual workshops.

With respect to analyzing the data, a number of procedures were used. Generally, qualitative techniques such as content analysis was employed. Emerging themes were noted and formed the basis of subsequent analysis and interpretation.

Results

Generally, results showed the overall effectiveness of the professional development activities, which took place during the PT3 workshops. Increased levels of skills for the use of applications and the Internet were demonstrated. Specific details about the results are provided below.

Faculty Reflections

Faculty members' reflections suggest that the activities presented in the program helped mentor and preservice teachers learn how technology could be incorporated into their curriculum. Suggestions from faculty included informing mentor and preservice teachers earlier of training dates for planning purposes and to facilitate more preservice teacher-mentor matches; introduce technology and hands-on computer activities on the first day; limiting lectures; and that a model of an UOP be given to participants at the beginning of the program. The faculty also observed that the UOP template did not ask teachers to make accommodations for students with special needs. The faculty recommended that for ESL and bilingual mentors and teachers a presentation on the Teaching English to Speakers of Other Languages (TESOL) standards be made and that these standards be incorporated into the UOP. The faculty also noted how helpful it was to have direct links to state academic standards since teachers are not always familiar with the state documents that actually drive district decisions about curriculum and assessment. The faculty also commented on the teamwork that developed between the mentors and preservice teachers. The classes provided the mentors and preservice teachers with an opportunity to work together before the school year started. The mentor teachers provided the expertise in pedagogy and content while in some cases the preservice teachers provided most of the expertise in technology. The faculty also remarked positively on the incorporation of technology into their classes such as the use of a digital camera and PowerPoint presentations.

Daily Participant Exit Tickets

Several themes emerged from the Exit Ticket responses. First, participants appreciated the exposure to a variety of technology and technology resources including Internet use, digital cameras, Inspiration, and PowerPoint. Additionally, they valued the time that was allowed to work with the technology while practicing and improving their skills including developing PowerPoint presentations, Inspiration and other applications for their classrooms. Participants especially appreciated ideas that worked with small groups in situations where limited numbers of computers were available. Finally, they particularly valued opportunities related to using Internet resources including website evaluation procedures, and connections to educationally relevant websites.
Technology Checklist

Evaluation of the preservice teacher-mentor teacher Technology Skills Inventory indicates most participants demonstrated 90% proficiency on the majority of skills listed.

Unit of Practice

Results from analysis of the Unit of Practice clearly show participants strengths in the Invitations, Tasks, Interactions, and Situations components. The weak areas were in the Abstract, Standards, and Assessments components. For example, participants failed to include appropriate academic standards. Additionally, ESL education teams failed to include TESOL standards.

Listserv

Participants surpassed expectations in use of the listserv. Examples of activities are sharing teaching ideas and resources, staying abreast of current events that impact their classrooms, sharing information about websites, information about how to accomplish assignments, and support for each other on how to complete their work at the university.

Discussion

It is apparent from the results that while there needs to be more emphasis placed on the importance of infusing standards throughout the UOP, participants benefited greatly from their experiences in the workshops. Results indicate teams had considerable skill growth and success in developing Internet skills. Participants routinely subscribed to listservs, sent e-mail attachments, created and saved bookmarks, and used search engines in research on the Internet. Additionally, participants developed skills in the use of Inspiration, PowerPoint, and Netscape Composer. For example, they used Netscape Composer to create and save a new page, add a hyperlink, and add a graphic from the Internet to create a curriculum homepage for their students.

Three important components of the Workshops facilitated skill development and subsequent application to the classroom setting by the preservice-mentor teacher teams. First, transfer of learning from the professional development setting to the classroom by participants was facilitated by providing learning opportunities that reflected those that would be used in subsequent classroom settings. Such “situated” learning opportunities allowed participants to engage in activities that they could use directly with their own classroom students, later. Second, the Workshops provided participants with significant amounts of time to learn how to use technology through practice with a variety of applications. Third, and importantly, participants were given ample time to adapt technology skills, materials, and techniques for classroom instruction. Specifically, participants were provided with large amounts of time and support to adapt technology for their own classroom use through the UOPs, which each team developed. Frequently, professional development focuses on the former, skill instruction and development without providing sufficient support for adaptation, which is essential to ensure subsequent application to the classroom. Fourth, participants then implemented the units in their K-8 classrooms.

The research reported in this paper was based on a project being funded by the U.S. Department of Education through a Preparing Tomorrow’s Teachers to Use Technology (PT3) Grant # P342A990351. The views and conclusions expressed are those of the authors and no endorsement by the U.S. Department of Education should be inferred.
Abstract: For anyone restructuring their undergraduate technology course for pre-service teachers, an important consideration should be the inclusion of a communication tool that promotes positive peer interactions. Using their recent award of a PT³ grant the University of Houston has implemented many changes in the teacher education core technology course including the offering of a hypergroup, a web-based communication tool. By the second month participation in the hypergroup was going strong with future teachers sharing ideas, posting resources, and communicating common concerns. The hypergroup, originally intended as an example of a mode for teacher communication, has turned into a true community-building tool. The hypergroup will stay intact for these pre-service teachers throughout their teacher education program and into their first year of teaching where it is hoped that these teachers will become a part of other online peer resource groups.

Introduction

The inability to communicate with peers concerning one’s subject area, classroom management, and other educational issues, is often cited as a negative in the teaching field. Pre-service teachers in the Pedagogy for Urban Multicultural Action (PUMA) program at the University of Houston are changing this negative into a positive. With the recent award of a Preparing Tomorrow’s Teachers to use Technology (PT³) grant, the Instructional Technology program in the University’s College of Education has restructured its required undergraduate three-hour technology course into three one-hour courses. One of the major changes in the restructuring of the technology class was to implement a mode of communication for all enrolled pre-service teachers.

Important to note is the fact that the University of Houston is a medium-sized, urban, multicultural university whose students are largely commuters. There are many nontraditional students from the Houston metropolitan area who attend the University on a part-time basis while working full-time jobs as they pursue their degrees. Many students are on campus only to attend classes. As a result, it is difficult to develop a strong sense of student community throughout the University. The PT³ grant implementers recognized this problem as one similar to professional teachers in general.

Application

The College of Education has long used a web-based newsgroup application in its graduate distance learning and face-to-face classes appropriately named Hypergroups, developed by a former doctoral student. Found in the NETS Professional Performance Profile is a category that focuses on peer communication;
Teachers “participate in online professional collaborations with peers and experts” (Number 18). To assist pre-service teachers in satisfying this technology requirement for their educational portfolio, one hypergroup was set up for all six sections of the first semester technology course.

Because this was a new mode of communication for many of the students, it was decided that students would learn to use the tool effectively if they were required to participate by posting to the hypergroup a minimum of 5 times within the semester. No restrictions on types of postings were given, however the idea of professionalism and the goal of the hypergroup as a resource for communication and sharing of ideas was reinforced by the technology fellows in the six sections of the course. The students were initially reticent about participating. The technology fellows initialized the group by posting welcome messages and demonstrating its use in class. Within a month, students had taken ownership of their hypergroup, posing questions, asking about assignments, posting ideas for topics and projects that will satisfy course requirements, and requesting help in other classes. For the most part, the comments shared on the hypergroup have been relevant and positive. The pre-service teachers are getting to know each other across sections through the hypergroup and are actively supporting one another.

The long-term effects of the hypergroup will begin to be apparent during the Spring 2001 semester when students are enrolled in the second semester of the technology three-course sequence. At this point they will already be familiar with their new in-class classmates and technology fellows having met them in the hypergroup and in other education classes this semester. The same hypergroup used this semester will be used in the second semester technology course. In the third semester, pre-service teachers will be out in various schools in the metropolitan area, the hypergroup will be available to them though the students will not be on the University campus. It has been decided that the hypergroup will stay intact for the students’ duration through the PUMA program and into their first year as professional teachers.

**Pre-service Teacher Reactions**

Throughout the semester, for evaluation purposes, students have been periodically interviewed concerning their thoughts on various aspects of the new technology course. Overwhelmingly the response by hypergroup participants has been positive. Comments, such as, students are able find and share “a lot of ideas,” and their ability to access “all the tech fellows,” not just their section technology fellow, who were able to provide helpful advice and information, is considered a great resource. Students also reported that the hypergroup was a place for inquiring about their other education classes, that the large network of pre-service teachers at various stages in their class work preparation, provided answers to their questions.

**Conclusions**

The technology fellows continue to participate by answering questions, developing mini lessons that are linked to the group, and supplying links to on-line tutorials and references for student use. The hypergroup is often referred to as a reference tool in class discussion. Originally, some of the students referred to the technology fellows as the experts, but as the semester commences students are realizing that they are or other students can become the expert in a given topic area. The activity has been a great leveler for the group; the students and technology fellows interact as peers.

Hypergroups in the PUMA program are now not only seen by pre-service teachers in their technology course but due to their effectiveness they are becoming widely used throughout the college for many professors have now implemented a hypergroup in their educational methods courses. The hypergroup, although a tool originally selected to assist students to meet a technology competency, will hopefully have a lasting effect on these future teachers, that of showing how technology can turn a negative, lack of communication among peers, into a positive.
An Assessment of Technology Skills and Classroom Technology Integration Experience in Preservice and Practicing Teachers

Jonathan D. Brinkerhoff, Heng-Yu Ku, Krista Glazewski, and Dr. Thomas Brush
Learning and Instructional Technology
Arizona State University
United States
jbrinker@asu.edu

Abstract: This study comprised the initial phase of a Preparing for Tomorrow’s Teachers to Use Technology (PT3) funded investigation into the effects of integrating technology skills acquisition and preservice teacher methods courses on preservice teachers’ use of technology during subsequent student teaching experiences. Two versions of a Technology Beliefs and Competencies Survey were administered, one for preservice teachers and one for practicing teachers. The results of baseline data on preservice and practicing teachers’ technology skills and beliefs are identified and discussed. Also examined are preservice teachers’ perceived technology barriers, and classroom teachers’ technology integration practices.

Over the past decade, rapid advancements in technology have created expanding possibilities for enhancing instruction. As a result, there is a growing need for augmenting the instructional technology skills of both practicing and preservice teachers (Hill & Somers, 1996; Northrup & Little, 1996). Meeting those needs, however, has proven to be quite a struggle for many (Strudler & Wetzel, 1999). Siegel (1995) reported that most K-12 teachers are generally not receiving sufficient time, access, and support to become comfortable with computers, while others have found that although some teachers have positive attitudes toward technology, many do not consider themselves competent to teach with technology (Office of Technology Assessment, 1995; Schrum, 1999; Strudler & Wetzel, 1999).

Researchers have advocated integrating technology training throughout the preservice teacher education program (Brush, 1998). Although most teacher preparatory programs offer stand-alone technology courses for preservice teachers, many have not developed courses or curriculum that meet the International Society for Technology in Education (ISTE) standards. This is especially true in states lacking specific computer competencies for teacher certification. Therefore, many preservice teachers are still entering the classroom with minimum exposure to technology (Strudler & Wetzel, 1999).

With the support of a three-year Preparing Tomorrow’s Teachers to Use Technology (PT3) grant, Arizona State University is investigating means for changing the way it prepares preservice teachers to meet current ISTE standards. This effort is focused on increasing both technology skills and technology-related instructional practices. Preservice teachers enrolled in the existing program are required to complete a one-credit, stand-alone technology course; the curriculum thus remains isolated from the environment in which it is to be applied. One goal of the PT3 grant is to investigate means for integrating the acquisition of technology skills with authentic teaching experiences. To achieve this goal, the stand-alone preservice teacher course addressing both technology skills and technology-related instructional practice is being eliminated in favor of integrating this content into three field-based courses covering instructional methods for teaching reading, math/science, and language arts/social studies. This field-based model, also known as job-embedded learning (Loucks-Horsley, Hewson, Love, & Stiles, 1997), is designed to provide preservice teachers with a combination of field-based technology workshops and authentic teaching experiences in real classrooms prior to their official student teaching assignment. A second goal of the project focuses on expanding the instructional technology skills and practice of teachers responsible for supervising the field-based, preservice teachers’ classroom experiences. This is to be accomplished through the participation of practicing teachers in the field-based technology workshops.

This initial component of the PT3 funded project focused on collecting baseline data from preservice and practicing teachers regarding their technology skills and integration practices. This data will be used to inform the development of curricula designed to support more effective technology integration with preservice and practicing
teachers, as well as serve as a baseline to assess change in preservice and practicing teacher skills and attitudes over the course of the grant. The data collection process was aimed at addressing the following research questions:

1) What is the current state of technology experience and skills of preservice and practicing teachers?
2) Are there any significant differences in technology experience and skills between preservice and practicing teachers?

Method

Participants

Participants were 111 preservice teachers and 13 practicing teachers serving as supervising teachers within the field-based, preservice teaching program.

Procedures

Data collection occurred during November of 2000. Preservice teacher surveys were completed during methods course regular class sessions. Practicing teacher surveys were completed on an individual basis.

Instruments

Instruments consisted of two versions of the Technology Beliefs and Competencies Survey, one for preservice and one for practicing teachers. The preservice teachers' version consisted of the following four sections: Background Information, Technology Skills, Technology Beliefs, and Technology Barriers. The Background Information section contained five items covering such things as future teaching goal, academic year, frequency of computer use, and basic demographic information. The Technology Skills section included 32 Likert-style items ranked on a four-point scale from “I Can’t Do This” to “I Can Teach Others How To Do This” covering the following six categories: basic computer operation, productivity software use, electronic communication skills, use of electronic references, World Wide Web utilization, and use of multimedia software and hardware. The Cronbach Alpha reliability for this section of the survey was 0.95. The Technology Beliefs section asked participants to rank 11 Likert-style items regarding the integration of technology into classroom instruction on a four-point scale from “Strongly Disagree” to “Strongly Agree.” This section had a Cronbach Alpha reliability of 0.86. The final section, Technology Barriers, contained nine Likert-style items asking participants to rank their perception of the importance of a variety of factors relating to successful technology integration in classrooms on a three-point scale from “Not a Barrier” to “Major Barrier.” Cronbach Alpha reliability for this part of the survey was 0.78.

The practicing teachers' version of the survey also consisted of four sections. The first section, Background Information, contained 10 items regarding grade level assignment, years of teaching experience, school characteristics, frequency of computer use, and home Internet availability as well as basic demographic information. Sections two and three, Technology Skills and Technology Beliefs, were identical to the version used for preservice teachers. For the practicing teachers' version of the survey, the Cronbach Alpha reliability of the Technology Skills section was 0.96, while the value was 0.82 for the Technology Beliefs section. The final section, Technology Integration, included 10 Likert-style items asking participants to assess their use of technology to support lesson design and presentation on a four-point scale from “Strongly Disagree” to “Strongly Agree.” The Cronbach Alpha reliability for the final section was 0.94.

Results

The reported results for this investigation are separated into four sections: Technology Skills for Preservice and Practicing Teachers, Technology Beliefs for Preservice and Practicing Teachers, Technology Barriers for Preservice Teachers, and Technology Integration for Practicing Teachers.
Technology Skills for Preservice and Practicing Teachers

Means and standard deviations of the responses for the six subscales of the Technology Skills section of the survey are reported in Table 1. Both preservice and practicing teachers identified Basic Operations (preservice $M=3.04$, $SD=.61$; practicing $M=3.10$, $SD=.52$) and Communications (preservice $M=3.31$, $SD=.63$; practicing $M=3.15$, $SD=.77$) as the technology skills with which they felt most comfortable. There was also general agreement between the two groups on those technology skills with which they felt least comfortable. Multimedia was ranked lowest by preservice teachers ($M=2.45$, $SD=.79$) and next to lowest by practicing teachers ($M=2.74$, $SD=.84$), while World Wide Web technologies were ranked lowest by practicing teachers ($M=2.56$, $SD=.74$) and next to lowest by preservice teachers ($M=2.73$, $SD=.65$).

Within the Basic Operation subscale, preservice teachers felt most confident in their ability to print either selected pages, the current page, or complete documents ($M=3.75$, $SD=.56$), while they felt least confident in using anti-virus software ($M=2.38$, $SD=1.00$). Practicing teachers felt most confident in their ability to cut, paste, and copy information within and between documents ($M=3.85$, $SD=.78$), while they also identified using anti-virus software ($M=2.31$, $SD=1.07$) as the skill they felt least confident about.

On the Productivity Software subscale, preservice teachers felt most comfortable with basic word processor functions for text formatting, as well as spelling and grammar checking ($M=3.84$, $SD=.45$). They felt least comfortable in their ability to use graphics, transitions, animation, and hyperlinks within presentation software ($M=2.23$, $SD=1.10$). Practicing teachers felt most comfortable using advanced word processor functions such as headers, footers, tables, and inserting pictures ($M=3.00$, $SD=.82$), while also identifying use of advanced presentation software features as the thing they felt least comfortable with ($M=2.15$, $SD=1.21$).

On the Communication subscale, preservice and practicing teachers' rankings were in agreement, with both groups feeling most confident concerning the sending, receiving, opening, and reading of email (preservice $M=3.85$, $SD=.85$; practicing $M=3.77$, $SD=.60$), while subscribing to and unsubscribing from a listserv received the lowest confidence rankings for both preservice ($M=2.77$, $SD=1.03$) and practicing teachers ($M=2.54$, $SD=1.13$).

Preservice and practicing teachers' rankings on the Electronic References section were in agreement as well, with both groups feeling most confident performing keyword searches (preservice $M=3.39$, $SD=.74$; practicing $M=3.00$, $SD=.91$), while feeling least confident using advanced search features with Boolean operators (preservice $M=2.68$, $SD=1.03$; practicing $M=2.54$, $SD=1.88$).

Concerning use of the World Wide Web, preservice teachers felt most comfortable using a web browser ($M=3.75$, $SD=.50$), while feeling least comfortable uploading webpage files to a server ($M=1.81$, $SD=.95$). Practicing teachers gave equal confidence rankings to using a web browser ($M=3.38$, $SD=.77$) and locating information on the Web using a search engine ($M=3.38$, $SD=.96$), while feeling least comfortable formatting web pages with tables, backgrounds, and links ($M=1.62$, $SD=.87$).

The final subscale of the Technology Skills section of the survey asked participants to rate their confidence with multimedia. Using basic features of a drawing program to create simple shapes was rated highest by both preservice ($M=3.24$, $SD=.96$) and practicing teachers ($M=3.54$, $SD=.78$). Preservice teachers felt least comfortable using authoring tools such as Hyperstudio ($M=1.82$, $SD=.84$), while practicing teachers felt least comfortable with photo editing of digital images ($M=2.38$, $SD=.96$).

Note. All responses ranged from 1 (I can't do this) to 4 (I can teach others how to do this).

Technology Beliefs for Preservice and Practicing Teachers

Technology Beliefs means and standard deviations are reported in Table 2. The numbers represent responses on a four-point Likert scale ranging from one (Strongly Disagree) to four (Strongly Agree). Both preservice and practicing teachers most strongly agreed with the statements, “I support the use of technology in the classroom” (preservice M=3.64, SD=.73; practicing M= 3.85, SD=.38) and “A variety of technologies are important for student learning” (preservice M=3.58, SD=.68; practicing M= 3.77, SD=.44). Both groups also gave the lowest ranking to the same statement, “Teaching students how to use technology isn’t my job” (preservice M=1.80, SD=.73; practicing M= 1.62, SD=.65).

Technology Barriers for Preservice Teachers

This section of the preservice teacher survey included 10 Likert-style items ranging from one (Not a Barrier) to three (Major Barrier). Items perceived to represent significant barriers to technology integration included “Lack of or limited access to computers in schools” (M= 2.50, SD=.65); “Not enough software available in schools” (M= 2.49, SD=.63); and “Lack of knowledge about technology” (M= 2.45, SD=.65). Preservice teachers identified the following statements as not representing barriers: “There isn’t enough time in class to implement technology-based lessons” (M= 1.89, SD=.62); “Technology-integrated curriculum projects require too much preparation time” (M= 1.80, SD=.64); and “Lack of mentoring to help me increase my knowledge about technology” (M= 1.96, SD=.66).
Technology Integration for Practicing Teachers

In this portion of the practicing teacher survey, participants responded to 10 Likert-style items ranging from one (Strongly Agree) to four (Strongly Disagree) concerning their technology integrating practices. The practicing teachers most strongly agreed with the statement "I use technology to assist me with classroom management and record keeping activities" (M= 3.46, SD=.78). They gave an equal ranking to the statements "I integrate computer activities into the curriculum" and "Technology helps me meet the individual needs of a variety of students in my classroom" (M= 2.92, SD=.49). Practicing teachers identified the following two statements as least representative of their teaching practice: "I use technology to support project- and problem-based learning activities in my classroom" (M= 2.54, SD=.52) and "I encourage my students to use technology to demonstrate their knowledge of content in non-traditional ways (e.g. web sites, multimedia products)" (M= 2.62, SD=.77).

Discussion

Currently, technology training is a major focus of many preservice teacher education programs. That training is provided through a variety of different models, most of which are stand-alone technology courses that are not aligned with ISTE standards. This research describes the first component of a PT3 grant designed to move technology training of preservice teachers from the university classroom to a field-based model incorporating ISTE standards. This initial survey was designed to assess the current state of technology experience and skills held by preservice and practicing teachers.

Examination of overall subscale results for the Technology Skills portion of the survey revealed that both preservice and practicing teachers felt confident in their ability with electronic communication, a likely reflection of the increased use of email. Additionally, both groups were fairly confident in their mastery of basic computer operations.

Minor differences between preservice and practicing teachers were evident on two subscales: Electronic References and Multimedia. Preservice teachers rated their skills with Electronic References moderately higher than practicing teachers, which may represent students' greater familiarity with electronic databases commonly used within university libraries. Practicing teachers rated their Multimedia skills somewhat higher than preservice teachers which may reflect the long-standing availability of Hyperstudio in many elementary schools.

Evaluation of individual survey items within the Productivity Software subscale indicated that both preservice and practicing teacher participants felt confident in their skills with word processors. They also felt comfortable using simple search strategies to locate information on the World Wide Web. Beyond these relatively commonplace activities, however, the survey revealed a low overall level of confidence with productivity software use. These results contribute valuable data upon which to base the designation of prerequisite skills for the field-based, preservice teacher experience. Further, by clarifying the technology skills largely lacking within this population, the survey serves to identify critical content for instruction within the field-based model. This baseline data is also useful for identifying baseline skills within the group of practicing teachers supervising the in-class portion of the field-based program. Including supervising teachers in the technology skills training supports their ability to serve as technology integration mentors for the preservice teacher population. Establishing baseline skills for the practicing teachers helps further define the technology related instructional goals and objectives within the field-based model.

Findings from the Teacher Beliefs portion of the survey revealed positive attitudes toward the importance of technology and technology skills in educational settings by both preservice and practicing teachers. Despite the relative lack of confidence identified in the technology skills' portion of the survey, both preservice and practicing teachers indicated a belief that teaching students how to use technology represented a valid expectation for elementary teachers and that there was sufficient time within the curriculum for that instruction. A belief in the importance of technology instruction coupled with a lack of technology skills represents an opportunity to impact instructional practice. By supporting the enhancement of technology skill levels, teachers may be better equipped to act on their beliefs regarding the importance of technology integration.

Preservice teachers completed the perceptions of Technology Barriers section of the survey. They indicated that their university assignments required the use of technology, however, they also indicated that a lack of technology knowledge and technology-integration techniques represented a major barrier to their integration of
technology in instruction. This suggests that university student technology use represents low-levels of competence or use of technologies unsuitable for providing preservice teachers with sufficient knowledge to support technology-based instruction. It further suggests that the technology use required of preservice teachers in their university classes failed to demonstrate meaningful ways to integrate technology within a curriculum. This inference is further confirmed by the overall low-level of skills identified in the Technology Skills section of the survey.

Results of the Technology Integration portion of the survey completed by practicing teachers revealed an apparent contradiction with their views expressed in the Teacher Beliefs section. Teachers expressed support for student technology use and the integration of technology into instruction. However, when responding to survey items specifying the nature of technology use in their classrooms, teachers reported their greatest use of technology for managerial and other non-instructional purposes, findings which support those reported by other researchers (Brush, 1998; Strudler & Wetzel, 1999). Participating teachers did indicate moderate use of technology in their instructional practice and by their students. However, the sample in this survey represented only 13 practicing teachers. As such, they are unlikely to constitute a representative sample upon which to base generalizations to the teacher population as a whole. As discussed previously, this apparent discrepancy between teachers' beliefs and behavior potentially represents an opportunity for impacting teacher practice through trainings on technology and integration techniques.

The discussion thus far has focused on the first of the research questions addressing the current state of technology skills and classroom technology integration experiences of preservice and practicing teachers. Overall findings indicate the technology skills of both groups were relatively low, while providing a basis upon which to delineate prerequisite skills and instructional objectives for the field-based model for teaching technology skills and integration practices. Due to the limited data collected from practicing teachers, comparisons between preservice and practicing teachers (the focus of the second research question) were not possible at this point. Additional data is currently being collected in order to make more meaningful comparisons.

Abstract: While most researchers agree that more technology training is needed for teachers, numerous suggestions exist in the literature regarding the content of the training and the methods for delivering the training. Many researchers believe that technology skills should be integrated with undergraduate methods courses, thus providing students with skills and experiences applying technology to their specific content areas. This field-based model is the basis for new undergraduate teacher education experiences at Arizona State University (ASU). The purpose of this paper is to provide an overview of a field-based model for integrating technology into pre-service teacher education; a model that provides pre-service teachers with opportunities to develop and implement technology-rich instructional activities in authentic teaching situations so that they leave ASU with the ability to integrate appropriate technologies in their future professional placements.

Introduction

There is little argument among leaders in the field of educational technology that teacher training institutions are not adequately preparing undergraduate teacher education students to effectively integrate technology into their teaching. Although the U.S. Department of Education and the National Education Association have stressed the importance of incorporating educational technology in pre-service teacher education programs (Ely, 1996), research continues to show that teachers feel they are not prepared to effectively use technology in their classrooms (Brush, 1998; Schrum, 1999; Strudler & Wetzel, 1999; Topp, Mortensen, & Grandgenett, 1995). Because of this, they continue to use computers for low-level, supplemental tasks such as drill and practice activities, word processing, educational games, and computer-based tutorials (Strudler & Wetzel, 1999; Willis, Thompson, & Sadera, 1999). Some researchers have even gone so far as to state that "...few teachers routinely use computer-based technologies for instructional purposes" (Abdal-Haq, 1995, p. 1).

While most researchers agree that more technology training is needed for teachers, numerous suggestions exist in the literature regarding the content of the training and the methods for delivering the training. Many researchers believe that technology skills should be integrated with undergraduate methods courses, thus providing students with skills and experiences applying technology to their specific content areas. In a survey of innovative teacher education programs, Strudler and Wetzel (1999) discussed how teacher education institutions such as Vanderbilt and the University of Virginia were focusing on collaboration among methods faculty and educational technology faculty in order to provide pre-service teachers with experiences integrating technology into their teaching. These programs emphasized the need to provide pre-service teachers with technology training in authentic teaching situations. This field-based model, also known as job-embedded learning (Loucks-Horsley, Hewson, Love, & Stiles, 1997), focuses on providing pre-service teachers with authentic training experiences in real classrooms prior to their student teaching experiences. This model goes beyond the idea of integrating technology training with teaching methods courses; instead, pre-service teachers learn to integrate technology into their teaching as part of field-based experiences in real classrooms. Thus, instead of learning to integrate technology into hypothetical lessons required as part of a teaching methods class, pre-service teachers develop, implement,
and evaluate technology-rich lessons during field-based teaching experiences, with modeling and guidance from mentor teachers and university faculty.

This field-based model is the basis for new undergraduate teacher education experiences at Arizona State University (ASU). Based on the concerns discussed above, the College of Education identified three key components of a model designed to provide pre-service teachers with the skills and experiences required to fully integrate technology into their future classrooms. These components include:

1. Providing pre-service teachers with field-based, situation-specific technology training that they are able to integrate into the initial teaching activities they complete as part of their teaching methodologies experiences. These experiences are the major component of their teacher education program, beginning in their junior year (the first year they are in the teacher education program) and continuing until they are ready for student teaching.

2. Emphasizing the importance of technology integration in pre-service teachers’ student teaching experiences by providing ongoing, field-based support to help them utilize technology in the activities they design for their classes, and including technology integration as part of the overall evaluation of their student teaching.

3. Providing College of Education faculty and field-based mentor teachers with training, guidance, and just-in-time assistance to both assist pre-service teachers with integrating appropriate technology into their teaching activities, and to evaluate the effectiveness of the integration activities.

The College of Education at ASU is committed to providing future teachers with the most innovative and effective training possible. This commitment includes the belief that technology needs to be infused into all aspects of teacher preparation and applied in authentic situations. This paper will provide an overview of a field-based model for integrating technology into pre-service teacher education; a model that provides pre-service teachers with opportunities to develop and implement technology-rich instructional activities in authentic teaching situations, and provides these individuals with guidance, support, and critical formative evaluation during their experiences so that they leave ASU with the ability to integrate appropriate technologies in their future professional placements.

The Traditional Technology Training Model

Prior to the Fall of 2000, pre-service teachers at ASU were required to participate in two technology experiences in order to graduate. The first experience was a general studies class that provided them with basic technology skills such as word processing, database and spreadsheet manipulation, and electronic mail and Internet usage. This class is required of all undergraduate students enrolled at ASU. The second experience was a series of courses specific to College of Education students. Each course emphasized different aspects of technology (e.g., technology basics, software integration, the Internet) and provided students with opportunities to develop, apply, and evaluate technology-based instructional materials specifically designed to be used in the classroom. Students completed activities relevant to the use of technology in their specific content areas and were evaluated on both knowledge of educational technology issues and selection and integration of appropriate technology resources.

Problems with the traditional model. Previous educational technology requirements for pre-service teachers at ASU were generally typical of requirements for many other teacher education programs. However, this model exposes problems regarding the relevancy of technology experiences students receive to the tasks and activities they will perform in the classroom. These problems include:

- *lack of integration between teaching methodology experiences and technology integration experiences.* Since the technology classes were taught as a series of three stand-alone modules, faculty had difficulty integrating the skills and experiences students acquire in the class with the experiences they are providing in their teaching methods classes. This tends to lead to a de-emphasis of technology integration into classroom activities once the students begin their initial teaching experiences.

- *lack of emphasis on technology integration in student teaching experiences.* Because the use of technology in teaching was not integrated into the overall teacher education program, there was little emphasis placed on the integration of technology into teaching and learning activities during pre-service teachers’ student teaching experiences.

- *lack of training among faculty and field-based mentor teachers with regard to effective integration of technology with educational activities.* Since the required technology components of the teacher education program were primarily designed and delivered by the educational technology faculty, there were few opportunities for other teacher education faculty and mentor teachers to utilize many of the
innovative technology tools and resources designed for use in the classroom. Thus, it is not surprising that these individuals failed to demonstrate appropriate uses of technology to the pre-service teachers with whom they were working.

The Field-Based Model

These concerns led to the development of a teacher training model that integrated technology experiences with field-based methods experiences in order to provide students with activities and experiences relevant to the tasks teachers perform in their classrooms. Implementation of this model required new roles for methods faculty, educational technology faculty, field-based mentor teachers, and graduate students (see Figure 1).

New roles for methods faculty and educational technology faculty. In the traditional model, methods faculty worked with field-based mentors to provide hands-on teaching experiences to pre-service teachers in authentic settings. Educational technology faculty, on the other hand, worked with educational technology graduate students to provide limited technology training to pre-service teachers in a less than optimal setting (i.e., a college computer lab). Thus, there was little if any interaction between methods faculty and educational technology faculty, particularly with respect to the types of field-based experiences provided to pre-service teachers. In this new field-based model, methods faculty team with educational technology faculty to develop projects and activities for pre-service teachers which focus on integration of technology into their field-based experiences. Educational technology faculty team-teach with the methods faculty to help pre-service teachers identify and integrate technology resources with activities they are currently completing, and implement and evaluate those resources in authentic teaching situations. Methods faculty and educational technology faculty work together to determine appropriate means for providing students with opportunities to apply technology in their teaching experiences, and collaborate on discussions of effective teaching methods and evaluations of student practice.

New roles for field-based mentor teachers and educational technology graduate students. In the traditional teacher training model, educational technology faculty worked with educational technology graduate students to provide pre-service teachers with minimal educational technology training in a college classroom setting. With the new field-based model, the educational technology graduate students work with field-based mentor-teachers in the local schools. Thus, each mentor-teacher has one to two graduate students with expertise in technology integration and utilization available in their classrooms, providing assistance to the pre-service teacher during the implementation of technology integrated instructional activities. This is the most important aspect of this new role for the educational technology graduate students: they are available to pre-service teachers and mentor-teachers at the point of instruction as opposed to in a classroom on campus. Thus, whenever an issue arises regarding educational technology, these individuals are available to help deal with any problems or provide their expertise. In addition, the educational technology faculty and the methods faculty provide the graduate students in the field with guidance and strategies for assisting pre-service teachers with technology integration activities.

New expectations for pre-service teachers. Through these new roles for key personnel involved in pre-service teacher education, the expectations for the utilization of technology by pre-service teachers have dramatically increased. Through the implementation of this model, pre-service teachers are expected to demonstrate the use of state-of-the-art technology in their teaching, and to understand how this technology can be leveraged to enhance numerous learning activities.
Figure 1. Field-based technology integration model.

Current Model

Field-Based Teaching Experiences
- Methods faculty at ASU collaborate with field-based teacher-mentors at local schools to provide pre-service teachers with authentic teaching experiences

No coordination/collaboration among faculty, mentors, or students.

Educational Technology Experiences
- Educational technology faculty work with graduate students to deliver technology training modules to pre-service teacher education students in a college classroom environment

Field-Based Model

Methods Faculty
- Work together to provide authentic teaching experiences to pre-service teachers

Field-Based Teacher-Mentors
- Grad. students will work in field-based settings to assist mentors and pre-service teachers in utilizing and integrating technology with their teaching

Educational Technology Faculty
- Faculty guide graduate students to help them work with methods faculty, mentor teachers, and pre-service teachers

Educational Technology Graduate Students
- Work together to provide guidance to pre-service teachers and to evaluate performance in field-based experiences
Implementing the Model

Providing training and field-based support to pre-service teachers. In order to provide appropriate technology training for pre-service teachers, educational technology and methods faculty collaborated to develop a set of technology competency activities that would serve as a guide for both mentor teachers and pre-service teachers. The competency activities were aligned with the content covered in the field-based methods experiences (or “Blocks”) so that the competencies could easily be integrated into the teaching activities pre-service teachers are required to perform as part of their methods experiences. The competencies included for Block I (language arts and social studies), for example, include:

- Drawing and Painting
- Desktop Publishing
- Digital Image Creation and Use
- Database Use and Advanced Searching
- Selection and Use of Computer-Based Educational Materials in SS and LA
- Classroom Management and Technology Integration in SS and LA

The competency guide is used by mentor teachers to provide appropriate activities to pre-service teachers during their field-based internships. In addition, the list of competencies serves as a guide to educational technology faculty and graduate students when determining the types of support pre-service teachers need as they complete required activities. For example, as stated above, one competency area for Block I of the elementary teacher education program is “Classroom Management and Technology Integration in Language Arts and Social Studies.” In order to demonstrate this competency, pre-service teachers need to design a classroom-based activity sometime during the semester they are participating in Block I (see Table 1). To assist them with this activity, educational technology faculty and methods faculty present field-based training sessions dealing with effective methods for using technology with social studies and language arts topics. In addition, educational technology graduate students are available in the schools to assist pre-service teachers with designing and implementing their activities with students.

Providing training and field-based support to mentor teachers and methods faculty. Although many of the methods faculty and field-based mentor-teachers already possess exceptional skills in integrating technology with teaching, there is still the need to provide many of these individuals with additional training regarding effective uses of technology in various teaching domains, as well as available technology resources in those domains. Methods faculty and field-based mentors cannot be expected to possess knowledge of the vast number of resources available to them, and moreover, which of the resources are appropriate for various teaching and learning activities. This is the purpose of our intensive summer institutes. Working in collaboration with the partner schools, these institutes are led by teams of educational technology faculty and methods faculty, and focus on the content areas for each of the methods blocks. For example, instructors responsible for the social studies and language arts methods block...
participate in workshops that specifically address the technology resources available in those content areas and provide instructors with hands-on opportunities to use the resources and discuss how those resources could be integrated into classroom activities. These institutes serve as opportunities for faculty and mentor teachers to learn about both the strategies for integrating technology into teaching and the vast technology resources available that teachers should be using with their students. With this ongoing training, methods faculty and mentor teachers are able to assist pre-service teachers in making informed decisions regarding effective technology integration during their field-based experiences.

In addition, ongoing support is provided in the field to methods faculty and field-based mentor teachers by the educational technology faculty and educational technology graduate students. Educational technology graduate students are continually placed in the schools to assist both pre-service teachers and field-based mentor teachers. These students have expertise in both teaching and technology integration; thus, they are able to assist the mentor teachers with activities they would like to attempt with their students, as well as activities the pre-service teachers are planning. This resource and support structure helps methods faculty and field-based mentor-teachers better model effective integration of technology into teaching and learning activities.

Summary

We are currently in the first year of our implementation plan for this new field-based model. During this year, we are implementing this model in three partner schools with 75 elementary education students and 75 mentor teachers. Our goal is to have the model implemented in all 12 of our partner schools (and all 300 of our pre-service elementary education students) by the Spring of 2002. We have already received enthusiastic responses from other teacher education programs at ASU (e.g., Special Education, Secondary Education), and have long-term plans to completely eliminate the stand-alone classroom-based technology classes in favor of the field-based model.

Abstract: “Preparing Teachers for the Digital Age: Implementing a Dynamic Model of Pedagogical Change” is funded by a PT3 grant from the U.S. Department of Education. Three public universities in rural Western Pennsylvania are infusing technology into the pre-service core curriculum and several teacher education programs. Together we place 1500 new teachers per year throughout the U.S. and abroad, guaranteeing that technology diffusion here will have significant impact. The obstacles we face are limited support staff, tight budgets, and faculty with little time for training. Appealing topics, incentives, and convenient formats address the lack of time. Incentives buy small technology items that departments cannot afford. The grant helps overcome the limited number of support staff by funding positions and facilitating peer mentoring. To succeed, it is also imperative to gain the buy-in of critical organizations. These strategies are increasing technology integration in teacher education, as intended in the grant.

A PT3 Project: Preparing Teachers for the Digital Age

“Preparing Teachers for the Digital Age: Implementing a Dynamic Model of Pedagogical Change” is a project funded by a $1.7 million PT3 grant (Preparing Tomorrow’s Teachers to use Technology) from the U.S. Department of Education to the ADEPTT Consortium (Advancing the Development of Educators in Pennsylvania through Technology Training). The ADEPTT consortium is composed of Indiana University of PA, Clarion University of PA, and Edinboro University of PA—all public universities in rural areas of Western Pennsylvania. The universities provide excellent faculty-student ratios but have limited support staff. Both faculty and non-managerial staff are unionized.

The goal of this grant is to infuse technology into the pre-service teachers core curriculum and several teacher education programs. Technology infusion at these institutions will have a significant impact. Founded as normal schools, they have a tradition of teacher preparation. Together the consortium members graduate some 1500 future teachers per year placed throughout the U.S. and 7 foreign countries. At present, Pennsylvania does not have the demographics to place all of these graduates in state, guaranteeing that many alumni will work across the country. The economic boom of recent years has passed much of this area by, leaving persistent pockets of unemployment, encouraging out-migration, reducing enrollment, and tightening departmental budgets at these state-owned institutions. These recent economic and demographic trends, coupled with the high number of teacher education graduates, mean that many recent graduates must look outside of Pennsylvania for employment. We hope to make our students better prepared to work in all situations, giving them an edge on their competitors.
Three major goals of the PT3 grant are: 1) Instructional Technology will be moved from the periphery to the core of our curriculum. 2) Future teachers will apply and integrate Instructional Technology into the teaching/learning process. 3) Additional faculty, instructional designers, and technical support staff will assist. We aim to help faculty to recognize instructional objectives that can be more readily achieved using technology, to learn enough technical skills to model appropriate uses of technology in teaching, to assign and assess student work that incorporates technology use, and to consolidate these innovations into their syllabi.

In large teacher preparation programs, these goals seem daunting at first. There are many reasons why some college faculty members have been slow to integrate technology into their teaching. Some faculty are exhilarated by the change brought about from integrating technology in their teaching, while others are concerned about how technology impacts their authority, control of students, and their role as teacher (Cuban, 1999). Other reasons include: lack of suitable training, the time it takes to master the required skills (exacerbated by the need for teacher preparation faculty to spend time on the road in student teacher supervision), lack of technical support, lack of incentives, and the lack of hard evidence that technology can make their work move effective (Albaugh, 1997, Freberg, 1995, Olcott, 1999, Oppenheimer, 1997, OTA, 1995, Spotts, 1999). It is clear that getting faculty to use technology remains a challenge (Olsen, 1999).

So how can we succeed in achieving these goals? As we enter the second year of this three-year project, we have tried a variety of approaches and identified what works best at this stage in our educational environment. Five strategies we have been using are 1) classroom mentoring, 2) mini-grants and stipends, 3) innovative training formats, 4) K-12 to university modeling, and 5) gaining buy-in from critical organizations.

Telescoping Stages of Diffusion and Integrating Skills

Classroom mentoring is a multi-step process in which a technology mentor (colleague, student assistant, or technology specialist) first teaches a class while the teacher assists. Then the teacher teaches while the mentor assists. Finally the co-pilot departs, and the teacher can solo, teaching the new or revised unit without assistance. This training model was based on the work of Donald Schoen (1988). It also matches the model of coaching set forth by Podsjo and Denmark (2000), where novices and first-year teachers observe and model the experienced teachers’ lead as they plan and implement lessons. Structured opportunities to discuss and analyze are provided. The experienced teacher may also coteach a lesson with the novice and then have the novice teach a similar lesson. Coteaching provides guided practice where errors can be corrected before soloing, offers the opportunity to teach parts of a lesson before taking on the whole, and is an excellent device early in the learning process.

We have used classroom mentoring successfully in both the university and the K-12 contexts. For example, at Indiana University of PA and Clarion University of PA, grant faculty, graduate assistants and technology specialists have taught one or more classes within a course, designing them with varying degrees of collaboration from the responsible faculty member. Using this model, a variety of topics has been presented at IUP in many disciplines: PowerPoint for teaching Spanish language lessons in immersion curricula; PowerPoint to support second language writing; web authoring as a portfolio tool for math and art education classes; webquests and technology sandboxes for English and elementary education majors; spreadsheets as grade book and mind tools for introductory technology classes at the College of Education. Similarly, at Clarion, a technology specialist taught hands-on classes, with faculty members following up with an assignment requiring use of the same software. Classroom mentoring has given faculty members the chance to learn or review a technology in the context of their specific discipline and courses, empowering them to teach it themselves later.

At the IUP University School, a laboratory school, grant faculty have taught units integrating technology into the school curriculum. One long-term project has been the teaching of spreadsheets in fifth grade—they have been used not only in the obvious units on budgeting but also in social studies units on states and elections and science units on such topics as weather. Moreover, spreadsheets have been integrated with other software such as Inspiration and PowerPoint to teach organizational and communication skills. Here the master teachers, who have faculty status at IUP, as well as student teachers, observers, and pupils, all have the opportunity to learn and apply technology as an integral part of the school curriculum. Thus, we can address multiple audiences at one time (Adams 2000). Before Spring Semester 2001, we will apply this lesson in a new context, offering workshops for cooperating teachers and preservice teachers together. We hope to foster a collaborative relationship and lay the groundwork for the preservice teachers to use the same technology in their student teaching as they learn alongside inservice teachers in the workshops.

Best of all, this model makes it possible to address multiple stages of technology training and diffusion
almost simultaneously. Basic technology training, application of technology to teaching, and integration into the curriculum were conceived in the proposal as separate and sequential and, therefore, were expected to require an extended time frame (Sherry & Billig 2000). But in this model, they can all be addressed in project-based, integrated units like webquests, electronic portfolios, or newsletters. Moreover, project-based learning also addresses the issue of motivation. The audience has a clear idea of a relevant, appealing or needed objective, which gives them a compelling reason to learn the technical skills.

Similarly, the proposal conceptualized the training and teaching process as sequential: Faculty are trained, faculty model for students, faculty give students appropriate assignments, students do assignments, students go forth and use the skills in student teaching. Several parts of the training, modeling and diffusion process can also be addressed at once, however, in the revised model: e.g., faculty training, modeling to preservice teachers, preservice teachers observing inservice teachers, inservice teacher training, and/or preservice teachers using technology in their field experience can be combined. For example, the IUP faculty member in art education ultimately sat down with his students to learn web authoring skills for electronic portfolios, which will enable him to carry on more independently next semester. For a faculty member, the motivation becomes even stronger in this scenario—my students are learning the skills, so I had better learn them, too!

**If You Feed Them, They Will Come!**

It is an understatement to say that education faculty members at our institutions are extremely busy. Student teacher supervising, professional activities, a teaching load of four courses per semester, large numbers of advisees, and service obligations leave little time for professional development, not to mention for revamping one’s entire approach to teaching. How can we motivate faculty members to learn and try technology in their courses? How can we make good use of the very limited time they are available for training?

At Indiana, Edinboro, and Clarion Universities of Pennsylvania, we sweeten the pot with incentives. Mini-grants are offered for technology related projects. Examples of funded projects included digitizing and editing video for use in social studies classes, using digital photography to record recently discovered paintings for use in art education classes, revising English education courses to use technology, purchasing interactive CD’s for anatomy and physiology classes, attending an institute on technology in second language learning, adding the Internet and presentation requirements to courses in a variety of fields, and more.

Stipends are also provided for workshops, but they work best if part of the stipend is paid for attendance and the remainder is paid for demonstrating changes in syllabi and teaching. Prizes and coupons for prizes are given for completing mini-workshops. Food helps! Incorporating a meal within a long workshop or teaching circles provides both a much needed break and a chance to interact informally with peers and instructors.

**What’s in a Name?**

Once we capture the attention of faculty with incentives, we offer a variety of training formats, topics and titles. Our formats range from individual consultation to short workshops, immersion workshops, technology sandboxes, and progressive workshops. (In the latter, faculty members earn coupons for each activity as they move among workstations in a lab. They can come for any part of the workshops, from 20 minutes to two hours, and complete as few or as many activities as they want. Coupons are turned in afterward for increasingly attractive prizes.) The format is adjusted to the time of year, with long workshops and immersion experiences offered during summers and breaks, mini-workshops and classroom mentoring during the semester, and stipends and individual consultation at any time. We rarely attract large audiences to any one event—varied schedules and demands on faculty make this unlikely. So it is who need to be flexible, offering many formats for help and training. The burden is on us to be supportive and proactive, and to follow up with those faculty that do participate in a training event or incentive program.

Workshop content is another important factor. Although our faculty and K-12 teachers do attend generic workshops on individual software programs and their application in teaching, they show a far greater interest in workshops that are project based. For example, workshops on webquests or electronic portfolios are inherently related to teaching, meeting standards, and satisfying NCATE requirements. With NCATE
accreditation reviews just completed at Edinboro and starting shortly at IUP, the need for electronic portfolios
has struck a chord among teacher preparation faculty. The most effective topics and titles are descriptive and
concrete with clear outcomes, such as “Putting Technology in Your Syllabus.” Catchy titles that are obviously
relevant to schools also help, such as “Technology Sandbox” and “Technology Chalkboard.”

At first glance, project-based teaching and learning seem more complex. They often require that
multiple skills be taught and learned, which may appear confusing. Nevertheless, this very multiplicity can
make them more effective. They inherently go beyond learning one limited skill to the creation of a product
that can immediately be used. How many times in an application-by-application training program does the
trainer long to teach how the various skills and applications can be integrated? How many times does the
trainer actually get the chance to do so? Time often runs out at the end of the session or program, and
integration is relegated to an afterthought. One key to success is to teach only basic, foundational concepts
for each application or piece of equipment needed in the multi-skill project. Another strategy is to provide a set of
generic templates that enable students to create the final product more quickly, but that can be modified and
expanded so that students still learn all major aspects of creating the product themselves.

K-12 Models

Thanks to the presence of lab schools at two of our campuses, it is possible to have modeling not only
by faculty to preservice teachers but also by inservice teachers to faculty and preservice teachers. Our
laboratory school classes encourage such observation. Faculty, students and other teachers merely have to sign
up to observe during a particular time slot.

In addition, the three universities have started teaching circles where faculty, inservice teachers and
preservice teachers learn from each other about infusing technology into curriculum. Success is being achieved
particularly where the local intermediate unit is actively involved, and where the event has both a professional
and social dimension (e.g., dinner). The first IUP teaching circle appealed to multiple audiences by featuring a
faculty member talking about using technology in early childhood classrooms and a K-12 teacher who spoke
about certification as a technology resource person. Following the presentations were question-answer sessions
and dinner. The second offered a panel of faculty, teachers and administrators who shared experiences with
integrating technology into the curriculum. The catchy, concrete title “Putting Technology in Your Classroom”
is the theme of this year’s teaching circles.

You Have to Plug in to Be Wired!

In this grant, it has been critical to find the right organizations through which to publicize and
demonstrate what we have to offer—to “plug in” to those existing organizations and networks. With the
obstacles cited at our institutions, particularly the lack of time and attention for technology professional
development, publicity and organization become essential. If faculty time is at a premium, how do we get their
attention and prove that our programs and goals are worthwhile?

For example, as mentioned above, Indiana University of PA has experienced considerable success in
establishing teaching circles by working with both its ADEPTT partners and the local intermediate unit (ARIN).
Nearly 100 participants attended the first two teaching circles jointly sponsored by Indiana University of PA
and the Armstrong-Indiana IU. ARIN already has a program of Academic Alliances, where faculty and
teachers in the same discipline gather each semester for presentations and dinner. Building on this format, we
created an Instructional Technology Academic Alliance. The first two meetings were of more general interest,
but our April 2001 meeting will regain a disciplinary focus with an emphasis on the use of technology in
teaching art and music. Publicity for the teaching circles is also a joint effort through ARIN, ADEPTT and the
IUP PT3 grant, enabling us to reach all potential audiences.

Similarly, on our own campuses, it has been important to gain buy-in by working through established
organizations and channels of communication (Durrington 2000). At Edinboro University of PA, which is
smaller than IUP, the PT3 faculty and staff are working chiefly with two departments, which simplifies
communication and support. They have made a systematic effort to promote services made possible by the
grant, which has been effective in bringing faculty into training programs and securing administrative support.
They also have a close relationship with their intermediate unit, which facilitates work with nearby districts.
At IUP, it has been a challenge to coordinate with a widely distributed network of grants, departments, and committees that are involved in teacher education or promote instructional technology. Our College of Education and Educational Technology does not house all the teacher preparation programs; many are housed in the specific disciplines scattered across campus. The need to identify and “plug in” to key organizations is even more critical in such a diverse environment. One such organization with which we have worked is the Teacher Education Coordinating Council. This council crosses college boundaries and includes representatives from all disciplines for which teacher certifications are granted at IUP. Getting these faculty involved in our training and incentive programs, keeping them informed, and discovering the values that will most motivate them to appreciate the use of technology in education has been critical. This is an ongoing endeavor that we are still perfecting as we write this paper. Other vital organizations have been the College of Education itself, through which we can identify and contact all needed audiences, and the ADEPTT Center (Advancing the Development of Educators in Pennsylvania through Technology Training, funded by Verizon), which offers K-12 and faculty training that complements PT3.

Reflections and Conclusions

Why do these techniques work best for us? Are there pitfalls that need to be addressed? In classroom mentoring, we must ensure that the teacher neither becomes dependent on the mentor nor stops trying to use technology. First and foremost, the sequence of observing, coteaching, teaching with assistance, and then soloing allows the faculty member to learn and take over gradually. While the mentor is teaching, we make sure that faculty members leave the role of teacher long enough to learn the skills and create some of the products themselves. Most of our mentees have already taken at least one technology workshop, which yields the same result. Further, it is useful to mentor or assist with the classes more than once so that the faculty member receives the benefit of repetition and review. The combination of repetition and co-teaching allows the mentee to assume increasing responsibility for the technology-enhanced unit. Some students can also be mentors (Gonzales et al. 1997; Beisser et al. 1997). Encouraging students to demonstrate their own expertise, since no one knows everything in the fast-changing world of technology, opens the door to another resource available in class. Providing materials, files, lesson plans, and templates gives faculty members a quick start when they are ready to coteach or solo. Finally, it is helpful to supply a safety net of resources and help after the faculty member has started soloing.

As stated, lack of time is a significant obstacle to technology diffusion in our environment. Busy faculty naturally want to know, “Why should I bother?” Thus, buy-in from faculty must be won. The more distributed the technology environment, the more important it is to identify and win over the key organizations that will need to buy into the project. Relevant and appealing topics and demonstrations, incentives and prizes, and convenient formats can also help to gain buy-in and overcome the obstacle of lack of time.

Incentives are especially helpful in our environment because departments and colleges at these public universities have extremely limited budgets. This lack of funds makes it difficult to acquire even small items like scanners and webcams or to travel for professional development. Our incentives help fulfill these needs. The grant has also helped to overcome the extremely limited number of support staff on these campuses, by funding additional positions, by putting student expertise to work, and by facilitating peer mentoring. These strategies are helping us reach our goal of infusing technology in teacher education courses, as intended in the grant.

The ability to telescope the anticipated stages of training and diffusion will be a key factor in reaching our goals within the limited timeframe of the PT3 grant. If we truly had to teach faculty, then have them model technology use for students, next make technology assignments to students, and only then hope to see graduates take the lessons with them into their student teaching and careers, three years would not be an adequate length of time. If we really had to wait for each skill, piece of equipment, or application to be mastered before applying them to teaching or integrating them with each other or into curriculum, time would again be an insurmountable obstacle. The realization that these “stages” can be telescoped is a vital timesaver that will make success feasible.

Our final challenge is to see that technology continues to be infused after the PT3 grant ends. Apart from seeking other grants, what assurances can we offer? We hope that by making faculty comfortable with technology, providing basic skills, and illuminating compelling reasons to use them, we will have changed the faculty sufficiently to carry on when the grant is complete. Their technology foundation will already be established, and the permanent staff will need only to maintain and update this foundation. Even more
Importantly, the syllabi of record for many teacher preparation courses will be changed as a result of the grant. By coordinating with established organizations that will remain after the grant, we hope to have a continuing influence. Finally, the institutions in the consortium have made a clear commitment to stay in the technology mainstream, which will ensure an environment in which technology plays a prominent role. All of these factors will make it possible for the PT3 grant to have a lasting impact.

Preparing Teachers for the Digital Age was funded by a $1.7 million grant from the U.S. Department of Education through the Preparing Tomorrow’s Teachers to Use Technology initiative. Matching funds in the same amount were provided by Indiana, Clarion and Edinboro Universities of Pennsylvania.
Technology Standards for Preservice Teachers: Where are We Headed?

Edward P. Caffarella
Department of Educational Technology
University of Northern Colorado
United States
caffarel@unco.edu

Abstract: This presentation is a discussion of the implications for preservice teacher education programs of (a) the new National Educational Technology Standards for Teachers (NETS), (b) the Commitment to Technology indicator within the NCATE 2000 Standards, and (c) the new Colorado Technology Standards for Preservice Teacher Education Students. The standards will be discussed from the national perspective and from the perspective of the responses of one institution to the standards through a Preparing Tomorrow's Teachers to Use Technology (PT3) grant.

The use of technology in K-12 classrooms has received a great deal of positive praise in several recent reports. Technology is presented as a means to improve schools and to raise student achievement. Federal policies and many state policies have lead to an infusion of technology into school classrooms across the country. A National Center for Educational Statistics (2000) study showed that 95% of public schools had Internet access in 1999. Although there has been a major investment in technology for K-12 schools, the actual utilization of this technology has been somewhat disappointing. Although 65% of teachers had Internet access only 20% were using advanced telecommunications in their teaching (NCES, 1997). A study by Persichitte, Tharp, and Caffarella (1997) showed that although the technology is readily available in teacher education programs, only 45% of faculty members regularly use technology during class and only 40% of the students are required to design and deliver instruction incorporating various technologies.

Technology Needs of Preservice Teachers

The National Educational Technology Standards for Teachers (NETS) were created under the direction of the International Society for Technology in Education (2000). There are six standards including (a) Technology Operations and Concepts, (b) Planning and Designing Learning Environments and Experiences, (c) Teaching, Learning, and the Curriculum, (d) Assessment and Evaluation, (e) Productivity and Professional Practice, and (f) Social, Ethical, Legal, and Human Issues. The six standards are presented for various stages in a preservice teacher education student’s program as a development process with full proficiency for the first year as a classroom teacher. The developmental profiles are (a) General Preparation Performance Profile, (b) Professional Preparation Performance Profile, (c) Student Teaching/Internship Performance Profile, and (c) First-Year Teaching Performance Profile.

The new National Council for Accreditation of Teacher Education (NCATE) 2000 Unit Standards indicate that technology should be a significant part of the conceptual framework for all teacher education programs. “A conceptual framework(s) establishes the shared vision for a unit’s efforts in preparing educators to work in P-12 schools” (p. 3). The Commitment to Technology within the conceptual framework ... reflects the unit’s commitment to preparing candidates who are able to use educational technology to help all students learn; it also provides a conceptual understanding of how knowledge, skills, and dispositions related to educational and information technology are integrated throughout the curriculum, instruction, field experiences, clinical practice, assessments, and evaluations. (p. 4) As teacher education programs undergo NCATE reviews, they are required to show how technology is integrated throughout courses and programs.
The needs reflected above on a national level are indicative of the needs within the State of Colorado. The Colorado Legislature recently passed Senate Bill 99-154, The Standards-Based Teacher Education Act of 1999. This act includes a provision that “each candidate for a provisional teacher license shall have and be able to demonstrate . . . the ability to integrate technology into instruction at the grade level for which the teacher expects to be endorsed.”

In response to Senate Bill 99-154, the Colorado State Board of Education enacted eight standards for licensing of teacher education candidates. The seventh standard is, “Knowledge of Technology” and is defined as, “The teacher is skilled in technology and is knowledgeable about using technology to support instruction and enhance student learning.” The standard requires that the teacher has demonstrated the ability to (a) Apply technology to the delivery of standards-based instruction, (b) Use technology to increase student achievement, (c) Utilize technology to manage and communicate information, (d) Apply technology to data-driven assessments of learning, and (e) Instruct students in basic technology skills. This standard and the five indicators are focused on the effective application and utilization in K-12 classroom settings.

Response by One University

The convergence of these national and state recommendations and requirements provided a window of opportunity at the University of Northern Colorado (UNC) to make technology a central component of the preservice teacher education programs. The availability of support under the U.S. Department of Education Preparing Tomorrow’s Teachers to Use Technology (PT3) provided the resources to facilitate the changes.

There are three overarching goals of the UNC PT3 project that will guide the project over the next three years. The goals are as (a) Graduates of the UNC teacher education programs will effectively utilize technology for instruction in their classrooms when employed as full-time teachers, (b) UNC student teachers will effectively utilize technology for instruction in the partner school classrooms, and (c) UNC teacher education faculty members will effectively utilize technology for instruction and model appropriate technology use for the preservice teacher education students.

These three overarching goals will be achieved through five initiatives designed to bring about systemic change within the teacher education programs of the University of Northern Colorado. The five initiatives are (a) Enhance the required educational technology courses for students in the professional teacher education programs, (b) Model appropriate technology use and integrate technology utilization in the general education and content area discipline courses, (c) Model appropriate technology use and integrate technology utilization in the general education and content area discipline courses, (d) Integrate technology use by preservice teacher education students in partner schools, and (e) Build a model for the effective use of technology in preservice teacher education programs. The project has been underway for five months with activities under all five initiatives that over time will change the way technology is used in the preservice teacher education programs.

The need for well prepared, technology proficient teachers who know how to infuse technology into the curriculum has been identified at the national level and also exists at the Colorado level. To effectively utilize technology in the classroom, preservice teacher education students must know both how to operate various technology systems and how to integrate that technology into their classrooms.

Abstract: This paper describes the results of efforts to enhance the technology components of the undergraduate teacher education program at Georgia Southern University. Preparing Tomorrows Teachers to Use Technology (PT3) provided incentive to faculty through increased access to hardware and software, faculty support and mentorship by technology proficient teachers, release time to assist in the course and curriculum development process, technology training for pre-service teacher education faculty and demonstration teachers in K-12 schools, and mini-grants to pre-service teacher education faculty to enable significant change to the pre-service curriculum. Results showed that these efforts could increase the quantity and quality of the technology use in pre-service teacher training.

Background

Pre-service teachers will be the teachers of the 21st century. As such, they must develop the necessary technology knowledge and skills to prepare the next generation of students. Pre-service education systems have struggled to keep up with the rapidly changing pace of technology development (Moursund & Bielefeldt, 1999). Willis and Mehlinger (1996) while reviewing the literature on information technology and teacher education found that, "Most pre-service teachers know very little about effective use of technology in education ... the virtually universal conclusion is that teacher education, particularly pre-service, is not preparing educators to work in a technology-enriched classroom" (p. 978).

National, state, and local analyses all come to the same conclusions concerning the use of technology in teacher education (Carlson, et al., 2000). Overall these studies recommend that:

- Technology should be integrated into all courses that pre-service teachers take.
- Institutions of higher learning should identify examples of technology integration for all courses that pre-service teacher take.
- College faculty, that teach pre-service teachers, should model effective uses of technology in their classroom.
- Pre-service teachers need more opportunities to apply Instructional Technology during their field experience.
experiences under qualified classroom supervision.

Research Goal

This paper describes the results of efforts to enhance the technology components of the undergraduate teacher education program at Georgia Southern University. One of several goals of the College's participation in the Preparing Tomorrows Teachers to Use Technology (PT3) grant funded by the U. S. Department of Education was to recommend revisions of the pre-service curriculum and the course content by integrating technology into the learning process. Educators agree that engaging students in learning experiences that are inquiry-based, problem-centered and integrative, enable students to understand concepts much more deeply than mere memorization. PT3 provided incentive to faculty through increased access to hardware and software, faculty support and mentorship by technology proficient teachers, release time to assist in the course and curriculum development process, technology training for pre-service teacher education faculty and demonstration teachers in K-12 schools, and mini-grants to pre-service teacher education faculty to enable significant change to the pre-service curriculum. Additionally, an expectation for technology use and integration was established throughout the college.

Research Design

This study was designed to determine if the PT3 project would increase the infusion of technology in the courses taught in the pre-service teacher-education program. The research design used in this study was both qualitative and quantitative. The qualitative method used was content analysis (Patton, 1990). In this method the researchers identify, code, categorize, and classify the primary patterns in the data. The primary purpose is to simplify the complexity of reality into some manageable classification scheme. Once the content was codified, quantitative analysis was conducted using a pre/post design. The population for this study included all syllabi used for instruction during Fall 1999 and Fall 2000. Course syllabi were analyzed for technology use and integration in Fall 1999, before the project was implemented, and in Fall 2000, after project implementation.

First, the number of references made to Instructional Technology in each syllabus was determined. This provided the researchers with a sense of the awareness of technology in each syllabus. Second, the researchers wanted to know how technology was used in the classroom. Each syllabus was carefully analyzed for instances where the use of instructional technology was required or included. Each instance was then classified into one of three categories: teaching, learning, and research. Finally, the researchers wanted to determine the quality of technology integration demonstrated in each syllabus. Using The Apple Classrooms of Tomorrow (ACOT) research findings that the introduction of technology into classrooms can significantly increase the potential for learning, especially when it is used to support collaboration, information access, and the expression and representation of student's thoughts and ideas. ACOT developed a taxonomy of technology integration to clarify those ideas (http://www.apple.com/uk/education/acot/acotresearch.html). These criteria were used to classify each syllabus.

Results

As a means of defining the current status of the integration of technology in the instruction of pre-service teachers, course syllabi were analyzed. Copies of course syllabi used for instruction with pre-service teachers were obtained from three departments (Early Childhood Education and Reading (ECER), Middle Grades Education (MGED), and Secondary Education (SCED). Table 1 lists the number of syllabi that were analyzed by department and semester. Twenty-one courses were analyzed both in Fall 1999 and 2000. Only when the exact course (identified by course number) was taught in both semesters was there a matched pair that. There were courses taught in the Fall 1999 that were not taught in the Fall 2000 and visa versa.

</tbody>
</table>

Table 2: References To Instructional Technology in Course Syllabi;
N= total references n= references per course

There was a 59% increase in the number of references made to Instructional Technology after the implementation of the PT3 project. These were not evenly distributed among the three departments. Early Childhood Education and Reading and Middle Grades Education made the greatest gains in terms of total references — an increase of over 70%, while Secondary Education posted a 20% gain. The percentage gains in total references were somewhat misleading, however, because Secondary Education had the most references to technology in the Fall 1999. A modest percentage gain of 20% in total technology references boosted the references per course to a substantial 15.6, while ECER and MGED had lower per course averages.

The Paired-Samples T-Test procedure was used to determine if there were statistical gains for the combined pre-service teacher programs. The result of the t-test, as shown in Table 3, revealed that there was a significant difference between the number of references in the Fall 1999 as compared to references in the Fall 2000 (p= .000).

Table 3: Paired Samples Test Between IT References during Fall 1999 and Fall 2000

Instructional Technology Use

Using content analysis, each syllabus was analyzed to determine how Instructional Technology was used. Technology use was classified into three categories:

1. Technology used in teaching – Applying computers and related technologies to support instruction in the classroom. For example, using technology for planning and delivering instructional units that integrate a variety of software applications and learning tools; and develop technology lessons that reflect grouping and assessment strategies for diverse populations.

2. Technology used in learning – Using computer-based technologies such as telecommunications and the Internet to enhance personal and professional productivity. For example, using software application packages to solve problems and assist in decision-making, collect data, manage information, make presentations, and develop an understanding of how technology is used to improve education.

3. Technology used in research – Using computer-based technologies such as telecommunications and the Internet for research.

Table 4 reports how technology was used in the Fall 1999 and 2000. Totals differ slightly from those in Table 2 because there were occasions in which references to technology could be counted but the context was
insufficient to classification the intended use of the technology. For example, a URL could have been listed in
the syllabus but it could not be determined exactly how the URL was to be used. Thus the number of references
is greater than the number which was classified. Applying computers and related technology through teaching
was the most frequent use of technology, while using technology for research was the least frequent use.

Of the 117 references made to using Instructional Technology in the Fall 1999, seventy-two percent were
references to using technology in teaching, eighteen percent were references to using technology in learning and
ten percent were references to using technology in research. After the implementation of the PT3 project 273
references to Instructional Technology were made. Sixty-seven percent of the references were made to using
Instructional Technology in teaching, twenty-seven percent in learning, and six percent in research.

</tbody>
</table>

Table 4: Technology Used in Pre-Service Training in Fall 1999 and 2000

The use of Instructional Technology both increased and shifted after the implementation of the PT3 project.
While the overall use of instructional technology increased from 117 to 273, an increase of 57%, the results of
the paired sample t-test revealed that there was a significant differences between the use of technology in
teaching (p=.001) and in learning (p=.046) but not for research (p=.526). The use of technology in teaching
increased from 84 to 123 (54%) and the use of technology in learning increased from 21 to 73, a seventy-one
percent increase. The use of technology for research did not increase significantly but it did increase from 12 to
17, a 29% increase. After the PT3 project was implemented, one can conclude that the use of instructional
technology in teaching and in learning increased significantly.

Integration of Technology
Using content analysis, each syllabus was analyzed and assigned a level of technology use according to a criteria adapted from the ACOT Study (http://www.apple.com/uk/education/acot/acotrsearch.html). The criteria used were:

- **Entry**: Little or no evidence of use of technology
- **Adoption**: Some evidence of technology being incorporated into the teaching, primarily to teach about technology and as a means of delivering traditional instruction.
- **Adaptation**: Evidence of integrating technology into the traditional teaching methods, however, classroom instruction is still primarily traditional.
- **Appropriation**: Pervasive use of technology. Integration of a variety of types of technology.
- **Invention**: Evidence that teacher and students are experimenting with new instructional technology. The entire teaching/learning experience is transformed with the use of technology being almost transparent.

Of the 25 syllabi analyzed in the Fall 1999, 92% indicated little evidence of technology use. These were divided into forty-eight percent that showed little or no evidence of technology (e.g. Entry Level) and forty-four percent that showed some evidence of technology being incorporated into teaching (e.g. Adoption Level).

After the implementation of the PT3 project, 31 syllabi were analyzed using the same ACOT criteria. Twenty-one of the syllabi were for the same courses used in the proceeding fall. The remaining ten were different courses.

While twenty-two percent of the syllabi showed little or no evidence of technology use (e.g. Entry) after the implementation of the PT3 project, eighty-eight percent of the syllabi showed evidence of using technology. Thirty-six percent of the syllabi indicated some evidence of technology being incorporated into teaching (Adoption), although most of the technology was used primarily to teach about technology and was used as a means of delivering traditional instruction. Twenty-nine percent of the syllabi were judged to have integrated technology into the traditional teaching method (e.g. Adaptation). Thirteen percent of the syllabi were judged to have pervasive use of technology indicated by the integration of a variety of types of technology (e.g. Appropriation).

Table 7: Changes According to the ACOT Study Criteria

**SUMMARY**

This study focused on the infusion of Instructional Technology in the pre-service teacher training courses. First, the study examined the number of references made to Instructional Technology in course syllabi before and after the implementation of the PT3 project. There was a fifty-nine percent increase in the number of references made to technology. A paired t-test revealed that this difference was significant (p=000).

The references to instructional technology were further analyzed to determine how technology was designed to be used in each syllabus. Each reference was classified into three categories according to its use of technology. The categories were (1) technology in teaching; (2) technology in learning; and (3) technology in research. Overall, the use of instructional technology in teaching increased fifty-four percent; the use of technology in learning increased seventy-one percent; and the use of technology in research increased twenty-nine percent. A paired samples t-test determined that there was a significant differences between the use of technology in
teaching (p=.001) and the use of technology in learning (p=.046); however the differences for the use of technology in research was not significant.

Finally, the study assessed how Instructional Technology was being infused into the pre-service teacher training courses. A careful content analysis of each syllabus was completed and a level of technology integration was determined. The criterion for determining technology integration was derived from the ACOT studies. Before the implementation of the PT3 project, 92% of the syllabi were determined to have little of no evidence of technology integration (e.g. Entry or Adoption). After the PT3 project this percentage dropped to fifty-eight percent. In addition, technology infusion was judged to have improved as indicated by the number of syllabi that demonstrated evidence of technology use: Adaptation-29%; Appropriation-13%. While these results are far from ideal, significant improvement in technology integration was demonstrated is a relatively short period of time.

Conclusions

According to the SEIR*TEC study (1998), pre-service education students often do not know how to integrate various technologies into their teaching. One place to help remedy this problem is in the pre-service teacher training classroom. This PT3 project demonstrated that pre-service teacher training courses could infuse more technology into the course syllabi. By the end of the project there was a 59% increase in the references to technology, a 57% increase in the uses of technology and an overall improvement in the quality of technology infusion in course syllabi.

The PT3 project brought about some measurable improvement in the use of technology, and an awareness of the need for technology infusion in the pre-service teacher training program. This study provides the following observations:

1. This project showed that an organized program with definite goals and a systematic approach could increase the quantity and quality of the technology use in pre-service teacher training.
2. ECER showed greater numerical gains because of a program-wide approach to technology addition to the syllabus. The other programs did not show the great percentage or numerical gains because they were working with smaller numbers of syllabi or started with a higher use of technology.
3. Teaching is by far the largest technology integration activity.
4. Research is not something that is utilized much in pre-service teacher training syllabi. Faculty may consider that as a way to increase technology integration in their courses.

Abstract: This paper describes the effects of an after-school program where preservice teachers and elementary school children play and work together using computer games and other technologies and then complete activities based on those games. The program, based on the 5th Dimension, a project developed at the University of California, San Diego, is designed to give preservice teachers experiences using and evaluating a variety of technologies. It also, of course, provides preservice teachers with opportunities to get to know children, learn to interact with them and guide their learning. The enthusiasm of the children often helps sometimes technologically-reticent college students. The paper will describe the project and highlight how this experience can help preservice teachers begin to meet national standards for new teachers.

Introduction

It's 3:00 ... and just as most of the school empties, one classroom comes alive. Two dozen youngsters rush in, anxiously looking for their buddies from St. Bonaventure. The college sophomores and juniors greet the elementary school students, and each buddy team immediately picks up from where they left off a couple of days ago. The partners check to see what they have completed and then decide what activity they will do today. Most choose a computer activity, so they find the right CD, read the activity card to find out what they must accomplish, and then get to work. The software is installed (often it's the fourth grader leading the college student in this effort), directions are read, and play begins. One pair traverses the Oregon Trail, while another tries to design products in a Factory. Others are taking digital photos for the web site or a Power Point presentation.

This is an afternoon in the WOLF Den an after-school program that is running at East View Elementary School in Olean, NY, as part of the PT3 (Preparing Tomorrow's Teachers to Use Technology, www.pt3.org) project at St. Bonaventure University (SBU). (The wolf is the University mascot, and of much interest to local children.) College students who run the program are just starting courses as elementary education majors. SBU's School of Education Conceptual Framework emphasizes that preservice teachers learn best in realistic and practical settings where theory is developed in context. That belief holds true not only for traditional methods courses, but also for helping preservice teachers learn about using technology to support teaching and learning. We have integrated experiences with technology across the entire undergraduate teacher education program – across all courses and field experiences – rather than situating learning about technology in a single course.

The WOLF Den – Where Outside Learning is Fun – is a local version of the 5th Dimension, a mixed activity system of education and play designed to provide a context in which undergraduates have opportunities to connect theory with practice. It also provides contexts for children to master knowledge and skills. The 5th Dimension was conceived by Dr. Michael Cole of the University of California, San Diego, and its many varieties are documented in an online Clearinghouse developed by William Blanton at the Appalachian State University (http://129.171.33.1/blantonw/5dC1hs/clearing11.html ).

There are several goals for the program. For the children, it provides opportunities to engage in learning-related tasks; it gives them one-to-one attention from adults who engage with them in conversation – on one level about games and activities, but on another level about problem solving; it is a safe, secure environment where the after-school hours can be fun and productive, often providing a haven for children who otherwise go home to empty houses. As with all of our field-based programs, children's learning is most important, but the goals for our preservice teachers drive the design of the program. In the WOLF Den preservice teachers are in a situation where they have to learn software and hardware, where they have to troubleshoot technology problems (printers, disks, cables, system settings, etc.). They have to read cryptic manuals and manage demanding children at the same time.
As a core part of our PT3 project, the WOLF Den provides an environment where preservice teachers can gain experience using a variety of technologies, where they can interact with children using those technologies, and begin to see the effect on children’s learning.

This paper will describe the WOLF Den and the experiences that it provides for preservice teachers. It will look at how experiences in the WOLF Den help preservice teachers begin to meet National Educational Technology Standards for Teachers and INTASC (Interstate New Teacher Assessment and Support Consortium) standards for new teachers. We will report data gathered from the preservice teachers, reactions from the children and ethnographic data collected by observers.

Description of the Program

The WOLF Den is an after-school program that brings college students (whom we call tutors) and elementary school children together in computer-mediated play and learning environment. The central artifact in the WOLF Den is a table-top maze, and the goal for the participants is to complete an activity in each room of the maze. Each maze room points participants to a choice of activities, one of which must be completed before passing through the room. Most activities are computer-based (play a game, create a presentation) or technology related (take digital pictures, make a video), but there are also non-computer activities (board games) that fill the gaps when all of the computers are in use. All activities have task or activity cards at three levels specifying what must be accomplished. (See Figure 1 for a sample activity card.) The beginner level requires players to complete a relatively simple task – play the game at its most basic level, for example. This is important since we have participants as young as seven years old, and they must have success. The good level generally requires more time and effort and a higher level of achievement; and the expert level is really challenging. Each child starts a trip through the maze using a simple token or “cruddy creature” to mark his/her place. One goal (which is extremely motivating for children) is to transform the “cruddy creature” into an “excellent creature” (a fancier, more desirable toy or token) – which requires completion of 11 games at the good or expert level.

![Figure 1: Sample Activity Card](image-url)

The WOLF Den is run by graduate assistants and a mythic figure – the Wolf, of course. The Wolf is a non-present participant who oversees the program and who is, ostensibly, responsible for upkeep, organization and creation of rules. The children can communicate by mail with the Wolf, expressing pleasure or frustration, or
simply conversing or asking questions. Writing to the mythic "overseer" is a characteristic of the 5th Dimension, serving a number of purposes. Since the Wolf oversees the functioning of the program, if a computer is broken or a game will not run, it is the Wolf's responsibility to fix the situation. This deflects blame from the site coordinators and the tutors; it also gives a frustrated child a way to vent—and a few minutes to calm down. A letter is written and a new game is selected. Most often, the problem is solved before the next after-school session. Writing to the Wolf also encourages "backdoor" language development—an underlying goal of the program. Children enjoy writing to the Wolf—and really enjoy getting return letters. See Figure 2 for sample letters to and from the Wolf.

Figure 2: Letters to and from the Wolf

Preparing Tomorrow's Teachers

What are the tutors doing? How does this experience help them learn about technology and push them towards becoming technology-using educators? First, and probably most importantly, they are interacting with the children using technology. Tutors are responsible for organizing activities for their assigned child or children, and they have to be comfortable with the hardware and software. This is no small feat for many of our preservice teachers who still arrive at college with only the most basic experiences involving technology. They can use a word processor and send email, but when faced with installing new software or troubleshooting a printer problem, they blanch. In the WOLF Den they often have to move from computer to computer to find one that will run a finicky computer game. They experience the frustration of computers that will not work; they struggle with software. They learn to deal with that frustration and troubleshoot the problem. More often than not, they get it to work. We think that this is a crucial part of the process of becoming a technology-using educator. The realistic fact is that in most schools there is not a computer technician available right when you need help with a piece of software that will not work. Teachers must be comfortable with problems if they are to be successful as they incorporate technology into their classrooms, and we are finding that experience in an informal setting such as the WOLF Den provides opportunities for preservice students to master some of these necessary skills. One tutor struggled with a particular game, and finally turned to the Wolf.

Today I was not looking forward to going to the tutoring session...This attitude changed, however when R and S arrived. They both seemed excited to be there. This made me look forward to working with them. They also were thrilled because the Wolf had written them back a letter, especially addressed to them. Because R and S have been having computer problems with the Lemming's Paintball, I suggested last week that they write a letter to the Wolf and let it know that there were problems with the game. S wrote the letter notifying the Wolf that the game would freeze up when they got on an advanced level in the game. R and S were frustrated when once again the computer froze as they progressed through the game. To be honest, I was not surprised that it did because I have a feeling that the lab top causes the problems.

The WOLF Den uses school equipment and a wide variety of educational and edutainment software. The problem of getting software to run on less-than state of the art equipment is one continually faced by teachers.
There are few standards for this software—video requirements, for example—are perennial problems. Novice users are simply stopped dead by a dialogue box stating

This program requires 256 colors.

and requiring them to change system settings (and then remember to change them back so that other programs will run correctly). In one interaction, a child was overheard complaining, “I want to play.” The tutor replied (with some anxiety), “I am trying to get the game to work...just hold on.” Tutors are learning that they not only have to be patient with the computer software, but they must be patient with the children they are working with. Tutors help each other solve problems, engaging in early collegial activity, and learning that, in schools, cooperation is paramount. By the way, children often know how to solve problems, and in settings such as the WOLF Den, the children often teach the college students. That’s a learning experience too.

Beyond basic technology-related tasks, tutors have to guide and facilitate interaction between children and computers. For example, in one instance, a tutor and two children were playing Oregon Trail. The children were getting too much meat and not enough vegetables (children like to hunt in this program). The tutor attempted to guide them, engaging them in conversation about the need for vegetables to sustain life. She was helping the students with decision-making skills and encouraging them to try different strategies. In fact, she was trying to help them be successful. Tutors help children make decisions, encourage them to try new games, give them positive reinforcement, and intervene during students’ conversations when necessary.

Children in the WOLF Den range in age from 7 to 11, and while each room in the maze has activities for children at different ability levels, the range of age and ability levels is an opportunity for preservice teachers to learn how to meet individual needs. One tutor arranged for her two children to use two computers next to each other, while she assisted and played along with each. Such situations mimic what the preservice teachers will face in the classroom, particularly when attempting to teach in new ways: new software, many children, too many questions, impatience with things that don’t work right now. The support structure of the WOLF Den helps, and preservice teachers are learning to cope, and ultimately to experience success. Tutors also learn that children often know how to do things that they don’t. Everyone learns in such an environment.

Over the course of the semester, tutors learn a lot about children. And they learn a lot about the process of learning. It is the serendipitous nature of learning that amazes beginning preservice teachers: you do not have to teach everything explicitly. Children will learn when they are in an inviting and challenging environment. When interacting with technology, this can be particularly evident. As one tutor played Where in the World is Carmen San Diego? he “saw” a child acquire knowledge as a result of the game. After a couple of rounds, the suspect was again in Zaire, and the child (who had not known where it was earlier in the game) knew what the information was referring to and found Zaire immediately on the map. Both child and tutor ended that afternoon with a sense of accomplishment and something learned.

Why will this experience prepare our preservice teachers to use technology? Tutors are using technology in a setting where the focus is fun but learning is occurring. Technology is simply the medium through which tutors interact with children, observe their learning and behaviors, learn to talk with children about problems and problem solving, all while learning to manage the technology itself. They use basic technology skills and develop more advanced ones. They learn persistence and tolerance for ambiguity—one of the known hallmarks of a competent technology user (Harris 1994; Fujieda & Matsurra [no date]; Bailey & Lumley [no date], Dockstader 1999). They begin to see that technology can support teaching and learning.

The tutors start the semester participating in this program because it is a course requirement. Little do they anticipate the powerful effect that they will have on children, nor the effect the relationships they build will have on them. They end the semester humbled about what they have learned—about children, about technology, and about the powerfully difficult profession they have chosen to enter.

“I was very pleasantly surprised when I was given this opportunity to do this program with this great group of students. I was honestly kind of dreading tutoring a little bit because I felt just sitting down with a student with a book would be so boring and mundane. But this experience has been sooo much better than what I had expected. Not only did I get to have a good time while playing some games, but I also was able to learn how to work with students on a one-to-one basis. Some of the lessons I have learned in this tutoring experience will benefit me for years to come.”

Meeting Standards
We are cognizant of the need to provide opportunities for our preservice teachers to develop knowledge and dispositions and to have opportunities to practice behaviors that will allow them to demonstrate that they meet standards for new teachers. We explicit attempt to build those opportunities into our field experiences, connecting preservice teachers with children, environments and experiences where they can begin to master the ISTE Technology Standards for Teachers (NETS-T). SBU also requires that preservice teachers demonstrate mastery of the INTASC (Interstate New Teacher Assessment and Support Consortium) standards for new teachers.

We are in the early stages of aligning our program -- courses and field experiences -- with both INTASC and NETS-T standards. Table 1 presents a representative sample of how we see the WOLF Den experiences lining up with NETS-T. (Alignment with INTASC standards is still at a very early stage.) The important aspect of this is that the performances required of the preservice teachers in the WOLF Den are real. They are learning about and using technology not to demonstrate competence in a college course, but to provide children with rewarding, challenging experiences. The children's attendance is voluntary -- and there is almost always perfect attendance. That speaks to the tutors' competence.

We are also beginning to examine how participation in the WOLF Den helps children meets the NETS-S (National Educational Technology Standards for Students). Early indications are that children benefit at least as much as the tutors, if not more.

We are extremely encouraged by observations of what tutors are learning. Specifically, it is interesting to note that many of their reflections indicate beginning mastery of knowledge, disposition, and performance indicators for the NETS-T and INTASC standards. One tutor stated, "I have learned the importance of being patient... I have realized not to give them the answers, but challenge them to find the answers. I have learned how much they enjoy the time you spend listening to them." Another tutor's response reflects his ideas of becoming a teacher, "I have learned a lot about what is expected of me as a teacher. I also learned a lot about classroom management and also discipline. I realize the amount of effort and ability that is needed to be a teacher. I have learned I need to continue to learn techniques and teaching strategies."

Finally, in reflecting on his experience in the WOLF Den, one tutor wrote, "I learned that technology is going to be very important in the future of teaching. I feel comfortable using technical equipment and part of the reason why is because of this program."

Abstract: This session will discuss a variety of online discussion “settings” and present preliminary analyses of discussions in terms of what they tell us about student thinking and professors’ responses. We will discuss how the use of online discussion can influence what and how we teach, and how that, in the long run, can affect preservice teachers’ development.

Introduction

With the advent of readily available Internet access, online discussions (particularly in the form of live chats) are commonplace for some students. However, for many students, venturing online to discuss course-related issues and content is a completely new experience. Research on the use of online discussion has focused on the effects of online discussions, and the need to develop community in the absence of face-to-face interaction (Ahern 2000; Klemm 1998; Charp 1998) and how to keep discussions going and focused (Ahern 2000; Wolfe 2000). Others have examined how best to prompt and moderate discussions (Scarce 1997; Johnson 1999).

If, as we believe, teachers teach as they were taught, and if current preservice teachers have not been taught using technology (which still remains the case), then it is our responsibility to help remediate that situation. We posit that a variety of sustained, positive experiences involving technology in teaching and learning environments during preservice teachers’ undergraduate courses will help them see the value of using technology in the classroom. One way that we are doing this is through the use of online discussions to supplement and extend in-class discussions. We are interested in the question of what we can learn about students’ thinking as a result of analysis of discussions. We are also analyzing how the use of online discussions affects teaching.

This paper presents a variety of online discussion “models” in terms of what they tell us about student thinking and professors’ responses. We will discuss how the use of online discussion can influence what and how we teach, and how that, in the long run, can affect preservice teachers’ development.

Implementing Online Discussions: Why and How?

Over the past several semesters, several of us have examined our courses and questioned how technology could be used to support and improve learning, we decided that we would incorporate online discussions in an effort to (1) increase the quality and quantity of student “talk” about course content and related issues, (2) encourage metacognitive reflection about course content, and (3) improve teacher/student communications. Working together and separately, we set up a variety of discussions to meet the needs of several different course structures. We have used several different models and at least two different technology-support structures.

Models for Online Discussions

One approach is to set up a teacher-led discussion. Using this model, the professor seeds the discussion on a regular basis; requires students to respond, and encourages them to interact with each other. The advantage of this model is that all students must respond to selected prompts. It can extend or supplement in-class discussion. Because the instructor leads the discussion, students approach the discussion as an obligation or course requirement and their participation has an obligatory tone. This approach is being implemented in one setting where students from a number of sections of the same field-based education course are assigned to small group discussions led by the faculty. The idea is to have students interact around course issues, and to share perspectives gained from different field sites.

Student-led discussions turn the tables, and put the onus on students to start and keep the discussion going. This approach has merits because it requires students to take some ownership of the course material. Each week one or more students are assigned to lead the discussion. This approach is being implemented in an introductory U.S. History course, where the professor hoped to change the classroom dynamic by forcing students to take some responsibility for intellectual leadership in the course.
Open-forum discussions are arguably the most effective if they work, and most closely mimic good face-to-face discussions. This approach is being implemented to connect two groups of preservice students working in two Professional Development Schools. These started as teacher-led discussions, but quickly took on a life of their own as the preservice teachers used the discussions to support their fieldwork experiences. The students want and like professors to engage in the discussions, but this group, at least, exemplifies the real purpose of online discussions.

Observations and Responses

In classroom-based discussion, professors can model higher order thinking, and even when discussions are student-led, professors can mediate the process. As we "listen" to the online discussions (and participate in them), we are struck by the need to help students learn how to ask appropriate questions in order to stimulate discussion. We are aware that students tend to focus on questions at the lower levels of Bloom's taxonomy, and we have learned that we need to model better questioning. On the history discussion, we have found that students who do ask better questions tend to ask counterfactual or "what if" questions.

Using discussions has forced us to think about our teaching in ways that are, ultimately, refreshing. We are forced to think about how we teach, particularly the need to teach thinking —disciplinary thinking, certainly, but also general higher order thinking skills. We are finding that online discussions provide opportunities for professors to analyze students' work from a very different perspective.

Student reactions to the discussions vary greatly. Some tend to like the safety of the forum, other find the technology problems overwhelming. Some remain bewildered about the technology, but have taught us that faulty design (even that of the default discussion web in FrontPage) makes a great difference in student's use of a site.

We have found (not surprisingly) that students who do not read textbooks also do not tend to read web sites; and many of those who refuse to participate in class do are not clamoring to be heard online. However, aggressive students cannot dominate in an online environment as they can in face-to-face discussions; quiet students with opinions have equal voice. Moreover, many students acknowledge that they like the opportunity to hear what others have to say. This is particularly true in discussions involving students from more than one class.

Overriding Issues: Usability, Access and Stability

We have been using discussions for several semesters, and each semester new challenges arise. While confident in our abilities to guide discussions and manage the intellectual aspect of the discussions, problems with technology have often proven to be intractable. One semester we used a discussion set up as a newsgroup. Even though more difficult to set up and maintain, it had the advantage that users could attach documents to their comments. We are currently using FrontPage to create and manage discussion webs. They are far easier to set up and maintain, but do not allow users to attach files. Every decision is a trade-off.

The major issue on our campus is Internet access. When the Internet is down, students cannot participate. When traffic is so high that access is unreasonably slow, they will not participate. There have been persistent Internet outages and periods of extreme slowness (for reasonably long times this semester). This has affected both professors and students. For those who are novice users of this type of technology, it has had a definite negative impact. Seasoned users are more tolerant. However, professors can bear only so much disruption of a course; students are not persistent or tolerant. If it doesn’t work after a few tries, they give up. End of discussion.

The final word: the technology must support learning, not get in the way.

Project Learning Links:
A Model for Integrating Technology into Teacher Education

Abstract: Learning Links is a PT3 project housed at the University of Nevada, Reno. The project uses a four-component model to infuse technology in all aspects of the undergraduate teacher education program: (1) modeling, (2) integrating, (3) enhancing, and (4) applying. University faculty are given technological assistance and incentives to develop the skills and uses for technology within their existing education courses. Data describing the current level of technology use by the faculty, as well as their attitudes toward technology, are shared and the implications for infusing technology in teacher education are discussed.

Introduction

Nevada is not unlike many states when it comes to infusion of technology into the teaching and learning environment of the public schools. Through legislate initiatives and local incentives, strides have been made to improve technology access in classrooms across the state. This initial investment has gone into hardware, software and connectivity in the schools. By the beginning of the 1999-2000 school year, every classroom in the state reportedly had at least one computer connected to the Internet. Many classrooms have more than one computer and many schools have fully equipped computer labs with Internet connections.

What remains a major gap in improving Nevada public schools through technology infusion is the lack of skills and knowledge on the part of teachers to make full use of the technology they find in their schools. According to Mark Knudson, educational technology specialist at the Nevada Department of Education, only an estimated 5% of teachers are at the point of technology infusion in the curriculum. As is commonly the case, the largest gaps and the greatest weaknesses in technology infusion exist in the most rural and low-income pockets of the state.

However it is not only in the K-12 system that gaps exist in the infusion of technology in teaching and learning. Similar gaps and weaknesses could be found in the teacher preparation program at the University of Nevada, Reno (UNR), one of only two four-year institutions of higher education in Nevada. The university has programs leading to teacher licensure in the areas of elementary education (grades K-8), secondary education (grades 7-12), and special education. While prospective teachers in each area acquire some technology skills through one required course in technology, few exit the program with the skills, knowledge, and understanding to truly infuse technology into their classrooms.

Like the public school system, a substantial investment has been made to equip university classrooms and labs with state-of-the-art technology. Some faculty have made good use of this technology, but many are still using traditional teaching methodologies to present their course content. Until very recently, the technical support and incentives to enable faculty to redesign their courses using teaching and learning technology have not been readily available.

In the spring of 2000, faculty from the UNR College of Education developed Project Learning Links in an attempt to address perceived weaknesses in the infusion of technology into the teacher education curriculum. Learning Links is a three-year federally funded PT3 grant. This paper describes the model used by the project. In addition, university faculty attitudes and expertise in using technology were assessed prior to the onset of project activities. Trends discovered relative to these attitudes and skills are discussed, as are the implications these findings have for the necessary activities of Learning Links.
The Learning Links Model

In order to efficiently use learning technology in school classrooms, teachers must think differently about the teaching and learning process, classroom organization, methods of content delivery, and the nature of student projects and assignments. To accomplish this, Learning Links makes use of four change components in the UNR teacher preparation program, illustrated in the graphic below.

These four components comprise system-wide changes in the way classes are taught, skills are demonstrated, and performance is assessed. The revision of the UNR Teacher Preparation Program will be a systematic process over the three-year period of Project Learning Links.

Modeling

This component of Learning Links is an important part of enabling future teachers to understand and appreciate the use of technology in teaching and learning, where learning technology is used both by the instructor and the students. To achieve this change component, university faculty are given opportunities to grow in knowledge and skill in the use of effective teaching and learning technologies. Learning Links offers incentives, through a Faculty Fellows program, for professors to effectively adapt their courses to model the use of teaching and learning technology.

Faculty in the College of Education apply for the Faculty Fellows program each semester. Applications describe the changes the faculty member proposes to make in a specific course by the infusion of learning technology. Making changes in the way they model the use of technology is classified as a Level I application. In the application they specify: (a) what technology will be used; (b) how delivery of course content will be modified; (c) how assignments and projects will use technology; and (d) how the infusion of technology into teaching and learning will be modeled.

From among the applicants, the dean of the college selects five faculty members each semester to participate in a Faculty Learning Fellows program. As Fellows, faculty members are able to get a course release; receive targeted hardware and software upgrades that relate directly to their course modifications; and receive extensive technical support from the Learning Links project staff.

Integrating

While it is important for pre-service teacher education students to have learning technology modeled by professors, it is equally important for them to devote part of their learning experience to understanding principles and concepts relating to integrating learning technology into the K-12 curriculum. The change component, integrating, emphasizes adapting the curriculum of key education courses. The focus is on providing prospective teachers with the skills and strategies that they will need to modify, organize, and execute technology-rich curricula in their classrooms as they take their places in Nevada's K-12 schools.

The actual changes to the content of key pedagogy or methods courses is accomplished through the Faculty Fellows program. Applications from faculty may be designed as Level II, indicating that their course would explicitly teach integrating technology into teaching practices. Incentives allow instructors to reconstruct their course content and assignments to incorporate more of an emphasis on methods of technology infusion. Examples of activities incorporated into reconstructed courses could include the following: (1) having students develop and present demonstration lessons that incorporate technology infusion; (2) discussing and demonstrating classroom management differences between a traditional and a technology rich classroom setting; and (3) demonstrating ways to incorporate learning technology into
inquiry and problem solving instructional approaches. Learning Links also involves a cadre of Master Teachers nominated by school district superintendents throughout the state for their use of technology in teaching and learning. These teachers give lectures, demonstrations, and conduct discussions within preservice teacher training courses about their use of technology in the classroom.

**Enhancing**

The intent of this change component is to move all pre-service teacher education students beyond the basic skills level in using learning technology to a level where they can function more independently in installing, maintaining, trouble-shooting, repairing, and managing classroom, computers, computer labs, and small computer networks. In most schools, teachers have district technology support. However, such support is often spread thin, and in some very rural areas, technology support is almost nonexistent. The so-called digital divide also plays a role in the degree to which technical support is available to teachers. Richer districts and richer schools are often able to find resources to maintain, repair, and manage computers and networks; whereas, in poorer areas, such resources are scarce. The teachers leaving the UNR program should be able to go beyond a “plug-and-play” level of computer expertise. The goal is to have them be as self-sufficient as possible, so that when they are in a school with little or no technology support, they can keep things going and provide stability for other teachers in their schools.

Training for future teachers in this component is accomplished by the re-design of the traditional three-credit course in the use of technology. This course was previously composed of modules presented in a self-paced format. Those modules have been condensed and redesigned, and additional modules were developed. These new modules cover topics such as trouble-shooting, making minor repairs, and management of simple computer telecommunications networks. Delivery of these additional modules of instruction is accomplished through involvement with the lab facilities at Truckee Meadows Community College, a nearby state institution.

**Applying**

This change component emphasizes field based and on-line experiences between future teachers and students in Nevada’s schools. These experiences give prospective teachers practice in using technology effectively with children. One type of experience occurs in practicum courses where future teachers participate in technology rich classrooms in nearby schools. A second type of experience includes interacting with children from rural/remote areas using the Nevada Bell Student-to-Student Network. Nevada Bell, the state telephone service provider, has provided dedicated hardware to establish connections by which future teachers may correspond with, provide tutorial assistance for, and share resources with children in rural schools. This gives teachers and students experience with synchronous and asynchronous teaching methods. Video conferencing, chat rooms, bulletin boards, and E-mail also can be used.

**Faculty Attitudes and Expertise in Technology Use**

Prior to beginning project activities in the fall of 2000, all faculty in the College of Education were asked to respond to a written survey about their use, level of expertise, and attitudes toward technology. The survey was designed to assess the areas of “personal productivity,” as well as “modeling,” “integrating,” and “applying” technology as described in the model above. “Personal productivity” related to faculty skills and uses of technology in their own scholarship, lesson planning, student assessment, and similar activities. The survey used a four-point, Likert-like scale in which the faculty indicated their rating of their skill from (1) “I do not use this technology” to (4) “I use this technology extensively.” In addition, faculty were able to check a box indicating, “I would like to learn more about this technology.” Attitudes were assessed in a section of the survey in which faculty rated statements about the use of technology from (1) “strongly disagree” to (4) “strongly agree.”

Thirty-seven (37) out of 49 teaching faculty in the college completed the survey (75%). Table 1 reports the mean ratings of faculty in their use of technology.

2092
Overall analysis of the results indicated that faculty rated themselves as using technology more in their personal productivity than in other areas. All faculty responding indicated extensive use of word-processing, e-mail, and Internet browsers. Of those responding, 41% indicated an interest in learning more about Web-page development and about scanning/digital camera applications. There was also interest in learning about audio and video editing (30%). Faculty also indicated that they modeled and integrated technology in their courses and course assignments. The most common applications used in this manner were word processing, e-mail, and Internet exploration, followed by the use of presentation software.

The lowest technology use came in application to field experiences and practica in the public schools. Few faculty used any form of technology in this context. In addition, as reflected in Table 2, few faculty felt that the explicit infusion of technology in these experiences was needed. This is in contrast to the relatively strong acceptance of technology in the areas of personal productivity, modeling, and integrating into the teacher education curriculum.

Discussion

The majority of university faculty at this institution have embraced the use of technology to enhance their professional productivity. They have been somewhat slower to infuse technology in their preparation of preservice teachers. The faculty at the University of Nevada, Reno, vary in their attitudes about the importance of technology in teacher education. The value of infusing technology into practicum or field experiences in public schools has yet to be widely recognized. This implies an assumption by faculty that campus-based experiences with technology are sufficient for preservice teachers to be able to infuse technology in their own teaching after graduation.

The results of the survey instrument indicate a willingness on the part of faculty to receive information, support, and tools to make effective use of technology in many aspects of teacher education. However, leadership will be needed in order to influence faculty attitudes about the importance of incorporating technology into the preservice teachers' real work with children in school settings. Although not reflected in the survey, anecdotal comments by faculty may indicate another impediment to the infusion of technology in the teacher education curriculum. Similar to conditions at many other state-supported universities, this faculty has often been asked to accomplish more with fewer resources. Requirements for in-depth performance assessment of students, increased standards for publication and scholarship, and emphasis on teaching effectiveness have not been accompanied by additional faculty, support staff, or material resources. There is hesitation and skepticism about new initiatives. However, there is some enthusiasm about Learning Links. This is largely because the project provides three very important and rare commodities: time (through release from teaching one course); support (through the technical assistance of Learning Links staff); and resources (by providing targeted software and equipment). It will be interesting to see how faculty skills, use, and attitudes toward technology are influenced by the three-year implementation of Project Learning Links.

E-mail: lleo120@ms1.hinet.net

Abstract: This study tested the effects of web pages design instruction on improving computer self-efficacy of preservice teachers. A sample of 206 preservice teachers participated in this research. A pretest-posttest design, including a 14-week instruction of web pages design, was conducted. The instruction of web pages design did significantly improve the computer self-efficacy of preservice teachers. Various computer experiences, including weekly computer use, weekly internet use, the use rates of word processing, e-mail, game, presentation software, were significantly related to computer self-efficacy. The use rates of word processing software and computer graph, weekly computer use, and age were the significant predictors of computer self-efficacy. The preservice teachers owning higher perception of computer self-efficacy revealed more confidence on web authoring software self-efficacy. Generally, it is confirmed that most educators' belief to increase the opportunities to learn and use computer may facilitate the confidence and competence of preservice teachers.

Instruction of web pages design has become popular in the courses of preservice teacher preparation due to the establishment of computer network infrastructure and the prevalent www application. However, the learning doesn't guarantee the owning of confidence or efficacy in implementation. According to the report from Milken Exchange on Education Technology and International Society for Technology in Education (1999), the technology related course in preservice teacher preparation did not increase the use of the future teachers in computer application in instruction. There were various issues surrounding that phenomenon including shortage of enough facilities and infrastructure, the inappropriate pace of courses agenda, and lack of the personal confidence and capability of some teachers. The current study aims to explore the last issue mentioned above. Focusing on computer self-efficacy that related to personal belief and perception of capability, this study tested the effects of web pages design instruction on improving computer self-efficacy of preservice teachers in addition to the analysis of correlated factors.

Conceptual Framework

Teachers' self-efficacy has always been a significant concern in teacher education. Research (Bandura, 1997) has verified teachers' self-efficacy would affect their instructional performance and then influence the students' learning outcome. Referring to the increasing application of information technology in education, computer self-efficacy of preservice teacher may affect their future instructional arrangement regarding information technology application. The concept of computer self-efficacy and correlates, therefore, deserve deep exploration.

Derived from Bandura's social cognitive theory (1986), self-efficacy was introduced to computer use and a variety of computer behaviors in late 1980's (Hill, Smith, & Mann, 1987; Gist, Schwoerer, & Rosen, 1989; Murphy, Coover, & Owen, 1989). Most of the early research focused on the identification and measurement of computer self-efficacy. Based on the original concept, computer self-efficacy refers to a judgement of one's capability to use a computer (Compeau and Higgins, 1995, p.192). Compeau and Higgins (1995) defined the dimensions of computer self-efficacy, include magnitude, strength, and generalizability.

However, Marakas, Yi, and Johnson(1998) divided computer self-efficacy into task-specific computer
self-efficacy and general computer self-efficacy. Task-specific computer self-efficacy refers to an individual's perception of efficacy in performing specific computer-related tasks within the domain of general computing (p. 128). Conversely, general computer self-efficacy refers to an individual's judgement of efficacy across multiple computer application domain (p.129). And they argue the general computer self-efficacy as a collection of task-specific computer self-efficacy and enactive experiences. A task-specific computer self-efficacy perception is associated with a specific task performance.

According to the literature, the interest in research with regard to the construct of computer self-efficacy has been to understand the mechanisms affecting individual computer behavior or the effect of training related to computer application. At one hand, various research have developed different instruments of measuring computer self-efficacy. On the other hand, the results of empirical research concerning the correlates of computer self-efficacy were equivocal. In terms of computer self-efficacy measurement, most of them are Likert type scale with point range from 3 to 7. Fewer of them use the approach suggested by Bandura (1986) that requires the individual to response dichotomously the questions. Although the computer self-efficacy measurements were almost unidimensional in nature, the strength (confidence), the credibility of the instruments was presented is use (Marakas et al., 1998).

As for the antecedent, consequent, and moderating factors related to computer self-efficacy, Marakas, Yi, and Johnson (1998) have done a thorough review. In the comprehensive analysis about the identified 40 papers, they grouped the various factors and discussed the issues of requiring further exploration. But, none of the cited paper used the preservice teachers as sample. The tasks involved in those studies were few related to the network that prevails in the new era. In the following sections, research factors used in this study will be reviewed.

Computer Self-Efficacy and Web Authoring Software Self-Efficacy

As mentioned above, Marakas, Yi, and Johnson (1998) divided computer self-efficacy into task-specific computer self-efficacy and general computer self-efficacy. They explained general computer self-efficacy is a product of a lifetime of related experiences and closely conform to the definition of computer self-efficacy that is often used in the Information Systems literature, while task-specific computer self-efficacy is associated with a specific task performance. The author accepts the notion of Marakas et al. in this current study. However, the term of computer self-efficacy is still used to indicate the general computer self-efficacy thought as a collection of all computer self-efficacy perception accumulated over time. Further, the term of web authoring software self-efficacy is adopted to refer to the task-specific computer self-efficacy because it more obviously presents the task in this study.

Computer Experiences

Experience is an important factor that affects human learning. Resulted from the interaction between environment and human being, experiences could enforce or decrease our learning. In the past empirical research regarding computer use, computer experience has been the important variable included in studies. In terms to computer self-efficacy, many studies also proved the significant effect of computer experiences (Busch, 1995; Henry & Stone, 1995). Due to the rapid development of information technology, the scopes of hardware, software, and application are quite various. The content of computer experiences needs to be defined more clearly. It could indicate the use period or familiarity degree of specific software, system, or frequency of use. The finding resulted from clear definition of studies would give more value of application. An example as the study of Ertmer, Evenbeck, Cennamo, & Lehman (1994), two kinds of computer experiences, e-mail and word processing, were compared in contrast with computer self-efficacy. They found experience on one system tends to increase computer self-efficacy on other related systems.

Computer Network Anxiety

An extensive amount of research has been done to explore the source and nature of anxieties about the computer-related technology. Generally, computer anxiety indicates the negative attitude toward
computer use or the feelings of fear, stress, and worries about interaction with computer. There exists a reciprocal relationship between computer anxiety and computer self-efficacy. That means people with higher computer self-efficacy may experience fewer computer anxiety, while individuals with high computer anxiety could present lower computer self-efficacy and performance in dealing with computer affairs. Empirical studies strongly support for the negative relationship between computer anxiety and computer self-efficacy (Martocchio, 1994; Henderson, Deane, & Ward, 1995). Therefore, George and Camarata (1996) suggested that the increase of the instructor’s self-efficacy in use of technology as the pivotal mechanism can eliminate the level of anxiety and then accept the technological change. In this research, computer network related conception was emphasized and added in the measurement.

Web Pages Design

Web pages design involves a skill set of multiple applications, including text processing, graphic arrangement, and links planning. Due to the web-based instruction getting popular, the teachers have to learn how to post the instructional materials and related information on web site. There are many kinds of HTML web authoring tools available in the market. Some of them are included in the most popular word processing or desktop publishing software packages. The development and trend of context make it desirable and feasible for teachers to learn the simple design and editing of web pages.

Research Questions

Surrounding the computer self-efficacy of preservice teachers, this study attempts to answer the following questions:
1. What are the relationships between computer self-efficacy of preservice teachers and their background variables and computer experiences before instruction?
2. What are the predictors of computer self-efficacy of preservice teachers?
3. Does the web pages design instruction improve computer self-efficacy of preservice teachers?
4. What are the relationships among computer self-efficacy, computer network anxiety, and web authoring software self-efficacy after instruction?
5. Can computer self-efficacy of preservice teachers affect web authoring software self-efficacy?

Method

Sample

In the spring semester of 2000, 206 preservice teachers who registered in five sections of a course related to computer network application in instruction, two hours each section every week, participated in this research. The usable number of sample is 203. The male preservice teachers were 60%, while the female preservice teachers were 40%. The range of age was divided from 25 and under (17.2%), 26-30 (54.3%), 31-35 (21.7%), to 36 and upper (6.4%).

Instruments

The instruments were drawn from previous research and revised. The computer self-efficacy scale consisted of 10 revised the statements that came from the scale of Compeau and Higgins (1995). The 10-item computer network anxiety scale referred many previous computer anxiety scales and added in the conception of network. The statements describe the conditions that may cause anxiety, for example, “use computer network to transfer data to friends”. Both the computer self-efficacy scale and the computer network anxiety scale are 5-point Likert type scales.

The web authoring software self-efficacy scale was developed based on the contents of instructional requirement. Ten items are comprised in the measure involving to the various functions of the selected web pages authoring tool and the required integration from the instructor. The subjects were asked to point out
the degree of difficulty in the range of 1 to 5.

The reliabilities for computer self-efficacy scale, computer network anxiety scale, and web authoring software self-efficacy scale were alpha = .79, .87, .89, respectively.

The data regarding computer experiences were collected in two parts. The first part included the hours spent in using computers and internet weekly. The second part was 5-point Likert items to ask the subjects to point out the rate of use in specific software activities.

Procedures

Background information, prior computer experiences, computer self-efficacy measure were included in a questionnaire which was completed by each preservice teacher in the first class section. Then a 14-week instruction of web pages design proceeded. Only difference in sections, the same instructor using the identical web authoring software and materials in the same computer lab at the identical pace taught all participants. Computer self-efficacy scale, computer network anxiety scale, and web authoring software self-efficacy measure were processed again at the end.

Design and Data Analysis

A pretest-posttest design was the basic research design. Pearson correlation coefficients were computed for background variables, various computer experiences, and the mean of computer self-efficacy scale in the questionnaires before instruction. To get the answer if the web page instruction improves the computer self-efficacy of preservice teachers, paired t-tests were conducted to compare the change between pre-post scores of computer self-efficacy scale. Regression analysis was performed to find the predictors of computer self-efficacy. ANOVA was also conducted to investigate if different levels of subjects in computer self-efficacy measure before the web pages instruction would show significant differences on web authoring software self-efficacy after a semester instruction.

Results

To answer the research questions, statistical results are reported as follows:

Research Question 1:

First, the relationships among background variables and computer self-efficacy before instruction were examined. Background variables included in the correlation analysis with computer self-efficacy were gender, age, computer access, weekly computer use, and weekly internet use. The gender variable showed no significant relationship with computer self-efficacy measure, whereas age appeared significantly negative relationship with computer self-efficacy. Computer access, weekly computer use, and weekly internet use were significantly correlated ($p < .05$) with computer self-efficacy measure.

Relationships among various software use rates and computer self-efficacy were then computed. Significant relationships were found among all of the various software use rates, which include word processing, spreadsheet, presentation, e-mail, computer game, computer graph, and computer self-efficacy, with the exception of the use rate of BBS.

Research Question 2:

Stepwise multiple regression was examined for computer self-efficacy measure before instruction using the significant correlates showed above in background variables and various software use rate. The results represent the impact of ten hypothesized causal variables on computer self-efficacy. According to the results of statistical analysis, the use rates of word processing software, weekly computer use,
computer graph software use rate, and age were the significant predictors of computer self-efficacy.

Research Question 3:

The comparison of computer self-efficacy measure before and after instruction was conducted to answer this question. The paired t-tests indicated that there was a significant difference between the means ($t = -6.679, p < .001$). The posttest score (Mean = 38.54, SD = 5.42) was significantly higher than the pretest score (Mean = 35.78, SD = 4.91). Apparently, the instruction of web pages design did significantly improve the computer self-efficacy of preservice teachers.

Research Question 4:

Significant relationships among computer self-efficacy, computer network anxiety, and web authoring software self-efficacy after Instruction were found. The posttest score of computer self-efficacy was reported significantly negative correlation with computer network anxiety score, while positively correlated with the measure of web authoring software self-efficacy.

Research Question 5:

ANOVA was conducted to answer this question. While the subjects were divided into three levels (low, middle, high) based on the score of computer self-efficacy measure before the web pages design instruction, significant difference was found among groups on web authoring software self-efficacy after instruction. A post-hoc analysis using the Scheffe test indicated that the web authoring software self-efficacy (39.64) of the high group was significantly higher than those (36.36) of the middle group.

Discussion

The purpose of this study was to explore the computer self-efficacy of preservice teachers, find out the correlated factors, and test the effects of web pages design instruction on improving computer self-efficacy. From the results, as many previous research findings, age and computer experiences are two important factors in computer self-efficacy. The most notable findings of this study were the indication of computer experiences content. Various software experiences provided more meaning than spending time in terms of computer application research. The frequency of word processing and weekly computer use as the predictors of computer self-efficacy is congruent with the recognition of the experienced trainer. The significant relationships among various software use rates and computer self-efficacy in addition to the effect of web pages design instruction on improving computer self-efficacy confirmed the importance of accumulation of computer experiences. The result is consistent with the finding of Ropp's study (1999) that used the preservice teachers as subjects. One unexpected finding was the use rate of computer graph as the significant predictor of computer self-efficacy. Further research is needed to explain the reason.

The other important result is, based on the conception of Marakas, Yi, and Johnson (1998) who divided computer self-efficacy into task-specific computer self-efficacy and general computer self-efficacy, that general computer self-efficacy indeed enhanced after experiencing more computer learning and using. In terms of specific task related computer self-efficacy, the web authoring software self-efficacy in this study, it showed the effect of general computer self-efficacy. The preservice teachers owning higher perception of computer self-efficacy revealed more confidence on web authoring software self-efficacy. This result proved the finding of the prior research (Ertmer, Evenbeck, Cennamo, & Lehman, 1994) that experience on one system tends to increase computer self-efficacy on other related systems. The result of computer network anxiety negatively related to computer self-efficacy and web authoring software self-efficacy is also consistent with most previous empirical studies.

Generally, this study supports almost all of previous research even with different kind of subjects. It also confirmed most educators' belief that increasing the opportunities to learn and use computer may facilitate the confidence and competence of preservice teachers.

Change as the Constant in Creating Technology Rich Learning Environments

Connie S. Collier, School of Exercise, Leisure, and Sport, Kent State University, USA, ccollie2@kent.edu.
Theresa A. Minick, Modern and Classical Languages, Kent State University, USA tminick@kent.edu

As members of the implementation team for the Preparing Tomorrow’s Teachers to Use Technology (PT3), we regularly participate in meetings focused on strategies for intensifying and broadening the use of technology rich practices in teacher preparation. Essential to our successful experiences with technology and innovative teacher preparation has been our willingness to participate in ongoing change. This change is multidimensional as it relates to the nature of our classroom, course content, and technological strategies used to accomplish our goals for student learning. If we have come to know anything as a result of our participation with technology integration it is that change is the constant.

Our PT3 grant is based upon the premise that if preservice teachers learn course content in technology rich classrooms, they will be more likely to use technology when they teach in their own classrooms. Those of us passionate about technology integration have sought ways to go beyond the boundaries of the 'classroom' and 'packaged' course content, and a 'particular' set of teaching strategies to an expanded interpretation of the dynamics of the learning environment. We are willing to share our interpretations of the dynamics and processes inherent to the nature of innovative practice. However, the strength of our offerings lies within your interpretation of how you can best generate learning experiences that will be most useful to your own context.

Each semester begins with change and uncertainty as we recognize how the individuality of our learners, uniqueness of our own identities, advancement of knowledge in our chosen fields, and onset of the latest technologies demand new ways of knowing within our learning environments. Freedom and choice are key to promoting exceptional learning opportunities. However, as students exercise their right to choose and their freedom to design more uncertainty emerges. Becoming comfortable with the resulting change and uncertainty stemming from these freedoms and choices takes time for the teacher and the students.

To create a teaching and learning environment that provides students the power to choose, the ability to exercise the freedom to explore knowledge relevant to their lives as future teachers has challenged us. We have critically examined what was needed to transform the traditional college classroom into a learning environment conducive to preparing teachers of future generations without compromising the rigor of a quality education. We called into question the way in which course content was structured, the nature of instructional strategies used to deliver the course material, ways in which we used in/out of class time, and the degree to which our learning experiences truly motivated our preservice teachers to want to learn. The following questions guided us on our journey of change and innovation.

Can course content be predetermined and fixed? We have found that to rely on the most recent edition of a single textbook by a prominent author or a selected list of readings is inadequate. Instead we identify lists of resources and place our students in the role of selecting what is most relevant for constructing knowledge to facilitate a quality learning experience. So by giving students the freedom to choose and the guidance to critically examine and synthesize the available information, instead of relying on a single authored textbook for knowledge, many of our students become authors themselves of authentic projects, presentations, CD ROMs, web pages and papers. As teachers we need to accept the possibilities of what can emerge instead of wanting to control what will develop (Richardson, 1999). Each semester we are surprised by the investment from our students, the quality of the products, and the magnitude of knowledge constructed.

Should the teacher solely deliver instruction? The typical snapshot of the college classroom is the lecture hall filled with students ready to learn from teachers who are the proverbial experts in their field of study. Sharing the responsibility for teaching and learning runs counter to what we have known as instructors and more importantly what students want as learners. To suggest if you give students choices and freedoms
that they will automatically embrace these learning experiences without resistance would be remiss. To alter the power structure within a teaching and learning environment requires both parties to learn to share the responsibility and this evolves as each become more comfortable with the changing roles. To make an abrupt change from a teacher directed classroom to a student-centered classroom is not suggested. Keys to a successful transition include taking time to prepare yourself as an instructor and your students for the change, excellent communication throughout the change, and constructing a range of options so that students with different comfort levels have choices that facilitate their learning. As instructors we find ourselves assisting our students by assessing progress, suggesting revisions and engaging conversations to help students negotiate meaning.

One of the features of technology that enables us to alter the learning environment is connectivity. Connectivity allows learners to carry on sustained discourse about their topic and participate in knowledge negotiation with fellow peers and experts. It allows the dimensions of time and space to no longer restrict learning opportunities. Students are able to shape unique projects representing complex authentic tasks, which include knowledge and theory beyond the classroom walls and the capacity of the teacher. The teaching and learning process is not linear. In our classrooms, students share in the construction and dissemination of knowledge. The teacher doesn’t stand at the front of the room as the expert but engages in a dialogue with students as a fellow learner.

Technology offers the opportunity for learning experiences to be authentic, which allows students to make meaning of their topics within real world contexts (Perrone, 1998). Technology allows 1) research; 2) interaction with a community of learners such as peers, instructor, professionals and experts; 3) self-assessment; 4) revision; 5) problem-solving; 6) organizing; 7) synthesizing; and these components are repeated cyclically and in a variety of combinations, which demands an extended investment of time from all involved. Technology assists teachers and learners to overcome the barriers and constraints of time and space that a traditional classroom imposes. Table 1 Methods for Integrating Technology demonstrates a few of the ways in which we have integrated technology rich learning experiences into our innovative classrooms.

All of these conditions help create classrooms full of uncertainty and differentiated learning and from these dynamic learning environments comes unexpected learning. Instead of finding ways to package the products and processes related to infusing technology into teaching and learning we invite you to create your own path and recognize the value in the unknown. We have learned a great deal in our quest to be innovative instructors and know that our future will depend on not whether we change but how we embrace the change.

Maryland Technology Outcomes and Performance Assessments for the Beginning Teacher

Marcia B. Cushall
Educational Professions Department
Frostburg State University
Frostburg, MD 21532 USA
mcushall@frostburg.edu

Abstract: A Maryland task force consisting of K-12 teachers and coordinators, higher education faculty, Maryland State Department of Education personnel, and personnel from the Maryland Higher Education Commission convened in April 1998 to begin to develop technology outcomes and performance assessment tasks for beginning teachers in Maryland. The draft outcomes developed by this task force were distributed to schools and professional organizations for feedback. The task force lead by the Maryland State Department of Education applied for and received a PT3 Catalyst Grant to continue its work. Supported by funding from the grant, the outcomes were revised and draft performance assessment tasks were developed for three of the seven outcomes. In fall 2000, these tasks were piloted on several campuses and work began on the assessments for the remaining four outcomes.

In 1995 Maryland’s Redesign of Teacher Education became state law. The law instituted a shift from courseware hours to demonstrated knowledge and skills, a move to accountability and assessment. Technology was identified as an area in the redesign that would be assessed. To define Maryland Teacher Technology Outcomes and performance assessment tasks for beginning teachers, a University System of Maryland (USM) task force was convened in April 1998. The task force consisted of K-12 teachers and coordinators, higher education faculty, Maryland State Department of Education (MSDE) personnel, and personnel from the Maryland Higher Education Commission (MHEC). During spring and fall of 1999, the draft outcomes developed by this task force were distributed to schools and professional organizations for feedback.

During this same time, the task force lead by MSDE applied for and received a PT3 Catalyst Grant to continue its work. The purpose of the grant is to ensure that teacher candidates are prepared to use technology in the classroom for teaching and learning. The task force membership was then expanded to create the Maryland Technology Consortium. The consortium included the original task force members, representatives from additional institutions of higher education and additional local schools, more representatives from MHEC and MSDE, and representatives from the Human Resources Research Organization and from the Regional Technology in Education Consortium.

The goals for the Maryland PT3 Catalyst Grant are 1.) curriculum redesign with provision for curriculum and field experiences for teacher candidates, 2.) development of consistent and credible performance standards and assessments to measure technology-related competencies of teacher candidates, and 3.) candidate development of electronic portfolios that incorporate technology-related performance assessments.

Supported by funding from the grant, the outcomes were revised and draft performance assessment tasks were developed for three of the seven outcomes. The revised outcomes address the following areas:

I. Technology Information Access, Evaluation, Processing, and Application,
II. Technology Communication,
III. Legal, Social and Ethical Issues,
IV. Assessment for Administration and Instruction,
V. Integrating Technology into the Curriculum,
VI. Adaptive and Assistive Technologies,
VII. Professional Growth.

As work on the performance assessments progressed, modifications were made to the outcomes.
In development of the performance assessment tasks, each task description was to include form, audience, topic, and purpose. The assessment task materials included the technology outcome, the technology indicators, the knowledge and skills needed to perform the task, a task summary, the scoring tool and criteria for evaluation, benchmarks, instructor notes, and curriculum connections. During year 1 of the grant the performance assessment tasks for outcomes 1, 2, and 7 were developed. The assessment tasks are:

Outcome I Task
Create an electronic research product for an intended audience using a variety of on-line resources related to a specific content question or problem.

Outcome II Task
Use technology effectively and appropriately to communicate information in a selected format. The ultimate goal is to create a web page to publish the information gathered for the selected topic.

Outcome VII Task
Task A. Part 1: Based on established criteria for evaluating quality on-line resources, identify at least three different emerging technologies along with relevant sources of information. Part 2: Select one of the emerging technologies. Write a reflective, analytical paper for your intended audience to describe how and why this technology could impact teaching and learning. Task B. Develop a Technology Professional Development Plan for continued growth in the use of technology to promote learning.

In fall 2000, year 2 of the grant, the three performance tasks were piloted on several campuses and work began on the remaining four outcomes. In spring 2001, the results of the pilot will be used to revise the tasks and determine benchmarks for the assessments. The remaining four performance assessment tasks will be completed and the consortium will begin researching and developing a process for creating electronic portfolios.

In fall 2001, year 3 of the grant, the consortium will continue its work on development of a prototype for electronic portfolios. State regional meetings will be convened to disseminate the outcomes and performance assessments and full-scale implementation of the outcomes and assessments within Maryland higher education will begin. Eventually, all teacher candidates will be required to perform at a satisfactory level on the Maryland Technology Performance Outcomes and this will become a part of the state program approval process.

Abstract: Transforming Learning and Teacher Preparation through Technology-Rich Cohorts is a Preparing Tomorrow's Teachers for Technology grant awarded to National-Louis University. This university is working with three school districts, Milwaukee Public Schools, Prince George (Maryland) Public Schools, and Prince William (Virginia) County Schools to train technology-proficient teachers in these districts. NLU recruits the preservice teachers who are provided with laptops and provides the faculty, while the districts provide the classrooms and computer labs. This paper is a description of the program to date working with the Milwaukee Public Schools.

Today's preservice teachers will be teaching the workers of tomorrow. These future workers must be trained for a world where projections indicate that five of the ten fastest growing job areas will be computer related (College Planning Network 1996). However, teacher training institutions are only beginning to respond to the need to train teachers who can provide these technology proficient students. Barksdale (1994), in a survey of graduates of teacher education institutions, found that fifty percent of the graduates felt that their training for technology integration was not adequate. At the same time, the National Council for Accreditation of Teacher Education (NCATE, 1997) estimated that 2 million new teachers will be hired in the next decade, creating an immense opportunity to train these technology-literate teachers. Indeed, to remain accredited through NCATE, teacher training institutions must demonstrate that they are addressing the need to train teachers in the use of technology (NCATE, 1997).

Research by the International Society for Technology in Education (ISTE, 1999) explored several methods of training teachers to use technology. They surveyed teacher education institutions and found that many institutions had separate educational technology courses for their preservice teachers. These institutions did not routinely require the use of technology during field experiences. Yet ISTE research concluded that technology infusion directly into the training program of preservice teachers such as their field experiences, demonstrated more success than separate these separate technology training classes.

In response to the need for training technology-adept teachers, a partnership between National-Louis University and the Milwaukee Public Schools in Wisconsin, Prince George’s County Schools in Maryland, and Prince William’s County Schools in Virginia was made, with the goal of combining their efforts to train teachers who will be fluent in technology integration for the participating schools districts. Funded by a PT3 grant, Transforming Learning and Teacher Preparation through Technology-Rich Cohorts, National-Louis University (NLU) is providing the faculty to teach the courses including technology experts who assist in technology integrated lessons in field experience and is recruiting the preservice teachers who will each be provided with a laptop computer to use. These students become members of a cohort group of students who complete teacher certification in 18 months. The teacher certification program that these NLU students take is
the same as the traditional teacher education Master of Teaching program except that these students are required to take a course in educational technology that is an elective course in technology for traditional NLU teacher certification cohorts. This class is integrated into the other teacher education courses, with the content and technology faculty working together to provide optimal relationships between traditional teacher certification content material and the technology requirements of this technology course. The goal of these professors is to offer the technology infusion in such a way that the candidates are provided not only with assignments for their coursework but at the same time, allowed an opportunity to interact with software commonly used in the K-12 schools. This technology infusion is designed to meet those skills identified by ISTE as the National Educational Standards for Teachers. In addition, the assignments for this technology course and the teacher education courses are developed as integrated assignments with a goal of creating artifacts for an electronic portfolio for each student.

The participating school districts are providing the location for the teacher education classes, the necessary computer labs for the training, and the clinical placements in technology-rich classrooms for the preservice teachers. These districts have been selected based on several characteristics. They must be a district with a significant number of minority students who are receiving reduced-price lunches. They must be able to provide networked computer labs and classrooms for training the teacher candidates, as well as district technology personnel who can provide a certain amount of assistance to the grant in setting up the labs for instruction. Finally, to participate, the districts must experience difficulty in filling teacher positions. Each of the three participating districts meets these qualifications.

Many of the teacher education courses are being provided online to the students who will be able to access the courses through their laptop computers. To facilitate this, a Web site is being set up to house the online courses. In addition, this Web site will provide the central location for the maintenance of an online relationship between all the school districts involved in the program, as well as the teacher education faculty and the cooperating teachers. In addition to the interaction among these project participants, the NLU Arts and Sciences faculty who wish to be involved in the project are being invited to become trained to converse online and to provide their expertise to the preservice teachers and their students. This relationship is intended to be a vehicle for exchanging information on pedagogy and on technology infusion, and to provide an avenue for including content area experts who will be available to add their expertise to the online conversations, i.e. suggesting resources to look for when a preservice teacher assigns his or her students a lesson in a relevant subject area.

Program to date

The program began as a pilot program with the Milwaukee Public Schools, starting with a cohort of sixteen students. The original plan was to begin with two cohorts of twenty students, one elementary and one secondary, however, however, due to the date of the awarding of the grant, only the elementary cohort was assembled. A secondary cohort is being planned for and currently being recruited to begin in January. In fact, a third cohort in elementary education is also expected to begin in January, due to the success and publicity of the program to date and the efforts of the NLU recruiters.

The students are currently taking three of the required courses, Introduction to Special Education, Introduction to Technology in Education and Practicum I. These courses are being taught in a face-to-face manner but in an integrated fashion, one evening per week. Faculty meet frequently to plan the integration. An example of the type of integration was one class in which the activity of the technology class was assistive technology while the activity of the special education and practicum classes was the facilitation of inclusion of students with a disability into the regular classroom. All classes met their separate goals on their separate syllabi.

Classes for the second term are being developed. One of these courses will be a foundations course that is being revised to be primarily an online course. This course provides an example of the type of joint assignment between education courses that occurs for this cohort. A goal of the technology integration for this program is that it serve as a tool for the assignments of the teacher education courses, and allow the preservice teacher to interact with software that is used in the K-12 schools. An example of one of the activities that reflects this philosophy is being planned for this foundations course. One of the foundations faculty plans to require that the preservice teachers develop Web pages using two of the software packages provided by the grant that are used in the local public Milwaukee schools. In this project, students will use their laptops to search the Internet for information on educational theoreticians such as Piaget and Vygotsky. Using Inspiration and Filemaker Homepage, programs used by the Milwaukee Public Schools, the foundations professor is
requiring cohort students to develop a concept map of one theoretician that will be turned into a Web page with links to pages describing the concepts of the theory. This project will be used in later courses to develop the preservice teacher’s concept of the “ideal” school, a Web-based map of a school that reflects the concepts of their theoretician. As a part of this project, students will be required to create their school’s policy handbook. This project became a joint project with the technology course whose instructor required the students to develop a handbook on technology operation and Internet usage. This technology assignment was subsumed to become part of the handbook requirement of the foundations course, the policy handbook of the “ideal” school that the preservice teachers will be developing. The result of these combined projects can be selected by the students as an element of their electronic portfolio.

As part of the grant program, cooperating teachers are selected who are generally more active in the infusion of technology in their classes. They are frequently invited to attend the cohort class to receive training in the technology usage. Thus far, three of the cooperating teachers have received training in Hyperstudio and Filemaker HomePage. Future inservices for other teachers is being discussed. In addition, extra meetings of the cohort outside the class time for the purpose of helping them increase their comfort levels with the laptop computers are being held. These meetings also provide an opportunity for the preservice teachers to interact with additional educational software.

Currently, at the time of this paper, the Web site for housing the online courses and the projected discourse is under development. Training for the Arts and Science professors is in the planning stages. The project director is beginning the arrangement of the cohorts in Virginia and Maryland. Publicity for the program continues based on its current success. Indeed, the program attracted the notice of one of the local legislators in Milwaukee who attended the class one night. Expansion of the program and replication for the program with its current success is being planned by National-Louis University.

Abstract: This paper is a progress report on a pilot study investigating the creation of an impartial, reliable, and feasible method of scoring preservice teachers’ electronic portfolios. Participants include four preservice teachers participating in intern teaching and the accompanying weekly seminar. Required portfolio components were developed to demonstrate competency of the INTASC standards. A four-point analytic rubric was created, which provides sub-scores on thirteen portfolio components and one overall portfolio score. Two faculty raters were trained and scored each portfolio. Each portfolio was also self-assessed by its creator and peer-assessed by another intern in the class. Quantitative results include interrater reliabilities of faculty, self, and peer ratings. Qualitative outcomes were studied through open-ended surveys of participants and raters.

Introduction

The assessment and evaluation of teachers, at all levels, is an overwhelming task. Typically, teachers are evaluated on the basis of infrequent classroom observations (Acheson & Gall, 1997). But recent definitions of effective teaching include much more than competent lesson delivery. Recent teaching standards, such as those developed by the National Board for Professional Teaching Standards and the Interstate New Teacher Assessment and Support Consortium, emphasize that teaching requires a combination of complex skills. The concern for assessing the entire range of teaching responsibilities was the inspiration for Stanford University’s Teacher Assessment Project (Shulman, 1998). The purpose of this project was to develop and test better means of teacher evaluation. Shulman theorized that combining assessment methods into one portfolio could yield a more authentic, valid, and reliable assessment of teachers. Thus, portfolios arose from this investigation as a better, more authentic way to assess teachers than stand alone methods.

Although teacher portfolios are utilized for a multitude of intentions in different contexts, typical goals of teacher portfolios include the following: (1) Improving teaching and learning; (2) assessing teacher effectiveness; (3) evaluating competency for certification purposes; and (4) strengthening educational programs. Research abounds on the benefits of paper teacher portfolios. Such portfolios have been shown to stimulate teachers to reflect on their instructional decisions (Bartley, 1997; Dutt-Doner & Personett, 1997; Dutt, Tallerico, & Kayler, 1997; Mathies and Uphoff, 1992; Richert, 1990; Stahle & Mitchell, 1993). Portfolios have also been found to be helpful in preparing for and participating in job interviews (Berry, Kisch, Ryan, & Uphoff, 1991; Dutt-Doner & Personett, 1997; Mathies and Uphoff, 1992; Winsor & Ellefson, 1995). Several preservice educators have also reported that portfolios allow them to assess teaching abilities not seen in classroom observations (Berg & Curry, 1997; Ekbatani and Pierson, 1997; Johnson, 1999; Stahle & Mitchell,
Finally, it has been suggested that preservice teachers who construct their own portfolios are likely to use portfolios with their own students (Grant & Huebner, 1998; Taylor, 1997). Several drawbacks exist, however, with using a paper medium for teacher portfolios. Skills such as lesson delivery and communication cannot be assessed with paper and pencil. Additionally, paper portfolios may quickly become huge stacks of paper, which are unmanageable for the reader. Other practical problems such as storage and reproduction can seriously affect the feasibility of paper portfolios.

Many of these disadvantages have been solved with the advent of multimedia electronic portfolios, which allow for easy storage and reproduction of teaching artifacts, and also the inclusion of a variety of media forms (Tancock & Ford, 1996). Electronic portfolios are quickly becoming popular assessment tools for both K-12 students and preservice teachers, and are showing similar benefits as their paper counterparts. Recent research, for example, has shown that preservice teachers who create electronic portfolios are encouraged to reflect on their teaching (Biddle, 1992; Jackson, 1998; McKinney, 1998).

Although the utilization of electronic portfolios is becoming widespread at both the K-12 and college levels, at the time of this study no research exists concerning attempts to create reliable techniques for scoring these portfolios. If such portfolios are used in high-stakes decision making such as student grading or certification, reliable scoring is essential. This paper will describe one attempt at creating an impartial, feasible, and reliable method for scoring preservice teachers’ electronic portfolios.

**Portfolio Development**

The participants in this study were four preservice teachers participating in their intern teaching experience at Lehigh University during the Fall 2000 semester. Two of the teachers were seeking elementary certification and two were seeking secondary certification. The setting for this study was a weekly intern teaching seminar session, which involved discussion of pertinent instructional topics and instruction in electronic portfolio development.

Student teachers in the seminar were required to create electronic, Web-based portfolios, filled with artifacts from their intern teaching experiences. The portfolio requirement was developed to more authentically assess student teachers, to stimulate self-reflection, to provide a job search tool, and to encourage the interns to use electronic portfolios in their own classrooms. Before the seminar, it was determined that a set of standards was necessary to provide structure to the portfolios and to determine what competencies the interns would demonstrate in their portfolios. Because of their wide acceptance and broad application possibilities, the INTASC standards were chosen to direct the electronic portfolio guidelines. The researchers generated portfolio artifacts that would demonstrate each INTASC standard, and then developed portfolio guidelines based on these artifacts. The following table (Tab. 1) lists the portfolio components and the corresponding INTASC standards.

15) Peer-assessment (rubric) 9

Table 1: Portfolio components and their corresponding INTASC standards.

The provision of specific expectations alleviated possible concerns about “what to include,” provided the structure necessary for fair scoring, and allowed the interns to concentrate their energy on the quality of their artifacts and the necessary technology-based competency skills.

Based on the guidelines, a rubric to score the portfolios was created by the principal researcher and endorsed by a group of Lehigh University faculty in the Technology-based Teacher Education program. The rubric details all the necessary characteristics for each portfolio component. A score of one (novice), two (developing), three (proficient), or four (exemplary) is possible on each of the thirteen components of the rubric: (1) Organization; (2) Spelling/grammar; (3) Philosophy; (4) Interdisciplinary unit; (5) Classroom management plan; (6) Family communication plan; (7) Teacher-created student assessment; (8) Lesson plan designed using student assessment data; (9) Lesson plan meeting the needs of diverse learners; (10) Lesson plan requiring student use of technology; (11) Video clip of teaching; (12) Evaluation of teaching resources; and (13) Reflection statements. For example, a score of novice (one) on organization is characterized by the following: “No apparent organization was attempted. Large parts are incomplete. Very difficult to follow.” A score of exemplary (four) on the same category requires that “organization is clear, well thought out, creative, readily apparent, and easy to navigate. All artifacts are labeled according to required component names.” Similar qualifiers are used throughout the rubric in each category. The scoring rubric was introduced and thoroughly explained to the interns in the first seminar meeting. It was emphasized that they should refer to the rubric throughout the portfolio development process.

After the portfolios are submitted, at least three raters will score each of the four portfolios. Additionally, each portfolio will be self-assessed by its creator and peer-assessed by another student in the seminar. Interrater reliabilities will be calculated for the three raters’ scores of each portfolio. Percent agreements between rater and self, rater and peer, and peer and self will also be computed. Finally, study participants will complete a survey regarding their perceptions of the electronic portfolio development process, including their general preparedness for creating electronic portfolios, their perceived usefulness, the quality of the rubric, and suggestions for improvements. Study participants will be asked to select true or false to each of several survey statements. They will also be encouraged to provide open-ended responses to questions regarding possible improvements to the development process.

In order to collect data concerning the scoring process, open-ended interviews will be conducted with each of the three portfolio scorers. The interviews will attempt to determine the perceived feasibility, validity, and efficiency of the rubric. Scorers will be asked to provide possible improvements to both the portfolio development and scoring processes.
Initial Findings and Discussion

Initial findings regarding the portfolio development process are emerging. First, similar to findings from other studies (Berry, Kirsch, Ryan, & Uphoff, 1991; Dutt-Doner & Personett, 1997), the interns in this study displayed initial anxiety when charged with the creation of electronic portfolios. Questions abounded during many of the weekly seminars; the interns overwhelmingly relied on the instructors to answer their questions, rather than reference the rubric specifications. The instructors had to explicitly remind the students that the rubric described the characteristics necessary for quality artifacts.

The time and energy required to complete entire electronic portfolios and simultaneously completing intern teaching was an issue that consistently emerged during the seminar meetings. Three interns agreed that requiring selected components throughout their preservice courses would simplify the final production of their portfolios. One intern, however, expressed that all of his artifacts were of a higher quality because he was now experiencing real classroom life. For example, he shared that although he created an interdisciplinary unit in a previous methods course, he now realized that the unit was not practical and would not be successful in a real classroom. The researchers and the Teacher Education faculty at large intend on investigating the possibility of requiring selected portfolio components throughout the preservice program.

The interns’ frustrations with the technological demands of creating an electronic portfolio clearly overshadowed any concerns about time, however. It was intended that the portfolio instruction focus on teaching and learning, but technological trouble-shooting soon dominated class time. The interns unanimously lacked prerequisite technological skills and did not have home access to necessary hardware and software.

It quickly became clear to the instructors that remedial pedagogical strategies were required. Two doctoral students, both well-versed in instructional technology, were enlisted as assistants in the weekly work sessions. The luxury of having four instructors and only four interns allowed for individual tutoring and support. This support was an absolute necessity in this context; it is recognized that such assistance is not available in most situations.

Before the interns could learn about basic web page development, they first had to learn simple computer skills such as organizing, saving, and naming files and folders. Templates including links to each required component were provided to students; the interns were subsequently instructed on basic functions of Dreamweaver. Students had access to the lab computers and Dreamweaver throughout the week. Unfortunately, none of the interns took advantage of this access; the interns all created their documents at home and brought them to class to cut and paste them into the program. As interns made progress on their portfolios, instruction included skills more relevant to portfolio construction: visual concept maps were used to illustrate how portfolios are organized.

One possible way for improving this process is to require interns to acquire an html editor for use at home. Relying solely on campus computers and not having the capability of working at home was a clear shortcoming for the interns. It is also evident that the preservice program must better integrate technological requirements throughout program courses and requirements. This is already being done at the college; the preservice program now includes a mandatory core course, which provides instruction in teaching and learning with technology. This course will include instruction in basic web design; an important prerequisite for electronic portfolio construction. It is hoped by the researchers that future students will therefore be better equipped with the technological skills necessary for creating electronic portfolios.

Abstract:  
This interactive session will describe the processes, instruments, and data collected from the University of Missouri-Columbia College of Education Preparing Tomorrow's Teachers to Use Technology (PT3) grant. The goals of the grant include:  
1. Faculty fluency with technology as a tool for themselves as instructors and as a subject for improving and changing methods of teaching in K-12;  
2. A revised curriculum for teacher education that utilizes technology (ISTE NETS Standards) and prepares future teachers to be technology users;  
3. A set of internet-based tools for enabling the teaching and learning processes of teacher education (ShadowPD netWorkspace);  
4. A total quality management (TQM) process modeled after continuous improvement processes that are proving effective in sustaining change and improvements in business and industry.  
The expected outcomes of this project are: faculty and teacher education students who are fluent in the use of technology in teaching, high quality experiences with technology in teacher education curriculum, tight integration of the curriculum with exemplary technology-using practices of K-12 teachers, and a program that is sustainable, owned by faculty, and continuously improving.

Reference  

Faculty Development Process

Purpose  
The ultimate purpose of all PT3 grants is, as the name clearly says, to "prepare tomorrow's teacher's to use technology". What isn't explicitly stated but is clearly implied is that we are preparing them to use technology to enhance learning. The faculty development activities of the MU PT3 grant are all focused on this idea of not just increasing technology use, but increasing a specific type of technology use -- uses that support learning. In this section we briefly describe our activities and results in this grant area for year one, as well as our plan and initial activities for year two.

Participants  
The participants for this portion of the grant consist of two cohorts of faculty who teach methods courses in content areas such as educational foundations, literacy, social studies, math, art, music, and early childhood in the undergraduate teacher preparation program. The members of each cohort included approximately 12-14 full-time faculty members teacher educators who participated in the professional development process. In addition to these primary members, other individuals who teach our K-12 pre-service teachers, such as graduate assistants and adjunct instructors, were also included in professional development activities. All cohort members receive a financial incentive as part of their participation in the grant. These incentives varied amongst faculty members but included such things as a one course buy-out, graduate student support, hardware/software, or travel money.
Year One Activities

Our faculty development in year one was based upon an individualized or customized learning philosophy. Most faculty development activities were delivered in a one-on-one setting focusing on that faculty member’s current needs and learning goals. We felt this was the best way to create an effective learning environment that would work for these already-busy faculty members.

We developed these activities based upon the results of our first step, a needs assessment. We administered a questionnaire, and conducted individual faculty interviews to identify cohort one’s needs. These instruments provided descriptive data that allowed the team to develop individual user profiles, determine needed hardware/software, and identify individual learning needs. The results of these activities showed that faculty in cohort one needed and wanted to work on improved technology skills in addition to then adding effective uses of technology to their pre-service teacher methods courses.

Second, we developed individual profiles for each member of cohort one; these were used to develop individual learning plans. Each faculty member worked with an educational technologist to identify personal learning goals and a plan to attain the goals. Each faculty plan varied in specific learning experiences, but all plans focused on developing fluency with technology and integrating technology tools into methods courses.

Third, to meet the goals of individual faculty, each participant was assigned a technology tutor who was a part-time student hired by the grant to assist faculty in meeting their technology learning goals. The student tutors - Student Wizards Assisting Teaching (SWAT) - were an integral component of the professional development process. The faculty member and the SWAT member met for two to three hours each week of the semester in the faculty member’s office for tutoring sessions. Each session was guided by the faculty members learning goals (i.e. learning basic skills, learning to develop web pages etc.). Following the weekly tutoring sessions, the SWAT members met with the educational technologist to review faculty progress, answer SWAT members technical questions, and troubleshoot problems raised by the faculty participant.

Fourth, in addition to individual tutoring sessions, professional development experiences were provided to increase the cohort’s awareness of technology uses in a wide variety of areas. We intended these opportunities to build general awareness about technology tools and uses. These activities included lunchon sessions where we demonstrated learning software, field trips to K-12 technology-rich classrooms, a day long seminar where the integration of technology and curriculum was demonstrated, and opportunities to work with K-12 teachers who were interested in helping extend technology use into the public schools.

At the end of the semester of professional development activities, a PT3 co-PI interviewed each cohort member to ascertain their perceptions of the professional development experiences. These results as well as examples of faculty technology activities will be discussed during our interactive session.

Year One Data Sources

Of course, a critical part of this process is assessing and evaluating the effectiveness of the faculty development efforts. To this end, we gathered a variety of data. Data sources included a variety of report forms, reflections, interviews and artifacts. The sources used to create each faculty member’s profile included: a) initial interviews that focused on establishing learning goals, curricular revision plans, and technology integration strategies and b) a skills survey that helped to identify current faculty technology skills and uses. Additional data sources included artifacts such as course syllabi from before and after professional development activities and descriptions of course projects. These artifacts were used to identify the extent to which faculty had integrated technology into their courses prior to the professional development semester.

Year Two Activities

Year one of the grant ended in late September. At the writing of this paper, we are just beginning activities with our year two cohort. We are basing our year two activities upon our successes and feedback for areas of improvement for year one. Although we anticipate many things will remain the same (e.g. the support of the SWAT team and individual professional development sessions with faculty and educational technologist), this year we are encouraging faculty to consider adopting uses of technology as "mindtools" or cognitive tools. Mindtools, or cognitive tools, are “computer-based tools and learning environments that have been adapted or developed to function as intellectual partners with the learner in order to engage and facilitate critical thinking and higher-order learning” (Jonassen, 2000). Students cannot use these tools without thinking deeply about the content that they are studying, and second, if they choose to use these tools to help them learn, the tools will facilitate the learning and meaning making processes. Cognitive tools include (but are not necessarily limited to) databases, spreadsheets, semantic networks or concept maps, expert systems, computer conferencing, multimedia/hypermedia construction, and microworld learning environments. The underlying premise is that if our teacher development faculty model the use of technology as mindtools in their methods courses, students will be likely to emulate these uses of tools in their future classrooms -- ultimately the goal of our grant!
As in year one, we began with a needs assessment. Again, we will administer specific questionnaires concerning cohort two's technology skill levels, current hardware and software tools and their hardware and software needs. Based upon year one feedback and observations, we decided we needed an additional type of information from our cohort faculty in order to create an effective faculty development program. Although we still needed to know about their hardware and software skill levels and needs, we also need to understand more about their desired learning outcomes for their students. If we want them to adopt uses of technology to support learning, then we need to understand what types of learning we need to support. To this end we conducted focus groups with cohort faculty. Focus groups consisted of between two and five faculty members from similar discipline areas (e.g. math and science educators). The goals of the focus groups were as follows.

- Determine the desired learning outcomes for the undergraduate teacher development courses in their discipline and grade level areas (e.g. "what outcomes do we want for our middle school social studies pre-service teachers?").
- Determine how technology is currently being used in these classes to support learning (e.g. this course is currently delivered in a web-assisted manner).
- Determine what existing interests faculty have about using technology to support learning (e.g. "I'd like to learn more about how to use spreadsheets to support learning.").

Our analysis of focus group notes resulted in scheduling a suite of five workshops on various ways technology can be used to support learning. The workshops we will offer are:

- Building simulations with spreadsheets
- Representing Complexity by Building Cognitive Flexibility Hypertexts
- Helping Kids Represent What They Know with Concept Maps
- Helping Kids Think Like Experts: Predicting and Decision Making with Expert Systems
- Developing Cases for Case-Based Instruction

At this writing we are in the process of scheduling these workshops. All workshops will be hands on; faculty will work at a computer to both learn new software, and more importantly, the pedagogical bases for using the software to support learning. Workshops will be open to our cohort faculty, graduate teaching assistants in the teacher development program, K-12 teachers who partner with our faculty, and other interested faculty from the college of education. Our student SWAT team members will also attend and we will conduct follow-up sessions with them on these uses of this software so they can effectively support faculty after the workshops.

### Total Quality Management Process

#### Purpose

TQM dictates that there be ample feedback within the areas of the PT3 grant and the Teacher Development Program (TDP) to determine the advancement of the purpose of the TQM project, and to inform the process for adjustment and achievement purposes. The evaluation for the MU PT3 grant will focus on the following critical control points as feedback and research items as suggested by the Malcolm Baldridge Standards for Total Quality Management for Education. This will ensure that technology is integrated in the TDP, that TDP students will meet ISTE Standards, and that technology integration will be sustained in the TDP.

1. Supporting the annual revisit of the goals of each area of the grant, including all the appropriate sub-areas.
2. Coordinating the collection of data where possible.
3. Identifying data collection points.
4. Releasing data findings appropriately to inform related critical control points.
5. Improvement of Communication within the Grant and between the Grant and TDP.

#### Data Collection

Data collection is identified as Phase Markers according to the structure of the MU Teacher Development Program (TDP) and aligned with ISTE NETS Standards. Each area represents Entry Level data collection and Exit Level data collection from our students.

#### Students Entry Level

1. Technology Self Assessment /Attitude & Importance Survey. This survey would be given at the beginning of each Phase and may be revised for the different Phase levels according to feedback and ISTE Standards. Technology skills would include: email, internet browsing/searching, word processing, digital images (scanning), audio editing, web authoring, multimedia presentation software, database, spreadsheet, desktop publishing, computer file management, and troubleshooting.
2. Technology Performance Assessment
3. Course Reflection - Topics would include: Reflection as an Independent Learner and Reflection concerning using asynchronous learning methods.

4. Initial Student Feedback Interview

**Students Exit Level**

1. Classroom Integration Evaluation: Student Level of Use Survey - Students identify alignment of Syllabus Review with technology integration. Purpose to get feedback from students concerning the integrated activities in their coursework. Specific questions can be added to the current feedback surveys used by individual instructors if available.

2. Portfolio Evaluation for Technology Elements. What technology elements are there, and what are the quality of student experiences?

3. Student Interview Feedback

**Student Critical Control Points**

**Description of Data Collection Items**

1. Technology Self Assessment: A self-assessment that indicates the level of proficiency on 15 different technology innovations, and the identification of importance of each innovation to the respondents future teaching and learning.
2. General Integration Feedback CAPS: An assessment conducted by the TDP to assess the strengths and weaknesses of the teacher preparation program.
3. Technology Performance Assessment: A performance evaluation to determine skill based competency for a group of technology skills.
4. Feedback Assessment from ED101 Technology Skills for Teachers: This instrument consists of a set of questions for students who are taking a course to learn basic technology skills.
5. Student Feedback Interview: Randomly selected students from each of the three phases in the Teacher Development Program are selected each semester to determine how they are making meaning in their program.
6. Flashlight Surveys: These surveys are offered on the Internet. Instructor's customs build an assessment that is particular to their class and teaching situation to determine the impact of technology integration in coursework and learning.
7. Class Room Observations of Technology Integration: Instructors are interviewed and observed to determine their integration strategies and successes.
8. Attitude, Level of Use & Importance Survey: A technology integration survey that determines the integration strategy, the level of use of technology innovations, and how important teachers feel the innovation and integration is to their teaching and students learning.
9. Technology Availability Survey: This instrument is used to determine the kinds of technology equipment, amount of technology availability in field experience classrooms.
10. Syllabus Technology Integration Identification: Teacher development program instructors' syllabi are examined for evidence of technology integration.
11. Focus Group Feedback: Informal interviews are conducted to get feedback that will guide the formation of Learning Communities made up of K-12 teachers and faculty.
13. Level of Support Analysis: An analysis to determine the kind and amount of computer lab support delivered to students.
14. Usage statistics: A determination of the number of hits and degree of use of the Shadow PD project.
15. User Feedback: An informal collection of feedback from users of Shadow PD.

**ShadowPD**

A set of Internet-based tools for enabling the teaching and learning processes of teacher education is being developed to function within Shadow netWorkspace (SNS) (http://sns.internetschools.org). SNS is an Internet-based workspace designed to support teaching and learning in K-12 schools. The core set of functionality found in SNS forms a flexible foundation for a learning community. The ShadowPD project is assisting teacher education faculty at MU in understand how they can use SNS to enhance learning in their classrooms. A quick and rough analogy of SNS is to imagine the desktop of a preservice teacher's (PST) computer existing on the Internet. Using a browser, such as Internet Explorer or Netscape Navigator, the PST connects via a secure login to the SNS Web site and her personal netWorkspace. Here she finds a desktop for accessing the file system, groups, communication functions, and applications. She also has anytime-anywhere access to her own work and applications, she participates in group work through SNS as well. Additionally, she participates in her class work via SNS, as it provides the core functionality of commercial Web-based instructional support systems (e.g., WebCT and CourseInfo).

Through working with the MU teacher education faculty, sharing ideas with other PT3 grant recipients, and reviewing the teacher education literature, the ShadowPD project has identified three problems that a great number of teacher education programs face. These common problems are: how to create a Web-accessible shareable document archives, how to facilitate the creation and maintenance of electronic preservice teacher education portfolios, and how to harness their network's potential to create better communities of practice into which students can be inducted. In addition to helping the MU faculty use SNS, the ShadowPD project is working to modify SNS to support these three important goals of teacher educators.
National University PT3 Project

Abstract: In the 1999-2000 school year, National University's PT3 Project staff trained 8 NU faculty members and 14 master teachers in a weeklong training series. The training covered a great deal of information, ranging from databases and word processing to publishing and multimedia. The evaluation data indicate that the majority of participants, both faculty and master teachers, were satisfied with the training (with the exception of three novice teachers from one school site). However, follow-up data suggest that faculty members and teachers have had mixed success in implementing their new skills within their classrooms. Some participants enthusiastically reported using their new skills in both their classrooms (primarily using the Internet to locate resources and lesson plans) and in personal activities such as finance and communicating with friends via email. Other master teachers reported that availability of appropriate hardware and time constraints hindered their implementation of the skills learned. Faculty members also reported using resources found on the Internet to enhance their course content, and others reported integrating PowerPoint presentations into their lectures. A CD-ROM containing trial versions of multimedia software used in the PT3 Grant Training will be distributed to attendees.

In the 1999-2000 school year, National University's PT3 Project staff trained 8 NU faculty members and 14 master teachers in a weeklong training series. The training covered a great deal of information, ranging from databases and word processing to publishing and multimedia. The project also established a consortium of industry partners to support and model technology outside the university community. Industry partners include: Datel (NU's vendor for computer hardware), Lightspan Partnership (a website development company), Qualcomm, Hewlett-Packard, Sony, Pachell, Cox Communications, the San Diego Supercomputer Center, and the San Diego Electric Training Trust. The PT3 faculty and master teacher training sessions were conducted at NU facilities in January and May 2000. Faculty members received 36 hours of training and master teachers received 24 hours over the course of one week. It was anticipated that faculty members who were trained in March would assist at the master teacher training; however, no faculty members who attended the initial training participated in the teacher training.

The faculty and master teacher training sessions focused on helping participants integrate information about technology into their pre-service courses and classrooms. Sessions addressed the following topics: How to (1) digitize photos and text on a scanner, (2) build web pages with animation, (3) edit student research papers and essays electronically, (4) send and receive emails with attachments, (5) design and develop online courses, (6) use a digital camera, (7) run a camcorder, (8) design weighted spreadsheets for calculating grades, (9) use adaptive technology hardware and software, (10) digitize voices and music for presentations, (11) understand technology copyright and intellectual property rights laws, (12) participate in chat rooms on the Web, (13) design electronic portfolios, (14) create a database for organizing Web resources, and (15) use the "screen capture" function to add embedded computer screen shots to presentations. The training was "hands-on", enabling participants to practice skills and pursue their own ideas about how to utilize technology in their own classrooms. The training facility had 15 computers and a Proxima projection system. Materials provided to participants included two textbooks, diskettes, CD-ROMs containing trial versions of multimedia, instructional software and an Internet browser. Ongoing support to assist participants in implementing skills learned is provided by the project coordinator via email, phone and in-person, if needed. The 22 NU faculty and master teachers were expected to implement the skills and knowledge gained from the training in their teaching and supervisory activities. It was anticipated that pre-service teachers who take courses offered by trained faculty and those who are supervised by trained master teachers would also increase their ability to integrate technology into their own classroom teaching.

Pretest scores indicate that the majority of participants possessed minimal proficiency in all competency areas. Post-test scores indicate that NU faculty members gained proficiency in all except four competencies. More specifically, eight competencies showed an increase in participants' proficiency; three areas decreased, and spreadsheet competency did not change from the pre to post-test. Teachers reported gains in all areas. The trainer
attributed the decrease in the three areas to faculty members' initial over-estimation of their competence in that area; but when faculty received further training, they realized how limited their knowledge of that area actually was. Pre-test scores indicate that master teachers possessed greater proficiency than faculty members in the area of word processing, while faculty members possessed greater initial knowledge in the areas of statistics and networking. The greatest gains from pre-test to post-test were in the areas of presentations and publishing. Faculty ratings in the areas of multimedia and word processing also improved substantially.

Figure 1: Faculty Computer Competency Survey

The evaluation data indicate that the majority of participants, both faculty and master teachers, were satisfied with the training (with the exception of three novice teachers from one school site). However, follow-up data suggest that faculty members and teachers have had mixed success in implementing their new skills within their classrooms. Some participants enthusiastically reported using their new skills in both their classrooms (primarily using the Internet to locate resources and lesson plans) and in personal activities such as finance and communicating with friends via email. Other master teachers reported that availability of appropriate hardware and time constraints hindered their implementation of the skills learned. Faculty members also reported using resources found on the Internet to enhance their course content, and others reported integrating PowerPoint presentations into their lectures. One of the eight faculty members reported modifying her course requirements to reflect a greater emphasis on technology. However, with the exception of one course, the majority of students enrolled in courses taught by trained faculty stated that they were not exposed curricula or strategies that prepared them to implement technology in their classrooms. Based on the evaluation data presented in this report, the first three project goals were partially met. Insufficient data were available to determine whether goal four was met. The following recommendations are made based on the data collected and a review of project activities in relation to GRPA criteria:

1. Participating in a weeklong training series proved prohibitive for many prospective teacher-participants. PT3 staff may wish to consider modifying the training for classroom teachers – one day a week for a month, for example.

2. The training met the needs of moderately experienced users, but less so the needs of novice users. Staff may wish to more carefully select target participants who would most likely benefit from the training, or modify the training to meet the needs of a wide range of proficiency levels.

3. Continue to provide on-site follow-up support to training participants. Some participants expressed the desire for further assistance in implementing the skills and knowledge learned in their classrooms.

4. Further support provided to participants should be aligned with project goals and GRPA criteria. For example, helping faculty members incorporate strategies that prepare their students to utilize technology in K-12 classrooms.

5. The ways in which faculty members and master teachers reported utilizing the training varied tremendously from participant to participant. This variation may be reduced if participants receive explicit information about the kinds of activities in which they are expected to engage in following the training.
EVALUATING THE INCORPORATION OF TECHNOLOGY IN HIGHER EDUCATION IN WESTERN PA

Abstract: Three Pennsylvania state universities (Indiana, Clarion and Edinboro) successfully obtained a 1.73 million PT3 grant. We developed a plan to infuse technology into teacher education programs. We present the evaluation plan for review and comment. The audience consists of people who have a PT3 grant and/or those who are interested.

OVERVIEW

Three Pennsylvania State Universities (Indiana, Clarion, and Edinboro) successfully obtained a 1.73 million PT3 Grant funded by the US Department of Education. The three universities developed a plan to infuse technology into their teacher education programs. Indiana University of Pennsylvania was responsible for developing the evaluation plan for the three years and for overseeing the grant progress.

It is assumed that technology infusion at the three universities will have a significant impact. All three schools are rural, multi-purposed universities with a background as normal schools. Teacher preparation remains an important part of their missions. Alumni of Pennsylvania teacher preparation programs are employed throughout the country as Pennsylvania produces more teachers than it has teacher positions. It is our belief that a successful outcome for this grant’s activities will make our students (the three universities graduate over 1500 new teachers each year) even better prepared to work in school districts throughout America.

The major goals of the PT3 Grant are:

1. Instructional Technology will be moved from the periphery to the core of our curriculum.
2. Future teachers will apply and integrate Instructional Technology into the teaching/learning process.
3. Additional faculty, instructional designer and technical support staff will assist. We aim to help faculty to recognize instructional objectives that can be more readily achieved using technology, to upgrade technology skills to a level where appropriate modeling of technology can take place and to assign and assess student work that incorporates technology use.

AREAS TO BE ASSESSED

The areas of activity by pre-service students, recently graduated in-service teachers, and faculty to be assessed using surveys, interviews, and observations include knowledge, attitudes, application, and integration. Knowledge
represents what one knows and can do with respect to the use of technology in the classroom. Attitudes indicate how one feels about the use of technology in the college and K-12 classroom. Application involves the ability to demonstrate the use of technology both in the college and the K-12 classrooms. Finally, integration requires the use of various technologies in achieving the goals of the lesson plan for the college and K-12 classroom. We expect to obtain an overall assessment of each area using a maximum of five self-report items per area.

DEMOGRAPHIC DATA COLLECTION

Demographic data will be collected from all pre-service teachers, recently graduated in-service teachers, and faculty who teach relevant education courses. This will include age, sex, year in school, number of credits, overall grade point average, major courses grade point average, socio-economic background, resident status, major, data available at admission to college, and other relevant information.

INSTRUMENTS

We developed Faculty, Student, Student Teacher, Teacher, Syllabus, and Workshop (both individual and group) assessment instruments. They will be presented for review during the presentation at the SITE 2001 conference. Instruments are also available from the presenters, who welcome e-mail requests.

YEARS AND COHORTS

There will be three years of evaluation with three pre-service teacher groups each year: sophomore, junior, and senior education majors. Each year there will be a faculty group and a recently graduated in-service teachers group. We expect that there will be 2,061 sophomores, 1,927 juniors, 1,898 seniors, 325 faculty, and 1,514 recently graduated teachers.

Table 1: Evaluation Timeline
BASELINE DATA COLLECTION

Baseline survey data for all cohorts will be collected during the initial year of participation for each cohort. Initial demographic data will be collected during the Fall of each year. All cohort members will be surveyed using the evaluation instruments. Further, we will collect syllabi from the faculty cohort for the education classes they teach. Finally, we will collect copies of portfolios from the senior cohort. Current data analysis in the form of Confirmatory Factor Analysis (assuming the data display the appropriate necessary assumptions) will be done to further bolster the assessment of the validity of the evaluation instruments. Also, Exploratory Structural Equation Modeling (assuming the data display the appropriate necessary assumptions) will be used to examine the factor structure of surveys and possible causal relationships. The demographics of the baseline sample will be compared with the population data from the consortium universities in an attempt to assess the extent to which the baseline sample represents the population.

FOLLOW-UP DATA COLLECTION

Follow-up data will be collected from each cohort during successive years of the project. Further, longitudinal analysis using analysis of variance with repeated measure will allow us to examine the means structure of the cohorts over time. Structural Equation Modeling approaches will allow us to look at the changes in factor structure and possible causal relationships over time. Further, we will collect syllabi from the faculty cohort for the education classes they teach. Finally, we will collect copies of portfolios from the senior cohort.

The demographics of the follow-up samples will be compared with the baseline data and population data from the consortium universities to assess the changing nature of the cohort samples and populations.

Every attempt will be made to incorporate the collection of follow-up data into the standard operating procedures of the consortium universities.

FORMATIVE AND SUMMATIVE EVALUATION

Both formative and summative approaches to evaluation will be used in this project. Formative evaluation will help us understand any success we may have along the way and highlight the need for mid-course corrections to the direction we are taking. Summative evaluation will help us understand the final results of the project and will be a natural precursor to dissemination through presentations and publications.

Formative evaluation will be accomplished through the comparison of baseline survey data and follow-up survey data for each year of the project. Also, we will examine the increases in the use of instructional technology through the evaluation of faculties' course syllabi and graduates' portfolios from year to year. Finally, the qualitative information garnered from the focus groups will be a valuable source of formative evaluation data.

Summative evaluation will be accomplished through examination of the final follow-up survey data for each cohort and the graduates' portfolios. Real proof of the value of the project will be in the level of use of instructional technology by in-service teachers. If, after all of our efforts, the graduates of the consortium universities do not have high levels of instructional technology use in the K-12 classroom, then our efforts will not have had the effect we wanted.
GOALS, OBJECTIVES, AND EVALUATION

Goal 1- Overview

To infuse instructional technology more deeply into the teacher education curriculum in both education core courses and selected majors. Students will be taught technology and it will be modeled by faculty teaching in the college of education core curriculum. In addition, technology modeling and application will occur within subject area courses. To evaluate this goal we will analyze survey data for each year's cohorts and over time, i.e. baseline data for the year one cohorts, follow-up data for year two for the same yearly cohorts, and follow-up data for year three for the same yearly cohorts. We will examine this data using analysis of variance with repeated measures, confirmatory factor analysis, and exploratory structural equation modeling. Further, we will evaluate in-service teachers' portfolios for the use of technology in their various teaching projects and teaching experiences using rubrics for consistent scoring. We will examine the portfolios each year and across years for change. And, we will examine the use of technology for teaching in the syllabi of faculty and look for changes in the syllabi across years. Finally, the information from the focus groups will assist in the evaluation of this goal.

Objective 1

Train faculty to effectively and appropriately use and teach the eleven key competency skills. This objective will be evaluated by basic record keeping of attendance by faculty at workshops. Further, simple workshop evaluation forms will document that faculty believe that they have learned how to utilize the 11 competency skills.

Objective 2

Have university faculty model how to teach effectively with technology in education core courses and elementary education/subject area courses. The collection, collation, and analysis of syllabi by the same faculty for the same courses over time will allow us to evaluate this objective.

Objective 3

Create assignments within education core and subject area courses based upon the appropriate use of the eleven competencies. Pre-service teacher and faculty survey sub-scale data will be used along with qualitative data generated by focus groups.

Objective 4

Revise course syllabi to reflect and recognize the integration of technology into the curriculum. Analysis of syllabi will be used for this objective used along with qualitative data generated by focus groups. Further, pre-service teacher portfolios will be examined across years to look for changes in the kind of assignments students' enter in their portfolios.

Goal 2 - Overview

Integrate instructional technology in the consortium's pre-service observation and field experiences. This will be accomplished by observing the best teachers in public schools through the use of video-conferencing equipment. These observations will include interviews with school personnel, including teachers, administrators, staff, etc. There will also be moderated chat room discussions about these observations. This goal will be evaluated in much the same way that the first goal was evaluated, but by using only the pre-service teacher cohorts and by focusing on...
the pre-student teaching field experience courses. Also, analysis of syllabi over time for the field experience courses will be used. Further, the level of participation of each student in the moderated chat rooms will be monitored. Lastly, focus group information will provide another way of doing evaluation.

Objective 1

Improve pre-student teaching observations. Using only the pre-service teacher cohorts and focusing on the pre-student teaching field experience courses, we will be able to do the evaluation. Also, analysis of syllabi over time for the field experience courses will be used.

Objective 2

Provide a broader range of field experiences. Analysis of syllabi will be used for this objective along with information provided by focus groups.

Objective 3

Establish web-based services to support the pre-student teaching experience. The participation level of each student in moderated chat rooms will be monitored. Focus group information will provide another way of doing evaluation.

Goal 3 - Overview

Provide a variety of professional support opportunities for faculty and pre-service teachers. These will provide opportunities for peer mentoring and the exchange of ideas and experiences in the effective use of IT in a variety of settings and subjects. To evaluate this goal we will find and possibly modify or develop questionnaires to collect factual participation information and surveys to assess the quality of participation. Finally, the information from the focus groups will assist in the evaluation of this goal.

Objective 1

Develop technology-based teaching circles for pre-service teachers, cooperating teachers and teacher education faculty. Basic record keeping will provide information for the evaluation of this objective. Also, focus group data will be used.

Objective 2

Provide technical support services for faculty and pre-service teachers. Help logs and simple open-ended user evaluation forms will be kept by the instructional technology assistance facility staff and analyzed for evaluation purposes.

Goal 4 - Overview

Enhance the technological infrastructure of the consortium members to better support the project initiatives to evaluate this goal an approach similar to the evaluation of Goal 3 will be used. We will find and possibly modify or develop questionnaires to collect factual participation information and surveys to assess the quality of participation. Further, basic university administration record keeping will be used for evaluation. To finish the evaluation of this goal, information from the focus groups will be used in the evaluation.
Objective 1

Provide modern computing laboratories for pre-service teachers including multi-media capability. The use of logs and simple open-ended user evaluation forms will be kept by the instructional technology assistance facility staff and analyzed for evaluation purposes. Focus group feedback will also be employed.

Objective 2

Develop campus networks that provide students access to modern network technology and that facilitate collaborative work. Simple university administrative record keeping will provide the necessary information.

Objective 3

Implement programs to assure faculty in the teacher preparation program and related subject areas have adequate computers. Simple university administrative record keeping will provide the necessary information. Focus group feedback will also be employed.

Objective 4

Have teacher preparation faculty actively involved in technology planning. Simple university administrative record keeping will provide the necessary information. Focus group feedback will also be employed.

Summary

The purpose of this paper is to present an evaluation plan for this kind of project. This plan is only the beginnings of a total evaluation. Comment and suggestions will be greatly appreciated.
Putting Mathematics on the Web has become a challenge to say the least. There exist clever applets, "keyboard translations" of mathematical symbols, along with charts of symbols that are available for use as gifs. These methods of putting this discipline on the internet are cumbersome and disjointed. They are simply not user friendly. For mathematics professors whose interests are in mathematics and the teaching of mathematics, the technology has not caught up with the specific needs.

Independent of the web, there are powerful computer algebra systems available that are available for research in mathematics and for the teaching of mathematics. Maple is such a computer algebra system. It is a powerful tool with which to explore, hypothesize visualize and compute. For us, it has a great influence in the mathematics classroom. Students are able to solve realistic problems that were beyond the scope of the course simply because they could not be done by hand or calculator. The use of the computer in the mathematics classroom has evolved from checking the validity of hand calculations to doing difficult calculations and then to visualization and animation of two and three-dimensional graphs. Topics like Riemann sums, linear transformations and Maclaurin series have come alive in animated graphics. After spending some years capitalizing on the potential of the computer algebra system, the web was our next logical step. It was another tool. However, we learned two major things from our experience with Maple. First, avoid the cookbook approach (press this key or type this code etc.). Second, do not use the technology for the sake of using it but rather use it only to further your pedagogical goals. The Internet is a technological tool with the emphasis on the word "tool." We should utilize the web but the student should not be aware that he/she is even using the tool. The student should be concentrating on learning or transporting the mathematics. The student does not consciously think about the pencil and notebook. Similarly, the student should expend little conscious effort in using the technological tool. The professor should also be able to reap the benefits of the web without an inordinate amount of work.

We first began to use technology in the classroom in an organized fashion when the computer algebra system Maple was introduced into our calculus classrooms in 1992. We have learned from the mistakes we made when we introduced Maple to our students. So when approaching the use of the Internet, we started with the question: "How can the web help us in the teaching of mathematics?" rather than "How can we integrate the web into our courses?" With the limitations of the web with mathematical symbols, the answer was not clear. We were already using a powerful tool - the computer algebra system and we had no desire to abandon that tool and start writing java applets so as to "get the mathematics on the web." We wanted to use the vehicle of the internet but we did not want to have to redesign its chassis so as to enable it to carry our mathematics. We wanted to just hop in it and drive.

In the end what we did was marry the classroom management system Blackboard with the Maple. Forgive the analogy but we figured out how to adapt the generic school bus to transport our mathematics so as not to allow the power of Maple to be lost. This method does have its limitations. We sacrificed the real-time interaction for the power of Maple and the ease of use. In our courses now we have added an Internet component. The student is able to view Maple worksheets with or without animation in a very simple manner with nothing else but a current browser. The student is able to discuss mathematics with other students through a discussion thread. The professor and the student can exchange maple worksheets via the drop box open and then open them up in Maple for manipulation (in this case the student does need to have Maple on his/her machine).

One can create a web page and incorporate many technological features. We chose a classroom management system as our vehicle rather than using our own web pages. We did this to help us get started on the web with a minimum amount of web programming. We think that this is an efficient vehicle for those who want to invest their time in learning how to use the Internet in a sound pedagogical manner. Also we wanted to extend the experience we had in Maple into the online environment. The course management system Blackboard allows us to do this with a minimal amount of web programming skills. While our experience has been with these course management systems, other course management systems have similar properties.

The most important lesson we learned from our Maple experience is that in a mathematics classroom, mathematical ideas must be the driving force behind every use of technology. Technology can certainly make solving problems easier. More importantly, previously unsolvable problems might actually be solved. The
graphical capabilities can make mathematical ideas easier to comprehend. But we have to control our enthusiasm. We have to learn from our mistakes. For example, our first Maple labs were overly ambitious. They typically covered too much material and required too much code. We discovered that an overabundance of syntax leads to less comprehension. We decided that “keeping it simple” in terms of the technological tool while challenging the students’ mathematical ability was the best way to use any tool. As we began to use the Internet in our classes, we kept these lessons in mind.

We propose to introduce the course management system Blackboard 5 at our session. This software allows faculty members to put course material online. For example, assignments can be created and updated, a grade book can be created, or students can participate in an online discussion. Specifically, our presentation would include:

- Announcements
- Tasks
  - Uploading and downloading documents
  - Uploading Maple HTML files for viewing
  - Uploading and downloading Maple mws files for manipulation
- Grades
  - Creating a gradebook
  - Exporting grades to Excel
- Links
- Forums
  - Creating a new thread
  - Managing a new thread

When using a class management system there are several overriding principles that will make the transition to cyberspace easier. To begin, have a vision of your overall hierarchy before trying to create a new course with a course management system. When you start to create your course, have your syllabus completed. This helps you organize the course into headings and subheadings. From the outset, be specific about your expectations. Explain your grading system thoroughly. If you have an online component, then you should tell the students how many times per week that you expect them to participate. If you post a discussion question, and you expect that students respond to each other’s comments, then you should tell them if a statement like “I agree with Nancy” counts as a comment. That is, be specific about your expectations concerning the content of these comments.

Familiarize the students with any online component in a non-threatening way. Give the students a few days to familiarize themselves with this new environment and with each other. Sometimes this can be accomplished by giving an assignment that has little or no credit attached to it. You can begin to establish a classroom community online by asking students to tell the class something about themselves. If you decide to do this, you can set the tone for the rest of the class by being the first one to respond. Let your personality shine through. Give the students the type of response that you would like to receive.

It is extremely important to be specific about your expectations concerning Internet etiquette. If you expect students to use proper grammar, tell them. It may be a mistake to let students post responses anonymously. Students should be held as responsible for their comments online as they would be for their comments in a classroom setting. Blackboard gives the professor the choice to allow anonymous posting or not to allow it. Consider the academic integrity of the classroom when making that decision.

Respond to students’ questions in a timely fashion. Whenever possible, use students’ names. Questions about class material should be posted to the discussion and shared with the class rather than sent to the teacher by email. Everyone should benefit from the questions of others. Be strict about this policy. If you start to respond to individual questions via email, you can easily get overwhelmed. There is simply not enough time to respond to individual questions. You will find yourself repeating the answers that you have already given to another individual.

Be timely. For example, if you tell your classes that an assignment will be available at a certain time, be sure it is posted by that time. If your course has a traditional classroom component and an online component, realize that any new information published online can have unexpected ramifications. For example, if you post the grades of a test that is being returned to the student the next day, your actions can affect tomorrow’s attendance.

If you have an online grade book, keep it up to date. If you have changed a student’s grade, change it online too. Expect students to point out any error you have made online. Don’t get impatient if they remind you about a mistake that you have not changed. Encourage them to remind you if the error has not been corrected within two or three days. If you have an online grade book, make sure that your grading system has been clearly explained. This will minimize confusion about how the final grade will be calculated.
Incorporating Maple into the classroom management system brings some complications. Users must be aware that browsers have a significant effect on what students see on the screen. Also, students must be aware that if they want to manipulate downloaded Maple worksheets, they have to have Maple on their machines. Putting mathematics on the Web is particularly difficult because of the limitations concerning manipulation of mathematical symbols. We have used the capabilities of Maple to "transport" our mathematics. There are two ways to do this.

First, it is possible to view a Maple worksheet as an html file in Blackboard. The student will be able to view the worksheet, but will not be able to interact with the worksheet. Even animations can be viewed using this method. This can be accomplished in the following way in Version V. When the Maple worksheet is completed, you can choose the options:

File      Export As      HTML
You then give the file a name. Suppose you give the file the name Animation. This automatically creates three HTML files:

Animation.HTML
Animation1.HTML
AnimationTOC.HTML

If you want to put this Maple worksheet online in Blackboard, attach the file Animation1.html to an item under course assignments or projects, etc. When you try to submit this you will be given the message that there are missing images. The names of these images will be provided. You will have to use the browser option to find these images in the images subdirectory. You can then submit this item.

Second, the student can download a Maple worksheet as an mws file and open it in Maple. This is more powerful than the first method because now the student can manipulate and run the Maple worksheet. This is where you may encounter various problems with the browser. Depending on the type of browser, the version of the browser, or the settings of the browser, different computers will display different screens. We have decided to rely on a rather generic way of downloading worksheets. Once the Maple mws file is pointed to via an external link or the drop box option in Blackboard, the student can right click on the link and save the file on the C or A drive. The student can then open the file in Maple. Some computers will open up the Maple worksheet automatically when the student left clicks but many will not. In either case, Maple must be on the student's machine or network. Maple is not being downloaded, only the worksheet is.

Throughout the presentation, we will illustrate some of the difficulties we found while using this software and we will make suggestions as to how we managed to circumvent these problems. We will also discuss the very difficult problem associated with trying to communicate electronically in the language of mathematics. Although the present technology does not support interactive Maple worksheets, we will demonstrate how to upload Maple worksheets into Blackboard courses. The students will be able to view the worksheets and their output, including animation. We will not require previous knowledge of Maple, or of HTML. We are also assuming that this presentation is for people who have not used Blackboard.
Abstract: Is your teacher preparation “program” really a team of education faculty, content faculty, and K-12 teachers? These groups face the same doubts, promises, and problems related to technology integration. Rather than a frontal assault on teaching technology usage to them, “Project Jericho: Breaking Down the Walls” took a back door approach, getting these groups talking, sharing, and cooperating with regards to technology. Results include professional development and program changes. English/Language Arts, Science, Math, and Social Studies Innovation Teams of nine K-12 teachers, three teacher educators, and three content faculty match up technology skills with state-mandated curriculum, then develop technology-rich units for integration in all parts of teacher preparation. Innovation Teams share on-line and meet monthly to analyze standards, develop a curriculum/technology matrix, work on lesson plans, and work in triads exploring and analyzing websites, lesson plans, and collaborations. Team members share and implement Innovation Team ideas and suggestions.
Technology Integration: A Collaborative Model

Abstract: The College of Education at California State University, Sacramento designed and implemented a collaborative model for technology integration. The teacher preparation program in conjunction with its school district partners redesigned existing curricula and field placements by simultaneously implementing technology-based lessons into preservice teacher education coursework and K-8 classrooms. These lessons were designed by participants who included teacher education methods faculty, K-8 collaborative teachers, and classroom teachers trained in technology integration. Design teams were formed around content areas and consisted of one university faculty, one classroom technology mentor, and two collaborative teachers from partnership districts. By designing teams around content areas, each course in the preservice program contained a significant unit in which every student teacher participated.

Introduction

The College of Education at California State University, Sacramento (CSUS) in collaboration with the Roseville (CA) City School District developed and implemented a collaborative model for simultaneous integration of technology in preservice coursework and K-8 field placement classrooms. This year long project was aimed at accomplishing the following objectives: 1) testing a model for generating technology-infused curricula which utilized technology leadership within a partner school district; 2) increasing the capacity of CSUS faculty and partnership teachers to integrate technology into their respective classrooms occurred, 3) increasing strong research based skills by student teachers for how technology can be integrated across the curriculum and grade levels. In this paper, we describe the project, its accomplishments and dilemmas, and draw lessons for subsequent improvements in technology use within our teacher preparation programs.

Teacher Preparation at CSUS

The California State University, Sacramento College of Education is one of the largest teacher preparation programs within the California State University System. Last year it granted nearly 700 preliminary credentials to elementary, secondary, and special education teachers. The credential program is a three semester, Fifth year post baccalaureate program. The College of Education structures its credential program into geographic “Centers” grouping preservice teachers into cohorts of twenty-five to thirty. A Center works within specified local public school districts. Half of the teacher preparation consists of field work (student teaching) that takes place...
within these districts. The resulting well-developed partnerships with cadres of K-8 field mentor teachers lead to outstanding field placements for student teachers.

The Roseville City School District is a member of the Placer County Teacher Preparation Center. Student teachers' field placements are with Collaborative Teachers. A Collaborative Teacher (CT) is an exceptional classroom teacher who serves in place of traditional university supervisors and receives university stipends and training in student teacher supervision. CTs in a Center also have more responsibility in designing and implementing the teacher education program (e.g. co-teaching methods classes).

The Roseville City School District has a strong commitment to the integration of technology and curriculum. Its technology plan, with its underlying philosophical commitment to collaboration, includes a robust technology integration training model for classroom teachers. These classroom teachers bring their curriculum expertise to the newest technology and develop meaningful ways to blend the two. Much of the technology leader training has been based upon Apple Classrooms of Tomorrow (ACOT) methodologies. This training is designed around a Unit of Practice (UOP), a specific process for thinking about and developing a classroom activity. Participants explored technology in the context of working through a sample UOP. Then using one of their own lessons, they developed an original UOP that incorporated technology in a fundamental way. In so doing, the curriculum remains rigorous and technology is not an end in and of itself. This model, of starting with the curriculum and infusing the technology, served as a springboard for this project.

The College of Education has a technology plan that puts much emphasis on the active learning of the student. This plan was in the initial stages of implementation during the course of this project. Recently, the College of Education was mandated by the California Commission on Teacher Credentialing to integrate technology into all of its methods courses. Newly developed statewide standards set criteria for teacher preparation programs. CSUS grouped these standards into three categories: admission requirements, technology skills and integration into curriculum. Admission standards require applicants to demonstrate the ability to use email and search the Internet. Additionally, technology modules are available for student teachers that need basic technology skill training. A third group of standards demand that technology be integrated into preservice coursework. Upon completion of the teacher preparation program, it is expected that all students meet exit criteria for technology based upon the standards. However, to do this in the isolation of a college classroom without coinciding practicum experience in a K-8 classroom results in little long-term capacity of new teachers to continue to use technology. This capacity building project allowed this to be done on two levels: in methods and foundations courses and simultaneously implemented within field placement classrooms.

Model

At the core of this project was the development of design teams. Four design teams were assembled. Each team consisted of one CSUS faculty, one classroom technology mentor teacher, and two Collaborative Teachers. The CSUS faculty was to include one from each content methods area: mathematics, science, reading/language arts, social studies, as well as educational foundations. However, due to scheduling conflicts, reading/language arts faculty was not involved during the academic year project. The five classroom technology mentor teachers were selected from the school district's first cadre of teachers trained in technology integration. These reflected a balance of grade levels and content emphases. Ten Collaborative Teachers from throughout the Center were selected from the pool of experienced field mentors.

College of Education faculty may have the content or pedagogical background while the Collaborative Teacher may have the pragmatic know-how of what really works in an elementary or middle school classroom, and the technology mentor teacher provided the expertise of having been through a similar implementation process previously. This mix provided for powerful and collaborative design teams.

The design teams were to develop two products over the course of the project. The first were K-8 lessons/units that would be posted on district and college websites for use by current classroom teachers and university preservice methods faculty and students. Design teams used model Units of Practice provided by the technology mentor teachers as the basis of their initial work. They also learned how to use...
rubric criteria to evaluate their lessons. The second product was a redesign of preservice coursework integrating technology into each methods and foundation course.

Timeline

In early fall, design teams were formed around content areas. For example, a fourth grade technology mentor teacher who previously developed a UOP infusing technology into a social studies unit was teamed with the social studies methods faculty and two upper grade CTs. Therefore, this team was expected to develop a social studies unit. By designing teams around content areas, each course in the preservice program would have a significant unit in which every student teacher would participate.

At the initial meeting, the technology trainers facilitated each of the teams working from their expertise in blending technology and curriculum. They shared the UOPs that they previously developed and implemented in their K-8 classrooms. These exemplary units set the standard for the units that the teams were setting out to develop. The lessons in the shared units served as the springboard to connect skills, assessment, content, problem solving, research and standards which needed to be components of the redesigned curriculum.

The teams also reviewed district and college technology plans as well as state and national technology standards upon which much of the work needed to be built. Each participant also took the "Profiler" self-assessment so that the participants could record individual growth. Throughout the fall semester, teams developed their first integrated lessons and communicated with one another in a variety of ways including listserv and email. As the semester progressed, teams continued to meet amongst themselves to develop their own lessons. The entire project group met every 6 weeks during which time each team shared their work in progress, and specific skills were taught to the participants per participant request. Additionally rubric scoring of the units was done at these meetings. The rubric is available on line at <http://www.classroom.com/edsoasis/>. Due to the variety of skills within each design team, team members assisted one another at their meetings much more than at the whole project meetings.

By the end of fall semester the first lessons were to have been developed and implemented in the K-8 classrooms of the CTs and preservice courses. These completed lessons were implemented in a variety of ways during the spring semester university coursework and in the CT classrooms.

During the spring semester, every student teacher encountered technology-based lessons in their Placer County Center coursework, with the exception of literacy courses. Built into the coursework was a component that had each of the student teachers teaching, planning, and/or observing and evaluating a technology based lesson. For example, as part of the final course project in elementary mathematics methods, the preservice students were to develop a lesson that integrated technology. Additionally, each design team was given an overhead presentation system for use among the team members when their newly designed lessons were taught.

The preservice faculty integrated technology in a variety of ways. For example, in educational foundations, an area in which some of the faculty had difficulty envisioning how technology integration could occur, preservice teachers did webquests based upon Howard Gardner's Theory of Multiple Intelligences. The educational foundations faculty designed an assignment in collaboration with her design team teachers in which the preservice teachers observed their classrooms and evaluated whether or not specific examples of the use of computers in teaching were appropriate or effective. The preservice teachers spent time over the course of two days observing elementary teachers (who were design team members) utilizing computers in the classroom. The documented data was to refer to both the multiple intelligences and effective lesson design with technology. The students were encouraged to refer to the project's rubric. The instructor worked very closely with the classroom teachers in obtaining permission to videotape these lessons and to establish schedules that would work well for all involved parties.

In Science methods, the course now included a means by which students could do some of their coursework on-line and each preservice teacher developed a webquest for a specific science concept for use in their student teaching placements. In mathematics methods, the student teachers learned how to develop algebraic thinking using spreadsheets with students in grades K-8. The student teachers also analyzed a variety of mathematics-related websites: some for teacher use and some for student use. The mathematics design team unit was "Creating a Playground." As the semester progressed, the unit was presented to the preservice students for participation, analysis and evaluation.
Outcomes

The integrated design teams allowed all participants to expand technology use in their respective teaching. As the social studies methods faculty stated, "As a result of being involved in this project several observations can be made. First, students have begun talking about how to integrate technology with instruction. I have made it a requirement for students to document at least one lesson that integrates technology and instruction. This was done in addition to going to the partner district's Technology Learning Center; so, in effect, the time allotted to technology integration was expanded this semester. Third, and possibly, the most exciting, another member of my design team and I have discussed his coming to The Technology Learning Center and demonstrating his own use of technology in his social studies classes. I asked a student teacher what she thought about this idea. Her reply was, "I think it would be great!"

Clearly one of the strongest outcomes of the design team model was the development of relationships between university faculty and classroom teachers. Here is how one of the technology mentor teachers described the results of this joint, collaborative work:

"The project has pushed me to explore how to use the Internet with my students. Previously the focus of my teaching revolved around teaching students how to acquire information from the Internet. This year, the focus has been more on teaching them how to transform that information or how to use the information to construct new knowledge. This especially happened with my "Gifted and Talented" students when I asked them to select a topic in history that has changed us. I required that they find primary sources such as documents, journals, pictures, maps, timelines and statistics. With the information gathered, I wanted them to analyze and evaluate its validity, and then use that information to draw their conclusions about the topic's impact on history. In other words, I focused a lot on instructing my students how to think and evaluate material found on the Internet. I learned a lot about how I taught the process and ways to improve my approach.

I also read more technology articles. I wanted to explore other people's philosophy about using technology to teach... From my readings, I created two Internet activities/lessons that I feel good about. I wanted to see how the Internet could provide music and visuals to enhance a lesson. I created a lesson on Civil War music, focusing on the songs of the Underground Railroad. Another lesson for 7th grade dealt with comparing art from the Classical period, the Middle Ages, and the Renaissance period. I really liked that lesson. The presentation system/projector from the project is a real blessing that encouraged me to design those lessons."

A Collaborative Teacher participant wrote,
“When I started with the project I really didn’t know what to expect. I thought we were going to be looking at technology and find ways to get student teachers to use it in their new classrooms. I was pleasantly surprised when I found out we were going to be putting together whole units for the teachers to use. It was really exciting to work with fellow teachers from other districts on a subject that was interesting to me.”

The design team model propelled much of the project. This collaborative process was instrumental in the development and implementation of technology-infused lessons and strengthened partnerships for all participants. Teams were self-selected and curriculum chosen by each team. This resulted in a variety of technology-infused lessons and units. Each team chose different times and places to work and develop their units. This occurred with the development of the curriculum and with the implementation.

Summary of Lessons Learned

This was a project that intended to build the capacity of the preservice program partners to infuse technology into coursework and fieldwork. In looking back at the evaluative data and our collective experiences, we have learned the following lessons that will guide the next phase of the Teacher Preparation Program technology components.

Lesson 1: It is possible to build effective partnerships between K-8 and university faculty for technology infusion into teacher preparation and K-8 classrooms. Arts and Sciences participation was minimal as partnerships here are just building, but are anticipated for the future to help develop additional content expertise for the K-8 classroom.

Lesson 2: Leadership for such collaborations can come from the classroom side as well as the university side. What is not yet clear is whether the reversal of the usual hierarchy of leadership could take place without the pre-existing university partnership already existing within the district.

Lesson 3: The design team approach worked will in producing lessons that were implemented in K-8 and teacher education. Strong collaborative relationships were a result of this project. What would have strengthened the design team model was more on-line communication at predetermined times when all members were on-line simultaneously.

Lesson 4: Faculty were more resistant to putting their lessons on the public website than were the classroom teachers. Perhaps this was due in part to the newness of the technology for many faculty members and a reluctance to expose the products of their initial attempts at technology infusion.

Lesson 5: Student teachers were able to focus simultaneously on the quality of technology in the lessons, following the rubric, and on the curriculum. This piece is important because it demonstrated that the technology was not so overwhelming to students that they could not attend to the curricular design elements.

Lesson 6: This preliminary work identified how we need to build future evaluation strategies to create strong formative feedback for lesson and program development.

Acknowledgements

We thank the Preparing Tomorrow’s Teachers to Use Technology (PT3) program of the U.S. Department of Education grant number P342A990085 for support of this project. Additional support was welcomed from the Roseville City School District, CSUS, and the Stuart Foundation.
Models, Mentors, and Mobility in the Teacher Education Program

Abstract: This paper is a report on the activities of a PT3 implementation grant, Project M^3: Models, Mentors, and Mobility. Project M^3 has three major goals: 1) To identify and develop model practitioners and models of practice for teacher education students, 2) To develop a network of mentors to support and train students, faculty, and partner school teachers, and 3) To utilize laptop computers, personal digital assistants, and online support and instruction to improve student access to technology.

Project M^3 reaches out to the university community, private and public schools, and private businesses to maintain a network of models and mentors and to support integration of technology in the college classroom and partner schools. Project M^3 also uses new advances in mobile computing to improve accessibility to technology by creating and modeling the use of wireless laptops and personal digital assistants in the classrooms in the College of Education and in PreK-12 schools. On-line instruction and support are also used to provide better access to learning experiences, training, and support.

Introduction

In the last decade, school districts in the United States have invested billions of local, state, and federal dollars to equip schools with computers and advanced telecommunications equipment. During this same time period, higher education institutions have scrambled to advance their own technology infrastructures. Unfortunately, technological advancement in higher education has proceeded unevenly in many instances, with Colleges of Education (COE) hard-pressed to match the resource bases of such Colleges or Schools as Medicine, Engineering, or Business (National Council for Accreditation of Teacher Education, NCATE, 1998). Even when resources are available in COEs and schools, it is not necessarily the case that the technology is used. This is often the result of untrained faculty and in some instances due to inadequacies in infrastructure (e.g., poor wiring).

The number of schools in the United States having access to the Internet has increased from 35% in 1994 to 89% in 1998 (National Center for Education Statistics, 1999), while classroom teachers in the United States are "least likely to report being very well prepared for activities...integrating educational technology into the grade or subject taught" (NCES, 1999, p. 74).
Wichita Public Schools and Wichita State University's College of Education (COE), generally, have reflected the national trends. Both have some technology, but few trained faculty and limited vision of how technology can be integrated into the curriculum. Both desire to address these issues.

Work in local PreK-12 schools involving technology has progressed steadily in recent years. All schools are connected to the district network. Partner schools for this grant have at least one network/Internet connected computer in each classroom. In their 5-year technology plans, the partner schools have as their goal to integrate technology into their curriculum. Wichita Public Schools are in the process of submitting a bond issue to the public. Electrical wiring is a key component of the infrastructure needs requested.

In the WSU College of Education, early technology efforts resulted in personal computers for each faculty member and a COE 20-station computer lab. Within the past two years the college has focused efforts on increasing the technology access and skills of faculty, staff, and students. As part of this effort, the college completed some major technology initiatives including (a) the development of a technology mission, vision, and commitments document that incorporates recent International Society for Technology in Education Standards (ISTE, 2000) and current and draft standards of the National Council for Accreditation of Teacher Education (NCATE, 1998); (b) completion of three technology needs assessments conducted both by the College of Education and the university, that yielded consistent results; and (c) the development and implementation of a one-year U. S. Department of Education Capacity Building grant, Expanding Curriculum Integration through Technology Education (EXCITE). All have produced forward technology movement in the college.

The needs assessments in the COE indicated that the faculty and staff are self-taught technology users who are quite comfortable with the basics of word processing and e-mail but who do not use technology to any great extent in their classroom teaching. Significantly, it was also apparent that faculty did not expect students to use technology in meaningful ways. However when asked, over 50% of the faculty identified 18 different technologies that they felt had either "somewhat high" or "high" potential for instructional impact.

Even more recently, a partner in Project M3, the Wichita State University Center for Teaching and Research Excellence, found similar results in an assessment of technology needs of WSU faculty. The Center’s assessment made it clear that faculty, university-wide, desire support to add technology resources to their courses.

Finally, a self-assessment of University and College of Education technology readiness, using STaR Chart: A Self-Assessment Tool for Colleges of Education (CEO Forum, 2000) also indicated a need for future technology training for COE faculty. The STaR Chart revealed a composite picture of a university and COE operating in the "Early" and "Developing" levels of readiness but anxious and excited about locating and implementing resources to move to the two higher levels of readiness, “Advanced” and "Target".

During this time, a vision, mission, and goals statement was developed to guide efforts along with the needs assessments. This document states, “The vision for the College of Education at Wichita State University is a technologically astute academic culture... in which students, faculty, staff, alumni, and the community work together ... to enhance learning through modeling and integration of appropriate technologies” (College of Education, 1999).

As a result of a capacity grant, the COE was able to provide professional development for faculty and partner school teachers in on-line instruction, presentation software, multimedia and Internet in the classroom, video-editing, and curriculum integration. These efforts focused faculty members’ attention on the impact technology integration can have on student and faculty performance. The increased awareness and skill level has resulted in a rising number of class activities using technology. Faculty began to request the computer lab for class sessions more frequently, and student use of open lab hours increased dramatically. These changes resulted in further increases of requests for technical and instruction support. The computer lab schedule and check out of equipment became more complicated as usage increased. It became apparent that the COE’s successes in raising the awareness level and adoption level of technology had created the need for more support and better access to the technology. An additional need surfaced as the COE looked for exemplary models of technology integration in field placements. Schools used for field placements were not always those at the forefront of technology integration.

The primary purpose of Project M3 Models, Mentors, and Mobility is to provide better access to technology in classrooms for teacher education students and to increase the number of exemplary models for students. To reach our goals, Project M3 developed three sets of activities that encourage and support teacher education faculty and students to integrate technology.
Models of Practice

Project M³ has its first element, Models. Models has two parts: (1) Teachers who model effective use of instruction in their classrooms (model practitioners), and (2) Technology Integration Projects for Students (TIPS) that are designed to be used as models for other teachers who might be struggling to find ways to integrate technology. In an attempt to prepare teachers who model effective use of instruction, WSU has taken a constructivist approach. ATE Standards for Teacher Educators (http://www.siu.edu/departments/coe/ate/atestand.html) require that master teacher educators model professional teaching practices that reflect best available practices in teacher education (Standard 1), systematically reflect on their own practice (Standard 3) and provide leadership in evaluating programs for preservice teachers (Standard 4). Included in the indicators is “regularly revise courses taught to incorporate recent materials, including technology.” Teacher educators have an obligation first to model appropriate instructional strategies for the preservice teachers they train, in order that students can participate in activities that they later will use instructing their own students. To this end, our university has attempted to support faculty in their acquisition of needed knowledge and skills as they integrate technology into their coursework.

The integration of technology standards into the teacher education program required breaking the standards into bits and methodically conferencing with individual faculty to see what they were modeling for and requiring of students. Following these initial information-gathering sessions, the curriculum resource specialist and the technology specialist conferenced with individual faculty members where the “relationship between the instructor and the students is one of cognitive apprenticeship, in which the instructor models problem solving, engineers learning experiences, provides scaffolding as students attempt tasks, and encourages reflection.” (Bednar & Charles, 1999, p. 1). We worked as a team to examine the course requirements and as “consultants” offered suggestions of ways technology could support these activities. Faculty were left to make decisions about what was best for them and for their students. After a semester’s implementation, elements of satisfaction are examined and refinements made. Those activities that are successful become part of a website designed to disseminate Technology Integration Projects for Teacher Education Students (TIPS for Teacher Education) to others for their modification and/or use. In addition systemic change is being made to the Teacher Education program document.

One major project with partner schools involves designing technology integration projects for elementary students that are tied to new text adoptions. The first project, Technology Integration Projects for Students (TIPS) for Science, completed summer 2000, again used an approach which allowed grade level teams of practicing teachers and preservice teacher education students to begin with what they knew and conference with technology and curriculum experts who could guide them to ways technology could support instruction. The resulting website provided two separate sites, one for students and the other for parents and teachers. The student site provides a science activity “card” designed as a technology-based research, analysis, or communication activity to supplement hands-on activities provided in the classroom. Student outcomes and technology used introduce the page and direct links to teacher-reviewed websites are included on the “cards.” The parent/teacher page provided connections to district science standards, ISTE NETS standards for students, ISTE NETS standards for students, district benchmarks, and instructions for teachers where additional preparation was needed. As teachers use these TIPS, WSU plans to showcase teachers teaching with technology and student projects developed with technology. (See http://education.twusu.edu/m3/tips/index.htm.)

Mentors

The Mentors component of M³ involves coordinating the development of a broad-based network of mentors who will provide training and support for teacher education faculty, LAS and Fine Arts faculty, K-12 partner schools, and pre-service teachers. Professional development activities for faculty and student mentors have been supported by EXCITE, a 1999-2000 Capacity Building grant, also part of the PT3 initiative, the university Center for Excellence in Teaching and Research, the college, partners, and M³. The outgrowth of EXCITE was that faculty increased their skills and comfort level in order to model the use of technology in their classes. As icing on the cake, faculty are now seen mentoring each other and students.
on technology that they now can use, growing more fearless as time passes and experience is gained. The primary projects for this grant include (a) training of preservice teacher education students as student mentors who work with faculty and partner schools on specific projects (b) identifying and collaborating with businesses in the community.

Student mentors have assisted faculty in media development, presentations, on-line instruction, and “wellness clinics” for desktop computers. Faculty members have requested mentor help in learning how to use a digital camera, video editing, developing Web pages, scanning, and researching and developing graphics. Cooperation and collaboration between faculty has also increased as faculty members develop recognition for their use of technology. One new faculty member became excited about offering her educational psychology course on-line and was so successful that she caught the interest of another faculty member who had shown no interest in on-line instruction. The two teamed up to develop their on-line course to include on-line assessment and began to work with their textbook publisher to develop support materials.

Mobility

The third goal of Project M³ is to utilize new technologies that provide better access to technology for students, teachers, and teacher educators. WSU COE faculty are motivated to increase their use of technology in classroom curriculum, but the classrooms that house pre-service teacher education courses, until recently, have had only basic technology such as overhead projectors and video players. A portable electronic lectern was custom-built with a Macintosh G3 equipped with Virtual PC, WWW browsers and Microsoft Office, VCR, speakers, video projector, and overhead camera to be used in seven classrooms. However, because of old wiring in the building, even the faculty who are lucky enough to secure the cart sometimes found that they had blown a fuse and couldn’t use any type of electrical technology during their class.

It is our assumption that technology will be better integrated into the curriculum if it is where the students and teachers are, not necessarily where the machines and technology experts are. Recent advances in wireless technology have provided the College opportunities to make technology transportable to any classroom or conference room with a single network connection. During the last year, the COE used funding acquired through a PT³ Capacity Grant (Project E.X.C.I.T.E.) and a PT³ Implementation Grant (Project M³) to acquire two airports and five laptops with wireless network cards to allow faculty to move the technology into their classrooms. Separate funding has increased the number of laptops available for instructional use. Faculty use these laptops for a variety of instructional uses such as searching for data on the Web, group problem solving, evaluating educational software, and on-line discussions.

In addition, Project M³ purchased mini-laptop labs for a middle school and a high school for the same purpose and has plans to purchase mini-labs for three additional schools. The laptop mini-labs may be checked out by individual teachers to be taken into classrooms where technology had previously been limited and/or absent. Project M³ personnel monitor and evaluate how the teachers in the partner schools use the mini-labs in their classrooms. Faculty members in the College of Education use the laptop mini-labs for Web searches, on-line testing, file sharing, developing instructional materials such as crossword puzzles, and brainstorming activities.

Because of the enthusiastic response to mobile computing on campus and in our partner schools, five HandSpring personal digital assistants (PDA’s) have recently been purchased for use in classrooms. Physical Education student teachers are currently using PDA’s for evaluation and assessment in the field. Faculty interest in handheld computing was strong enough that the grant recently organized a university-wide user group to explore instructional uses.

A grant kickoff highlighted our new wireless capabilities in 10 different subject areas. The kickoff demonstrated the old (slide-rules, tables of numbers, antique texts and globes) right beside the new (computers, software, visual imaging Web sites, robotics). Guests from University Computing, Media Resources, Liberal Arts, partner schools, and university administration were impressed with the technology displayed and we have received numerous requests for follow-up demonstrations from public schools and biology, engineering, and business faculty at WSU. The interest in laptops and PDA’s has resulted in expansion of the M³ Web site to include a section on purchasing, configuring, and integrating mobile technology. (See http://education.wichita.edu/m3/mobility.htm.)
These recent additions to the technology infrastructure allow modeling of technology integration in curriculum and engage the students in experiences that lead to more effective and successful technology integration. With the appropriate models and exposure to technology, students experience a 'hands on' approach to develop the foundational skills and knowledge necessary to appropriately select technology tools for problem solving, research, communication, and collaboration.

Conclusions

With faculty trained, resources available, and creativity unleashed, the process of implementing technology into schools continues. We begin with the conversing and encouraging of faculty to try new things with on-the-spot technology support. As faculty learn more, they seem to want to use technology and to learn more. Second, students and student mentors help faculty implement, reflect, and revise technology activities. At times, faculty learn from their students as the students learn from them. Finally, teacher education faculty make changes in their own behavior and in the teacher education program to assure the continued use of technology in the all schools.

“We are all exploring right now and when you explore new territory, the terrain is always unknown. We are just making it a bit more smooth for those who follow—the second time—and learning to climb the molehills and/or mountains in our way, going around the fallen trees, finding the tunnels, swimming the rivers—all without sinking or crashing in the process” (faculty e-mail, October 5, 2000).

“The road ahead will take us places we've never been before...that's for sure!” (Faculty log entry, June 5, 2000).

Abstract: The teacher education program at the University of Cincinnati has undergone substantial revision over the past seven years. It now is a five-year program culminating in two bachelor degrees, a yearlong load bearing compensated internship, and a portfolio documenting each student’s progress during the year. Our students have reported that their experience with technology has been a deficiency in the program. Steps are being undertaken to increase the role of technology both in their teacher education courses and their arts and sciences courses. In order to give the students a higher skill level with technology, students will begin transitioning over to digital portfolios pressed to CD. The portfolio will serve as a means to self-analyze their growth during the year. In addition, the digital portfolio will give the students confidence in their own technology skills and demonstrate to future employers that they have the necessary technology skills.

The University of Cincinnati has in place a five-year baccalaureate teacher education program culminating in a series of degrees including a Bachelor degree in an Arts and Sciences subject area, a Bachelor degree in Education, and, with an optional additional summer of coursework, a Masters degree in Education. A centerpiece of that program is a 5th and final year of paid internship in a school where the student assumes a load bearing responsibility for half day for the entire year and is compensated by the participating school district. There is no traditional student teaching experience. Instead, existing teachers in the schools who have acquired adjunct instructor status through the College of Education mentor these students.

In the course of this program it has become apparent that technology skills among the students in the program varies widely. Some of the students are extremely skilled in the use of technology in their teaching, lesson planning, and overall teaching behaviors. Others come into the programs with less skill and often have deep anxieties toward the use of technology in their teaching. Complicating matters is the uneven experience of the classroom teachers who mentor our students and the lack of appropriate hardware, software, and teaching skills using technology in the schools. Often the personnel in these mentoring schools have little knowledge themselves about how to improve the situation and display a deep lack of knowledge of the content standards and the ISTE standards toward the use of technology at their respective grade levels.

To correct these deficiencies, the College of Education at the University of Cincinnati, in collaboration with the mentoring schools as partners, applied for and has received a PT3 grant to infuse technology throughout its teacher education program and require its students to develop a technology project as part of its capstone experience, just prior to graduating from the program. The faculty in the College of Education Teacher Education program is undergoing training on how to use and infuse
technology in their own subject specific areas. These faculty members are developing technology plans that will explore ways of infusing technology throughout the methods sequence. Our college-based faculty will be paired with school-based faculty in the mentor schools to develop a consistent plan to infuse technology throughout the entire experience.

In addition, the students themselves are expected to create technological solutions to their own teaching in the schools. During the internship year (year five), the students have been required to create a paper portfolio documenting their professional growth through the five years of the program. Typically this portfolio consists of a paper notebook expressing their philosophy of education and teaching, with examples of their work and the work of their own students. The students often include representative examples of their own work (papers, photographs of their own teaching, recommendations from mentors, peer evaluations from their own colleagues, statements of their philosophy of education, and written descriptions of their own teaching style) (Loughran & Corrigan, 1995; Wiedmer, 1998; Darling-Hammond & Snyder, 2000).

There are several problems with a paper style portfolio. First, teaching is a visual medium. If one wants to see how one teaches, they either need to see the person teach in a live format or they need to see a video clip of the person in action. Providing videotapes as part of the portfolio has been very expensive. Furthermore, watching an entire lesson is, at best, intellectually tedious. Video editing equipment has traditionally been too difficult for our students to use to extract small vignettes (3 minute segments). The second problem is that it is so difficult to create even a single paper copy of the portfolio that the candidate is unwilling to leave it for the building principal, department head, or human resource officer to view at their leisure. Since many of our students wish to use the portfolio as a selling tool, they are saddled with the cost of making duplicates of a very expensive document.

Our solution to these problems is for our students to create a digital portfolio that they can duplicate on CD-ROM for under 50 cents a copy (Barrett, 1998; Read & Cafolla, 1999). The digital portfolio includes all of the aspects of the paper portfolio (including sample work, philosophy of teaching, resume, examples of student work) and also includes brief video clips (Barrett, 1998; Read & Cafolla, 1999), in a QuickTime format, of their teaching. This solves several problems. First, the viewer is able to actually watch the individual teach. (All of our interns are videotaped several times during the year.) The vignette can be tied to a standard, or as a demonstration of a philosophy of teaching. For example, if the teacher espouses a Constructivist view of instruction, the implementation of that view in the classroom could be the short video clip in the digital portfolio. Secondly, the cost to reproduce a CD is around 50 cents a copy, plus the cost of the label and jacket. Students can make multiple copies of their portfolio for pennies compared to what it would cost to reproduce a paper portfolio (Wiedmer, 1998). Digital portfolios are also more navigable. Searches on portfolios based on a thematic organizational model can yield specific outcomes much more quickly in digital as opposed to paper format (Niguidula, 1997).

An additional benefit is that building principals under pressure to hire technologically competent teachers are more inclined to hire someone who hands them a CD and says, “here, put this in your CD-ROM and learn all about me and my teaching style, oh, and by the way, I created this myself!” than someone who simply comes in and discusses what they may do with technology in the classroom (Waugh et al., 1999).

A final benefit of the digital portfolio is that lessons that utilize the technology show very well in this portfolio environment. This makes it more likely that our students will use the technology in their own teaching, recognizing that it will be a better demonstration of their own technological capabilities within the digital portfolio (Niguidula, 1997).

Currently we are developing a model of what these portfolios will look like. Several prototype examples have been created. The technology to scale this into an environment that graduates over 200 teacher education students per year is being scoped and acquired. Over the next three years of our PT3 grant we hope to make significant improvements in the approach and plan to collaborate with other PT3 grantees developing similar approaches.

Abstract: The impact a World Wide Web (Web) site may have on any community may be either of two extremes, integrated into the daily activities or barely tolerated, or somewhere in between. The impact a Web site would have if focused specifically upon university faculty, inservice and preservice teacher educators could be beyond the hopes of the creators; however, the usefulness of the Web site must be extremely user-friendly and directly impact the user's daily experiences.

Introduction

The impact a World Wide Web (Web) site may have on any community may be either of two extremes, integrated into the daily activities or barely tolerated, or somewhere in between. Obviously, the positive impact of a Web site within the community is preferable, which is why the thoughtful design, development, testing and revision of such a site must occur in a considerate, painstaking manner. The impact a Web site would have if focused specifically upon university faculty, inservice and preservice teacher educators could be beyond the hopes of the creators; however, the usefulness of the Web site must be extremely user-friendly and directly impact the user's daily experiences. The design and development of a Web site for a Department of Education Preparing Tomorrow's Teachers to Use Technology three-year grant for the University of Houston – Clear Lake is focused upon the preservice teacher candidate, the inservice teacher and the university faculty; further, this Web site must be developed as a self-sustaining environment.

Interactive Environments

Interactive environments aid a Web site in offering useful elements that may be used on a daily basis. For example, chat rooms and discussion lists that are created for specific schools' use makes available the opportunity for ownership and integration into the preservice teacher educator's, inservice teacher educator's, and university faculty's daily harried schedule. The chat rooms and discussion lists would offer innumerable possibilities, such as virtual chats in which the preservice and inservice teacher educators meet to discuss possibilities for future technology-rich activities. Or perhaps the university faculty members would like to integrate weekly chat sessions with groups of preservice teacher educators who are supported at three separate schools through out two districts on either side of a county; instead of the students driving an hour to meet the university faculty member, an online chat room makes available a virtual meeting place where all meeting members will be available for discussions and opinions. This is just one example of interactive environments that focuses upon the learner.
Numerous interactive elements are integrated into a technologically rich Web site that offers innumerable possibilities to the teacher education community. Interactive environments for university faculty, inservice and preservice teacher educators are imperative towards a successful cooperative experience that focuses the energies and attention on the learner.

Web Site Design Elements

There are numerous elements associated with the design of a Web site. Along with these imperative elements are the desired aspects that are to be included within the Web site. Focusing upon the desired aspects, following is a list of areas that are to be developed within the Web site:

- Schedule of Professional Development Opportunities or Events for First-Semester Teacher Educator Candidates
- Schedule of Professional Development Opportunities or Events for Second-Semester Teacher Educator Candidates
- Technology-Integrated Lesson Plans
- Online Professional Journal
- Online Professional Development Opportunities
- Listserv Area
- Discussion List(s) Area
- Chat Session(s) Area
- Site Navigation Structure
- Background Information of the UHCL Professional Development Opportunities Web Site

Each aspect of this Web site will take on a life of its own, with sub-categories within each developing area. The self-sustaining elements that are imperative towards the fulfillment of the Web site vision are integrated into each area of the Web site. For example, the listserv will have form areas to subscribe, unsubscribe and post messages to the listserv, without the added difficulty of moving between digital environments (such as from an Internet browser to the e-mail environment). A second example would be the Online Professional Journal section, where users may upload their developing manuscript and make it available for all users to review. Once the manuscript is uploaded to the server, the reviewers will have the ability to add their comments to a discussion list that will be available at the bottom of the manuscript’s Web page; this offers the manuscript author the ability to obtain relevant feedback from the professional community, as well as offers the professional community the opportunity to discuss evolving theoretical and application-focused manuscripts.

The development environment for this Web site is a Cold Fusion server. The decision to develop this Web site within a Cold Fusion environment was elemental; the design and development team desired a database structure underlying the visual display area, to ensure the seamless integration of information and ease of use. The underlying database structure enables the swift employment of uploaded information within the Web site, without the constant maintenance of a Web site or server administrator. Therefore, the decision to build a Web site around a database structure, specifically Cold Fusion, was an appropriate decision.

Conclusions

The design and development of a Web site creates an environment that impacts the community in either a positive or a deficient manner. The thoughtful inclusion of useful elements within a Web site that is focused specifically upon the needs and desires of preservice teacher education candidates, inservice teacher educators and university faculty can create an interactive environment that focuses upon the learner. Designing interactive environments within the Web site design elements is imperative towards the success of the Web site’s inclusion within a learning environment and its sustainability.
Abstract: Teachers trying the Internet for the first time can get the feeling that all they've based their career on is suddenly wildly shifting. The growth and development of the Web allows us the vision of a community of learners who are literate in information access and use. Can this vision be accommodated in a classroom environment which embraces student-centered inquiry learning and communication?

Introduction

Teachers trying the Internet for the first time can get the feeling that all they've based their career on is suddenly wildly shifting. As pressure is exerted upon educational systems to implement instructional technologies, teachers' abilities to accept change and adopt innovations become key factors for success. The growth and development of the Web allows us the vision of a community of learners who are literate in information access and use. Can this vision be accommodated in a classroom environment which embraces student-centered inquiry learning and communication?

Teachers adopting the Web into their teaching toolkit are presented with a large set of possible teaching techniques. The Web with its elements of text, hyperlinks, graphics, photographs, sound, animation, and video generally allows nonsequential or nonlinear access to the elements providing for flexibility and interactivity (Levin & Matthews, 1997.) With its multimodal presentation, Web-based instruction can be effective for accommodating the needs of different learners in learning cognitive and procedural information (Ayersman, 1996). Computer technology in general has not had the impact expected in the schools because of inadequate preparation of teachers (Dupagne & Krendl, 1992; Ingram, 1994). Will the same findings prevail with the innovation of the Web?

Preliminary research has begun to reveal whether professional development can be designed to help teachers find a starting level with the Web within their comfort zone. There is a wide range of entry points for methodology. Introducing the Web as a teaching and learning tool is an innovation that needs a supportive social environment in order for diffusion to occur. (Rogers 1995). Teaching in a high-tech classroom situation involves risk and loss of control for teachers. This may be explained by MacArthur et al.'s (1995) findings that an unexpected obstacle to success in implementing technology was that the teachers became competent with computers but were overwhelmed by a fear of their students' misbehavior. Alleviation of the concerns this loss of control causes may spring from observations of good experiences of peers.

Web Methods

The point of entry for methods for using the Web can start at various levels. A teacher can provide guidance for students by printing a list of websites on paper. A next step might be organizing personal bookmarks and loading them on the students' machines to use. Going further, a Web page with links for students can be made with a template (such as Filamentality, Geocities, or School Notes). Research for students can also be guided by making a Web page with an editor (such as Composer, Dreamweaver, or Front Page) or going even further by building a Web page using html code.
Other methods for using the Web for instruction can include printing material from the Web for display or transparencies, using lesson plans found on Web, or writing lesson plans and putting them on Web. In addition, a teacher may use search websites (such as Google, Dogpile, or Hotbot) to find content or teach students effective methods for search sites. Good teaching about search methods will include teaching students proper Web reference citation style. In addition, design of instruction can include downloading data from Web, submitting data collected by students to a website, students making Web pages for presentations, using the Web as a source for PowerPoint presentations, and downloading images.

Examples of Classroom Practice

Describing examples of classroom practice with the Web may help teachers find a way to bridge from their tried-and-true teaching methods to incorporating new technologies. These can range from online scavenger hunts to virtual field trips to interaction with Java simulations or be as simple as printing Web pages to hang on the bulletin board or use with the overhead. Other examples in use are free student research, guided research as in building a webzine or WebQuest (Dodge 2000), and online quizzes. Communication examples include online discussion boards, cooperative experiments between distant classrooms, and talking to an expert online. This technological environment in classrooms can serve the needs of many types of learners and can be an asset for the teacher willing to approach students as a facilitator (Heller, 1990).

Early Results

Results of workshops taught by the MentorNet project at NC State (Park & Grable 2000) and the Science House (Grable 1999) may serve as an outline for designing workshops for teachers and may suggest further avenues of research. In an exploratory study a group of 50 teachers from three high schools in a rural eastern North Carolina school district were given access to the Web (in classrooms and the media centers), received two days of training with the Web, and were asked to incorporate the Internet in their teaching. The teachers responded to surveys and were observed teaching after six months of computer and Internet availability. When listing the skills and concepts used in teaching on a free response item, 45% of the teachers had used searching in the media center, 5% had made a Web page, and only one teacher had used the Internet in the classroom.

The teaching methods most often used were students searching (14%), downloading data (13%), printing Web pages (13%), finding lesson plans (12%), and teaching the students proper Web citation (10%). The least used methods involved contributing to the Web, i.e. writing Web pages, submitting lesson plans, etc.

The Web activities most often used were research projects, printed Web pages, and online worksheets. The Web activities most often never used were WebQuest, online discussion, and encouraging the students to talk with an expert.

These results indicate that teachers may need more instruction and modeling in areas of Web use where interaction and communication are involved. To encourage more use of the Web in the classroom may involve providing observation opportunities or videos of teachers who are successfully using these techniques. To encourage teachers to produce their own content to contribute to the Web, or to encourage Web page writing by students may mean finding quick and easy page building methods and demonstrating the learning gains possible with these techniques.

Abstract: “Preparing Teachers to Deliver Technology-Rich, Problem-Based Learning Experiences” is a PT3 catalyst grant for the state of Mississippi. The project is a collaboration between the Mississippi Research Consortium members, partner community colleges, and local school districts. The main goal of the project is to infuse technology and hands on science practices in the Mississippi Educational System. This is being accomplished by training elementary education candidates in a technology-rich environment. Training is provided to elementary education candidates as well as their faculty and the teachers with whom they complete their field experience.

Preparing Tomorrow’s Teachers

The goal of providing a technology-rich learning environment for elementary education candidates in Mississippi has been accentuated by a grant funded by the U. S. Department of Education. The grant “Preparing Teachers to Deliver Technology-Rich, Problem-Based Learning Experiences” is made possible through the Preparing Tomorrow’s Teachers to Use Technology (PT3) Program. The Mississippi Research Consortium, made up of Mississippi State University, Jackson State University, the University of Mississippi, and the University of Southern Mississippi, provided the basis for the promotion of the project.

Consortium Training

Consortium members are providing training for university and community college faculty, mentor elementary (Grades 1-8) schoolteachers and elementary education candidates. Training includes the GLOBE protocols for elementary schools, assistive technology, and training concerning the use of technology in the classroom. The consortium members are collaborating with community colleges and school districts in infusing the technologies.

In an effort to better prepare education professionals for the diverse classroom we are providing opportunities for them to become familiar with the need to address accessibility issues. We have also provided avenues for increasing awareness in addressing these issues.

Elementary Education Candidates

The elementary education candidates are being introduced to the GLOBE (Global Learning and Observations to Benefit the Environment) protocols. Candidates are learning to collect scientifically viable data, how to report them to an international database, and how to use the database to visualize data and to conduct experiments. They are using hands-on activities and technology-rich content in preparing lessons. Working with mentor teachers, they will learn how to implement these techniques in their field placements.
Training for participants in the use of various presentation and productivity software has been initiated. Topics covered include: the use of office products (word processing, spreadsheet...), classroom specific products (grade books, lesson planners...) and research specific products (encyclopedias...). Special training has been conducted in the use of the Internet and other software for teaching. A Project Learning Tree Workshop was held last summer for elementary teachers.

Summary of Accomplishments

- Held workshops for faculty (topics included: Productivity Tools, Adaptive Technology, Internet Resources and Searches, Power Point, WebCT, Arcview GIS, Global Positioning System (GPS and Remote Sensing) and in-service teachers (topics included: Productivity Tools, Adaptive Technology, Internet Resources and Searches, GLOBE, and Project Learning Tree) during the summer.
- Presented topics on Web searches and Adaptive Technology to pre-service classes in March and April.
- Put technology pre survey on the web for use by all 4 sites to collect baseline data for faculty, teachers, and candidate teachers.
- Compiled and submitted IRB for human subjects approval for all 4 sites.
- Coordinated schedule for training pre-service teachers in the fall.
- Presented “GPS and Plastic Recycling” at the Jackson Public School Environmental Learning Center summer camp on July 19, 2000. Graduate assistants helped forty summer camp students (grades 1-10) learn how to use GPS handheld receivers.
- Collected data on student and teacher technology needs.
- Assembled Teacher Education Council and Faculty support committee (PT3 Advisory Council).

Significance

Over the last several years educators across the Mid South, including Mississippi, have made a concerted effort (a) to develop and disseminate K-12 curriculum guides in mathematics and science that are aligned closely with associated national standards and place heavy emphasis both on the use of constructivist-based, “hands on” and “field-based” (NCATE 1996) learning activities; (b) to look closely at, if not adopt, the new standards for instructional technology proficiency prepared by the International Society for Technology in Education (ISTE 1999), and (c) to allocate hundreds of millions of dollars to facilitate LEA-level development of technology plans and related implementation strategies directed toward ensuring that every school district has the hardware, software, and level of connectivity needed to integrate technology into their K-12 instructional offerings. This focused effort of reform and technology infusion occurring in public schools across the Mid-South is taking place in an educational environment made up of many very poor, rural school districts that are striving to improve the educational offerings of needy students (Stone 1989; The Annie E. Casey Foundation 1997; Mississippi Department of Education 1998). This challenge is further exacerbated by a narrowing field of well-qualified teachers, who have much needed experience in the areas of mathematics, science, and special education (Mississippi Public Education Forum 1998).

While there has been a significant commitment to reforming mathematics and science education in K-12 public schools as well as enhancing the utilization of technology in instruction, no comparable, parallel initiative has been undertaken to ensure that teacher education faculties or the faculties in Arts and Sciences responsible for providing the subject matter expertise to teachers

- Have kept abreast of the significant changes occurring in grades K-12,
- Have acquired the requisite background and skills needed to use the array of new technologies in their own teaching (i.e., to concretely demonstrate how those new technologies can be effectively integrated into their respective subject areas), or
- Modified their teaching strategies to reflect the content, procedural, or technological changes that are occurring.

Thus faculty in Teacher Education and Arts and Sciences are becoming generally unfamiliar with the new technologies and their applications to instruction.
Purpose

With this in mind, the purpose of this project is to strengthen the teacher preparation programs in the partner institutions. The associated goals are: (1) to provide professional development opportunities for both Teacher Education and Arts & Sciences faculties across Mississippi, particularly with regard to the infusion of (a) different technologies, including the array of adaptive technologies available to help serve special needs learners, and (b) an inter-disciplinary, problem-based perspective into the post secondary curricula for which those faculties are responsible, and (2) to initiate a programmatic pre-service teacher preparation effort focused on helping elementary education candidates learn how to effectively create and integrate technology-rich content and to use constructivist-based, "hands on" teaching strategies in mathematics and science.

In order to achieve the preceding purpose, the members of the Mississippi Research Consortium (MRC), and a cooperative alliance among the four major research universities in the State, are serving as the primary partners for the project. This arrangement builds upon existing linkages among consortium members (e.g., their ongoing commitment to having faculty certified as GLOBE trainers who have subsequently been involved in training K-12 teachers to use the environmental education curriculum) and capitalizes on the partners' ongoing efforts to enhance the quality of their respective teacher preparation programs in accordance with Mississippi Department of Education (MDE) guidelines and NCATE standards (NCATE 1996 and 1999). At the same time, the Consortium partners are working to address the State’s growing teacher shortage—the four partner institutions prepare almost 90% of the new teachers in Mississippi. Additionally, the overall effort is supported by the State’s Commissioner of the Institutions of Higher Learning (IHL). This broad base of support, coupled with the intent of the collaborators to involve as many other teacher-training programs in Mississippi and the surrounding states is seen as increasing the probability that the project will result in sustained changes in pre-service teacher preparation across the IHL system in Mississippi.

As presently envisioned, during the first two years of the project the primary consortium partners are initiating the immersion of lower division potential elementary education candidates in a field based experience that is interdisciplinary, problem-based in nature, involves technology-rich content and learning processes, and affords them multiple opportunities to observe and engage elementary students in an active constructivist-based, "hands on" learning environment.

Conclusion

Acquainting the targeted pre-service candidates, from their very first exposure to an "education" course with concrete applications of different interdisciplinary problems/issues, meaningful and programmatic examples of how to utilize technology to foster learning, techniques for helping to address the unique needs of diverse groups of students, and ways to foster active, "hands-on" learning offers a substantial realm for progressive accomplishments. The Teacher Educators and the Education and the Arts & Sciences Faculties serve to reinforce and expand Education and content area courses.

Overall, the project is contributing to major, systemic improvements in the pre-service teacher preparation programs offered by the cooperating partners. The fact that the four MRC universities prepare roughly 90% of all the new teachers in Mississippi means that the project will directly impact 500 or more pre-service elementary education candidates per year. When those candidates graduate they will represent between twenty and twenty-five percent of the total number of new teachers entering the State’s educator workforce every year. Furthermore, the proposed strategy and associated materials will serve as the foundation for a model that can be replicated more broadly across other teacher preparation programs.

Technologically Enhanced Cornerstone Courses: A High Impact – Low Cost Approach to Modeling Technology for Pre-service Teachers

Kendall Hartley
Department of Curriculum and Instruction
University of Nevada, Las Vegas
United States
khartley@nevada.edu

Abstract: This paper reports on the project rationale and design of one initiative to better prepare preservice teachers to integrate technology into their future teaching. This project, technologically enhanced cornerstone courses, brings together teams of teacher educators to redesign large courses taken by most of our preservice teachers. These teams also worked to develop research questions related to the project. By focusing on the large courses taken by most of the preservice teachers the impact of the project is high.

Introduction

Our college of education has a goal to make technology infusion a systemic component of preservice teacher education. Several initiatives have begun in support of this goal. This paper will report on one such initiative, the development of technologically enhanced "cornerstone courses." These courses generally have large sections and are taken by most preservice teachers in our institution. We feel that it is in these courses that we can impact a large number of preservice teachers by modeling effective uses of technology. In addition to the modeling of technology, we are interested in how technology can help develop a more student-centered approach to instruction in large classes.

Project Rationale

The rationale behind this project is two-fold. First, we believe that the modeling of technology integration is key for preservice teachers. There are several opportunities for the teachers to experience the modeling of technology in the classroom. They may see it used in their own K-12 schooling, in the teacher preparation program or in field experiences. We obviously have little control over their own K-12 experience as a student, but we can impact their teacher preparation and field experiences. However, without a concerted effort on the part of the institution as a whole, the experiences will be haphazard. The same course may have one instructor who is well versed in the integration of technology while another may completely avoid its use. This project will focus on modeling technology use in the courses taken by preservice teachers.

The second component of the rationale behind this project is that lasting change must be generated from the bottom up. In other words, mandates about technology use in teacher preparation courses will be much less effective than supporting teams of educators in the development of effective and appropriate technology integration strategies. These teams of educators have a variety of competing demands on their time and energy. Technology integration must work in concert with these demands to make any lasting impact. Beyond the demands of teaching, these educators also have a substantial research commitment. By learning about the interests of these professors, the project facilitators will work to incorporate these interests in meaningful ways through the use of technology.

Project Design

Six courses that are taken by a large number of preservice teachers will be redesigned in three years to incorporate a more learner-centered approach through the use of technology. We refer to these courses as "cornerstone courses" as they are either requirements in the teacher preparation program or are taken by a
A large percentage of our preservice teachers. Three courses will be chosen from within the college of education and three will be from other colleges in the same university. The courses within the college were selected based upon the recommendations of the various department chairs in the college. The courses outside the college will be selected through an application and selection process.

One course within the college will be targeted each year. Participants in each cornerstone course project include the project facilitator, a coordinator and course instructors. The role of the facilitator will be to provide technical and pedagogical guidance. The coordinator will be a course instructor who also agrees to be the point person for the project. The hope is that the coordinator will take a lead in encouraging implementation now and in the future. An important goal of the project is to insure the activities are not simply viewed as a one-time occurrence, but rather become a part of the culture of that particular course. The coordinator will also play a key role in identifying the needs of the course and the best way to infuse technology in a way that will increase student centeredness. The course instructors who choose to participate will be involved by implementing the enhancements developed.

Each course identified in the cornerstone project will likely result in a wide variety of approaches. The participants are charged with enhancing the identified course by utilizing technology to increase the student-centeredness of the course. How they go about this is ultimately up to them and again can be guided by their own interests. The facilitator’s role is not to dictate the approach but rather to listen to needs and provide suggestions for addressing those needs. Below is a description of how these development activities progressed with the first course targeted, Introduction to Educational Psychology.

The First Cornerstone Course: Introduction to Educational Psychology

This course certainly met the criteria of a cornerstone course by being a required course as well as the fact that the sections are quite large (about 60 students) and getting larger each year. This course was also appealing because of the large number of full-time faculty that regularly teach the course. The large number of faculty would insure that the impact of the project would be broad. One of the first steps in the process was to identify the participants that would be involved in the project. The natural choice for the project coordinator was a professor who had participated in some previous technology integration initiatives and also served as the coordinator of this course for the department. The other participants were recruited from the pool of professors that regularly teach the introductory course. All four of the professors who regularly teach the course expressed an interest in participating.

The coordinator and facilitator met regularly during the first semester of the project. These meetings turned out to be very fruitful in terms of project design and scholarly inquiry. During these meetings, two main course enhancements were identified. The first activity was to develop Web “Case Pages” for use in the course. A case page will be a multimedia Web page that describes a case that exemplifies a course concept or presents an opportunity to apply a course concept. For example, a case page could describe the concept “learned helplessness” by describing relevant research, showing a video clip of a student explaining why she cannot perform a task, links to other information sources and reflection questions. Case pages will be used to set the stage for class and bulletin board discussions. They may also be used in a distance-learning version of the course.

The second activity focused on scaffolded discussions. Advanced discussion board “modules” will be developed and then utilized throughout the course. These modules will utilize the most current ideas in the areas of computer supported collaborative learning (Koschmann, 1996) and knowledge building (Scardamalia & Bereiter, 1991). The approach used to facilitate the scaffolded discussions will be determined through a literature review of the above areas. It is expected that the review will produce several alternatives programs and/or approaches to the facilitation of these discussions. To make plausible the use of the case pages and scaffolded discussions, the project facilitator will work with the participants to move their courses online with WebCT.

Once the main activities were identified, we then delineated the expectations of each of the participants:

Coordinator

- Supervision of Case Page development
- Discussion board questions (scaffolds)
- Sharing with course instructors
- Participate in orientation meetings
- Meet w/ facilitator every two weeks

Facilitator

- Work with case page development
- Research scaffolding software (e.g., Knowledge Forum)
- Work with course instructors
- Coordinate participant meetings
- Meet w/ coordinator every two weeks.

Course Instructors

- Participate in two orientation meetings (prior to implementation)
- Participate in three meetings (two during implementation and one end-of-semester)
- Use WebCT
- Integrate Case pages and scaffolding tools into their courses

Needs related to the project were then discussed. It was clear that a Web development person was necessary to develop web case-pages, provide assistance with capturing the multimedia materials necessary for the cases and developing a home page for the course that could be used by all the sections of the course. Other needs included materials such as software (e.g., scaffolding program such as Knowledge Forum and video editing software) and hardware (e.g., video capture equipment). These needs and a small stipend for each of the participants would be funded by the Preparing Tomorrow’s Teachers for Technology grant program.

Research Potential

A key component requirement of this project is that the activities meet several needs and not be limited to the need to model effective uses of technology. The instructors involved should also have the opportunity to use the project as a way to address some scholarly questions. By using electronic tools such as Listservs and WebCT, data collection becomes much easier than traditional methods. When the participants learned about some of these tools, they immediately envisioned several scenarios that were ripe for investigation.

As a result of the team discussions, several research projects were discussed. The first project will report on the efforts of the faculty to renovate the courses through the use of technology. This project will utilize a listserv as a forum for discussion of the group activities, trials and successes. Several different levels of expertise are represented in the group of instructors and it will be interesting to follow the discussion between them as the course proceeds. Another project will compare the perceptions of students in sections before and after the course improvement. One of the problems with a large introductory course such as this is that students fail to see connections between the course content and their goals and experiences. Our hope is that the use of technology will help make some of these connections by fostering greater communication with their peers.

In addition, to research projects that will review the cornerstone project, several other studies will be conducted the deal more directly with the interests and expertise of the participants. The coordinator for the Educational Psychology course is interested in argumentative reasoning and will investigate several research questions while observing the course discourse in the online bulletin board. How these discussions are facilitated is an area that is in dire need of investigation. Other members of the group are interested in various learner characteristics that they have studied in more traditional forums. For example, one member is interested in the relationship between epistemological beliefs and achievement. How these beliefs impact students participation in the online discourse is another area the will be further investigated as a result of this project. Investigating so many questions in one semester would be extremely difficult if it weren’t for
the collaboration that has occurred and will continue to occur during the implementation of these course enhancements.

Discussion

While the activities related to the project have only just begun, it is clear that the approach has the potential to have a lasting impact for virtually all of the preservice teachers in our program. It has also resulted in some powerful collaboration between different departments in the college both in terms of pedagogical and research issues. Insuring the next generation of teachers can use technology in an effective way will require a systemic and multifaceted reform of our teacher preparation programs. The cornerstone course can play a key role in that reform.

Technology In The College Classroom - Preparing Teachers To Use Technology

Betty Hatcher, Gerald Burgess, K. C. Chan, Barbara Holmes, Rani George

Abstract: The panel presentation herein shares strategies and outcomes of the implementation of the SOWEGA PT3 (Preparing Tomorrow's Teacher to use Technology) Project at Albany State University (ASU). The strategies are: (1) infusing technology into core courses that will serve as models for future teachers, (2) providing technology training to faculty in collaboration with the Education Technology Training Center to strengthen technology competence system-wide, (3) encouraging the development of technology-intense course materials, (4) awarding mini-grants to faculty members who will promote the interests of the SOWEGA PT3 project, (5) targeting pre-service teacher for Intensive Technology (Intech) training, and (6) collaborating with area schools to encourage student teachers utilizing technology at schools where they are doing student teaching. The PT3 project has fostered multi-disciplinary activities that promote active use of technology.

Introduction

The SOWEGA Project is the Preparing Teacher To Use Technology (PT3) - funded initiative on the campus of Albany State University, a 100-year-old historically black university in southwest Georgia with a College of Education that graduates over 140 teachers each year. To prepare graduating teachers proficient in using technology in the classroom, the SOWEGA Project proposed a multi-disciplinary effort across the Colleges of Education and Arts and Sciences that would engage college faculty to model technology-rich teaching. Using this approach, a mini-grant process enabled faculty to address changes through revising syllabi, taking training courses in technology applications, working with technology-trained K-12 faculty and student teachers.

The panel presentation intends to share outcomes of the first 18 months of this effort, using evaluation outcomes and faculty participant interaction to enrich the panel. College faculty in mathematics, in the natural sciences, in English and modern languages, in social science and education courses revised their teaching strategies. In the course of designing new syllabi, faculty all engaged in a training process designed for Georgia teachers, called Intech. This intensive 7-day process uses skill application from Microsoft Office, coupled with other software and Internet tools to guide participants through a process that results in four new one-hour lesson plan designs. The InTech model is being adopted in other states for its excellence and relevance to INTASC standards for technology in the classroom.

Student teachers are also engaged in going through the InTech process, which has recently become a requirement for re-certification in Georgia. A culminating activity held at the end of year one was the "Summer Seminar," a day filled with presentations shared by SOWEGA Project mini-grantees, student teachers and K-12 teachers who completed the year of learning to enrich teaching through applications of technology. Some outcomes of the first year include: revisions of critical core courses, including Trigonometry or Pre-Cal, a process that engaged all mathematics faculty who periodically teach the course. One immediate outcome has been that 90% of the mathematics faculty have been trained in Intech, exceeding the proposal objective expectations; the faculty in English and Modern Languages also experienced a high rate of participation in the Intech training. In Teacher Education three faculty revised the Foundations of Education course and other faculty revised a reading course to produce student-produced multimedia books. In physical science, one of the core lab sciences taken by teacher education and all other majors, faculty used Java programming to design a web-based simulation of basic principles of physics; and in history, faculty revised syllabi to enrich core courses using Internet resources. It is sharing of the cross-disciplinary efforts demonstrated in the SOWEGA Project, resulting in new technology skills for college faculty and for teacher education students that will be the focus of the panel presentation.

The first presenter of the six panelists, Betty Hatch will introduce the vision and planning of the project. Then Gerald Burgess will present the importance of Intech in PT3 project. Next Samuel Math will provide insights on faculty development and implementation of a technology-intense Pre-calculus course. Our third presenter Rosemarie Mundy-Shipard will share the excitement of infusing technology in English and social science courses. Next K.C. Chan will showcase the infusion of Java simulation technology for natural sciences and web database for the e-commerce. And finally Rani George will present a summary of the progress of the SOWEGA project using the results and findings of both the internal and external evaluations.

Panelist 2: Gerald W. Burgess, New Roles in Teacher Education: Creating Technology Connected Lessons

The media's attention on our nation's dependence on computer technology has no greater evidence than the impact of Y2K. Website addresses have become part of the language where the phrase "dot com" permeates our speech and is seen on billboard advertising. As future teachers move through our schools of education, technology is being taught as both an educational delivery method and instructional communication tool (Intel, 1999). Quality teaching in the 21st century will require teachers to be knowledgeable about a technology influenced student body and how to create learning environments, which integrate technology in the support and delivery of instruction. Teachers in the new millennium should view technology as a cognitive tool that has the potential of encouraging inquiry-based learning and reinforcing instructional concepts. Planning technology connected lessons will require teachers to think more creatively about how students learn and plan lesson which respond to the vast variety of learning needs. The positive effects of technology far outweigh their disadvantages when applied correctly. The greatest effect is that of contextualized learner-centered activities with the emphasis placed on student learning not teacher teaching. This multimedia paper will discuss technology connected lesson plans, their impact on teaching, student motivation and instructional delivery. The authors will outline strategies for developing technology connected lessons and discuss a model used by the Georgia Framework for Integrating Technology in the classroom.

Colleges of Education, especially those in teacher education, are entering a new era if they are not already in it. It is the era of the Technology Connected Lesson. The new technologies of the late-1990s, television broadcasting, satellite transmission, Microcomputers, the Internet, and the World Wide Web (WWW) are shaping the way we deliver information in the classroom. It's not so much that lesson planning is different today than 20 years ago, but planning a technology connected lesson today has more to do with the way we think about technology, use it, and focus student's attention on it. Technology is a tool. It's not the process, it's not skill development, it's a tool to research, communicate,
and to publish. The problem is that we continue to think about lesson planning the way we did 20 years ago in terms of delivery of information rather than student involvement with the information and knowledge we expect them to gain. This paper will explore some of the issues surrounding developing Technology Connected Lesson Plans and their impact on teaching, classroom, student motivation and instructional delivery. The authors will strategies for developing lesson plans and discuss a model used by the Georgia Framework for Integrating Technology into the classroom.

InTech Program Description:

InTech is an intensively structured, 50-hour, Georgia Department of Education Professional Development Program. It provides many examples of effective technology-based strategies that support and enhance curriculum and can serve as a catalyst for fundamental change in the overall teaching and learning processes. One of the strengths of the program is peer-instructor modeling of technology-connected lessons. Developing skills in the following five critical areas characterize this integrated training approach: (1) Use of Modern Technologies, (2) Curriculum Integration, (3) Designs for Learning (4) Enhanced Pedagogy and (5) Classroom Management. Participating teachers learn basic technology skills while focusing on project-based activities that use Georgia’s Quality Core Curriculum.

Initial training includes five-days and two follow-up days. DOE and DOE Regional ETTC’s coordinate the on-going training of trainers and the publication of technology-connected lesson plans. Support for this training will make extensive use of the Georgia distance education networks, Peachnet, PeachStar and GSAMS.

Program Criteria: School Principals will agree to:
- Select a team of five teachers from selected critical content areas and grade levels, or technology specialists and/or administrators. The team will agree to the requirements for participants listed below.
- Plan for seven release days from classroom duties for each team member.
- Plan to provide a multimedia workstation and software for each participating teacher.
- Attend an information session prior to the first training day.
- Attend a minimum of 10 hours of InTech training.
- Attend two one-half day workshops: #S775 Understanding the Classroom Module and #5880 Evaluating Teachers in a Technology Connected Classroom.

InTech Participants will agree to:
- Attend seven eight-hour training sessions (8am-4pm).
- Critically examine their own instructional practices to determine how technology can play a role in enhancing the teaching and learning process.
- Implement four technology-connected lesson plans and complete all InTech assignments (journal reflections, professional readings, email responses, etc.).
- Develop a group project that displays teacher-created materials and student-created projects developed during InTech. The project may be a tri-board, portfolio, electronic portfolio, etc.

Creating Technology Connected Lessons require a change of perspective, a process, standards, and the teacher. The place to start is with the curriculum – your expertise. Technology-connected activities should be based on ideas and concepts that you are teaching, with the activities bring of critical importance to what students need to learn. As plans are developed, technology is used as the tool or the vehicle for acquisition, organization, evaluation and application of knowledge. Teachers in the new millennium should view technology as a cognitive tool that has the potential of encouraging inquiry-based learning and reinforcing instructional concepts. Planning technology-connected lessons will require teachers to think more creatively about how students learn and plan lesson, which respond to the vast variety of learning needs. The positive effects of technology far outweigh their disadvantages when applied correctly.

Panelist 3. Samuel Masih (Mathematics and Computer Science), Pre-Calculus Instruction Incorporating Technological Tools

The purpose of this activity is to provide a model of teaching and learning using the technology. In order to implement this objective, the PT3 provides mini-grants for mathematics faculty to acquire any technological tools and necessary release time as needed to revise their syllabi and to develop technologically rich lessons for presentation and delivery of course content. The intent of the mini-grants was not to teach the students technology know-how, but to construct an effective model of applying the technology in their teaching. This project incorporates technology in the pre-calculus course, which is required of all mathematics and science pre-service teachers and is taught by arts and science faculty. Since there are several sections of pre-calculus course, it became evident that in order to truly implement this objective all sections of pre-calculus would have to participate in this venture. For this reason there are five faculty in the Department of Mathematics and Computer Science that are Co-PI’s in this mini-grant. The strategy for incorporating technology in the pre-calculus course was to develop a common syllabus for the course that addresses the use of technology. Fortunately, the Department of Mathematics and Computer Science at Albany State University already had many of the needed technology components that could be used to accomplish the objectives in the mini-grant. The course was redesigned to incorporate several major technological tools in the delivery of the course content. These were as follows:

1. Interactive Pre-calculus Software (IPS)
2. Maple V mathematics software
3. Access to the Internet
4. Technology Training Center (INTECH)
5. Microsoft Office Tools such as Power Point
6. Graphing calculators such as TI-83

All faculty in the mini-grant took INTECH training in the summer. Each faculty developed some technology rich lectures that could be shared by other faculty. A web-based tutorial system was developed for the course that provides common syllabi, study guides, homework assignments and help on the homework assignment (http://www.asuemath.asunet.edu/precalc). From this page a student could branch out to
specific assignments given by individual faculty. Access to the page is authenticated to keep track of the use of the web-based activities in a database. The database keeps records of student activities and provides feedbacks to individual faculty about their student activities for the purpose of evaluation. This page also provides means of collecting data on the web about students in the pre-calculus course.

Another important component in the course is the use of the existing Interactive Precalculus Software (IPS)(http://www.imacs.org/httiOnewton.asurams.edu/precal). This software provides interactive multimedia instruction in the precalculus. The software is installed in the computer laboratories and is made available to students and faculty. It is used by the faculty for providing interactive simulations in the classroom as a part of their lecture and to subsidize instruction. The software is useful in simulating discussion in the classroom. Students who are not doing well in the class are required to go to the laboratory and use the software to remedy their weaknesses. The computer laboratory also provides access to Maple V software. Maple V is a powerful software tool for doing mathematics and a great tool for simulations and graphing in the classroom. General workshops are conducted outside the classroom for the use of IPS and Maple V. Students are required to attend the workshops. As an incentive, the students earn 10% of their grade through doing activities using technology.

Several pre-service teachers are hired as student assistants by the mini-grant faculty. The faculty act as mentors to these students and use them in creating technology rich lessons and web-based material for their classes. These students are required to take INTECH training. An in-service teacher in the school system is associated with the mini-grant. The pre-service interns visit this teacher’s classroom and provide help in the incorporation of technology rich lessons.

Outcomes. The following table shows the impact on arts and science faculty and pre-service teachers. A survey instrument is used to determine the number of pre-service teachers in the pre-calculus courses. A survey instrument is used to determine the number of pre-service teachers in the pre-calculus courses. An evaluation survey is conducted to use the impact of the use of technology. The following table provides a rough data concerning technologies used in instruction.

| Percentage of potential Education majors in pre-calculus courses in the Fall 2000 |
|---------------------------------|------------------|
| On a scale from 0 to 5 the result of the Technology Survey is as follows | 29 |

| 1. The use of Interactive Precalculus Software in the class in teaching | 4 |
| 2. The use of Interactive Precalculus Software installed in the computer laboratories | 3 |
| 3. Web-based exercises and homework assignments | 3 |
| 4. Help provided for the Web-based exercises and homework assignments | 4 |
| 5. Workshop in the use of Maple V software teaching | 3 |
| 6. Using graphing calculator | 4 |
| 7. Over all technology use in the class room | 4 |

Table 1. Percentage of potential education majors in pre-calculus courses in the Fall 2000

Some of this data is incomplete at the time of the writing of this paper. At the end of the Fall Semester 2000, all the data will be looked at for seeing the impact of all the technology components incorporated in the mini-grant.

Panelist 4: Technology Infusion in English Classroom, Rosemarie Mundy-Shephard (English)

The implementation of Technology Infusion in the English Classroom carries the following components: selection of the English Composition II-1102 course for technology infusion, in-depth training for pre-service (student) teachers, forming partnerships with service elementary and middle school teachers in prompting the use of technology, and, most importantly, establishing a technology team in the English Department at Albany State University. English Composition II was targeted for the implementation of technology. The students were first given a pre-course survey to gauge their technology backgrounds and attitudes. To demonstrate the use of the technology in teaching English, wireless laptops were used in the classroom by students to perform literature searches via the Internet, some learning games were designed (such as Dante’s Inferno Game) to arouse students’ interests, and the digital camera was used to illustrate the power of imagery in conjunction with literature. Parts of these activities supported the technology-enriched assignments for the students. For instance, to prepare for the full participation of the game, students completed a rigorous review of their work. Also, students tested their literal learning and review online as they competed and answered trivia questions on the assigned readings. Overall, students in the English Composition 1102 class completed a basic search for research materials, learned about useful composition websites and sent email communications to the instructor and at least one other student in the class. Moreover, instruction was enhanced because students enjoy using computers for research. All the work described required intensive preparatory effort. Pre-service students were required to participate in the implementation of the above strategy. The pre-service students attended an intensive In-Tech training class, where they learned how to use hardware (digital cameras, scanners, printers, laptop computers, and zip drives) and software (such as Microsoft Office Excel, Database, and Inspiration). These pre-service teachers also prepared Newsletters and created a Totem and templates for assignments, involving every aspect of preparing technology for teaching. To further prepare the student teachers for technology, we have established partnerships with in-service teachers in the local schools. In the process, these teachers were In-Tech trained as well. Because of the pilot project, we have generated enough interest in the department to assemble a team of teachers interested in adopting the technology and continuing the expansion of infusion of technology into the classroom; four of the full-time faculty members on the team were In-Tech trained because of the process. In conclusion, PT3 has made a significant impact on the Department of English to incorporate the use of technology core-level English instruction.

Panelist 5: K. C. Chan, Infusion of Java Interactive Technology into the Physical Sciences (Natural Sciences) and Infusion of the Web Technology Into Fundamental Computer Applications (Bus. Admin., Chihou-Ping Wang)

A. Infusion of Java Interactive Technology into the Physical Sciences

Science is a difficult subject to learn because it involves concepts based on dynamic events and spatial entities that are awkward to be presented on 2 dimensional media such as textbooks and blackboard. Computer technology has broken this barrier and the Web has rendered
computer simulation and visualization tools widely available. Thanks to Java technology, Web browsers today are capable of performing highly
interactive computer simulation for all kinds of science disciplines. Many high quality interactive Java applets for sciences are available on the
Internet. The Interactive Java Project supported by the SOWEGA PT3 has decisively helped introducing Interactive Java into physical science
course PHYS 111YK offered at Albany State University, a core course required by non-majors and education students. The intention of the project
is to provide a learning and teaching model for student teachers who take this course.

The implementation of infusion of interactive Java includes the following stages:
1. Develop and compile existing Java applets that are suitable for physical science curriculum.
2. Train the student to write his or her own web pages and use InTech for files access.
3. Train students to use the applets selected for the class project.
4. Ask students, as a class project, to develop an instructional web page based on their understanding of the applets and integrate it with
   the applet to develop a lesson page—not a lesson plan—to teach their fellow students the content conveyed by the applet.

This project is technologically intensive for the students in the course. First the student spent 10 hours learning how to create web
descriptions via the InTech program. Then each student had to select an applet related the course content or be assigned one in random. The student
must then master the content knowledge of the applet and the idiosyncrasy of operating the applet before creating an effective lesson. Then the
student would present the result before the class. Students who had successfully finished the project would have a good grasp in how to apply
interactive technology in teaching science and how to tap into vast Java resources available on the Web. Consequently, the project has
developed three interactive Java applets in house plus more still in development. Table below list eight such applets representing phenomena that
are easy to understand when simulated but hard to understand when present in static media.

<table>
<thead>

</tr>
</tbody>
</table>

Table 2. Selected applets

Evaluation. Students performance was evaluated not by objective testing. Instead students were graded according the following rubrics:
1. Do students understand the concepts well? (Based on student presentation and from the contents of their web pages)
2. Could a third person follow the instructional steps constructed by student author to use the applet effectively and correctly? (i.e. is the
   instruction clear and easily to follow?)
3. Are the steps or construction of the lesson clearly leading to learning objectives conveyed by the Java applet?
4. Are the concepts and instruction steps coherently represented?
5. Are student technology competent?
   - Can the student create the web page and upload it to the server location successfully
   - Can the student transfer file via the Intranet?
   - Can the student manipulate the Applet?
   - Can the student use the multimedia equipment to present the result properly?

Outcomes. Basically we have accomplished the mission of infusing technology into the classroom in a way that students can apply their new
skills in how to use the technology for learning and teaching. The outcomes of the project could be viewed in two aspects: the technology know-
how and the content knowledge. Since our emphasis is on content knowledge based on the foundation of technology, the outcomes of the project
could be tabulated as shown in Table 2. In the end, eight web lessons were created.

Infusion of the Web technology into Fundamental Computer Applications, Chiou-Ping Wang P. (Department of Business Administration
and Education)

Microsoft InterDev 6.0, HyperCam, and Access Database were added to the traditional Fundamental Computer Applications for Business
BISE2010 that teaches only word processing, spreadsheet, and PowerPoint presentation and database. The modified course demands students to

2161
create a database driven Web Pages using the InterDev. To get students up-to-date to the e-commerce technology, they must master the Web pages creation, Web forms and database concepts, connection of database to the server from the client, retrieval and update of database records. All these, even with the help of InterDev is procedurally too complex for students to learn in a short period of time, so HyperCam is used to prerecord some intricate procedures for playback by students later, just in time of need. Also, simple built-in Java and Visual Basic scripts were the first time introduced into this popular course. The class devotes 1/5 class time to the Web-based database. A post and pre-survey given to gauge the level of student understanding on the web-based database after a summer session is given below. It demonstrates the approach is working well.

Panelist 6: Results of the Evaluation, Rani George

A. Results of the Evaluation

The major aim of any evaluation is to collect, analyze, and interpret information on the need for, implementation of, and efficiency of programs and intervention efforts. The evaluation helps answer the following fundamental questions: (1) Has the PT3 project achieved its goals? (2) How does technology impact learning? (3) How can we prepare tomorrow's teachers to use technology in their classrooms? (4) What changes are required in the curriculum for teacher preparation programs?

To answer these questions the project performs bipolar measurements, one set from the student and the other from the instructor. On the student side, the measures are student testing, projects, essays, extended performances, portfolios, student attitudes, morale, and satisfaction. On the teacher side, we evaluate Teacher's use of technology in the classroom, attitudes, satisfaction, competence, and curriculum changes.

I. Baseline studies

Subjects for baseline evaluation consists of 493 students, 18 ASU faculty, 7 mini-grant recipients, and 22 Summer Seminar Participants. Students answered a 37-item computer attitude survey. More than 85% reported positive attitudes toward the use of computers and a high degree of comfort in using the computer. Faculty responded to a survey, which measures faculty use of basic technology in their teaching and regular daily activities. Based on the results it can be stated that competency with basic computer operations ranges from beginning to more advanced. A system wide survey is underway to get a better understanding of faculty's level of technology competence. Of the 22 participants who attended the summer seminar 95% rated the seminar as an "outstanding activity" and stated that they received "ample information." Further evidence of technology comes from data that show that 32% of the faculty in the Colleges of Education and Arts and Sciences and 5% of Education majors have had InTech training. All the students enrolled in Prep for Teaching are currently undergoing InTech training.

II. Evaluation of the syllabi redesigned for technology infusion

Six of the seven original syllabi had little or no technology components. The seventh added more advanced features to the technology already in use. Another set of 8 faculty members (2 English + 5 Math + 1 Business) have signed up to add technology components to their teaching. The findings related to the revised syllabi are complex. Two questions stood out in the evaluation of a syllabus (1) How often does the revised syllabus include technology? (2) What evidence is in this syllabus to indicate that, as a result of this course, students will know and/or be able to do the competences indicated in the standards? When judged against the National Education Technology Standards, the syllabi were found to echo strongly with the standard Technology Operations and Concepts but weak in Social, Ethical, Legal, and Human Issues. The table below shows two of the standards and the extent to which the seven course syllabi echo the standards.

2162
In conclusion, we have presented here our overall strategies on implementing a system wide approach to prepare tomorrow's teachers to use the technology. Our framework is based on faculty peer training and InTech training, technology based model classes, intensive technology training for pre-service teachers, and collaboration with in-service teachers from local schools which desire to implement technology in the classroom. InTech plays a crucial role in training faculty and pre-service teachers and students alike who lack the fundamental technological skills. Based on the InTech foundation, we then build technology-based core courses and use them as models to showcase them to pre-service teachers as well as to faculty. It is important to notice that, as demonstrated by the presentation of the panelists mentioned above, the level of technology sophistication could vary significantly from discipline to discipline. Instead of standardizing education technology across the board, peers in each discipline, such as the mathematicians and English departments mentioned earlier, should be given an opportunity to decide on their own comfort level of technology needs. An appropriate technology, which matches the need of the discipline and its courses, is more important than the sophisticated and state-of-the-arts technology skills ever invented. For instance, the use of a scanner and computer to help capture images for the construction of a manual storybook by a child is highly effective for promoting early childhood reading; yet too much technology may dampen the effectiveness of the hands-on approach. Based on this philosophy, the SOWEGA PT3 project is going to continue its effort to create more model courses that encompasses all kind of technological usages so that, in the end, no matter which core course an education student and hence the future teacher may take, he or she will be exposed to an usage of the technology.

Abstract:
Educators emphasize unit construction as an important part of teacher preparation. Technology-enhanced problem-based learning units are particularly exciting because they have the potential to involve students in complex, realistic problems that are both engaging and cognitively challenging. These units are difficult to develop, however, particularly for elementary education teacher candidates who often have limited content knowledge. The authors have enlisted arts and science faculty experts to participate as members of "development teams" to assist in the design of problem-based units in science and social studies. This collaboration produced units in which content is richer, problems are more complex, and resources are more substantive.

In teacher education, science and social studies methods courses typically include unit development as an essential skill for teacher candidates. Units of study provide an important vehicle for presenting content in a cohesive way, for integrating information from different disciplines, for putting content into a relevant, meaningful context, and for blending skills with content. Noted educators and educational researchers have long emphasized the value of curriculum integration (Whitehead 1929) and cautioned against the teaching of skills in isolation (Perkins 1986), so unit construction is an important competency for teachers.

Technology-Enhanced Project-Based Learning

Units come in many formats, each with its own strengths and underlying principles. In our methods courses at Elon College, we recently adopted technology-enhanced project-based learning as the unit model to use with our teacher candidates. In a project-based unit, students are presented with a situation or scenario that calls on them to accomplish a task or develop a product. They may be placed in roles that demand the adoption of a particular approach or the use of a particular set of skills. For example, one team of our teacher candidates developed a project-based unit that placed their fourth grade students in the role of journalists covering flood relief efforts in eastern North Carolina after a series of devastating hurricanes hit the coastal region of the state. The fourth graders were asked to investigate the storms, the resulting damage and subsequent relief efforts, then to write articles for "North Carolina Today," a magazine they fashioned after prototypical news magazines.

We selected the project-based learning unit model for several reasons. First, a project-based learning unit provides an authentic learning environment. Activity theory suggests that we learn by doing (Jonassen & Rohrer-Murphy 1999). Vygotsky, Leont’ev and other Russian psychologists (Wertsch 1981) have brought this idea to the educational forefront and given it theoretical validation, but it has immediate
face validity as well. We learn when we want to learn, when we need to learn, and when we are interested. Learning happens almost without our being aware of it when we are deeply engaged in a project that is meaningful to us. Too often "school learning" is neither engaging nor meaningful. Skills are learned, but never applied in real-life situations; facts are learned, but never associated with important principles; concepts are memorized, but without being understood. Research confirms that transfer to out-of-school situations is unlikely when learning is so contextualized, so embedded in the classroom environment (Lave 1988; Perkins & Saloman 1988).

Second, project-based learning allows us to explore a content area in depth. With the amount of information in mandated curricula today, coverage is a major issue with teachers. The result is sometimes referred to as the "iceberg" approach to teaching, where only the tips of many knowledge areas are touched upon, none in depth. Project-based units provide opportunities to delve into subjects and emerge with deep understandings. For example, students in fourth grade might be expected to define a hurricane and to distinguish it from a tornado, and/or they might be expected to identify relief agencies and to list their functions. Approached this way, the topic of storms can easily be covered in a day or two, but activities such as these do not encourage the in-depth learning that is demanded by the project scenario developed by our teacher candidates.

Third, project-based learning encourages both content integration and skills infusion. Projects are by their very nature integrated. Science, social studies, language arts, and mathematics all figure into the flood relief scenario outlined above. In addition, the writing assignment is a natural one. Students learn how to write in a particular fashion, to a particular audience, because they are placed in a role where that is what they must do – it is their job. It gives a whole new meaning to the writing assignment and actually does not seem like an assignment at all.

Though we could enumerate other reasons, the last one we will mention here is that project-based units provide a natural way to integrate technology into the curriculum. It is crucial for teacher candidates to begin to integrate technology into their instruction so that when they enter the teaching profession they can teach necessary technology competencies to their students. Project-based learning provides a natural vehicle for technology use because it is so clearly enhanced by technology (Moursund 1999). There are opportunities to organize information using databases and spreadsheets, to study new concepts using computer models and simulations, to present ideas using multimedia, and to conduct research in an authentic, collaborative environment.

Problem-Based Learning as a Type of Project-Based Learning

Some projects involve solving a problem, and when this is the case, project-based learning becomes problem-based learning (PBL). Though the difference is not always clear, the two can be distinguished in the following way: With project-based learning the emphasis is on the product, with problem-based learning the emphasis is on the process. The project-based learning unit we outlined above had students concentrate on locating information and writing a news article. If students had been asked instead to devise a plan for minimizing flood damage following hurricanes in eastern North Carolina, then they would have had to engage in substantial higher level thinking. The concentration on the complex thinking required in the project, rather than on the final product, suggests a more problem-based approach.

Because critical thinking and problem solving are crucially important skills, we encourage teacher candidates to develop projects that center on problems. As Rutherford and Ahlgren (1990) point out when they report on Project 2061, it is important to have students interact with significant problems:

Students should be given problems – at levels appropriate to their maturity – that require them to decide what evidence is relevant and to offer their own interpretations of what the evidence means. This puts a premium, just as science does, on careful observations and thoughtful analysis. Students need guidance, encouragement, and practice in collecting, sorting and analyzing evidence, and in building arguments based on it. However, if such activities are not to be destructively boring, they must lead to some intellectually satisfying payoff that students care about. (pp. 188-189)

However, we have found that problem-based learning units are considerably more difficult for our teacher candidates to develop than are project-based units. While candidates have little trouble identifying meaningful products, they have a great deal of trouble finding worthy problems. Before considering why this might be so, let’s briefly address what makes a problem “worthy.”
Stepien and Pyke (1997) stress the importance of PBL problems being “messy,” or “ill structured.” That is, the problems require more information than is initially available to solve them, and there is no single “right” answer (Barrows 1985). These qualities encourage students to think creatively, form hypotheses, identify issues and questions, search for relevant information, and think critically about the data they collect. Gallagher (1997) points out, however, that being ill-structured is not enough. PBL problems should be constructed around learning goals and should have a conceptual focus and disciplinary relevance. Content is not incidental, but central to this form of problem solving. Because PBL is premised on the assumption that problems will motivate students to explore curriculum topics in greater depth, the problems themselves must be carefully designed to lead students into that curriculum.

Boyce, VanTassel-Baska, Burruss, Sher, & Johnson (1997) point out the importance of problems being realistic. They have found their science curriculum units are more powerful when the problem is tailored to create a localized ill-structured problem, rather than an entirely fictitious one. This encourages students to use a rich variety of local resources to address the problem. Indeed, the location and use of appropriate resources is another important aspect of PBL. Boyce et al. note, “Students need to do more than check the encyclopedia. Science books and databases, local resources and experts, journals, and Internet consultations with people across the country enrich the creation of students’ solutions for the problem” (p. 375).

In summary, worthy PBL problems are open-ended, complex, realistic, and steeped in significant content. Now we must ask what it takes to find such problems. At the very least, it takes a sound foundation in the content area. In order to identify worthy problems that are realistic and that implicate core disciplinary content, one needs a deep understanding of the subject matter and its current status. This may explain the difficulty our elementary education majors have with problem-based learning.

Content Knowledge and Elementary Education Majors

The lack of adequate content knowledge among elementary education teacher candidates has been studied and well documented. In The Rise and Stall of Teacher Education Reform, Fullan, Galluzzo, Morris, and Watson (1998) identified the need for a stronger knowledge base for teacher candidates. Stoddart, Connell, Stofflett, and Peck (1993) investigated the mathematics and science content knowledge of elementary teacher candidates and reported, “many teacher candidates enter elementary teacher education seriously deficient in understanding the mathematical and scientific content they will be expected to teach” (p. 238). This was the case even though these teacher candidates entered the teacher education program after successfully completing college math and science requirements. The majority had grade point averages in the upper quartile of their college class. In a similar finding, Schifter (1993) suggested, “a major obstacle in the transformation of the mathematics classroom into an environment that produces mathematical understanding is that most teachers have not learned to think mathematically” (p. 271).

Our own observations of teacher candidates reflect these concerns. We find that teacher candidates are not only lacking in content knowledge, but they do not always recognize the need for a thorough knowledge of the content. They incorrectly believe that as long as they know more than the students, they are adequately prepared. An equally troubling concern is that even when teacher candidates recognize their lack of content knowledge and want to rectify it, they do not always know how to access the information they need. Combine these deficiencies with the recognition that teacher education faculty are not content area experts either and we have the scope of the problem. It is clear that, as Quinn (1997) says, “changes should be made in (teacher candidate) content courses, their methods courses, or both” (p. 112).

Development Teams

In order to effect such a change, we heeded the words of Jerome Bruner (1977), “The experience of the past several years has taught at least one important lesson about the design of a curriculum that is true to the underlying structure of its subject matter. It is that the best minds in any particular discipline must be put to work on the task” (p. 19). For us, getting “the best minds to work on the task” meant involving arts and sciences (A&S) faculty in assisting us to develop problem-based learning units of study. In fall 2000 we began a project (supported by a Preparing Tomorrow’s Teachers to Use Technology grant)
that provided for the formation of collaborative Development Teams. In doing so, we were not only heeding the words of Bruner but also the admonition of the American Council on Education (1999) to coordinate the education faculty and the arts and sciences faculty in teacher education:

A common problem in colleges and universities is that faculties and programs become isolated behind departmental lines. The responsibility for preparing prospective teachers in the subject areas they will teach rests not only with school of education faculty but also with faculty of the institutions as a whole – especially the arts and sciences faculty. (p. 21)

Recruitment and Collaboration

At the beginning of the project, we sent out a general meeting notice to A&S faculty who were recommended by teacher candidates or who previously had expressed an interest in working with future teachers. Encouraged both by the number of A&S faculty who responded to our call and by their level of enthusiasm, we met to explain the project. Afterward, we selected five faculty members with areas of expertise most closely aligned with the topics teacher candidates had been asked to address by their K-5 cooperating teachers, and Development Teams were formed. Each consisted of an A&S “mentor,” four or more teacher candidates from the same grade level and/or with similar topics, their associated cooperating teachers, and a teacher education faculty member (one of the methods instructors). Content areas included geography, history, biology, and physics. Topics varied widely, ranging from “Matter” to “The First Thanksgiving.”

Each of the five A&S faculty came to a methods class to listen to questions and to talk about their subject area. Teacher candidates were required to write a research paper on their selected topic and, in many cases, the A&S faculty reviewed the papers and provided helpful feedback. After that, it was the responsibility of teacher candidates to contact and communicate with their A&S faculty mentors. Not all Development Teams continued to meet, but at least four groups kept in close contact throughout unit development.

One of the most successful collaborations occurred in two teams of teacher candidates assigned to fifth grade social studies classes. Both teams were asked by their cooperating teachers to “teach about the western region of the U.S.” They were asked to cover landforms, natural resources, major cities and landmarks, the economy, government, and people of the region. Knowing little about the western United States, the teacher candidates were at a loss about how to develop a problem-based unit on such a topic. Their A&S faculty mentor suggested that they address the topic through the problem of water shortage and water allocation, which would incorporate and focus much of the content they were asked to address. She worked with teacher candidates to help them develop this problem and locate pertinent print and Internet resources. At the end of the semester one of these students wrote, “Without Dr. G. I do not think that I would have been able to come up with a problem about the western United States. It definitely helped to get an expert perspective on things.” Another wrote, “The water shortage issue was a good problem, a little hard to understand, but a good one because it tied geography into the issue. Before talking with her (Dr. G.) I was unaware that there was even this issue, so it is nice to have expert advice...” The water shortage problem and the issue of resource allocation provided an extremely rich problem situation for fifth graders to address.

Outcomes

We are encouraged by this initial attempt to establish and use Development Teams for problem finding, and we can report two positive outcomes at this point: (1) Many A&S faculty are willing (even eager) to collaborate with teacher education faculty and teacher candidates on problem-based learning unit development, as this comment from an A&S faculty member indicates: “I think the interaction and discussion between faculty in the larger classroom was wonderful – a wonderful model of collegiality and of ‘process’ for the students. I thoroughly enjoyed interactions with students in the Development Team – this is where a lot of work and sharing and learning can be accomplished.” We can also report that all five of the A&S faculty who served as Development Team members have stated their willingness to continue with the project.
(2) The quality of the problem-based learning units produced by Development Teams is discernibly higher. Unit evaluations indicate that in units developed in collaboration with A&S faculty:

- content is richer
- problems are more complex
- resources are more substantive

There are, however, some issues that need to be worked out. Only about 25% of teacher candidates developing PBL units worked in collaboration with their Development Teams beyond the initial meeting. One question, therefore, is how to get more active involvement between teacher candidates and A&S faculty on Development Teams.

Another issue is illustrated by a comment from one teacher candidate: "I did feel at times that Dr. G. got a little carried away about the topic, forgetting that we only had 10 days to teach the unit and that we were teaching fifth graders." This comment suggests that A&S faculty can overwhelm elementary education majors with the amount and the complexity of the information they give. So, another question is how to facilitate a meaningful dialog between the “experts” and the “novices” so that the information provided is ultimately useful.

A Technology-Enabled Knowledge-Building Community (Use of Knowledge Forum)

In recognition of the need to provide a platform for collaboration among Development Team members, we elected to use Knowledge Forum, a second generation CSILE (computer supported intentional learning environment) product. CSILE, an asynchronous discourse medium, was originally designed for information sharing and knowledge building among a group of learners. The conceptual bases of CSILE come from research on intentional learning and on the process aspects of expertise, and from analysis of how discourse in knowledge-building communities contrasts with that of the discourse found in typical classrooms (Scardamalia & Bereiter 1994). This discourse also differs from current "ask the expert" arrangements that are being tried through e-mail. The CSILE-based approach more closely resembles "a community engaged in solving shared problems" (Scardamalia & Bereiter 1999), which provides an excellent fit for our project.

During this first semester we have not been able to do more than install Knowledge Forum and familiarize ourselves with its operation. Development Teams used email to communicate, and both teacher candidates and A&S faculty expressed the need for a better method of communication. Neither email nor the threaded discussion feature of our college courseware (CourseInfo) has proven satisfactory in providing a platform for the kind of dialog in which the Development Teams should ideally be engaged. Initial trials with Knowledge Forum look very promising in this regard.

Conclusion

The use of Development Teams in problem finding is an exciting component of our work with teacher candidates in the development of technology-assisted problem-based learning units. It clearly addresses the need for a strong knowledge base in the identification of worthy problems, but there are other benefits as well: A closer collaboration with the arts and sciences in teacher preparation, and the use of technology in a problem solving environment.

Mentoring Collaboration to Integrate Technology into Science Curriculum: A PT3 Project

Seung H. Jin
Curriculum and Foundations
Cleveland State University, USA
seung.jin@csuohio.edu

Abstract: This paper describes an exemplary case in mentoring collaboration between the student teacher and cooperating teachers to integrate technology into the curriculum and discusses various activities that have occurred during the project. The educational technologist provided one-on-one and just-in-time coaching customized to needs in the context/placement classroom for a semester through the whole technology integration process. The project addresses three important problems/issues including: 1) collaboration between student teachers and cooperating teachers, 2) a model for integrating technology into the curriculum, and 3) communication among faculty in higher education, cooperating teachers, and student teachers.

Introduction

Every year hundreds of northeast Ohio K-12 teachers serve as cooperating teachers, opening their classrooms and providing guidance to pre-service teachers fulfilling their field experience requirements. We believe that the role of cooperating teachers is one of the critical factors to prepare pre-service teachers to model technology integration in their classrooms.

In the 1999-2000 MIMIC (Modeling Instruction with Modern Information and Communication Technologies) Project, a U.S. Department of Education grant program, K-12 cooperating teachers were recruited for mentoring from school districts that accept student observations, practicum students, and student teachers. Educational technology faculty from the participating institutions mentored small numbers of cooperating teachers to assist them in the development and implementation of technology in their teaching. Each team paired with an educational technologist and cooperating teachers implemented a context-based and content-specific approach for modeling the integration of technology for pre-service teachers.

This paper describes an exemplary case in mentoring collaboration between the student teacher and cooperating teachers to integrate technology into the curriculum and discusses various activities that have occurred during the project.

Background

Many researchers have reported that student teachers have few opportunities to apply what they have learned in the teacher preparation program. A study about effective supervision of student teaching points out that student teachers abandon what they have learned in teacher education courses in as little as two weeks rather than applying it into the placement classroom. In conventional student teaching, student teachers adapt and replicate the practices and attitudes of their cooperating teachers to facilitate the smooth function in the classroom (Richardson-Koehler, 1988). Rodriguez, Sjostrom and Alvarez (1998) report that nontraditional student teachers viewed and interacted with cooperating teachers as peers and friends, whereas traditional student teachers felt they could not overstep boundaries. The result of a survey on student teachers' success/failure in student teaching indicates that student teachers exhibited less confidence when using nontraditional approaches to teaching, particularly cooperative learning, individualized instruction, and integrated approaches (Gormley, et al., 1991).

Over the past decades, the administration in K-12 schools has focused on educational technology and teacher preparation programs in universities have emphasized integrating technology into the curriculum. America's progress report indicates that 78% of teachers received professional development that focused on the integration of technology in the grade and subject they taught in 1998. However, in too many schools, most teachers and students still use computers only as the equivalent of expensive flash cards or as the tools for drill and practice. The...
productivity side of computer use in the general content area curriculum is neglected or underdeveloped (Moursund, 1995). With this environment, student teachers have no or little opportunity to integrate technology into the curriculum during the student teaching. In addition, another major problem in student teaching is the isolation. Although student teachers need more help to solve the difficult realities and complexities of classrooms, student teachers are often disconnected from university training, peers, and other classrooms (Schlagal, Trathen and Blanton, 1996).

While many researchers have pointed out some limitations in student teaching, there are several successful student teaching models that have applied learning from universities or tried an innovative approach. As an example, Wetzel (1996) describes the implementation of a project to prepare mentor and student teachers to teach mathematics and science through the integration of multimedia technology. He found that student teachers were better prepared to integrate technology and that mentor teachers changed how they taught mathematics and science. To release student teachers from the isolation of the placement classroom, Schlagal, Trathen and Blanton (1996) suggest the telecommunications that can link members of the student teaching triad. Student teachers can use e-mail to discuss their classrooms with university supervisors and peers in other classrooms.

The project described in this paper addresses three important problems/issues, including: 1) collaboration between student teachers and cooperating teachers, 2) a model for integrating technology into the curriculum, and 3) communication among faculty in higher education, cooperating teachers, and student teachers. The educational technologist provided one-on-one and just-in-time coaching customized to needs in the context/placement classroom for a semester through the whole technology integration process.

Case Study

A case study was used to determine the effectiveness of the proposed mentoring approach for preparing preservice teachers with technology. The participants of this study were two cooperating teachers and a student teacher in an urban school district. These teachers chose to participate in the MIMIC project preparing preservice teachers to integrate technology into their teaching. One cooperating teacher (K) was identified with moderate skills in the use of technology and the other (C) was at the novice level. Both of them have been teaching for more than 10 years, mostly at the primary level. Teacher C has worked with student teachers for the last 10 years, Teacher K for 5 years. They currently both teach 2nd grade—all subject areas. The cooperating teachers have been working in collaboration to exchange instructional ideas and resources. They both have laptop computers supplied by the district and have taken a technology class offered by their district. In their school, technology consists of three IBM computers with one printer in each classroom. The software selection is limited to about 15 titles. The student teacher from a major urban university has learned various technology tools through the teacher education program and has developed several lesson activities or material with technology as a course work.

The Planning Phase

In the beginning stage of collaboration, the educational technologist helped two cooperating teachers and the student teacher recognize the various ways in which technology-based activities may be integrated into or transform traditional subject area curricula. To develop an initial plan, the collaboration team including two cooperating teachers, the student teacher, and the educational technologist reviewed technology and science standards in national and local levels such as state, district, and school building. After analyzing the standard, the educational technologist introduced several sample projects that enhance students' learning with technology to help them. During the project, the educational technologist visited the school building on a regular basis (every other week) to support the cooperating teachers' technological skills and to discuss the integration ideas. With assistance of the educational technologist, two cooperating teachers and the student teacher developed an initial plan and timeline for the project. They also discussed an appropriate technology tool and integration methodology that provides more possibilities for students' learning in the placement classroom. HyperStudio was selected as a multimedia instructional design tool for this project. Although HyperStudio was available on three machines in each classroom, many teachers in the school weren't aware of the availability of the software and didn't know how to use it for their teaching.

To choose an appropriate topic for a lesson, the collaboration team outlined all topics which will be taught in the 2nd grade science for the Spring semester. They selected the solar system to be covered at the end of semester.
as a major topic for the project for two reasons. First, they needed reasonable amount of time to develop instructional material with their regular routine. Although they received some technology training by their school district, it focused on computer literacy skills rather than context-based activities that can be used to teach curriculum in a subject area. Teacher C expressed that group training through one time workshop was not helpful for novice users like her who need step-by-step guidelines and on-going supports. In addition, since this project was their first experience in instructional design with technology tools, they needed enough time and support to learn many major components in instructional design and as well as technology skills. Second, they thought that the multimedia lesson including images, audio, and animations would be a useful method for students to understand the key concepts of solar system.

The Design Phase

Once a topic and design tools were selected, the collaboration team developed an outline of the lesson unit to teach Space. Through the collaboration work, Teacher K who has moderate skills with technology took the major role in the design process, Teacher C collaborated with K as a subject matter expert, and the student teacher provided just-in-time help to solve technical problems and to improve the instructional material with technology. All participants also relied on e-mail to share work in progress, ideas, and to plan the next steps. The educational technologist provided feedback and suggestions on their work progress through face-to-face meeting or e-mail.

The solar system lesson unit includes one main card and nine sub cards about each planet. The main card including a graphic of nine planets used non-linear design that allowed students to select any topic to learn about our solar system. Each sub card consisted of a planet graphic, the text explanation of an individual planet and voice recording of Teacher K.

The Implementation Phase

Upon completion of the lesson unit, the integration of technology was implemented in the real classroom setting. In the implementation phase, we used Teacher K's classroom which has three IBM computers with headphones and more space for student activities. For the first period, Teacher K taught the solar system lesson unit for her own class for 45 minutes. She provided a workbook including several questions on each planet and divided students into four activities. She set up the computers into three different ways: 1) Solar system created by team, 2) Commercial science program including the solar system, and 3) Internet. The students in pairs explored the solar system on the computer. After exploring the computer for 10 minutes, the students returned to the big group. The students in the big group searched information in reference books prepared by the teacher. Students during this lesson were required to think critically and solve problems through inquiry and collaborative activities. In the second period, Teacher K switched her students with Teacher C's class and used same strategies for the lesson implementation. Teacher K repeated these activities for a week to teach the solar system and gave equal opportunities to all students.

The Evaluation Phase

Two cooperating teachers and a student teacher were observed developing a technology-based instructional material to teach the 2nd grade science and two classes were observed implementing a science lesson using a technology tool during the Spring of 2000. According to Apple Classrooms of Tomorrow (ACOT) study, there are five stages: 1) Entry - learn the basic of using new technology, 2) Adoption - use new technology to support traditional instruction, 3) Adaptation - integrate new technology into traditional classroom practice (usually productivity tools), 4) Appropriation - focus on cooperative, project-based and interdisciplinary work--technology is one of many tools, and 5) Invention-discover new uses for technology tools. Through this project, two cooperating teachers changed their stage before entry or from adoption stages to appropriation stage and the student teacher could apply what she learned in teacher education program in the meaningful and complex context.

During the classroom observations, the researcher wrote comments in her notes that indicated the extent to which the plan, goals, and expectations, as defined in the planning stage, were reached. The researcher also took note of how technology seemed to be influencing the teaching of science. The majority of the students picked up on the main objectives of the lesson and were interacting with other students in the group. Some students needed more
Discussion

In the beginning of this project, two cooperating teachers pointed out common problems in many professional development programs as following:

- Training occurs in isolated, short, "stand-alone" sessions.
- Training is delivered by non-teachers so that technology and pedagogy are not linked or connected.
- No long-term professional development plan is in place.

Our efforts to overcome these problems were successful. Although a one-to-one mentoring approach may not impact on teacher modeling to larger groups, this approach provided context-based comprehensive training in-depth from needs assessment to evaluation rather than isolated technology literacy skills or a one-day workshop.

Through the technology mentoring collaboration, we found varying degrees of possibilities and limitations to integrate technology into a curriculum. The limitations were related to the instructional time, teachers' preparation time, limited access to equipment or software, and administrative support. The possibilities could be increased by teachers' willingness and collaboration with peers or educational technologists. Most importantly, the project produced very positive results on students' learning with technology in the classroom. Also a one-to-one mentoring collaboration model to integrate technology into curriculum can easily be conducted among cooperating teachers and student teachers at any school site. According to Knapp and Glenn (1996), the process of educating teachers must include both academic practice, and practical knowledge and skill gained only by working in actual schools and classrooms with experienced educators. Therefore, teacher preparation must involve collaboration between the two sites of the university and the school.

References

Abstract: This paper describes the successful development of a one-year capacity building grant funded by the U.S. Department of Education's Preparing Tomorrow's Teachers to use Technology (PT3) program. The focus of the grant was to prepare teacher candidates to become proficient in developing and delivering classroom lessons that effectively incorporate technology in the learning process so that all students (Pre-kindergarten to 12th grade) use technology in demonstrating mastery of lesson plan objectives. Qualitative and quantitative results indicate that the preparation model has been successful with teacher candidates becoming proficient in developing and delivering technology-integrated lesson plans. Moreover, participants' (i.e., teacher candidates, mentor-teachers, and university faculty) comfort level with technology and frequency of technology usage has increased.

The Lack of Technology Integration within the Curriculum is a Nationwide Issue

In elementary and secondary schools throughout the United States, the ability to incorporate technology within the curriculum is one of the most difficult tasks for teachers (Benton Foundation, 1997; Driskell, 1999). Teachers' lack of familiarity with varieties of technological hardware and software appropriate for curriculum integration has contributed to this development (U.S. Congress, Office of Technology Assessment, 1995). Trotter (1997) indicates that while teachers may have received sufficient preparation with content and pedagogy, they have not been sufficiently prepared to exercise technology within teaching; thus, creating a huge bottleneck in the use of computers in the nation's classrooms (Benton Foundation, 1997).

Technology Literacy is a National Mandate

Research studies indicate that technology can serve to positively impact student learning in terms of academic achievement, skill development, and attitude toward school attendance (Kane, 1994; Kulik & Kulik, 1991; Kulik, Kulik, & Bangert-Drowns, 1985; Pisapia & Perlman, 1992). Technology in the classroom serves as a tool to develop students' critical thinking, resourcefulness, and collaborative skills as well as to improve students' self-concept and attitude toward learning, and to increase student/teacher interaction (U.S. Congress, Office of Technology Assessment, 1995). Technology literacy for all students is a national mandate of the United States (U.S. Department of Education, 1997). An increasing number of educators and technologists believe that computer and communication technologies can provide a vehicle to help facilitate the evolution of a new education system to provide more accessible, higher-quality learning opportunities for everyone (Hunter, 1993).
Teacher Education Programs Need to Provide Technology Integration Preparation

University and college teacher education programs continue to produce teachers who do not possess the skills to integrate technology within the curriculum. Only eighteen states require technology preparation as part of their teacher certification program (NEA, 1997). The 1998 report, Technology and the New Professional Teacher: Preparing for the 21st Century Classroom, commissioned by the National Council for Accreditation of Teacher Education (NCATE) strongly urges schools of education to prepare future teachers in the use of technology in the classroom (Driskell, 1999). The NCATE includes in its accreditation review process of teacher education programs a set of twelve national standards for educational technology as developed by the International Society for Technology in Education (1992). The sixth standard directly relates to the integration of technology in the curriculum stating, "Evaluate, select, and integrate computer technology-based instruction in the curriculum of one's subject area(s) and/or grade level(s)" (Driskell, 1999, p. 121).

Technology Integration Strengthened in UHCL Teacher Education Program

The University of Houston-Clear Lake (UHCL) in partnership with eight rural and urban school districts in the Houston, Texas area has established a successful, field-based teacher preparation program. The University of Houston-Clear Lake (UHCL) is an upper-level university, i.e., junior and senior and graduate level students. UHCL has an enrollment of approximately 7,500 students, and serves the academic and professional needs of regional students, as well as national and international students. UHCL is accredited by The Commission on Colleges of the Southern Association of Colleges and Schools (SACS), the National Council for Accreditation of Teacher Education (NCATE), and the Texas State Board for Educator Certification (SBEC). The UHCL School of Education has earned one of the highest cumulative pass rates on the statewide test for teacher certification with a pass rate of 97.2% (1997-1998).

While a collaborative, field-based teacher education program has been effectively developed at the University of Houston-Clear Lake with teacher candidates receiving technology education linked to standards, teacher candidates still needed specific preparation to integrate technology within the curriculum. The United States Department of Education’s Preparing Tomorrow’s Teachers to use Technology (PT3) grant application process provided the impetus to review the technology preparation of teacher candidates at UHCL. The first step in the review (grant development) process was to assess the current teacher education program components in light of the research on technology integration within the curriculum, specifically the ten factors for technology integration.

Ten Factors for Technology Integration within the Curriculum

For integration of technology to occur within the curriculum, ten factors need to be incorporated in a professional teacher preparation program (Driskell, 1999). The ten factors include (1) access to technology tools; (2) technology training; (3) pedagogy behind effective integration of technology; (4) assessment of teacher candidates’ skills using technology effectively in the classroom; (5) models that demonstrate the integration of technology within the curriculum; (6) incentives for teacher candidates to integrate technology within the curriculum; (7) time for teacher candidates to learn about and plan for technology use; (8) school climate that encourages use of technology resources in innovative ways; (9) collaboration among teachers (teacher candidates and mentors) about technology integration; and (10) technology integration support.

Analysis of Factors in the UHCL Teacher Preparation Program: Identifying Specific Gaps

In analyzing the current teacher candidates’ preparation in technology at UHCL, four of the ten factors were being directly met: (1) access to technology tools; (2) technology training; (3) pedagogy behind effective integration of technology; and (4) assessment of teacher candidates’ skills using technology effectively in the classroom. These four factors were being addressed through a technology course entitled “Computer Use in the Classrooms” (INST 3133). Although receiving technology preparation, teacher candidates were not developing and delivering lesson plans that effectively incorporate technology in the learning process (following an assessment rubric) so that classroom students (Pre-kindergarten to 12th grade) used technology to demonstrate mastery of lesson plan objectives. Three major gaps were identified in the technology preparation of teacher candidates.
**Gap #1: Integration and Modeling by Faculty**

Authentic lesson plans with technology integration are not specifically taught in any class at this time. Education faculty members, some of whom are part-time, teach lesson plan development and delivery, but not the integration of technology within lesson plans, including technology standards, e.g., International Society for Technology in Education (ISTE) Standards. While able to use technology, most faculty members are not proficient in the integration of technology within the curriculum. Consequently, many of their course syllabi do not include this requirement. In addition, the technology course entitled "Computer Use in the Classrooms" (INST 3133), a required course for teacher candidates, focuses more on technology skills development than on technology integration within lesson plans. Most sections of the course are taught by part-time faculty some of whom have not been classroom teachers, thus, have little or no experience in developing lesson plans. Because of this gap, some factors are not being addressed: (5) models that demonstrate the integration of technology within the curriculum; (6) incentives for teacher candidates to integrate technology within the curriculum; (7) time for teacher candidates to learn about and plan for technology use.

**Gap #2: Field Placement of Teacher Candidates**

Teacher candidates are not necessarily placed with mentor-teachers proficient with technology. While mentor-teachers have extensive teaching experience, many of them have not received the necessary technology education to model technology usage and integration. While experienced teachers participate in mentoring training to become mentor-teachers, they are not required to participate in a technology education program. Moreover, most school districts do not have sufficient resources to provide technology education to classroom teachers, much less in a specific area of technology integration within the curriculum. Because of this gap, a couple of factors are not being addressed: (8) school climate that encourages use of technology resources in innovative ways and (9) collaboration among teachers (teacher candidates and mentors) about technology integration.

**Gap #3: Support System**

Teacher candidates do not have ready access to an established support system at the university and campus levels that provide assistance in technology integration. While individual faculty members and campus teachers may have knowledge of technology integration, teacher candidates do not have ready access to these resources. Moreover, university faculty and campus teachers are unaware of teacher candidates' technology needs. No central clearinghouse component exists, e.g., Web site, that provides names and addresses of resource people at both the campus and university levels, as well as allows teacher candidates to ask questions and find models of lesson plans. Because of this gap, (10) technology integration support is not being addressed.

**Development of Lessons Plans to Demonstrate Technology Integration within the Curriculum**

Once the assessment phase was completed and needs (gaps) identified, then, objectives and strategies were developed to address current needs. The objective of the grant proposal was to develop a program model that addressed the factors in preparing successful teacher candidates to integrate technology within the curriculum, specifically, in classroom lesson plans.

The central proof of a teacher's ability to effectively incorporate technology within the curriculum is the development and delivery of classroom lesson plans that integrate technology. The implementation of these lesson plans will result in classroom students (Pre-kindergarten to 12th grade) using technology to develop products that demonstrate mastery of lesson plan objectives. To become proficient in lesson plan development, teacher candidates need preparation in two areas. The first need is in the application of various types of technologies, e.g., computers and computer software appropriate for classroom use. Second, they need the ability to compose lesson plans that incorporate the appropriate technology within the curriculum for student application. The central strategy in addressing these two needs is the development of an interactive professional development technology practicum.

**An Interactive Professional Development Technology Practicum**

After receiving a one-year PT3 capacity building grant, the UHCL Collaborative developed a three-day, interactive professional development technology practicum to prepare teacher candidates to develop and deliver lesson plans that integrated technology within the curriculum. The practicum included the following components: (a) vision of student-centered technology-rich classroom environments, (b) technology integration with one (few)
computers in a classroom, (c) guidance of students in creating successful multimedia presentations using multimedia software, (d) guidance of students to use higher order thinking skills in technology use, (e) use of electronic educational templates, (f) technology and performance standards in a lesson plan, (g) development of student electronic journals, book reports, and technology portfolios, (h) guidance of students in researching on the Internet and (i) effective uses of telecommunication tools in education. The practicum also addressed the needs of economically disadvantaged campuses. For novice computer operators only, an additional one-day basic technology skills session was provided prior to the three-day technology practicum.

Teacher candidates, along with their mentor-teachers and university faculty, became proficient in the application of technologies and gained understanding of the pedagogy behind the specific technology's usage, and collaboratively developed authentic lesson plans that integrated technology following a designed lesson plan template. Lesson plans were assessed for appropriateness and completeness using a designed lesson plan rubric. Teacher candidates delivered their lesson plans to classroom students (Pre-kindergarten to 12th grade) and student developed products (using technology applications) that demonstrated mastery of lesson plan objectives. The technology consultant and project evaluator assessed student products for relevance and completeness. This developmental process allowed teacher candidates to assess their own progress in developing and delivering technology-integrated lesson plans, as well as to improve their delivered lesson plans. Teacher candidates published their lesson plans on the Project’s Web site.

After completing the three-day professional development technology practicum, participants were provided ongoing professional support via the Project’s Web site as they developed and delivered lesson plans in the classroom. Ongoing professional support for participants is a critical element of success (Brooks, & Kopp, 1989; International Society for Technology in Education, 1992; Benton Foundation, 1997), especially in a constructivist learning environment (Wilson, 1996). The interactive professional development technology practicum was successful in addressing the ten factors (See Fig. 1 below) that effect the integration of technology within the curriculum.

### Evaluation of the One-Year Capacity Building Study

The methods of evaluation provided performance feedback and permitted periodic assessment of progress toward achieving intended outcomes (Erlandson, Harris, Skipper, & Allen, 1993). The participants in this capacity building study represented three groups: teacher candidates, mentor-teachers, and university faculty. Participants attended training sessions to assist them in developing lesson plans with appropriate technology that met established standards.
At the beginning of the first session, participants completed three locally developed instruments designed to document areas where change was expected over the course of the training. The instruments included a Technology Comfort Scale, a Frequency of Involvement in Technology Scale, and an Attitude Toward Technology Scale. The scales were determined to have a Cronbach's alpha reliability coefficient of .91, .95, and .98, respectively. The magnitude of these coefficients indicates good scale reliability for each of the three scales.

In this capacity building study, thirteen teacher candidates, twenty mentor-teachers, and six university faculty participated in the practicum to become proficient with the application of various types of technologies for classroom use and to develop lesson plans. The training consultant guided the participants through exercises designed to gain proficiency with various technologies. Teacher candidates demonstrated their ability to develop lesson plans that integrated technology to meet established standards. The technology consultant used a scoring rubric to assess the successful construction of lesson plans that integrated technology. With feedback and assistance from the consultant, teacher candidates developed lesson plans that included components required for proficiency.

At the end of the third day of training, participants were tested a second time using the same instruments as exercised at the beginning of the practicum. This method allowed for a pretest/posttest comparison to demonstrate change during the project. The training days were not sequential, which allowed participants to return to their classrooms to use skills learned prior to the beginning of the next session.

The teacher candidates gained an average of slightly more than 8 points on their level of comfort with technology. However, by the end of the three days of training, the rating of frequency at which they were using various aspects of technology had increased approximately 5 points. The positive attitude of the teacher candidates toward technology increased by about 1 point by the end of the practicum.

The mentor-teachers gained an average of slightly more than 1 point on their level of comfort with technology. However, by the end of the three days of training, the rating of frequency at which they were using various aspects of technology had increased by nearly 7 points. The positive attitude of the mentor-teachers toward technology increased approximately 2 points by the end of the practicum.

The university faculty gained an average of slightly more than 12 points on their level of comfort with technology. However, by the end of the three days of training, the rating of frequency at which they were using various aspects of technology had increased by nearly 13 points. The positive attitude of the university faculty toward technology increased by approximately 2 points by the end of the practicum.

In each case, the gain in positive attitude was minimal; however, the positive attitudes toward technology in each group were very high from the beginning of the study, and this most likely accounts for the lack of change. Additionally, since each of the groups was relatively small (thirteen teacher candidates and six university faculty), the documentation of any change should be considered a success. It would be useful to gauge these developments with a larger sample over a longer period of time (longitudinal study) to analyze whether similar results occur.

In addition to the quantitative approach described above, samples of classroom student work (the results of teacher candidates’ delivery of lesson plans) were reviewed using the scoring rubric developed by the training consultant. The lesson plans were found to contain the required elements indicating that teacher candidates had effectively integrated technology into their teaching and that classroom students were using technology in demonstrating mastery of lesson plan objectives. Examples of student work were placed on the Project's Web site.

Conclusion

During this one-year, PT3 capacity building study, teacher candidates, mentor-teachers, and university faculty participated in developing a program model to prepare teacher candidates in integrating technology within the curriculum. This process took the form of developing and delivering lesson plans that integrate technology so that all students (Pre-kindergarten to 12th grade) use technology to demonstrate mastery of lesson plan objectives. Qualitative and quantitative results indicate that the preparation model has been successful in preparing teacher candidates to become proficient in technology integration and that participants’ comfort level with technology and frequency of technology usage had increased.

Along with addressing the ten factors for technology integration within the curriculum, this educational process developed the three agendas for school reform in the information age. These agendas include (a) developing agreement about learning and teaching, (b) integrating technology, and (c) restructuring (Mehlinger, 1996). Participants discussed the pedagogical process of integrating technology in classroom lesson plans with developmentally appropriate hardware and software, during which process they became more confident and competent in using technology applications. In this developmental process, participants were describing ways to restructure learning in the classroom, making it more active, and student-oriented. As one principal in the UHCL Collaborative declared, "The operations of this grant has moved our school into a new century."

Abstract: Three types of data were obtained in order to objectively determine faculty development needs in the area of technology in teacher education. On the basis of the data it was determined that most members of the faculty needed to acquire specific skills and knowledge about generic technology tools, about subject specific technology applications and about creating technology based activities or products for incorporation into teacher education courses. A Technology Learning Team model of faculty development was created.

This paper provides a description of an ongoing PT3 project at a comprehensive teacher education institution. The primary focus of the project is to provide faculty development in knowledge and skills to infuse technology into courses across the teacher education curriculum. The paper will describe 1) the steps taken to objectively identify faculty development needs, 2) the strategies developed to effectively respond to these needs, 3) the resources, in addition to those provided by PT3, necessary for successful implementation of this PT3 grant, 4) the obstacles encountered in the initial implementation of the grant, 5) the solutions developed to overcome these obstacles, and 6) recommendations for comparable institutions engaging in similar activities.

I. The steps taken to objectively identify faculty development needs.

Three types of data were gathered: 1) a survey of faculty based on a modified version of the School Hardware Technology Survey (Edmin Open, 1998), 2) data from faculty focus groups, and 3) a rating of the faculty on the Ohio SchoolNet Professional Development Matrices (Ohio SchoolNet, version 1). These data revealed that all full-time faculty members who completed the survey (n=31) have a computer in their office. Data from the Office of the Dean further indicated that all full-time members of the faculty have been assigned an office computer.

Two thirds of the surveyed group have a computer that is Internet capable and most have machines that are CD-ROM capable. While all have either an ink-jet or laser printer, their access to other devices, such as scanners or digital cameras is low (less than 10%). Faculty access to technology in classrooms is less frequent. Aside from a computer workstation in the math methods classroom, few classrooms are equipped with audio/visual equipment such as overhead projectors and VCRs with monitors. Such equipment can be reserved from a central audio/visual department for use in class. However, this is a relatively cumbersome process involving the transportation of the equipment from a different building on a 3-building vertical campus.
Only one member of the faculty was specifically hired to teach in the area of technology. Two additional members of the faculty include technology as a major area of their expertise, but were not hired on technology faculty lines. The following can be said of the technology skills of the faculty in relation to the Ohio SchoolNet Professional Development Matrices, which rate technology skills in the areas of productivity, information, network, and hypermedia tools.

Approximately 6% of faculty members are at the expert level across the four areas. (These are 3 faculty members described above). Most faculty members are at the "novice" or building capacity level in 3 of the 4 areas. About 25% of faculty members are at the "practitioner" level in at least one technology tool. (In general practitioners adopt models of technology and apply them to specific curricular lessons or units).
The most common uses of technology by faculty are word processing and accessing e-mail. About 65% report using e-mail; 39% have developed web-based activities, mainly, posting course syllabi on the Web; 4 have online chat rooms that serve as an integral part of their courses.

II. Strategies developed in response to the needs identified by the faculty.

These include faculty, staff, and mentor teacher development workshops as well as significant improvement in a range of technology hardware. The hardware, which was not provided by the PT3 grant, is discussed in Section III, below. The development activities consist of placing all of the faculty, staff, and mentor teachers, in cohorts of approximately 20 each semester, into Technology Learning Teams (TLT). Each TLT comprises four to six participants, consisting of a cross section of individuals from the above groups. The focus of each team is on using technology as a teaching-learning tool, and on integrating this tool function into instruction in a content area of interest or relevance to team members. (For non-teaching staff the focus is on the support services they provide). The TLTs work with external consultants with expertise in technology knowledge and skill development and their application to teaching and with unique collections and resources in the arts. The latter is an area of interest to a significant number of faculty members who have recently worked to incorporate art across the teacher education curriculum. The role of the consultants is to provide workshops and serve as facilitators to help TLT members achieve the following objectives:

- Acquire specific skills and knowledge about generic technology tools.
- Acquire knowledge about subject specific technology applications.
- Create learning activities or products that incorporate technology or that are technology-based.
- Assess the impact of the product or activity on learning in a course or in a classroom.
- Provide unique collections of resource materials and pedagogical practices.
- Assist in the development of meaningful, effective and creative ways of combining these with technology.

The TLT staff development model consists of 4 phases each consisting of principal objective and method for achieving it.
Phase 1: The acquisition of skills in a technology tool domain through modules/workshops conducted by expert consultants.
Phase 2: The design and development of technology products or activities for use in a course for pre-service teacher candidates.
Phase 3: The incorporation of developed technology products or activities
produced into courses for pre-service teacher candidates and into student support services.

Phase 4: The evaluation of the effectiveness of the implementation of the technology products.

III. The resources, in addition to those provided by PT3, necessary for successful implementation of PT3.

Since PT3 did not provide significant resources for the purchase of hardware, and required evidence institutional capacity in this area, funds provided by the college's administration, and foundation grant support were necessary. Evidence of the institutions capacity building include:

- Ongoing replacement of outdated computers in faculty offices (25 new or refurbished PCs received in last 2 years, with additional ones due next year)
- Renovation of the computer laboratory with 24 networked computers and a teacher workstation controlling all multimedia functions
- Creation of a "Smart Classroom", with a high-end presentation, hypermedia workstation (Internet-access, satellite feed, VCR, computer input and audio system)
- Creation of a multifunctional, multimedia conference room with video streaming capability opening a cyber window between the college and several public schools that serve as field sites for teacher education candidates
- Acquisition, through a state grant, of a set of laptops for the Teaching English to Speakers of Other Languages (TESOL) Program

IV. Obstacles in the initial implementation.

The obstacles that were encountered were of several different varieties: 1) facilities; 2) prior faculty commitments; and 3) competing grant-funded activities. Within the area of facilities, delays in the construction of the adjacent space for the "smart classroom" and the education technology lab, prevented theses two facilities from being on-line during the fall 2000. The demand for other technology facilities on campus by other faculty members, students and administration resulted in a delay of the technology skill development workshops. Alternative arrangements had to be made to provide facilities for the required technology-based courses in our various programs.

Faculty selected for Cohort 1 were not available to participate in the proposed technology training during the Fall 2000 semester because of required participation in the state-mandated redesign and reregistration of every teacher education program in the School of Education. Approximately, 40 programs had to undergo redesign in light of new certification requirements. Moreover, faculty who had administrative responsibilities as program coordinators, about a dozen faculty members, were restricted in the amount of additional released time from teaching that they could receive during any given academic years. As program coordinators, these faculty members had additional responsibilities during the program reregistration process.

Finally, additional grant opportunities threatened the faculty eligible to participate and receive the prescribed incentives from the PT3 initiative. Theses grants include federal and state training grants and school district grants to support school reform and curricular change initiatives. In particular, a university-wide technology grant to support distance learning was
received at the start of the fall semester. Faculty were offered a substantial cash incentive for participation in that initiative and many faculty from HCSE applied for this opportunity.

V. The solutions developed to overcome these obstacles.

The solutions that were developed were varied and also were designed to support the goal of faculty development of course-related technology skills that would directly impact the instructional environment of the teacher candidates.

1. There were no alternatives to the lack of needed facilities so the technology workshops were postponed until 2001.

2. The highest priority in HCSE was the completion of the reregistration process. Thus, there was another reason, in addition, to the lack of available facilities to delay the start of the project.

3. With the help of the Dean of the HCSE and the project staff, a group of faculty were selected who would serve as pivotal individuals within programs or disciplinary areas and were invited to participate in the project. The nominations were made in light of existing commitments to grants and administrative responsibilities. Faculty members, who had applied for the university-wide technology grant, were not included in the current project initial cohort.

Abstract: When we integrate technology into teaching and learning, our challenge is to imagine and enact technology-rich learning environments in which both teachers and students can succeed in ways that technicians and administrators can sustain. We suggest three approaches to designing such environments; each approach is useful at a different level of specificity. In the classroom, technology autobiographies help teachers learn about their students' technological backgrounds and capabilities. At the institutional level, a "multiculturalism" metaphor helps teachers and administrators imagine locally appropriate models of technology support. In the context of pre-service and in-service teacher education, a heuristic we've developed encourages critical reflection by teachers as they learn and implement new technologies.

Background

Teachers are using technology more frequently than ever before as schools try to respond to student needs and get in step with new federal and state computer literacy initiatives. Yet, technology in the classroom does not exist for its own sake: It exists to support teaching and learning. When we teach with technology, we consider ourselves remiss if we don't first establish expectations for student learning, and then build in technologies that can help us to enact those expectations. Yet, for students to learn and for teachers to teach, complex technological systems must work smoothly. Moreover, teachers must learn how to teach with technology and how to use technology to facilitate scholarly and administrative work.

However, in many cases, computers, training, and curricular implementation occur concurrently, as schools hasten to meet student needs and administrative mandates. Teachers are left scrambling, striving to retool with complex new skills while simultaneously revamping their teaching strategies. Individual teaching styles, content parameters, institutional constraints, and student characteristics all compete for teachers' attention. Meanwhile, administrators, eager to implement technological enhancements to curricula, struggle to fund the support systems that teachers so desperately need. Critical reflection on the entire system, not unexpectedly, often takes a back seat in such a chaotic environment. But it doesn't have to. In our on-going struggles to imagine and enact technology-rich learning environments, we have employed several strategies that appear to allow teachers and students to succeed in a way that technicians and administrators can sustain.

One of the problems is that students—who often possess the technological skills that teachers need to learn—are trapped with teachers in an inflexible model of education. In a familiar pattern of learning and power dynamics that Margaret Mead (1970) called postfigurative learning, students learn while teachers teach. Although outside of school, the larger technoculture relies heavily on configurative or peer-to-peer learning and on prefigurative learning, in which the young teach the old (Mead 1970), when it comes to schooling, we are stuck in a post-configurative mode of operation in which older citizens teach younger citizens. The challenge we face as technology-using teachers and administrators is to find ways to tap into technological knowledge wherever it resides and subsequently make it possible to distribute that knowledge throughout our institutions.
Starting in the Classroom: Technology Autobiographies

Teachers of writing often find that asking students to consider the history of their literacy practices, early memories of reading and writing, and the writing and literacy expectations of their parents and teachers can help reveal the personal—and oftentimes unspoken—contexts that students bring to the classroom. Accordingly, literacy autobiographies are sometimes employed as a way for students to write about and reflect on those memories. Similarly, technology autobiographies can be assigned in many types of classes to help teachers understand the experiences with and attitudes toward technology that students bring with them to the classroom.

We have become convinced of the value and usefulness of assigning technology autobiographies in a variety of classes for several reasons. First, and perhaps most obviously, we already know—that it's seldom mentioned in the context of literacy education, and academics understand it only at surface levels—that students are entering our classrooms with sophisticated technological literacy skills and charged attitudes toward technologies (Mead 1970; Tapscott 1998). We think of students as the users of educational environments and consider ourselves to be the primary designers of such environments. With technical communication scholar Robert Johnson, we believe that designers of systems are “obliged to learn how to value, how to see, the knowledge that users produce and then to learn how to make this knowledge an integral part of the technologies we use” (Johnson 1998). As teachers, then, we need to know more, and know more intimately, what is behind the literacy skills and attitudes that students bring to our classroom.

Secondly, we have observed that teachers work within an increasingly complex system of technologies within technologies. By that we mean that on one level, teachers are important stakeholders in the construction of systems of teaching and learning, systems that we have come to regard as technologies (Johnson). Teachers' objectives for teaching and learning may vary considerably, but we all start out with the intention of creating learning systems or environments for students that will also function effectively within the social systems or institutions within which we work. In our efforts to accommodate these institutions, we attend to influences on the technology of teaching and learning. Included among these influences are the efforts of curriculum committees, institutional missions and values, budgets, building layouts, time schedules, purchasing conventions, the abilities of support personnel, administrators' needs, the work of state and national professional organizations, and our own intellectual interests and physical capabilities.

Increasingly, teachers attend as well to a range of electronic systems that influence and complicate course and curriculum planning. Such electronic systems make up another set of technologies within the technology of teaching and learning. As we construct classes (or, more accurately, construct learning and teaching environments), we often have the opportunity to decide whether—and how—to incorporate technologies. Teachers no longer simply design classes and lesson plans: they are the architects of technologies of teaching and learning. Teachers don't just use tools. They construct learning environments in which they and their students live for a time.

A third reason for our interest in assigning students to write technology autobiographies has to do with the fact that teachers think of themselves as creators of courses and curriculum, just as engineers think of themselves as creators of cars and the other mundane artifacts of our culture. However, teachers usually work alone on the design of teaching and learning technologies, influenced, of course, by the particular institutional environments in which we work. In contrast, engineers usually work as productive partners in development teams. We don't dispute that teachers should adopt the label of creator and curriculum designer: this designation certainly makes clearer our responsibilities to the students with whom we share the learning environments that we create. It is, however, not enough for teachers to imagine themselves as creators. They must also acknowledge the needs and values of the people for whom they create teaching and learning spaces and incorporate such needs and values into the curriculum design process.
Armed with the rich data to be found in technology autobiographies, teachers can begin to draw on the strengths their students bring to the classroom. Technology autobiographies also enable teachers to map changes in students' attention and aptitudes over time, thereby helping them to understand technocultural changes at a very localized and specific level. In some regions, technology autobiographies may reveal deep-seated inequities among student populations and suggest learning outcomes that are not measurable with standard assessment tools. For example, some students' technology autobiographies demonstrate that problem-solving and collaboration skills can be learned by playing video and computer games. Others illuminate the types of risk-taking behaviors that often accompany technological success. These learned behaviors—stemming from early and prolonged exposure to complex, fast-paced, and highly interactive technologies—can suggest curricular innovations that build on what has already worked for these students.

Locally Appropriate Technology Support Systems: the Multiculturalism Metaphor

As technology has become simultaneously more complicated and more ubiquitous, departments have begun to hire specialists to support the integration of technology into curricula, classrooms, and research contexts. Sometimes, a faculty member or librarian takes on the role of technology specialist. But a number of schools at all levels are hiring professional staff members to support technology, rather than assigning the task to tenured or tenure-track faculty.

Schools don't really know how to integrate these new types of employees. They have professional credentials, yet they are not teachers. Paradoxically, though, they teach the teachers, who, in turn, are charged with teaching the students. In an apt metaphor, technology specialists are rather like “foreigners”; they are “different, outsiders visiting the territory of other disciplines, and their interaction with the local residents helps to bring about change” (McLeod 1995). McLeod was writing about directors of Writing Across the Curriculum (WAC) programs, but her characterization of the foreigner roles played by technology specialists is right on target. Similarly, Julia Kristeva discusses the fleeting and sporadic nature of interactions with foreigners. She notes that it is considered exceptional when a foreigner has something to teach the natives. Moreover, once the foreigner’s purpose has been accomplished, he or she is expected to “depart, as a friend taking leave of friends, and be honored by them with gifts and suitable tributes of respect” (Kristeva 1991). In other words, a foreigner’s stay is expected to be short-lived, to last only as long as he or she is contributing something to the community or at least is not poaching excessively on the community’s resources.

McLeod (1995) outlined five short-lived foreigner roles that WAC directors sometimes adopt. These five roles are similar to roles that technology support specialists may assume—briefly—within academic departments. Conquerors impose programs from above. When a technology specialist acts as a conqueror, technology becomes “something done to rather than with faculty.” Because imposing a program from above can position the technology support person as “the tool of an insensitive, even hostile administration,” the practice often engenders faculty “defensiveness” and “active resistance.” Diplomats are emissaries from one department to another. Often, these emissaries come from the central computing organization, and, although they may have the best intentions, nonetheless represent their departments’ interests. Ultimately, diplomats perpetuate the idea that technology is the purview of the technology department, not the English department. Peace Corps volunteers tend to regard technology development as a kind of selfless service. They “work for the sheer love of it,” requiring “no released time, no funding for workshops, no administrative support.” Missionaries “go forth to convert,” armed with the conviction that their “particular beliefs and practices are superior to all others.” Their goal is one-dimensional: “to teach their own views as the correct ones.” Change agents, which McLeod regards as the least objectionable of the five foreigner roles, couple an “unfamiliarity with and respect for the local culture” with a “willingness to listen and learn from that culture” that makes them “appealing visitors.” They regard their own knowledge as something to be discussed and perhaps broadened through dialogue (McLeod 1995).

Each of these foreigner roles can be used to accomplish specific goals, but no single role can or should stand alone as a unified approach to departmental technology support, because each has its dangers and limitations. What I submit may be more effective is a “multicultural” approach to technology support, in which the technology specialist—still the foreigner in many educational contexts—assumes different roles as needed: diplomat, Peace Corps volunteer, missionary, and change agent. In addition, faculty, staff, and students who
work with technology within the school or department also take on roles and responsibilities, regardless of their discipline or field of expertise, adding to the multicultural atmosphere.

A paradox faced by foreigners is that to change the system, they need to be integrated into it. That is, they need either to attain some respectable level of power or to establish a significant degree of engagement with the system. In short, they need to feel some connection to the system and to care about what happens to it. Engagement and power cannot easily be attained within alien turf, but if we construct educational environments as “borderlands,” following Gloria Anzaldúa, we may be able to understand why some technology specialists, despite being “foreigners,” are able to become engaged and to exert power. Borderlands are “physical places where two or more cultures edge each other, where people of different races occupy the same territory, where ... the space between two individuals shrinks with intimacy.” They are “place[s] of contradiction,” where it is difficult to keep intact “one’s shifting and multiple identity and integrity.” But they are also places of “exhilaration.” Because the border dweller or mestiza lives constantly in the midst of contention, discomfort, and alien-ness, he or she is a “participant in the further evolution of humankind” (Anzaldúa 1987).

When technology specialists join departments, a kind of borderland is created. Both faculty and technology specialists at first experience some of that discomfort with which Anzaldúa is so familiar. The owners of the turf—the faculty—may feel threatened, both by the presence of a newcomer and by the prospect of using computer technology to support and even to deliver their courses. As a result, the technology specialist may feel at odds and unwelcome. Anzaldúa writes, “The coming together of two self-consistent but habitually incompatible frames of reference causes... a cultural collision.” In its most unproductive form, such a collision may result in a metaphorical standoff or duel that ends when the newcomer, the technology specialist, “decides to disengage from the dominant culture, write it off altogether as a lost cause, and cross the border into a wholly new and separate territory.” Anzaldúa advocates a different course of action: instead of disengaging, she suggests that border-dwellers can survive best if they “shift out of habitual formations” and move “toward a more whole perspective, one that includes rather than excludes.” Border dwellers cope, in short, by “developing a tolerance for contradictions.” They operate not in a dualistic but in a pluralistic mode—“nothing is thrust out, nothing abandoned” (Anzaldúa 1987).

In a technology-rich educational environment, everyone—not only technology specialists, but also teachers, students, and administrators—dwells on the border. Like the mestiza, the most successful border-dwellers “straddle two or more cultures,” willing to be “vulnerable to foreign ways,” to give up safety and familiarity. The mestiza consciousness turns border-dwellers from foreigners to multicultural shape-shifters, available to move in and out of relevant roles as needed (Anzaldúa 1987).

Thinking Critically About Technology: Pre-Service and In-Service Teacher Education

A heuristic for critical reflection on technology would encourage teachers to become local technological activists (as opposed simply to technological advocates). Specifically, our heuristic suggests that those who teach with technology should attend to “infrastructure”: the material, institutional, and human conditions that surround their classes, students, and instructional effort. Part of any technology activist’s job is to help set up institutional infrastructures that facilitate the design of productive technology-rich systems. In addition, because technological systems are already in place in many institutions, the technology activist must understand how to influence existing systems.

We should expect a critical technologically literate activist, then, to take a three-pronged approach:
1. Learn as much as possible about how technologies influence literacy practices;
2. Determine which practices are worth encouraging; and
3. Finally, learn how to help sustain those practices over time and across the social spectrum, or “digital divide.”

Technological activism is a state of mind, an attitude toward the important work we do as educators. With that state of mind, even overworked teachers, technicians, and administrators can accomplish a great deal if they distribute their efforts over many years.

Evolution of an Online Data Acquisition System

Gerald Knezek
Rhonda Christensen
Institute for the Integration of Technology in Teaching and Learning (IITTL)
University of North Texas
Denton, Texas USA
gknezek@unt.edu

Abstract: The evolution of online data collection systems implemented by the Preparing Tomorrow's Teachers to Use Technology (PT3) Millennium Project team (US Dept. of Ed. Capacity Building Grant # P342A990474) during the 1999-2000 school year is described. Examples of the software and survey instruments, database structures, and feedback systems that were initially developed as well as those which are now in place are presented. Participants can access and complete surveys on an experimental system that provides immediate educator feedback by graphing profiles of their responses against the database norm.

Introduction

Paper-based surveys are often expensive, time-consuming, and cumbersome ways to gather data required for evaluation or assessment of project activities. Many projects have moved away from paper surveys to web-based acquisition of data from teachers and students. This paper covers alternatives explored by members of the U.S. Department of Education project team for The Millennium Project: Pathways for Preparing Tomorrow's Teachers to Use Technology. The paper addresses survey procedures and instruments, database structures, and feedback systems which are now in place on servers at the University of North Texas. Plans for merging the PT3 system with a similar one needed for a U.S. Dept. of Education Technology Innovation Challenge Grant evaluation are described as well.

Online data acquisition alternatives

Paper surveys. Paper-based surveys have been the traditional method of gathering responses for many decades. For many populations, such as young children, paper continues to be the most viable alternative because paper surveys require little or no special technology to administer or complete and can be tallied by hand. The method is familiar and fault tolerant. However, it is also labor-intensive and time-consuming for large volume applications. A decision about whether or not to use paper is often strongly influenced by the accessibility of online submission technology for respondents and whether or not there is a time critical need for mass administration and collection of data in a single sitting. Examples involving actual situations in these respective categories may serve to illustrate these points. During 1999-2000, the UNT PT3 Capacity Building grant team began the year using online data collection techniques but ended the year with a front/back one-page paper form. This was because there was great difficulty in getting all 321 teacher preparation students into a lab with computer access for the first half of the year, and there was a need to quickly gather data from all who completed the survey in one mass administration at the end of the school year (Knezek, Christensen, Zoeller, & Griffin, 2001). By contrast, for the Key Instructional Design Strategies (KIDS) project evaluation (Knezek & Christensen, 2000), approximately 75% of the 9,029 baseline data surveys gathered during the fall were paper-based and required 6 months to compile, while more than 90% of the 9,712 spring 2000 surveys gathered were completed via the WWW and required less than 1 month to organize for analysis. The magnitude of the problem necessitated finding an alternative to paper surveys in the latter case.

Mark Sense/OCR. Pre-printed forms that utilize machine-readable bubble-coded responses have been common in the educational area for many years. Typically these can be completed and scored very quickly,
but they are also expensive when commercially produced, quite rigid in response format, and require lead time and printing volume that make their use impractical in many research environments. In the case of our PT3 activities for 1999-2000, the volume of surveys was not large enough to make this approach cost-effective, and the process of designing and printing mark-sense forms would have taken too long. In the case of the Technology Innovation Challenge grant, it was anticipated that some of the survey instruments would need to be modified between pretest and posttest administrations, so a large volume printing would have been wasteful. There was the additional issue of some survey instruments being sufficiently long to necessitate more than one mark-sense form per questionnaire. Initial recommendations to use generic (pre-printed) mark-sense forms along with photocopied survey instruments were soon discarded when the issue of dealing with multiple mark-sense forms per survey surfaced. Newer optical character reader (OCR) technology that can actually sense which response was circled by a teacher or student holds promise for improvements in this area. In these kinds of systems, multiple page surveys simply have the staple removed and each page is fed through a photocopier-type feeder mechanism. If the scanner mechanism has a problem deciphering the mark, it stops and requests that the operator make a judgment based on the scanned image.

HTML forms/E-mailed responses. This elegant approach was developed for experimentation during the fall of 1999 and discarded before being placed into full operation. The concept was simply to have each workstation's local browser post the survey, gather the responses, and E-mail the completed form to a centralized E-mail address when the respondent pressed the 'submit' button at the end of the form. These E-mailed messages then went through a response processing procedure that placed the item ratings in a text file or database. Unfortunately this approach had to be discarded as a universal solution when it was learned that many school-based browsers were not typically configured to send E-mail. Nevertheless, in a modified form the approach could be used throughout the fall of 1999. For the KIDS project in particular, a web server was used to post the survey and gather the information, and the server itself launched the E-mail to the central collection site. Post-processing difficulties related to hidden characters, incomplete data caused by randomly-distributed failures by respondents to complete selected items, and space limitations (500-1000 messages) for E-mail inboxes, all contributed to the perception that this system was too cumbersome to be workable with 1999 technology. Still, even with all the difficulties encountered, because the collection system is totally decentralized (survey could even be loaded from and responses written to a local floppy), this system is the most scalable of all the approaches explored. It appears likely that a system capable of surveying all teachers in the USA in one day, or all teachers in the world in one week, would need to be based on an approach similar to this.

HTML forms writing to text file(s). This system was developed during the fall of 1999 and continues to be our backup approach as of the fall of 2000. In order to speed development for PT3 pretest administrations, survey instruments were placed online for web access using FrontPage as the development tool and FrontPage server software running in a Windows NT environment as the delivery mechanism. The server presents the form to the respondent and gathers the data when the respondent clicks the "send" button after completing the survey. The server writes the data into a tab delimited text file for further processing via SPSS or a database program. Practical limitations we have encountered have to do with the server becoming swamped and unable to process in real time all responses whenever more than 20-25 users are pressing 'submit' nearly simultaneously. This limitation has forced us to move to the database system described below. Future plans call for not abandoning the text-file-writing approach but instead using CGI scripts on a Unix-based platform in order to ameliorate some of the practical shortcomings of the current system.

HTML or Database-published forms writing to database via the Internet. This approach is centralized and elegant. Theoretically it should work well. However, we have found that when administering long (> 100 item) surveys using FrontPage, we still sometimes encounter 'multiple hit' bottlenecks. This is true even when running on a Pentium 500 Windows NT server with a large amount of RAM and a multiple gigabyte reserve of unused hard drive space -- even when using Access as the database. As a result, we sometimes have difficulty simultaneously administering surveys in two student labs of 32 machines each, and we have found ourselves needing to develop a schedule to spread 12 schools from a large suburban school district in Texas over a six week data collection time period.

Competing database approaches
Several competing database approaches appear to be vying for universal adoption in the not-too-distant future. Microsoft Access interfaces well with FrontPage, and is widely used. FileMaker Pro works well with web server software, is easy to use, and has been successfully used in producing graphical feedback (color bars) for a teacher who has completed his/her form. Commercial packages akin to voter polling systems or product advertising/feedback systems have made inroads into the realm of educational survey administration as well. However, many of these are based on hardware/software platforms costing an order of magnitude more than the solutions envisioned by the authors as affordable for an individual researcher or school district.

Compatibility with data analysis systems

One problem that arises with most database solutions to the problem of online survey administration is how to get the data out of the database and into a tab-delimited or comma-delimited text file for use in a statistical data analysis package such as SPSS or SAS. Typically a researcher will not be sufficiently familiar with Access (a relational database package) or FileMaker (a flat file manager) to be able to merge files and write the proper output in a single record as text. Reliance on a database appears to create the need for manager at the server site who can transform these files on short notice.

Prospects for the future

Our long-range plan is to consolidate the data acquisition approaches currently in trial operation into just one or two types, regardless of whether the service will be used by PT3 respondents, by others, or in combination. We are not optimistic that in the short run all of our needs can be met through a single platform, so we plan to maintain development toward a fully interactive system that gives immediate graphical feedback to the respondent, and also toward a large-scale, highly efficient system for simply gathering and perhaps screening the data. In both of these approaches we plan to begin more clearly separating the (forms serving) data presentation and acquisition process from database management and analysis.

Abstract: This paper describes P3T3: Purdue Program for Preparing Tomorrow's Teachers to use Technology, a PT3 project designed to: (1) prepare pre-service teachers to demonstrate fundamental technology competencies, and (2) prepare teacher education faculty to teach pre-service teachers in technology-rich environments, modeling approaches that future teachers should use themselves. The paper describes the project's three complementary components: (a) a comprehensive faculty development and mentoring program; (b) use of two-way communication technologies, notably IP-based video conferencing, for distant field experiences designed to expose students to diversity and technology use; and (c) development of a dynamic web-based digital portfolio system for pre-service teachers.

Introduction

Deficiencies in the preparation of teachers to use technology in the classroom have been highlighted in a number of national reports (e.g., Moursand & Bielfeldt, 1999; Office of Technology Assessment, 1995; Panel on Educational Technology, 1997). These reports indicate that technology is not central to teacher preparation in most colleges of education. Problems include limited use of distance education and computer-assisted instruction in teacher education courses, an emphasis on teaching about technology rather than teaching with technology, lack of faculty modeling of teaching with technology, insufficient funding and faculty professional development opportunities, and lack of emphasis on technology in students' field experiences.

Given that an estimated 2.2 million teachers are expected to join the work force in the next decade, the time for teacher education to change is now. The recent study by the International Society for Technology in Education (ISTE) commissioned by the Milken Exchange (Moursand & Bielfeldt, 1999) recommended: (1) institutional planning for integration of educational technology into teaching and learning, (2) technology integration across the teacher preparation curriculum rather than limited to stand-alone courses, (3) increased opportunities for student teachers to use technology during field experiences, and (4) faculty development to bring about appropriate modeling of technology uses in their courses.

After five years of reform planning by its faculty and administration, the School of Education at Purdue University has begun the implementation of completely restructured elementary and secondary teacher education programs that make significant strides toward addressing the recommendations of the ISTE/Milken report. The new programs, which were launched with students entering teacher preparation programs in the fall of 1999 and will not be fully implemented until the spring of 2002, feature a cohesive set of block courses
and practical experiences that are anchored by four strands – technology, diversity, field experience, and portfolio assessment.

In Purdue's new teacher preparation programs, the technology strand is manifest in: (1) concentrated course work focused specifically on educational technology (e.g., EDCI 270, Introduction to Educational Technology – an introductory course that focuses on helping students build basic technology knowledge and skills within the context of planning, implementing, and evaluating instruction); (2) integrated instruction in the application of technology in specific disciplines and with a variety of learners throughout block courses and in methods courses; and (3) reliance on supporting technologies for communication and to provide examples of exemplary practice. The diversity strand is supported through appropriate course work and by exposing pre-service teachers to various forms of diversity (e.g., socioeconomic, rural/urban, religious, cultural, intellectual, special needs/gifted populations) during field experiences in neighboring schools. However, Purdue is not located near a major urban center and hence cannot easily expose students to certain types of cultural and ethnic diversity.

The field experiences strand is supported by a Theory Into Practice (TIP) component that accompanies each block of courses in the new program. The TIPs provide more and more cohesive field experiences for our students than were available in the past. Finally, in the new program, each student will develop a professional portfolio that will: (1) be used for self-reflection on learning, (2) document professional growth, and (3) provide the foundation for performance-based licensure. Helping to guide implementation of the new programs and ensure that technology is integrated as originally intended, Purdue is engaged in a PT3 implementation grant, entitled P3T3: Purdue Program for Preparing Tomorrow’s Teachers to use Technology.

The overall goals of the P3T3 project are to (1) prepare pre-service teachers to demonstrate fundamental technology competencies, using technology as a tool for teaching/learning, personal productivity, communication, and reflection on their teaching, and (2) prepare teacher education faculty in Education as well as colleagues in Science and Liberal Arts, to teach pre-service teachers in technology-rich environments, modeling approaches that future teachers should use themselves. The project will meet its goals via three complementary components: (a) pre-service teachers will be taught by technology-proficient faculty who participate in a comprehensive faculty development program in which they learn new teaching/learning technologies and practice using them with mentoring and technical support leading to lasting technology integration into teacher education courses; (b) pre-service teachers will participate in rich and diverse field experiences enabled and enhanced through the use of technology; and (c) a dynamic assessment system will provide pre-service teachers the tools and opportunities to select multiple ways of viewing their evolving teaching practice, reflect on that practice, and use digital representations to meet performance-based assessments as they build digital multimedia portfolios. Ultimately, the pre-service teachers will learn about technology, integrate it as they see it modeled by their instructors, and reflect on their own learning about teaching via digital technologies that they will eventually model and use with their K-12 students.

This paper provides an overview of three implementation components of the P3T3 project: faculty development, technology-enabled field experiences, and a dynamic digital portfolio system. Together, these three components provide a cohesive solution to many of the problems related to technology integration that confront colleges of education, and one that fits well the particular needs of teacher education at Purdue University.

**Faculty Development**

The faculty development component of the project focuses on helping faculty to develop technology knowledge and skills by modeling learner-centered approaches that they can use with their pre-service teacher (who, in turn, can use them with their K-12 students). In technology-rich classroom environments, teachers tend to shift toward more learner-centered practices (Sandholtz & Ringstaff, 1996). Adopting a problem-based perspective to teaching technology (Hill, 1999) offers an approach that aligns with the learner-centered characteristics of the technology-rich classroom. P3T3 faculty development approaches include problem-based workshop experiences, use of mentoring teams with technical support, and online support.

As originally conceived, the professional development component of the project for a group of faculty was intended to begin with a week-long introductory workshop followed by year-long participation in
mentoring teams. Faculty development workshops were planned for the summers when most faculty members have times of availability. Each workshop was to enroll about 20 participants consisting of about 10 Education faculty members, 4 graduate teaching assistants who work with teacher preparation courses, 2 faculty members from Liberal Arts and/or Science, 2 Education undergraduates, and 2 master technology-using teachers from our K-12 partner schools. In this, the first year of the project, we were forced to make a change because a late start left us unable to organize workshops for the summer of 2000. Instead, we scheduled the first faculty workshop as an abbreviated two-day start-up workshop during the fall semester break and then followed this with a variety of mini-workshops for faculty at times scattered through the fall semester. Our first workshop also was not as representative of all of the constituencies as we wanted, because no non-Education faculty or undergraduate students participated. However, a mixed group of participants remains a goal for each of the workshops to come.

Our initial two-day mini-workshop was designed to model problem-based learning processes as described by Torp and Sage (1998). In this process, individuals are confronted with a complex problem, define the parameters of the problem, conduct an investigation, and communicate the results. For our workshop, we had groups of faculty members address the question, "What technologies are available at Purdue University to support teaching and learning, how can they be used, and what do faculty and students need to know about them?" Teams of participants developed their own investigations, gathered information, and prepared a multimedia report about their investigation for the other groups. Technology was used during this process to acquire background information (e.g., Internet), produce artifacts (e.g., digital camera pictures), and prepare a presentation (e.g., Powerpoint). Through this process, faculty members were exposed to constructivist approaches to technology integration in the service of content learning. They were able to observe the processes, reflect on the roles of teachers and learners, and see certain applications of technology in the classroom. Following the problem-based learning activity, a variety of available technologies were demonstrated simply to raise awareness of them. Faculty cannot be expected to integrate technologies unless they have some conception of what they can do and how they might be used. Then, we asked faculty to develop their own concrete plans for integrating technology into one of the courses that they teach. The project provides support, in the form of expert assistance and funding, to help implement these projects during the coming year.

As a final step, we offered a number of "how-to" workshops throughout the semester for participating faculty and others. Topics included: web page design, use of the WebCT environment, graphics, managing one's university computer account, and so forth. To achieve extended support, an academic year-long mentoring program (abbreviated to one semester in the project's first year) is underway. Experienced faculty members who integrate technology in their teaching, along with the project's graduate assistants, work with a team of less-experienced faculty members who completed the workshop. Each team member pursues his/her personal and course technology integration goals established at the end of the workshop. Teams meet regularly to discuss implementation activities and to provide mutual support. In addition, work is underway to establish a web-based electronic community where faculty can exchange ideas and gather resources. Faculty who successfully complete a year of professional development activities, and who effectively integrate technology use into a course, will be eligible to lead professional development activities in subsequent years.

Technology-Enabled Field Experiences

Many colleges of education face difficulties placing students in field situations that provide for needed experiences such as interaction with diverse student populations and implementation of exemplary technology use. This problem is particularly acute for Purdue, which is not located near a major metropolitan center. As one way to address this problem, Purdue's P3T3 initiative is making use of two-way video conferencing to link college students and classrooms with K-12 students and classrooms.

Several video-based conferencing technologies are available for use depending on the nature of the activity and the types of interactions desired. For person-to-person interaction, desktop videoconferencing over the Internet provides a convenient and low-cost option. Each party must have a computer equipped with a microphone, speakers, an inexpensive camera, and appropriate software such as White Pine's CUSeeMe or Microsoft's NetMeeting. The grant provides equipment for equipping partner school classrooms with this.
technology. We will be exploring this option for one-to-one interaction, such as tutoring, between a Purdue pre-service teacher and a child in a K-12 classroom but as of this writing we have not implemented any activities using it.

For group interaction, a higher quality video conferencing solution is needed. High quality videoconferencing can be obtained by systems that operate over high-speed telephone lines (e.g., fiber, ISDN) or over the Internet. In Indiana, over 200 schools are part of a fiber optic video network called Vision Athena that is operated by the Corporation for Educational Communications, a partner in the P3T3 project. Although Purdue is not part of the Vision Athena network, we can link our ISDN-based PictureTel videoconferencing unit to the Vision Athena network via a network bridge. While the quality is not as high as the purely fiber network, this system has already been used on multiple occasions to link Purdue classes with classes at K-12 school sites, and it will continue to be used in the P3T3 project. A new option is the use of IP-based videoconferencing systems, such as those made by Polycom (http://www.polycom.com) and other vendors, which support the H.323 standard for video conferencing over the Internet. These units can operate at data rates from 128K to 768K and yield results comparable to ISDN-based compressed video systems such as the PictureTel unit that Purdue already uses. Initial experiments in the use of this technology, which is markedly superior to computer-to-computer desktop video conferencing, suggest that it provides a viable alternative for some types of student observations and interactions in school-based settings that typically occur through traditional field placements. As long as adequate bandwidth is available between the school and university site, this technology can support class-to-class videoconferencing.

In the first P3T3 project experiment in implementing two-way connections with a K-12 site, Professor JoAnn Phillion used a Polycom Viewstation to connect her class to an elementary school classroom in East Chicago, an urban area in the northern part of Indiana. The students in Professor Phillion's class, who were enrolled in the first block course in the teacher education program, were able to make observations of the class, interact with students and the teacher, and even teach some small instructional units via the two-way video connection themselves. The connection at 256K was solid with only occasional dropped packets resulting in a high-quality two-way video linkage. This experience suggests that these two-way video connections can expand opportunities for our students to engage in "field" experiences reaching the kinds of diverse sites, such as urban settings, that would ordinarily be very difficult because of Purdue's geographic location.

Dynamic Digital Portfolio System

Portfolio assessment is becoming an important way to address competency-based standards for teacher preparation programs. There is growing interest in the use of electronic multimedia portfolios for documenting growth and development of pre-service teachers (Barrett, 2000; Read & Cafolla, 1999). As part of its P3T3 project, Purdue is developing a dynamic web-based assessment system that will provide pre-service teachers with the tools and opportunities to select multiple ways of viewing their evolving teaching practice, reflect on that practice, and use various representations to meet performance-based assessments as they build digital multimedia portfolios.

Digital, or e-portfolios, take many forms from simple repositories of disconnected student artifacts stored digitally on CD-ROMs or web servers to highly organized and systematically retrievable work representing the synthesis of professional growth (Campbell, 1997). In our project we have focused on the latter. We are attempting to build an e portfolio component as one part of what we call a dynamic assessment system. The system is dynamic because unlike traditional text-based portfolio systems, it emphasizes interaction and ongoing reflection rather than archiving of artifacts; and, unlike many existing digital portfolio systems, it emphasizes the complexity of teaching practice through a variety of web-based components that provide resources about how ongoing teaching practice and assessment are tied to existing theoretical frames, and provides a "community of learners" component where pre-service teachers can interact with peers about their mutual experiences in their evolving practice.

The dynamic assessment system uses the e-portfolios as one component of a Unit Assessment System (UAS), the plan in the School of Education that indicates how pre-service teachers are meeting new performance-based state licensure guidelines. The e-portfolio is comprised of two primary components: (a) a
web-based input template in which all pre-service teachers can enter digital artifacts (pictures, video clips, audio clips, text files) they can categorize according to three broad Principles in Practice that organize how they are thinking about learners, curriculum in context, and ongoing professional growth and participation in the teaching profession, and (b) a query component in which they can systematically acquire a "presentation" version of the portfolio in which all artifacts classified according to performance assessments, theoretical frames, instructional principles, and ongoing reflective themes, can be retrieved for formative assessment purposes (pre-service teachers' ongoing assessment and reflection on evolving practice) and summative purposes (presentations to portfolio evaluators at key checkpoints on the teacher education program). On the input side, we anticipate that several links will be available: (a) Communities of Learners in Practice, (b) Theory in Practice, (c) Performance in Practice, and (d) A Continuum of Growth. The Communities of Learners in Practice page will include our P3T3 partner schools and their web sites, along with our own P3T3 site and the national PT3 site and a page explaining the various projects at Purdue that are related to these initiatives. Theory into Practice will include resources about theoretical foundations of teaching, learning, and reflection on teaching. Performance in Practice will link to a variety of resources providing examples and models of various teaching practices that students can compare with their own evolving practice. Finally, A Continuum of Growth will provide links to a Purdue University's Professional Development Schools and the school web sites, other courses or collaborative initiatives of the School of Education that a student or visitor might be interested in, and links to various professional organizations.

Both faculty and students will have the ability to log in and have tools and features accessible to them when they enter the e-portfolio area from the main page. For example, a student who logs in might go to the site of a P3T3 partner school and locate a video of a teacher using a project-based activity with science students. The teacher education student may watch the video, see the teacher's lesson design and comments about the lesson, and then activate a "reflective writing" tool to comment on what he or she sees. The observations made in the reflection box/pad (dialogue window) will then be automatically recorded in the student's portfolio in a designated place. When artifacts are retrieved via a query, the retrieval will occur in such a way that all artifacts, their interrelations to one another, and the student's ongoing reflections of evolving practice are all displayed along with a map that shows how a given student is meeting performance goals of the UAS as he or she moves through the teacher education program. Ultimately the e-portfolio system will meet the primary goal of the P3T3 project by providing a forum in which pre-service teachers, though their use of technologies needed to build and use the portfolio, learn about and feel competent with the very technologies we want them to use with their future students.

Conclusions

Purdue University's PT3 initiative, P3T3: Purdue Program for Preparing Tomorrow's Teachers to use Technology, seeks to prepare our teacher education students to effectively utilize computers and allied technologies for personal productivity, for documenting and reflecting on teaching practice, and for effective teaching and learning. Three interrelated components form the basis of our approach for achieving these aims: (1) a faculty development program, (2) use of two-way communication technologies for virtual field experiences, and (3) development of a dynamic web-based digital portfolio system for pre-service teachers. The faculty development program focuses on the use of problem-centered approaches to technology use with a year-long mentoring and support program to help faculty integrate educational technologies their own courses so that they effectively model its use. Two-way video communication technologies, notably IP-based videoconferencing, allow students to observe and interact with school sites from a distance. This permits students to experience diverse school sites unavailable in the vicinity of the university and so broaden their horizons and preparation. Finally, the development by all pre-service teachers of digital portfolios is a component of a dynamic assessment system for the School of Education. Through the development of web-based portfolios, students will reflect on their emerging practice, demonstrate competencies needed for licensure, and, at the same time, learn about and use the very technologies that we want them to use with their students. Through these approaches, we seek to ensure that teacher education reforms at Purdue, initiated less than two years ago, are implemented according to a vision that emphasizes diversity, field experience, portfolio assessment, and technology as key to the preparation of all teachers. For more information about the
project, visit the project website at: http://research.soe.purdue.edu/p3t3.

Abstract: This paper presents program goals implemented through a
Preparing Tomorrow’s Teacher’s to Use Technology PT3 implementation
grant at Clarke College. One goal is to design a “school” environment in
real and virtual spaces to transform learning throughout the liberal arts and
education departments. These new “school environments” provide space
where new knowledge is created together as a community of learners. A
second goal is to build a web-based virtual space to facilitate
communication between and among our learning communities: K-12
students and teachers, teacher preparation students, and liberal arts and
education faculty. This virtual learning space provides tools for “digital”
exchanges using email, the Internet, and the Iowa Communication
Network (ICN). A third goal is to create an Alternative Licensure Teacher
Preparation Program. This graduate licensure program offers technology
learning opportunities to prepare re-entry teachers, mid-career changers,
and out of field teachers for the 21st century workplace.

Part I. PT3 Program Goals

This paper presents program goals of our Preparing Tomorrow’s Teacher’s PT3 implementation
grant. Clarke College, together with its partners, the Catholic Schools of the Archdiocese of Dubuque and the
Iowa College Foundation, has created a program to improve instruction of our pre-service teachers through
effective use of information technologies. Components of this program incorporate new teaching paradigms
implemented through program goals and a technology-learning plan.

One component of our program is the creation of “school” environments in real and virtual spaces to
transform learning and teaching. These new “school environments” are where students and teachers explore,
discover, and create new knowledge together as a community of learners. This component includes a program
for designing strategies for infusing information technologies throughout liberal arts and education
coursework. Faculty development programs provide instructional training on techniques for creating “smart
technology” environments.
A second component is the building of a web-based virtual space to facilitate communication between and among our learning communities: K-12 students and teachers participating in Clarke's education program, pre-service teachers, liberal arts and education faculty. This virtual learning space provides tools for "digital" exchange of information and resources through email, the Internet, and the Iowa Communication Network (ICN).

A third component is the establishment of an Alternative Licensure Teacher Preparation Program. This graduate licensure program provides learning opportunities to prepare re-entry teachers, mid-career changers, and out-of-field teachers for the 21st century workplace.

Grant goals form the framework for implementation of program objectives, activities, training, and support transforming learning environments throughout liberal arts core courses and teacher preparation program. They are as follows:

Goal 1: To create innovative improvements in our existing liberal arts and teacher preparation program by enhancing coursework and student activities through transparent use of technology resources.

Goal 2: To create a learning exchange to facilitate digital connections between and among Clarke College faculty and K-12 teachers and students in our Archdiocesan Catholic Partner Schools.

Goal 3. To create a new graduate Alternative Licensure Teacher preparation program for preparation of re-entry teachers, mid-career adults and out-of field teachers.

Continuous achievement of performance objectives sustain a climate for college faculty, students, K-12 teachers and students to facilitate building collaborative models for exploring "learning how to learn" together through transparent use of information technologies.

Ongoing project activities exemplifying innovative improvements are:
1) offering one-to-many and one-to-one learning opportunities to faculty,
2) developing techniques for strategizing support to liberal arts and education faculties for integrating new models of instruction into coursework,
3) providing student training in technology skills through the Student Technology Assistants Plus+ (STA+) Program to extend technical support to faculty,
4) creating an online structure for collaboration and community building where students and teachers connect, communicate, and share resources through a web-based digital exchange,
5) developing a telementoring program as a vehicle to sustain support for first-year teachers during their critical first year of teaching, and
6) creating an Alternative Licensure Teacher Preparation Program to meet the critical shortage of K-12 teachers in Iowa as well as to prepare new teachers with technology rich models for teaching and learning.

A Technology Education Center (TEC) provides space for one-to-one and many-to-one training sessions for faculty. This center is equipped with hardware and software to provide opportunities for learning new technologies, such as, high-end computers for creating multimedia projects, scanners, digital video cameras, and content specific software appropriate to education and liberal arts courses.

Additional learning opportunities for faculty are provided through an "Anytime, Anyplace Technology Learning Space" (AATLS) consisting of a wireless mobile unit containing 15 laptop computers for teacher training sessions. This AATLS provides a flexible, hands-on learning/training space using portable laptops and a multimedia projector. A technology resource specialist utilizes these spaces offering designing and planning opportunities for faculty. STA+ students are trained to assist the technology resource specialist in extending support across the liberal arts and education departments.

Our project creates innovative models to improve the current teacher preparation program. The National Educational Technology Standards (NETS) aligned with the Interstate New Teacher Assessment and Support Consortium (INTASC) standards provide a framework for assessment of pre-service technology skills. These standards are incorporated into education department course syllabi to promote a seamless integration of technology into all education courses.

The following vignette is one example of a learning model for our teacher preparation students exemplifying a best learning practice using technology. Three secondary education/biology majors completed research on types of authentic prairie plants and animals native to Iowa prairies. Students used electronic data base programs as well as PowerPoint and digital imaging processes to produce their electronic product. They presented their research results to Clarke College Administrators and requested a piece of land on the Clarke
campus to plant a prairie. This prairie will become a permanent authentic learning environment for Clarke students and K-12 students in Dubuque.

Learning with technology extends from the Clarke Campus to our two Archdiocesan Professional Development Schools where pre-service teachers are placed for field, student teaching, and clinical experiences. The Professional Development School was created in collaboration with St. Mary's/St. Patrick's and St. Anthony's Catholic Schools in the Archdiocese of Dubuque At the professional development site Clarke students attend college classes and collaborate with faculty and K-12 teachers "on-K-12-site" to practice a seamless integration of technology within the learning environment.

Pre-service elementary teachers bring laptop computers into the K-8 environment to implement strategies for incorporating technology into the curriculum. Students use programs, such as, Inspiration, HyperStudio, Microsoft Office Suite, and the Internet to produce new learnings through effective uses of technology.

New “digital” web based communication exchanges facilitate and maintain communication between and among members of our learning communities: Clarke faculty, K-12 teachers and students, pre-service and first year teachers, and teacher mentors. Examples of digital tools utilized are: email, the Internet, and the Iowa’s Communication Network (ICN). New web applications support communication between and among our learning communities through the creation of discussion forums and chat rooms. This virtual space showcases technology rich learning processes and products created by Clarke education students, education and liberal arts faculty and K-12 teachers. Projects can be accessed at the following url: http://www.clarke.edu/pt3.

Another project is the creation of a new graduate Alternative Licensure Teacher Preparation Program. The goal is to recruit and prepare new teachers through a program enriched by technology instructional models. This program offers re-entry teachers, mid-career adults, and out of field teachers a technology rich program to prepare them for the 21st century workplace. The Iowa Communication Network (ICN) is one technology utilized for course delivery. This system provides a two-way audio/video course delivery utilizing ICN classrooms across the state of Iowa. This program description is explained in part II of this paper.

Part II. Alternative Licensure Program

Justification for Program

It is projected that 40% of Iowa’s teaching force will retire within the coming decade. Our current teacher education programs are not graduating sufficient teacher candidates to make up this loss (Heldt, 2000). During the summer of 2000 the Iowa State Department of Education proposed rules for an alternative preparation license and urged colleges within the state to design programs that would meet these requirements and also attract a broader audience.

The development of alternative routes to teacher certification is a trend that has grown steadily since the 1980’s in this country, particularly in states that faced fast-growing populations and teacher shortages earlier than Iowa. In 1999, forty states reported having alternatives to approved college teacher education programs for certifying teachers (Feistritzer & Chester, 2000).

Determination of Target Population

National statistics indicate that prospective teacher candidates are to be found among people who already have degrees in fields other than education, people older than the traditional 18-22 year old college student cohort, people who are changing careers, former military personnel, and among ethnic and racial groups that are currently underrepresented in our teaching force (Feistritzer & Chester, 2000). Of 63 non-traditional aged (over 24 years) daytime students at Clarke College (5% of the student body), 27 (22.5% of the non-traditional group) are currently enrolled in our teacher preparation programs, but a number of them have expressed the difficulties they face trying to maintain their other job and family responsibilities and also attend classes given in our usual daytime format. (Clarke does have 227 non-traditional students participating in evening classes in fields other than education.) We anticipate more adult students being interested in teacher preparation if the scheduling and course delivery methods meet their needs.
Investigation of Viable Models

Roth as quoted by Turley and Nakai (2000), noted that alternative routes to certification typically seek to fast track or circumvent traditional university-based teacher education. Some see alternative routes as a serious threat to university sponsored professional preparation. Still others maintain that the issue is not over professional preparation per se but over the timing and institutional context for teacher preparation. Programs are operated by the local school district, by state departments of education, and by colleges and universities. It is our contention that it is possible to develop programs that provide high quality professional preparation and provide that training through means and with schedules that are accessible to adults with family and job responsibilities.

As a college, we determined that the model that appeared most likely to gain approval by our institution and by the State Department of Education of Iowa would be grounded in the competencies that a beginning teacher needs in order to teach and manage a classroom environment effectively and that would meet the requirements of the state’s proposed rules for alternative preparation. The core of knowledge provided to our current pre-service teachers had to be made available through delivery systems and on a schedule that would serve the new populations we were targeting.

Inclusion of Stakeholders

At this point, contact was made with stakeholders in this endeavor. Conversations were held with directors of personnel in the local public school district; the superintendent of the Archdiocese, a parochial school district of ten K-8 schools and one high school; the teacher representative of the local teacher’s union, and a list of key personnel in schools within a nearby three-state region. An informational meeting was held with administrative and student services departments on our campus whose buy-in and support is crucial to the success of such a program. These stakeholders included the academic vice president, the vice president for adult and continuing education, the vice president for college advancement, the vice president for business and finance, the public relations department, the grant-writing department, and the library. The needs of this program for distance, online, and evening services such as admissions, registration, fee-paying, financial aid, academic and career advising, library and bookstore services were addressed. The stakeholders expressed support and appreciation for being brought into the program early in its development.

Design of Proposed Program

A first decision was to target adults who already have a bachelor’s degree. Therefore, rather than develop another undergraduate program, ours would build on their prior education and provide both a master’s degree and the competencies necessary for teacher licensure in Iowa. The education core courses were re-envisioned at a master’s level.

Both elementary and secondary education candidates would take the six three-credit-hour courses that form the education core. The titles of these courses and the key topics for each reflect the mission of the college to develop personally and socially responsible individuals. They include: Introduction to Reflective Teaching, Active Learning: Constructing Knowledge, Teaching in a World of Diverse Learners, Balanced Assessment and Issues in Evaluation, Managing the Classroom Environment for Effective Instruction, and Teaching for Social Justice in a Multicultural World.

After completing the education core, the elementary and secondary tracks would diverge. Elementary majors would take two intensive three-credit hour curriculum and instructional methods courses. Secondary majors would take a general middle school/secondary school methods course followed by a discipline-specific methods course dealing with music, art, physical education, laboratory science, foreign language, English or history methods related to the student’s content area.

The optimum timeline for students in this program would be eighteen months, completing the core and methods courses in fall, spring and summer semesters. One semester would remain in which the candidate would do a sixteen-week, all day internship or student teaching requirements for which twelve credit hours would be granted.

The delivery method(s) envisioned for the first twenty-four credit hours include heavy use of WebCT courses with strongly interactive elements including scheduled chat rooms and listserv, email, or forum exchanges of ideas, reflections and beliefs regarding course readings and online lectures. To simulate some of the classroom observation and participation that the best practices teacher preparation programs provide a collection of video clips of exemplary teaching practice in action will be utilized. Students will develop lesson
plans to provide instruction similar to the best practices videos. In addition to web and video, a third technology, two-way audio-video classes will be used to allow students to participate in and view peer teaching in which students teach their classmates. Two-way audio-video class meetings using the Iowa Communication Network (ICN) may be used to introduce courses and to build community among the cohorts of students who will continue through this entire program as a group.

Partnerships with schools in communities where our students reside will aid us in providing opportunities for a minimum of forty hours of live classroom experience prior to the internship. Forty hours is the current Iowa state requirement. This program will of necessity have to be flexible in finding alternative ways to meet the requirements and develop the needed teaching skills.

Funding and permission to provide internships with a stipend to cover cost of living for the sixteen-week final semester are being sought. A strong mentorship with a teacher in the school where the internship takes place is a requirement. Clarke faculty or Clarke-hired adjunct faculty will serve the same role they currently fill in student teaching, including weekly observations of the student teacher or intern.

This proposal is being evaluated by the Clarke Education Department, the Clarke Educational Policy Committee, and will then be taken to the Iowa State Department of Education for program accreditation.

Developing a Foundation for Enhancing Modeling of Technology Integration

Abstract: Recent national survey shows that most college and university faculty do not model the use of information technology skills while most student teachers do not routinely use technology during field experiences. This paper discusses a consultant-client model related to the current issues in teacher preparation, and reports the development and progress of the federally-funded "Teaching to Learn" project at Oakland University involving urban and suburban school districts partners. We believe that a strong, positive and collaborative relationship between the pre-service student and the in-service educator (university or K-12) is a potent force for change and success in technology integration. A project course is presented, with discussions on the model’s goals, needs, challenges, and opportunities.

Project Purpose, Context and Model

Technology has the power to improve teaching and learning. However, making informed decisions about effective use of technology requires more than just an understanding of hardware and software. It requires the knowledge and wisdom of an experienced teacher who understands issues related to curriculum, and learning processes and outcomes. A teacher preparation program needs to take the perspectives into consideration. According to a survey commissioned by the Milken Exchange on Education Technology on how schools, colleges, and departments of education in the United States were preparing new teachers to use information technology in their work (Moursund, 1999), the following concerns were identified:

1. Most faculty do not model the use of information technology skills.
2. Most student teachers do not routinely use technology during field experience and do not work under master teachers and supervisors who can advise them on information technology use.
3. The “integration factor”, composed of items that addressed graduates’ classroom skills and the actual use of information technology during college training was the best predictor of other scores on the survey.

The School of Education and Human Services (SEHS) at Oakland University identified these concerns a number of years ago and set out to remedy the problem. Oakland University has a long history of preparing our teacher education students to use technology in the classroom. For almost 20 years, Oakland has offered a Microcomputer Applications in Education Certificate at the graduate level and for over 10 years has required our pre-service elementary teacher education students to take a technology applications course. Graduate students in both the Master's and Doctoral programs in Reading and Language Arts can minor in Instructional Systems Technology (IST) Programs that include courses in exploring the use of advanced technology in the classroom in light of current brain research, multiple intelligences, and information processing and Constructivist perspectives (Caine & Caine, 1991; Gardner, 1983, 1985; Stepich & Newby, 1988; Duffy, Lowyck, & Jonassen, 1993). Those courses have laid emphases on multimedia authoring, exploring educational software, using basic computer tools for classroom management and learning activities, exploring electronic stories, using software to enhance higher level thinking skills, teachers telecommunicating, advanced Hyperstudio, authoring for the WWW, digital video editing, teachers and students using the WWW, etc.

Our most recent efforts involve a U.S. Department of Education, Preparing Tomorrow’s Teachers to Use Technology grant entitled: “Teaching to Learn: A Consultant/Client Model to Enhance Classroom Integration of Technology.” This project places digitally literate pre-service teacher education students and established educators in a mutually supportive and collaborative environment which results in a major shift in the information...
technology experiences available to these and other students as they learn to construct effective learning environments.

**Project Course: IST 464 Consultation: Integrating Technology in the Classroom**

The “Teaching to Learn” project is a Student Initiated Model. This model is designed to use the technology skills of our students to assist educators (university or K-12) in bringing computer mediated communication and information management to be modeled in university or K-12 classrooms, and to enhance the technology integration modeling our students experience in their field placements.

Our pre-service students are also beginning to develop a digital portfolio in their required technology course (IST 396: Education Uses of Microcomputers and related technologies) which will serve as documentation that they have achieved competency in the areas identified within the SEHS Technology Plan and the National Educational Technology Standards (NETS), International Society for Technology in Education (ISTE). For purposes of the model proposed here, the digital portfolio will serve as the "certification" of competency that is used as a prerequisite to registering for a course where the student functions as a technology consultant.

Once a pre-service teacher education student has completed the required technology course, that student is eligible to register for a 4 semester hour Technology Consultant class (currently designed as a project course - IST 464: Consultation: Integrating Technology in the Classroom). This class is offered as a regular university class, though the requirements are unique. The instructor of this class is responsible for overseeing and evaluating the experiences of students in their placements. For instance, suppose we have 25 pre-service teacher education students in the Technology Consultant class: some are elementary and some are secondary education students. Each of these students has a number of possible placement options. They can work as a technology consultant with a faculty member at the university, or work with an elementary education teacher in a classroom setting, or work with a secondary education teacher who is teaching in that student's major area. The student can also work as a resource person in our Educational Resource Laboratory (ERL) to help other students who are developing their technology integration skills and their digital portfolios. During Technology Consultant course sessions, students receive instruction on consulting skills and are provided with opportunities to enhance their technology application skills through whole group presentations and small group hands-on collaborative learning experiences.

When assisting an in-service educator (university or K-12), the technology consultant agrees to spend 10 hours per week for 10 weeks helping the client (in-service educator) more effectively model technology integration in the classroom. The consultant may attend and assist in sessions of the faculty member’s classes. However, the technology associate is not responsible for the content of the class, but rather for helping the faculty member identify and implement the modeling of technology in support of the faculty member’s goals for the class. Students have the opportunity to collaborate with a professional in their field in the design of technology supported learning environments, gain experience in doing technology integration needs assessments, and in making technology integration decisions and experiencing the outcomes of those decisions. Further, all of our student consultants gain increased exposure to a variety of continuously evolving models of technology integration. When assisting a collaborating educator (university or K-12), the students spend approximately the 10 hours per week on consultant related activities in and outside of the client’s classroom. All student Technology Consultants communicate electronically to share their experiences and resources with their classmates during the process of their work.

**Challenges of Fitting Project Course into Teacher Education Program Requirements**

To date we have offered the Technology Consultant course as a pilot course with 8 student consultants and as a fully approved course with 18 students. Without a doubt, the most difficult challenge we have encountered is finding a way to make the course attractive to students who already feel they cannot possibly fit one more thing into their busy schedules. In the beginning, this course was viewed by students as both an extra expense and an extra time commitment which had no legitimate place in students programs. Only the most committed students chose to participate. By the time the grant ends we must demonstrate that this is a “don’t miss” opportunity that students will seek out even though it does require extra effort.
While we operate under the grant we can offer extras which will not be available when the funding runs out. We have employed various incentives during this development period. Our Vice President of Academic Affairs demonstrated his support of the project by partially subsidizing the tuition of the students in the pilot course. For the first regular course offering we purchased a classroom set of textbooks which students can use for the duration of the course and return at the end. Through the grant we will also be able to return a portion of the cost of tuition to the students after successful completion of the course. Much more important than these short run incentives, we have been successful in getting the course approved to count as an elective in students' majors and minors. By careful placement of student consultants with either university faculty or K-12 classroom teachers matching their majors or minors, we have been successful in having the Consultant course approved as an elective in the various majors and minors for the participating students.

**Support Required to Develop and Maintain this Model**

We have pledged that we will continue to support the technology integration efforts of students who have completed the Consultant course by continuing to provide technology workshops and equipment which can be checked out through the duration of the grant. This means that students will have technology support throughout their student teaching and possibly into their first year of teaching. We have intentionally developed the course to the extent that the students who have completed the course are major advocates for the course among their peers.

In addition to the efforts described above, funding from the grant has provided for the development of an on-line "problem-solving" data base which contains step-by-step instructions for using various software applications in classroom activities. This data base is open to all on a university server and can be downloaded by the user at "http://pt3.oakland.edu/consultants/labform6.asp".

At the same time, our university is providing increased course support to all classes through a web-based course support application which provides on-line chat, discussion forums, calendars, email, etc. Incorporating these other support components has enabled us to modify our required technology course to help all of our teacher education students learn first-hand how the integration of technology can help students become much more independent in terms of developing self-help skills and much more collaborative in making it easier to develop "communities of learners". In the Consultant course, our students have been particularly effective in developing this concept of community of learners through their use of the discussion forum. They have made it very clear that they expect to maintain their community as they move into the next phases of their educational preparation, which for many of them is student teaching. Their discussion forum will continue on a university server.

While we had hoped that our grant activities would provide valuable information we could incorporate into our other courses, we are pleasantly surprised at how quickly our experiences with the grant project development have facilitated change beyond the immediate scope of the project. We have already mentioned the changes occurring in our required technology course. Technology support in our Educational Resource Laboratory (ERL) has been dramatically enhanced through the Teaching to Learn project. Our ERL is a unique facility which combines the roles of an educational resource library and a technology laboratory. By assigning grant funded technology support personnel (students with strong technology skills who are not necessarily education students) to work in the ERL, the ERL has become a magnet for education students who are interested in informal technology support. The director of the ERL, excited by the increased student interest, has become an active technology integration advocate. She had her staff are developing a variety of technology workshops which will continue, independent of grant funding. These workshops can be offered at the request of students, professors, or departments, again, increasing the general level of technology support available and lowering the threshold for integration.

While it is still too early to predict long term results, we are beginning to consider the possibility that perhaps we are close to a critical number of students and faculty who have decided to make an active effort to incorporate technology into their teaching strategies which will function perhaps as a tipping point, making adoption of technology integration much quicker and easier among those remaining. We are certainly seeing an obvious increase in technology related activity. It will be interesting to see if the momentum continues to increase.
Various Project Participants, Challenges and Opportunities

In addition to Oakland University, the “Teaching to Learn” project involves Michigan Virtual University, an urban school district, and a suburban school district as partners. The Michigan Virtual University is to act as a systems integrator or broker between colleges, universities and training providers. Its role in the “Teaching to Learn” project is to provide support in the development of an online set of modules which introduce and provide models for best practices in online learning environment. The participating urban school district has about 25 instructional sites and 13,500 students, with diverse refugee, immigrant and migrant populations. While the District scores are well below the state average on standardized tests that measure students achievement, the school district has demonstrated its commitment to ensuring that its students have the critical experiences and enhanced learning opportunities offered through the classroom integration of technology. The participating suburban school district, on the other hand, has 18 instructional sites with over 13,000 students. Integration of technology into the teaching and learning environment is a top priority and the district has made great strides in the development of technology for its students and staff over the past few years.

Various partners in the “Teaching to Learn” project allow both in-service educators and pre-service teachers to experience technology integration from different perspectives. Overall, the participants expressed positive opinions about the changes in their views and skills of technology integration throughout their participation. They are pleased with the resources provided by the project and agree that their role as a consultant or a client allows them to experience a fundamental mental shift in the understanding of how technology can be used to help improve their classroom teaching practices and enhance the students’ learning environment.

The ‘Teaching to Learn” project also witnessed challenges and opportunities for the participating consultants (pre-service teacher education students) and clients (in-service educators). One of the major challenges for the consultants is lack of time, since they are usually taking four or even five courses at the same time. The clients also feel difficult to find time to meet with the student consultants, owing to the fact that they are so occupied with their teaching tasks. The lack of hardware and software in some school and classroom settings seem to be another major challenge, especially for the urban participants. Both consultants and clients have to work out ways to deal with the consequent issues. Therefore there are slow progresses in some cases. Some consultants (pre-service teacher education students) may face with potential role conflict because they are functioning as a consultant for the project course and may be placed with the same teacher (client) as a field placement for other classes where this classroom teacher is serving in a supervisory role. Some clients, on the other hand, may encounter negative peer pressure related to their extra efforts to incorporate technology.

With the challenges come the opportunities. The participants become aware that technology is very much their own response to overcome obstacles that stand in the way of a better, more productive way of education, and that technology is their tools, their methods, and their creative attempts to solve problems in the teaching and learning environment.

Michigan COATT Certificate

The “Teaching to Learn” project also aims at a goal of technology achievement for the participants. Early in 1998 Michigan’s senior U.S. Senator, Carl Levin, hosted a gathering of over 400 Michigan leaders to focus on the issue of how we were using technology to advance education in Michigan. This meeting resulted in the formation of the “Working Group on Teacher Training in Technology”. The “Working Group” completed a plan to create the nation’s only standards-based credential to be awarded to teachers (both pre-service and in-service) who demonstrate outstanding achievement in the use of technology to enhance student learning as judged by a multi-institutional review panel. June 3, 1999 was the date of the kick-off news event for the Consortium for Outstanding Achievement in Teaching with Technology (COATT) (visit its website at http://www.coatt.org).

The COATT Certificate is a key factor in the long term institutionalization of the “Teaching to Learn” project. This certificate provides a strong incentive for achievement to students who wish to document that they have achieved technology competence at a level which prepares them to be technology leaders in their schools. Oakland University has participated from the beginning in the development of this certificate. Through workshops, first developed through the “Teaching to Learn” project, then continued through the ERL workshop program,
students who began developing their electronic portfolios in their required technology course will receive the sustained support they need to earn the COATT Certificate, external documentation of their high level of achievement in the area of technology integration in education.

Summary

This paper has presented a consultant-client model in developing a foundation for enhancing modeling of technology integration in university as well as K-12 environments. Oakland University's recent involvement with the "Preparing Tomorrow's Teachers to Use Technology" grant project is reported, starting with a description of project purpose, context and model, followed by a presentation of the project course development and applications progress. Challenges and opportunities related to the current issues of teacher preparation and technology integration have also been discussed. Both consultants (pre-service teacher education students) and clients (in-service educators) participating in the project have experienced positive changes in views and skills in using technology for classroom teaching and learning.

Abstract. Teacher integration of technology in K-8 teaching has remained limited despite increasing connectivity and increasing numbers of computers in classrooms. Few teachers use analytic and project-oriented software on a frequent basis. Recent teacher education graduates report that they do not feel prepared to integrate technology in their curriculum. To address this low technology integration in teaching, ASU West through its PT3 grant, is introducing preservice teachers and their mentor teachers to the Unit of Practice (UOP). The UOP, a product of Apple’s ACOT project, builds on several learning theories, addresses educational standards, and provides a framework for organizing thought and integrating technology into classroom instruction. It helps classroom teachers guide students’ learning through multiple sources of information. The authors discuss the nature of the UOP, how teacher-student teacher pairs develop UOPs that reflect standards, and how the UOPs are assessed in this PT3 project.

Introduction

Using computers as facilitators of students’ learning represents a challenge for inservice as well as preservice teachers. Although by 1999, 95 percent of US schools had Internet connectivity (NCES, 1999) and the student-computer ratio was 6:1 (Anderson & Ronnkvist, A., 1999), teacher integration of technology in K-8 classroom teaching has remained limited. Only about one third of teachers assign computer work on a regular basis and elementary teachers still make frequent use of game and drill software (Becker, Ravitz, & Wong, 1999). Few teachers use analytic and project-oriented software on a frequent basis (Becker, Ravitz, & Wong, 1999). The fact that recent teacher education graduates report that they do not feel prepared to integrate technology in their curriculum (U.S. OTA, 1995) exacerbates this situation as they enter the classroom.

As part of a PT3 implementation grant to help teachers integrate technology into their teaching, Arizona State University West provides preservice teachers and their mentor teachers with technology training and an introduction to the use of ACOT’s Unit of Practice (UOP). This Practicum Plus Program pairs of preservice and mentor teachers attend a week-long all-day summer workshop followed by monthly sessions during the Fall semester in exchange for 3 graduate credit hours. This paper provides a historical and theoretical framework for the UOP, as well as a description of the UOP and its assessment.
To study how the regular use of computers in the classroom by teachers and students might change teaching and learning, in 1985 Apple Computers began a research and development collaboration with public schools, universities, and research agencies in conjunction with university researchers. ACOT research looked at how computers should be used by teachers to improve students’ learning. The project provided computers and training for teachers in selected classrooms known as the Apple Classrooms of Tomorrow (ACOT).

This project was timely and much needed for studying classrooms where students and teachers had immediate access to a wide range of technologies. The rich data from the thirteen years of ACOT demonstrated that the introduction of technology into classrooms significantly increased the potential for learning, especially when it is used to support collaboration, information access, and the expression of students’ thoughts and ideas (Fisher, Dwyer & Yocam, 1996).

As part of the ACOT project, Apple Computers, the National Science Foundation and the New American Schools Development Corporation collaborated to create a structured curriculum framework and named it Units of Practice. The UOP is a thematic approach to planning for integrated learning with technology that meets educational standards. This integrated approach allows children to explore knowledge in several subjects (Humphreys, Post and Ellis, 1981) through meaningful association of curriculum areas in a holistic way that reflects the real, interactive world (Shoemaker, 1989).

Underlying Learning Theories

The UOP builds on several learning theories. Brain compatible learning perceives the brain as a social brain that has an innate need for meaning. It also proposes that complex learning be enhanced by challenge (Caine & Caine, 1997). The UOP encourages student collaboration, inquiry and problem solving. Constructivism emphasizes learning rather than teaching, encourages learner autonomy and initiative, encourages learner inquiry, nurtures curiosity, emphasizes performance and understanding, encourages learners to engage in dialogue with other learners, and provides opportunities for constructing new knowledge and understanding through authentic experiences (University of Pretoria, 1996). The UOP exhibits each of these constructivist characteristics. In addition, the UOP reflects Dewey’s emphasis on projects and concrete activities, Vygotsky’s social interaction, and Bruner’s social construction of ideas or concepts based on current knowledge and integrating experiences.

Essential Elements of UOP

The UOP is a framework for organizing thought and embedding technology into teachers’ classroom instruction that draws on principles validated through research. These principles inform teachers in how to design classroom activities relevant to students to foster their learning through doing. The UOP brings into focus seven elements of instruction used to align curriculum with developmentally appropriate standards across grade levels and content. The seven elements (Invitation, Situations, Tasks, Interactions, Standards, Assessment and Tools) are part of the three phases of teaching: planning, instruction and evaluation. The UOP provides teachers with a common language as they integrate technology. It centers on the student as learner with the teacher as a facilitator of learning through modeling, reflecting, and supporting self-inquiry.

The first element of the UOP, the Invitation, focuses on what the students are going to learn and do. It is the curriculum question that teachers and learners will be addressing throughout the entire unit. It is designed to be a thought-provoking question that invites inquiry during teaching and learning process. It is intended to spark students’ interest in the unit and provide then with a project overview. It is the teacher’s invitation to the students to join in the process of learning, exploring, finding information, raising further questions and finding an answer to this initial unit question.

The second element, Situation, is a clear description of where, when and for how long students will engage in the unit. It not only frames the chronology, but also identifies where learning activities will occur. It specifies the time required for the unit, i.e., a day, week, month or semester. It also addresses the arrangement of the physical environment where instruction will take place.

The third element is Tasks. This is a clear-cut description of what students will do to achieve the goals and standards incorporated in the unit. It explains the activities that are linked to the selected
standards. The tasks must clearly correlate to each standard included in the unit of practice. Each task includes situational or interactional activities.

The fourth element, Interactions, describes group dynamics and the roles of the teacher and students. It spells out how students interact among themselves and with the teacher. This fourth element specifies who does what. It specifies if the teacher or the student initiate the dialogue process that generates the appropriate learning experiences.

The fifth element, Tools, lists everything needed for the unit including clearly defined software titles with appropriate references so others can easily locate them. Tools are the resources provided by the teacher to engage students in the act of learning and the creation of their own knowledge. They can include specific software programs, Web pages, reference books, and informational videos.

The sixth element, Standards, clearly states what the learning objectives are and links them to curriculum and technology standards across grade levels. The objectives also incorporate mandated district, state and national standards. All specific standards addressed are listed in the UOP. These standards delineate the expected student outcomes, as well as the criteria for evaluation of learning.

The seventh element is Assessment. This element of the UOP gives a clearly stated description of how students will be evaluated on the academic standards, goals and learning objectives set forth in the unit. The key question asked during the assessment process is: Did students meet the standards through their completed tasks?

An additional element was added in the PT3 Practicum Plus Program, an Abstract/Overview. This element provides a concise, clear summary of the content knowledge and skills expected of students. The Abstract/Overview gives other teachers a frame of reference as they look at the UOP online at the ACOT website and relate it to their own classrooms.

**Assessment Procedure**

The purpose of assessing each UOP is to objectively and precisely validate the design of instruction and technology integration. The assessment looks at participants' application in the UOP of standards and their integration of technology as a means for student learning.

**Figure 1: Unit of Practice Evaluation Rubric**

External evaluators, teacher education faculty and PT3 personnel having teaching and UOP experience, validate the UOPs through refereed review. They assess each UOP following a rubric (see Figure 1). The rubric, adopted and expanded from one used by the Arizona Learning Interchange (2000), provides a scale from 1 to 3, with 1 being the lowest, for assessing each element and the degree to which it was accomplished. The UOPs developed by preservice-inservice teacher teams can also be accessed through the ACOT website, fostering networking, collaboration and sharing of ideas and strategies across the United States and around the world.

**Conclusions**

Implications for the importance of the UOP lie in classroom teachers who are trained to break out of the textbook dependency mode, guiding students’ learning through multiple sources of information. Training teachers to develop and use UOPs for instructional planning and delivery will invigorate learning for students by allowing their interests to help guide the lessons. Teachers will become empowered through increased confidence in technology integration, breaking away from games, drills and word-processing limitations.

The benefits for students are multiple. First, they are learning in a carefully thought through, sequenced course of study on a particular topic that addresses academic standards. They are learning to explore topics deeply, looking for and accessing information through a variety of sources. They are learning that the textbook is not the know-all, end-all for knowledge acquisition. Most importantly, they are developing technology skills that foster and promote research habits that will be useful throughout their educational careers and continuing in life after school.

To address the issue of low technology integration in classroom teaching, ASU West through its PT3 grant, is introducing student teachers and their cooperating teachers to the UOP as a way of planning for technology integrated learning. The presenters will share the nature of the UOP, how the pairs develop their UOPs to reflect standards, and how the UOPs are evaluated. The presenters will provide examples of UOPs and the evaluation rubric. Handouts will be available for the participants.

Abstract: The purpose of this research was to examine the benefits of one-on-one mentoring for technology coaches and teacher preparation faculty as they learned to use technology. Participants included 33 teacher preparation faculty and 14 technology coaches, teacher education majors. The technology coaches worked with the faculty members in their offices and classrooms as they learned to use technology for their personal benefit and to integrate technology into their teaching. Interviews and observations indicated that coaches as well as faculty members gained in their knowledge of technology.

Faculties often need one-on-one, just-in-time assistance with technology as they learn to use it for their personal benefit and as they explore opportunities to use technology in their teaching. With the rapid increase in the available technologies, faculties are overwhelmed as they attempt to learn to use technology. Faculty development workshops provide a foundation upon which to build technology expertise (O'Bannon, Matthew, & Thomas, 1998). However, faculties also need just-in-time instruction as they attempt to use the knowledge gained from technology workshops and as they attempt to incorporate what they have learned into their teaching. MacArthur et al., (1995) found that technology mentors are one way to provide individualized and ongoing support to faculty members as they move through the complex task of changing the way they teach to maximize the potential of technology to enhance student learning.

Dusick's (1998) review of literature revealed that several factors impact whether or not faculties use computers for instruction. These factors include: 1) administrative support, 2) computer availability, 3) resources, 4) support staff, and 5) training in the use of computers. Reporting on a three-year program focused on infusing technology into a teacher education program, Thompson, Schmidt, and Hadjiyianni (1995) identified these essential factors for success: 1) easy access to technology, 2) allowing faculty to become personally comfortable with technology before using it for instructional purposes; 3) having technology integration as a department goal; 4)
receiving strong support from the administration; 5) inviting participation in the program; and 6) one-on-one mentoring for faculty.

A national survey conducted by the International Society for Technology in Education (ISTE) commissioned by the Milken Exchange on Education Technology found that teacher preparation programs are not preparing teachers to effectively teach with technology (Moursund & Bielefeldt, 1999). Results of this survey indicate that teacher preparation faculty do not model technology use in part because they lack the skills to do so, and they lack the necessary hardware and software. Teacher preparation faculty includes faculty in the colleges of arts, sciences, and humanities many who do not recognize themselves as preparing future teachers (White, 1994).

In order for preservice teachers to integrate technology into their classrooms, they need to see it modeled in the university classes they are taking. Teacher preparation faculty in all content areas must model how technology can be integrated into the curriculum, not added on as an afterthought (Beichner, 1993). If preservice teachers are not required to use technology in their teacher preparation classes and they do not see it modeled by their professors, they will not use technology in their classrooms. Additionally, they must participate in classroom activities designed to provide experiences in enhancing instruction with technology to meet the individual needs of students. Through these experiences they will see the benefits and limitations inherent in teaching with technology. Preservice teachers will teach tomorrow the same way they are taught today (NCATE, 1997).

Faculty members who are not comfortable using technology for their own personal benefit are unlikely to integrate technology into their teaching. Stewart (1999) and Thompson, Schmidt, and Hadjiyianni (1995) found that one-on-one faculty mentoring assures faculty members receive the support they need to become comfortable using technology. Mentoring assures the faculty members receive individualized attention focusing on what they want to learn, a self-paced approach to learning, a comfortable setting, flexible times, and on-going support during the learning experience. Faculty members who participate in mentoring programs not only learn to use technology they are more likely to model technology use in their classes (Gonzales et al., 1999).

Faculty Technology Use

Faculty do not incorporate technology into their classes for a variety of reasons including, lack of access to appropriate hardware and software, limited technology skills, lack of knowledge of how to integrate it into their teaching, and lack of technical support. Lack of access to technology in university classrooms and faculty members' offices is often a major problem. However, when it is available faculty members need instruction on how to use the technology. Workshops provide them with the skills to use the technology, but do not provide them with the ongoing support needed to adapt the skills learned to their classroom teaching. Additionally, workshops often focus on teaching the technical skills, but do not show faculty how to integrate the technology into their specific subject area. Furthermore, in order for technology to reach its full potential, faculty members need to change the way they teach which is often not addressed in workshops.

Since faculty members have different work schedules they need to have assistance available when they are in their office, at flexible times. It is difficult for them to match their schedules to the times of scheduled workshops. Workshop participants are on a variety of technology levels and interests, so it is often difficult to provide the specific help faculty members need. One-on-one support in their offices and classrooms can be tailored to their personal interests and matched to their ability levels.

Each year students are arriving on college campuses with more technology and more technology skills (Olsen, 2000; Sheffield, 1996). When they see technology use modeled in some classes and find some course materials on the web they begin to question why other professors are not using technology and not placing course materials on the web. Hence, students are applying pressure to faculty members to learn to use technology and to incorporate it into their curriculum (Olsen, 2000; Thompson, Schmidt, & Hadjiyianni, 1995).

Technology Coaches

Thompson, Schmidt, and Hadjiyianni (1995) found that successful technology staff development included not requiring participation, but inviting participation and the use of one-on-one mentoring for interested faculty. One key to the integration of technology into teaching is ongoing coaching or mentoring for faculty after initial technology workshops as the transfer of skills to the classroom requires ongoing support (Ritchie & Wiburg, 1994). McKenzie(1991) found that faculty members need comfortable, familiar environments in which to learn to use technology as well as personal support. Faculty members want immediate help when they have problems, they want...
help from someone with whom they feel comfortable, and they want just-in-time instruction specific to their own personal needs. Technology coaches meet with faculty in their offices where they have access to their own computer and coaches provide the faculty with personal support in a non-threatening manner as they experiment with technology.

A United States Department of Education Preparing Tomorrow's Teachers to Use Technology (PT3) grant provided funding for technology coaches to assist teacher preparation faculty as they learned to integrate technology in their teaching. Support staff for the coaches included two technology proficient College of Education faculty members. Through collaboration with another PT3 grant within the College of Education, technical support and instructional support personnel provided coaches and faculty with additional onsite assistance. The purpose of this research was to examine the benefits of one-on-one mentoring for technology coaches and teacher preparation faculty as they learned to use technology.

Methodology

Participants

Participants in this study included 33 teacher preparation faculty and 14 preservice teachers. Faculty members (33) from the College of Education, College of Applied and Natural Sciences, College of Liberal Arts, and the University Lab School received one-on-one assistance from the technology coaches. Three of the coaches were married with children, one was married and pregnant, one was married, one was a single mother, and the remaining eight coaches were living at home or in a dormitory on campus. The coaches were 14 full-time female preservice teacher education majors who had completed the required teacher preparation technology course and had a high interest in learning more about using technology. During the 1999-2000 academic year there were eight technology coaches. During the summer 2000 there were nine technology coaches, three of who had been coaches during the academic year.

Procedure

At the beginning of the fall quarter professors who taught the initial technology class recommended students they felt were proficient in technology. Since many of the technology coaches would not be attending summer school, additional coaches were recruited during the spring Kappa Delta Pi initiation. Some students applied to be technology coaches after hearing about the positions from other students and learning that the salary was above minimum wage. Students were asked to complete a form indicating which hardware and software they had previously used and to indicate their proficiency levels. Students were also asked to provide information as to when they were available to work with faculty within the 20 hour per week limit set by the university. Students were reminded to not miss classes in order to work with faculty and to allow themselves enough time for studying.

The availability of the technology coaches was introduced at department and lab school faculty meetings and through memorandums placed in faculty mailboxes. Faculty members were asked to complete forms indicating the areas in which they needed assistance. They were reminded that the coaches were there to assist them in using the technology, rather than to complete projects for them. Forms completed by the coaches and the faculty were used to match student expertise with faculty needs.

In order to assure that the coaches had the necessary skills to assist faculty, opportunities were provided for them to work through tutorials and attend workshops on HyperStudio, Microsoft Office, Inspiration, and Netscape Composer. When faculty requested assistance with graphics, email, and using a digital camera, coaches were given individual instruction prior to their meeting with the faculty member. Coaches were at first concerned about their limited technology expertise. They were assured that they were not expected to know all of the answers and that support staff was available to assist them in finding the answers. They quickly learned that the support staff did not have all of the answers. However, they also learned that the support staff worked together to find the answers they needed and helped them to learn the skills they needed to assist the faculty. As new software arrived for the faculty computer lab and the campus model technology classrooms, students assisted in the installation, learned to use the software, wrote up step-by-step directions for using the software, and worked with faculty members as they used the software with their students.

Faculty development workshops were provided to preservice teacher education faculty during the day and after school for the university lab schoolteachers. The coaches attended the workshops and provided support to the faculty members during the workshops. The workshops provided opportunities for the coaches and faculty members
to meet one another. Relationships formed during the workshop were often continued as faculty members requested that the students work with them in their offices and classrooms. Faculty workshops in the College of Education were not well attended, however, faculty members were interested in having coaches work with them one-on-one in their offices and classrooms. Lab schoolteachers attended workshops in their school library as part of their monthly faculty meetings and appreciated the opportunity to learn to use technology while working with one another.

Coaches worked with faculty in their offices on their own computers, which provided a safe, comfortable environment for the faculty as they were familiar with the software on their own computer. Coaches assisted faculty members as they attempted to use skills learned in workshops. Simple things such as differences in the configuration of the toolbar between the computer used in a workshop or the computer in another faculty member’s office and the computer in their office frustrated faculty members as they learned new skills such as centering or underlining text. Coaches were also available to assist faculty in their classrooms as they learned to use the multimedia carts for classroom presentations. These carts contain a VCR, speakers, document camera, laptop, and a presentation system and had to be checked out prior to class and returned after class. In addition to being overwhelmed by the buttons, cables, and keys, faculty members soon discovered that since the equipment on each cart was from different manufacturers the configuration and the setup varied. If they could not check out the same cart each time, they were faced with figuring out how to operate the equipment on the available cart.

Some faculty were interested in learning to create their own web pages and placing course materials online. Coaches varied in their ability to create web pages and they were given additional instruction in web page design and development. A simple web page template was designed and placed on the College server so that the coaches could download it directly onto the faculty member’s own server space. Instructions on placing web pages on the faculty member’s server space were developed for coaches. Faculty members were given directions on how to locate, maintain, and edit their web pages.

With the opening of three distance education classrooms the need for proctors became evident. Since funding for distance education proctors was not available, technology coaches were asked to proctor the classes. Convinced that knowledge of teaching via compressed video would be beneficial to them professionally, students volunteered to learn to proctor the classes. Since many of the distance education classes were taught at night, this provided students additional work opportunities that did not conflict with their university classes. The director of the campus Center for Instructional Technology and Distance Learning (CITDL) and his staff conducted a proctoring workshop for the technology coaches. Additionally, on the first class meeting one of the grant support staff worked with the coaches to assure that the equipment operated correctly and that the coach was comfortable with the assignment.

Technology coaches were asked to write down a brief description of their visits with faculty members and to have them sign the forms to verify that the student had worked with them. Faculty members were also provided separate forms for comments to send directly to the grant director about the mentoring sessions. Interviews with the faculty and the coaches conducted by an external evaluator and grant personnel provided additional data about the mentoring process.

**Results**

Interviews with and observations of teacher preparation faculty and technology coaches indicated that both showed growth in their technology skills, which led to them feeling more comfortable using technology and more willing to incorporate technology into their teaching. The coaches were at first intimidated by the prospect of teaching their professors and because they felt they did not have the expertise needed to teach someone to use technology. However, faculty members and coaches soon developed a working relationship. Since the coaches did not know everything about technology, the faculty felt comfortable asking for their help. One student commented that she thought the faculty felt comfortable working with the coaches, because they were not "techno-experts." The coaches accepted the faculty at their level of technology expertise and tailored the instruction to meet the needs of the faculty member. However, two coaches were rather disconcerted to discover that a faculty member did not know how to type and did not know the location of the keys on a keyboard.

Faculty members expressed appreciation for students helping them learn to fully utilize their office computers, such as organizing files on their computer hard drives, sending email attachments, using spreadsheets, and writing down instructions for the faculty member to be able to do things on their own. The coaches worked to accommodate faculty members’ schedules; however, they were frustrated when faculty members set up appointments and then failed to keep them. The coaches came to understand that faculty members’ schedules were often beyond their control.
One coach worked with a professor loading math software on a laptop computer on the multimedia cart and assisted the professor as the software was demonstrated for the students. This student then made herself available for her classmates as they worked problems in the computer lab using the software and printing out their answers. Another coach learned to use several pieces of early childhood software and then worked with the professor in her classroom as she used the software with her students. Several professors asked for assistance learning to use PowerPoint and to create slide shows for their conference presentations. Coaches were successful in teaching faculty members to use PowerPoint, but were less successful teaching faculty members about design issues. Coaches reported that faculty members insisted on putting excessive amounts of text on the slides in small font and including distracting sounds and animations. Jarring colors, small fonts, and irrelevant animations were also a problem with faculty web pages.

At first the cameras, microphones, monitors, computers, document cameras, fax machines, telephones, and VCRs in the distance education classrooms were overwhelming to both the proctors and the professors. However, they soon developed a routine for working together and operating the equipment. One student became particularly adept at moving the camera and operating the equipment and took great pride in her work. Although no longer employed as a technology coach, she volunteers her time whenever she is registered in a distance education course. During the summer session one professor overwhelmed by the prospect of using any technology was assigned two proctors for his compressed video class. The students at the distant site continually asked to see his notes on PowerPoint slides saying that it would be easier to follow along. The professor resisted until one of the coaches assured him she could create a slide in less than a minute and then proceeded to do so. Knowing that they were to teach the professors rather than do everything for them, the proctors insisted that he create one or two slides for each class and they would complete the others. The two coaches enlisted the assistance of other coaches and they all worked together to create PowerPoint presentations for some of the professors other courses. At the end of the class the professor took the students to lunch and he continues to maintain close contact with the students as they complete their teacher education program.

The individualized attention and on-going support of the coaches facilitated faculty members' growing expertise and use of technology. Having assistance available in their classrooms when working with their students encouraged faculty to weave technology into their teaching. Some faculty members did make changes in their teaching by allowing students to work together and solve problems using technology. Some faculty members saw the potential of technology to enhance their teaching and continue to ask to learn new ways to use technology. For example, one faculty member with the assistance of a technology coach created her own web page and was ready for another challenge, so she decided to establish a listserv to use with her students. Other faculty members simply created web pages and put course syllabi on-line with no appreciable change in their classroom teaching. Some faculty members had a difficult time understanding that with all the different configurations of computers in the College what coaches learned to do on the computers in the lab may not work on the faculty members' office computers. For example, one faculty member's office computer did not have sufficient memory to work with graphics.

Overall the technology coaches indicated that after working with faculty they felt more comfortable using technology and had gathered ideas for using it in their own classrooms. During interviews three of the coaches expressed interest in obtaining a master's degree in instructional technology. One coach graduated in May, immediately applied for the master's program, and continued her work as a technology coach during the summer. Over the summer she spent time using the computers and printers to create things for her classroom and to plan activities for her new students.

The technology coaches developed a sense of pride in their technology expertise and developed problem solving skills as they encountered hardware and software problems. Coaches learned to move between Macintosh and Windows computers with ease and became familiar with a wide variety of software for use in their classrooms. The teacher preparation faculty and their classmates see the coaches as valuable resources. A real commitment to class and they would complete the others. The two coaches enlisted the assistance of other coaches and they all proctors for his compressed video class. The students at the distant site continually asked to see his notes on employed as a technology coach, she volunteers her time whenever she is registered in a distance education course.

The adoption of technology is a complex process that takes time and resources in addition to requiring ongoing individualized support. The results of this research supports the research of the others (MacArthur et al., 1995; Gonzalez et al., 1999; Stewart, 1999; Thompson, Schmidt, & Hadjiyianni, 1995) regarding the benefits to faculty of having one-on-one mentoring as they model the integration of technology in the classroom curriculum. One-on-one assistance in their offices provided faculty members the support they needed to become comfortable using technology, an essential first step to using technology in their teaching (Thompson, Schmidt, & Hadjiyianni, 1995).
As evidenced by the students in the distance education class who requested that the professor use PowerPoint presentations, students are applying pressure to faculty to incorporate technology in their teaching (Olsen, 2000). Having preservice teachers mentor teacher preparation faculty benefited both groups as they worked together to learn to use technology for their own personal benefit and in their teaching. Furthermore, they established positive relationships that continued after the mentoring ended.

Abstract:
Last year our School of Education received a PT3 Capacity Building grant. This year we received a PT3 Implementation Grant to continue our work with integration of technology into our teacher preparation program. In addition, last year we received a 5 year Title II Partnership for Teacher Enhancement grant to assist us redesign our teacher education program. The PT3 grants support this effort.

A panel of university faculty will interact with the audience as they share their experiences on lessons learned and the continuous assessment that occurred during this period of change.

Overview:

The University of Alaska Anchorage School of Education (http://www.uaa.alaska.edu/ed/) has been redesigning its teacher education programs. The goal of the redesign was to provide preservice students with an education that meets the needs of educators in Alaska and to provide practicing educators with ongoing professional development support. An additional goal was to be able to become NCATE accredited.

A five year Title II Partnership for Teacher Enhancement grant, Alaska Partnership for Teacher Enhancement (APTE), provided assistance with the redesign our teacher education program. UAA, through the APTE Title II partnership grant is creating a post-baccalaureate Professional Development School model. Four schools in Anchorage and 5 schools in the rural school districts have been identified for the 2000-2001 school year. In addition, the APTE program will be developing a distance-delivered program for village teacher aides that will lead to a Liberal Arts Bachelor's degree and elementary teacher certification. The APTE grant allowed School of Education faculty to interact with Pre-K to 12 faculty, administrators and private sector partners. The first task was to create a new post-baccalaureate program and begin implementation within one year.

In addition to this major task, faculty were being asked to integrate technology in their classes. The Alaska PT3 grants assist with this process. Our PT3 grant addresses four specific goal areas: Program Development, Faculty Development, Student Development, and K-12 Partnerships. They are part of a systemic change in teacher education and linked to each other and to other projects and programs within the SOE. These are the goals of the PT3 grant.

STUDENT DEVELOPMENT: SOE GRADUATES will be well prepared, technology proficient educators.

FACULTY DEVELOPMENT: SCHOOL OF EDUCATION AND CONTENT AREA FACULTY will be knowledgeable about current practice related to the use of computers and technology and integrate them in their teaching and scholarship.

PROGRAM DEVELOPMENT: SCHOOL OF EDUCATION PRESERVICE TEACHER EDUCATION PROGRAMS will reflect best practice including the integration and modeling of technology in all courses, using distance technologies to erase the differences between urban campus-based and rural programs.
K-12 PARTNERSHIPS: SCHOOL DISTRICTS WILL BECOME FULL PARTNERS in new teacher preparation through mentor teachers modeling best practice supporting pre-service year-long internships and shared training activities.

To help faculty members develop the vision needed as they experiment with using technology in their current courses and model use of technology in the field, as part of the 1999-2000 Capacity Building project, UAA faculty members participating in this project have already received laptop computers with software comparable to what the students have in the SOE lab. A small projector and "smart cart" with student laptops is now available for check out.

One immediate benefit of the PT3 Capacity Building year has been increased awareness of technology integration into instruction. The team building resulting from UAA sending 10 people (SOE, CAS, ASD) to the SITE conference in February 2000 was a pleasantly unexpected outcome of this activity. Faculty were asked to think about the lessons they have learned from these experiences. Those attending the SITE conference in March 2001 will participate in this session by sharing lessons they have learned.

Abstract: Large-scale projects often depend in critical ways on points of leverage where modest effort has significant influence on outcomes. The purpose of this paper is to describe how a coordinated system of Web resources served as such a point of leverage in a federally-funded effort to promote technology in support of teaching and learning. We believe two other decisions were important in the success of our Web tools as a point of leverage. One decision was to avoid high-tech proprietary systems (i.e., “groupware”) in favor of a loose collection of relatively “low tech” tools. The second was that we sought to build on, rather than replace, existing workplace practices and protocols. We believe these decisions also significantly enhance the generalizability of the model we have developed for preparing teachers to teach in an information age.

Introduction

Initiatives in teacher education are complex enterprises that typically involve large numbers of participants and a wide range of constituencies. In addition to technical issues related to curriculum, credit hours, and certification, there are many practical matters related to working practices and protocols in university and K-12 academic settings. Given such circumstances, it is critically important that initiatives intended to promote institutional change establish a broad collaborative base of knowledge from which change can emerge. This paper describes how “low-tech” Web technologies have been applied to create and support the development of a collaborative organizational knowledge base with the objective of promoting in-service and pre-service teacher development in the area of technology integration.

Although it has become something of a straw figure, it may still be useful to emphasize that technology integration that relies simply on investing as much as we can in the latest hardware and software is not likely to lead to desired outcomes. There is ample evidence that simply introducing new tools in the absence of continuing support will be unproductive (Maddux, Cummings, & Torres-Rivera, 1999; McGregor & Pachuski, 1996; Bork, 1995). Moreover, teacher educators and the institutions they work within have well-established workplace protocols and practices that reflect local needs and knowledge (Walters & Pritchard, 1999; Slick, 1998; Maddux, Johnson, & Harlow, 1993). Depositing the “latest and greatest” technologies in a teacher’s classroom may be the equivalent of sending a tractor to a third world farmer who has no ready access to gasoline. In principle, it has utility, but it presupposes a context that is missing. Teacher education initiatives are further complicated by the fact that they almost invariably are required to bridge institutional boundaries (Slick, 1998). Efforts to revise a curriculum will often require participation by state licensing offices and field placements and internships can only be arranged working with colleagues in PK-12 school systems (White, 1994). Even purely physical constraints can result in serious obstacles to reform when participants are scattered across school systems, cities, and states.

As participants in a federally supported Preparing Tomorrow’s Teachers to Use Technology (PT3) project, we were eager to begin but wanted to be sure to coordinate our efforts so that our work could effect institutional changes that would not disappear with our federal funding. From the beginning, we felt that the power of the Internet (and specifically, the Web) would be central to our efforts. At the conclusion of the first year of work it is now clear that, if anything, we underestimated the potential of the Web as a platform for our efforts.
Project Overview

Our project has three major objectives, all related to technology integration in PK-12 or post-secondary classroom settings.

1. Assist pre-service teachers in developing teaching styles that make effective use of technology.
2. Promote pre-service teacher experience with technology-enhanced learning in their own education.
3. Establish a model for technology integration that can grow and change as technology evolves.

Our project achieves these objectives within a training and internship program that places digitally literate pre-service teacher education students as technology consultants with established public school and university educators interested in learning more about technology integration. This consultant/client model is designed to introduce new teaching and learning technologies in a mutually supportive collaborative environment that benefits the pre-service interns, the teachers with whom they work, and the students in the classrooms where technologies are introduced. The project is also intended to develop a broader, more flexible model for technology integration to ease technology transitions for individuals and institutions in a variety of settings.

We believe the ultimate success of our efforts will be demonstrated by the extent to which tools and practices we develop are institutionalized in our programs and in our collaborative interactions with field-based colleagues and school systems. As a consequence, we made an early choice to adopt a collection of inexpensive and widely used “low-tech” tools (email, listservs, discussion boards, Web pages, and WebCT, a course development and delivery system) to build a foundation for our project knowledge base. Our decision to opt for a “low tech” approach had a number of important consequences for us.

One consequence was that most project participants were already familiar with many tools we had chosen, an important benefit in getting project activities started. A second more complex consequence was that, since most participants used the tools we had adopted, they had already established practices and protocols for this use. While this sometimes was an advantage, it occasionally resulted in problems since established patterns of use could run counter to our objectives. One instance where this led to some difficulties was where students had come to rely on workplace Internet access rather than on the access provided by the university. Practices and protocols that might be appropriate in a workplace setting (e.g. no Internet downloads) could make essential project activities impossible, even when employers were sympathetic to our objectives. Finally, a third consequence of our choice to use “low-tech” tools was that institutionalization would not require resources to support specialized hardware or software when external funding ended. The success or failure of the institutionalization effort would thus depend on practices and protocols for technology use we could develop, not on resources we had managed to accumulate when outside sources supported our work.

In the fall of 1999, project activities began with participants from Oakland University (OU), Michigan Virtual University, Pontiac City Schools, and Rochester Community Schools. The working groups we established included OU faculty and students, colleagues from the Michigan Virtual University, and local school administrators, including technology coordinators, and an assistant superintendent for curriculum. We began our work by identifying expectations, points of contact, and participant roles and responsibilities. Although the implementation of the project would not begin until the following term, it soon became apparent to us that the Web-based systems we planned to use in supporting our technology consultants would probably be equally important to us in planning, coordinating, and documenting project activities. Our online information and document management systems thus became an important early priority.

In January 2000, we began creating technology and content components that would be a part of the course for the student technology consultants. A small group of 8 students helped us pilot this new 4-credit course, co-taught by faculty from Instructional Systems Technology and Human Resources Development. From January to June of 2000 we broadened our technology base and significantly expanded the “content” we could deliver. By mid-winter our Web server was fully operational, the Web development team had created a wide range of project support materials, and the outlines of our broader framework for information management and distribution were established. In the fall of 2000, our first full class of technology
Building a Foundation for Knowledge

Well before our first group of technology consultants began their work in the field, we had come to the realization that our success would depend on capturing what we were learning in a well-organized and accessible knowledge base. It was clear that, given our existing workplace practices, documents would be a central element in our knowledge base. Proposals and planning documents had been the foundation for our future work and had helped us establish timelines and assess progress. We also expected to produce a variety of user guides, project reports, and research papers. We were also well aware that managing the flood of paper generated by a large-scale project like ours could be difficult. Distribution of printed documents would create unnecessary and unproductive duplication, requiring participants to manage their own hard-copy document archive, as well as inviting versioning problems that arise when multiple drafts of a document are circulated.

One approach to solving these problems is to create a single centrally managed print document archive, but this approach is usually expensive and relatively inflexible, as a result of the administrative infrastructure that must be created to support intake, registration, and distribution. We opted for an alternative "distributed" approach to document management that allows individual project participants to submit, review, and retrieve documents through our project Web site. The foundation of this distributed approach is a database system that helps us organize materials, while it simultaneously solves problems related to versioning and duplication by providing a single readily accessible but authoritative source. One advantage we had in considering how we might manage the documents produced in our project was the fact that we had immediate control over our Web site, since the project Information Services Coordinator was also the server administrator. It has been our experience, however, that while this degree of control can confer some advantages (e.g., we can rely on our operating system to manage user access), the methods we have developed do not depend on this arrangement. Although working both sides of the traditional IT "divide" has given us an appreciation for the role of technology administration, our decision to emphasize low-tech tools meant we were looking for generic tools that would not require special server access.

Our server platform is a Windows NT machine running Microsoft's Internet Information Server 4.0. One feature of this platform that has been central to our project is its support for Microsoft's Active Server Pages (ASP), an environment for integrating a variety of server-side scripting languages into our Web site, and Microsoft's ActiveX Data Objects (ADO) that support our database connections. Fortunately, however, these technologies provide relatively straightforward methods for creating dynamic database-driven pages without sophisticated programming skills, an important element in making our methods generalizable. Moreover, these techniques can be implemented in a step-by-step incremental fashion that helps those involved in developing and delivering information services acquire skills as they bring new capabilities online.

Overview of the Web-based Systems

As illustrated in Figure 1, our Web-based information system includes two main components, a document management system (DMS) and a course delivery system (CDS). The DMS runs on our project Web site, while the CDS (WebCT) runs on a university server. One disadvantage of assembling project-specific and university resources as we have done is that it requires participants to manage multiple user accounts (for access to different components), but we have not had problems with users managing accounts. Moreover, although these systems are distinct, we have found that information is easily shared since both components are Web-based resources on our local university network. While this arrangement limits our control somewhat, it also means we do not need to manage the CDS, a complex software system. All things considered, we believe our distributed approach has important benefits for both the sustainability and generalizability of our model.

Figure 1 provides an overview of our Web-based systems. Rectangular regions represent users, oval regions represent information, tools, and documents, and arrows represent the flow of information. Some groups are exclusively "consumers" of information, while others also contribute information to the system.
Both the Web Development Team and the PT3 Administrative Team, for example, are linked to the DMS with double-headed arrows indicating they receive and contribute to this resource. Likewise, both Consultants and the PT3 Administrative Team are linked to the CDS, indicating that these groups participate as both consumers and contributors. In effect, these double-headed arrows represent the interactive elements in our system, places where participants contribute as well as consume information.

The DMS includes five main types of documents. The oval at the top represents documents created and contributed by the PT3 Administrative Team, the group that leads the project. This part of the system supports operations that are "internal" to the administrative team. Most documents created by this group start out as restricted-access "working" materials, available only to other members of the administrative group. Some of these documents are, however, eventually moved out into the public area. The lowest central oval in the DMS represents a part of the system set aside to support development of support materials. Since members of the Web Development Team have primary responsibility for authoring these materials, this group has authoring privileges and is linked to the system with a bi-directional arrow. As with the administrative materials, support documents are initially held in a restricted-access region but usually move quickly into the public-access region. The final elements in the DMS are private, password protected discussion/bulletin board areas intended to promote and support private interaction within the client and consultant groups. As indicated by the arrows, only members of these groups have access to their respective discussion boards.

As indicated on the right side of Figure 1, the course delivery system (CDS) involves two participant groups, consultants and the administrative team. As a part of their project participation, consultants register for a 4-credit consulting course that helps them establish effective working relationships with clients (i.e., participating teachers.) Since our online courseware includes a variety of interactive features, both consultants and members of the administrative team who co-teach the course are linked with a bi-directional arrows.

Some Participant Perspectives

From the Project Director

As project director, my role is leading, coordinating, and making sure that all of the individuals involved have what they need. In order to do this effectively, I need relevant information about all aspects of the project and continuous two-way communication. Because my responsibilities also include teaching our student consultants, I am also in continuous communication with the students. I consider on-demand access to information resources and computer mediated communication essential ingredients in the success of our project. Our Web-based systems make my job much easier.
While our Web resources certainly facilitate the work of the PT3 administrative team, I am most fascinated by observing the use of resources by our student consultants. There is no question that they are personally experiencing the possibilities technology offers in support of learning. Our students have come to consider themselves a community of learners. They build on each other’s knowledge through discussion boards and classroom interaction. They often answer each other’s questions and provide one another support when challenges arise. They use the technologies at their disposal as just-in-time tools instead of just-in-case last resorts. Perhaps most important of all, they are not learning about technology integration in the abstract, they are actively applying technologies to meet personal learning needs in a way that will transform both their view of the tools and their ideas about teaching and learning. Although it is still too soon to know for sure how their experiences in the project will influence their future professional practices, what we see suggests they will be less likely to limit their future students to a “book learning” model.

Although we are pleased with the tools we have developed, what we have learned about how to more effectively support student learning leads us to conclude that we must continue to expand and develop the communication and information resources we deliver online. Administratively, we have created models that help us manage programs and create, store, and retrieve knowledge more efficiently and effectively. Further, I think we will find that many of our administrative Web resources will evolve into classroom learning support tools – teachers morphing into learning team managers – that’s an interesting thought to ponder!

From the Web Development Team

The primary focus of the Web team is to create support materials for use by consultants and clients. We began by identifying common technology tasks (e.g. how to create a Web page using Netscape Composer) and then created (or linked to) support documentation. For the most part we worked independently. An online “job board” (part of our WebAdmin site - see Figure 1) allowed us to choose a task, keep work records and, ultimately, upload the final version of our completed support material into our “PT3 Problem Solver Database.”

In addition to regular Web team meetings, one team member attends meetings with consultants. This provides us an important user perspective on our support system, helping us learn how documents are being used, which documents are the most useful and what, if any, problems are encountered. We are also testing documentation in face-to-face consultant workshops in an on-campus computer lab. Hard copies of documentation are distributed to each consultant at the workshop. Consultants use the documentation as a primary learning resource to acquire new technology skills while Web team members observe their use of the documents. Consultants have an opportunity to raise questions both on a one-to-one basis as they work at a computer or in a group debriefing session immediately following hands-on learning. We have been very pleased with the quality of the feedback consultants have provided us, particularly in our workshop sessions.

From Student Consultants (based on interviews)

Overall, student consultants seem very pleased with the resources they are provided. Our discussion boards systems seem to have had the greatest influence in reshaping the way these students think about their learning. The students have begun using phrases such as “community of learners” in describing their experiences. Although one of our two discussion boards is private (the one in the DMS), we know from server stats that they are using this resource. Moreover, based on their comments in interviews, they appear to be differentiating their use according to their perceived role. Discussions that focus on consultants’ roles as students appear more commonly on the CDS discussion board, while those that deal with field-based issues related to their roles as consultants appear more likely to crop up on the DMS discussion board.

When asked about whether they felt their PT3 experiences were likely to change their classroom teaching practices, consultants expressed strong opinions that their use of technology will be dramatically different that what it would have been, had they not participated. Consultants indicated they felt they had crossed both a “confidence threshold” and a “competence threshold”, in addition to developing practical skills
and ideas about integrating technology in classroom settings. It appears that fundamental mental shifts have taken place in the awareness of PT3 consultants concerning teaching, learning, and technology.

Summary and Conclusions

As a result of our Web-based management tools, project participants can interact and share their work with one another through the project Web site. Working groups usually have short weekly face-to-face meetings to talk over issues but our document management system has helped automate processes that can be time-consuming and error prone. Web Development Team members can select "jobs", track and annotate their work, record hours, and ultimately submit the work they complete (primarily support documentation) directly into the DMS, where it can be accessed by other project participants. A job completed and uploaded becomes immediately available to everyone else, something that seems to reinforce the important idea that the team is developing materials for users, not for their team leader. Our administrative systems have promoted the same sense of immediacy and audience in our project management materials and in the future we expect to initiate a similar consultant management system to help track and support our consultants who are working in the field.

We believe that our success thus far is due in large part to three factors. One factor is our decision to build our knowledge systems around Web technologies. A second factor is our decision to avoid high-tech proprietary systems (i.e. "groupware") in favor of a loose collection of relatively "low tech" tools (e.g., Microsoft Office, email, bulletin boards, and Web-enabled Access databases). And the third (related to the second) is to build on, rather than replace, our existing workplace practices and protocols. We also believe the model we have developed will generalize effectively. It requires only modest tools, modest levels of expertise, and modest changes in the working practices of participants. Once created, the technological and cognitive infrastructures that support the system are easily maintained and can continue to develop incrementally.

Abstract: To implement our PT3 grant, we needed to answer three questions. First, we needed to identify the current level of computer skills in our faculty, both at the University as well as in two public schools that are participating in our grant. Second, we needed to know how the faculty were currently using computers in their teaching. And third, we needed to gain information regarding the faculty’s attitudes toward integrating technology in education. This paper discusses the development of a brief survey questionnaire that can be used to help design computer support services and training workshops, help individual teachers and professors design professional development plans, and help administrators and program evaluators assess the effectiveness of these types of professional development activities. The paper will also show how survey data of this type can be used to help identify how receptive a group of educators is to increasing the role of computers in the curriculum.

To implement our PT3 grant, we needed to answer three questions. First, we needed to identify the current level of computer skills in our faculty, both at the University as well as in two public schools that are participating in our grant. Second, we needed to know how the faculty were currently using computers in their teaching. And third, we needed to gain information regarding the faculty’s attitudes toward integrating technology in education.

This information was needed to serve several purposes. We had to assess the faculty’s current computer skills as well as their use of computers in their teaching in order to design support services and training workshops that would meet their needs and be well received and utilized. This information was needed to design workshops and support services for the faculty as a whole as well as for designing individual professional development plans. We wanted to gain an idea of the faculty’s attitudes regarding the integration of computers in education for the same purposes, but also to gauge how receptive the faculty might be with regard to increasing the role of computers in the curriculum. It was also very important that we would be able to measure the effectiveness of the grant activities, so we needed an instrument that would provide useful baseline and follow-up data.

A literature search found no available questionnaires which could serve these purposes well, so we incorporated some of the best approaches from other instruments to create a comprehensive questionnaire that is brief and user-friendly but still provides useful information. Initial statistical analyses of the 23-item questionnaire have found scores on the instrument to be psychometrically reliable.

Our PT3 grant is focused on increasing faculty use of computers at both the K-12 level and the university level, so we have used this survey questionnaire with both K-12 teachers as well as the professors who teach the students in our teacher preparation program. To date, the entire faculty at two local public schools and the entire teacher education faculty at the University have completed the survey, and we are beginning to survey all of the faculty in
the College of Arts and Sciences and the College of Communication. The data currently being collected will serve as baseline data, and the questionnaire will be readministered annually to help establish the effectiveness of the activities undertaken as part of our PT3 grant.

This paper will demonstrate how a brief survey questionnaire can be used to help design computer support services and training workshops, help individual teachers and professors design professional development plans, and help administrators and program evaluators assess the effectiveness of these types of professional development activities. In addition, the paper will show how survey data of this type can be used to help identify how receptive a group of educators is to increasing the role of computers in the curriculum.
Forming a Cadre of Learners: Effective Educational Technology Integration in a Teacher Preparation Program

Abstract

West Chester University's USE-Tech Partners (PT3) program has been a catalyst for increasing interest in and cooperation for preparing technology proficient teachers. Project activities during the capacity-building year included monthly participant meetings, development of integration strategies by faculty, consortia partnership development, completion of the university technology plan, and project evaluation activities. Nineteen participating faculty had released time during the Spring semester or Summer of 2000 to develop and test integration strategies in one or more of their courses. Faculty enhanced the learning of preservice teachers through: e-mail, the Internet and web-based learning applications (e.g., BlackBoard), content specific software, presentation software and other productivity tools, and video-conferencing.

During the past year and a half West Chester University's (WCU) Preparing Tomorrow's Teachers to Use Technology (PT3) grant, (the USE-Tech Partners, University-School Educational Technology Partnerships grant), provided funding and focus to technology integration. The program is working to ensure that all teacher candidates are able to integrate technology effectively into classroom instruction. Our vision is to use this capacity-building grant as a springboard for making WCU a model in preparing technology-proficient teachers, and to become a school that attracts the best teacher candidates and is closely connected to the K-12 schools we serve. The first year activities of this PT3 grant laid the groundwork for ultimately achieving a two-part goal, namely, the modeling of technology integration by WCU faculty in both methods and content area courses, and the achievement of specified technology competencies by preservice teachers. The grant, a catalyst for greatly increasing interest in and cooperation for preparing technology-proficient teachers at West Chester University, has formed a cadre of learners including university and K-12 administrators, university faculty in the School of Education and the College of Arts and Sciences, preservice teachers, K-12 students and teachers, and business members which joined together in these technology integration efforts.

The USE-Tech University Partners Program Activities

Project activities during the capacity-building year included monthly participant meetings, development of integration strategies by faculty, consortia partnership development, completion of the university technology plan, and project evaluation activities. A program extension has been granted by the Department of Education and a new application is being made for a PT3 implementation grant so that this work can continue to expand -- "scaling up" the positive impact on preservice teachers and inservice teachers documented through collected data.
Nineteen participating faculty had released time during Spring semester or Summer of 2000 to develop and test integration strategies in one or more of their courses. They enhanced the learning of preservice teachers through: e-mail, the Internet and web-based learning applications (e.g., BlackBoard), content specific software, presentation software and other productivity tools, and video-conferencing. Four categories of faculty support, i.e., released time, frequent meetings to share successes and challenges, workshops and training sessions, and ongoing support of individual learning, were essential to learning how to integrate technology into the curriculum.

In a state-funded higher education institution such as WCU, faculty are expected to produce scholarly work, serve the university, students and community; and teach a full 12-credit course load. Release time from this hectic schedule is not easily found. The alternative work assignment (AWA) 3-credit course relief provided by this grant was seen as a valuable and rare support by all of our 19 participants. Having adequate time to work on appropriate technology resources that would support their teaching was appreciated by every faculty member.

Through regular gatherings of USE-Tech faculty participants found a supportive environment during which participants shared successes and challenges related to their work with technology integration for more effective teaching and learning. These meetings established a forum for faculty members to talk about technology issues in new and productive ways and learn from one another in a collegial setting.

A week-long workshop, the “USE-Tech” Winter Institute, was held at West Chester University in January 2000 and included visits by guests (consultants) from other universities. In addition to the opportunity to speak with other higher education faculty who have successfully included technology in their own teaching, West Chester University USE-Tech participants enjoyed, hands-on workshops related to their own personal goals. Ongoing support for faculty learning is provided through the Faculty Technology Center (FTC), and includes workshops and just-in-time support from staff and students.

Collaborative planning sessions included: consortium members, additional members of the WCU academic community, and representatives of the K-12 School Districts we serve. Groups within the university, K-12 school districts, businesses, and community are working toward a common goal of integrating technology into teacher preparation as a result of project activities. An objective of this project was to have collaborative partners agree to support the project, and identify roles and responsibilities. Written agreements of participation, roles and responsibilities already include 7 school districts, and 5 business/community groups. As a result of our USE-Tech efforts we have successfully expanded our goals in the area of collaboration to include the introduction of a new graduate educational technology certificate program, the “Teaching and Learning with Technology” program designed for inservice teachers from local school districts, and the creation of a proposal for a PT3 implementation grant. University collaboration led to renovation of technology facilities in the School of Education during the summer of 2000.

Lessons Learned from the USE-Tech Program

Baseline survey data on faculty skills and use of integration activities was collected at the beginning of this project in the Fall of 1999. Attendance numbers and a rating of on-going professional development activities have been collected. End of the year survey data on faculty skills and use of integration activities will be collected by the end of the Spring term, and interviews with faculty regarding their experiences are now being completed. Some the findings of this grant include the following:

- As faculty become more adept at the use of technologies, they become more comfortable with taking informed risks in their teaching; expansion of original technology goals was common.
- Although much of this professional development and support work has been accomplished by USE-Tech staff, some has also been done through the collaborative effort of participant-teams and through the use of existing university resources, such as: training offered in the SOE by a university web instructional specialist. Existing university resources have been better utilized when project faculty have learned about them from their project colleagues.
- Faculty become more interested in technology when they see students using technology -- preservice teachers and K-12 students and teachers.
• Making technology easily accessible to students and faculty enables its effective use for enhanced teaching and learning environments. Easy access to technology when and where it is needed is very important for higher education faculty.

• Faculty members experience different parts of the shared vision for technology integration -- time is needed to communicate these ideas with one another.

• Released time is a good incentive for faculty for the specific purpose of improving technology skills and integration of technology. Faculty need and appreciate the time allocated for their professional development.

• There are clues that something different is happening at WCU as a result of PT3 grant activities as faculty from three schools of the university join together. There are some definite hints that systems change is possible.

• Faculty began to feel part of a special cadre of tech-users, attending meetings that included displays of new technology integration and were often attended by not only faculty but by deans, the Provost and even the university president. Faculty members mention in their interviews that they received support not only from the FTC, or from their assigned “buddy” but also from colleagues who were available at the right time and place.

The USE-Tech program instilled new confidence in faculty participants to use technology which is captured in the following words of one member: “Before my work with USE-Tech, my understanding of technology was very limited - I didn’t even know where to begin or what questions to ask. Now that I have gained some level of comfort with technology, I have a sense of what I need to know, and how I can use these new resources with my students.”
Building the Capacity to Infuse Technology in K-6 Classrooms: A Training Model

Abstract: A recent effort that enhanced university/K-12 school partnerships is Project PICT (Preservice Infusion of Computer Technology). This project, piloted in 1999-2000, and funded by the U.S. Department of Education, used a team approach to promote the infusion of technology in the teacher education and K-6 curricula. This paper will describe the Technology Training Model design, implementation and results collected from participants regarding their perceptions of the model. In addition, a lesson library of technology rich lesson plans, developed by K-6 teachers and preservice teacher teams, and artifacts will be shared. Findings from this pilot study determined the design of the Technology Training Model adopted for the three year Implementation Project, now underway.

Introduction

Teachers that are capable of preparing technology proficient students for the 21st century is notably one of the most critical needs in public schools today. This need has challenged teacher preparation programs to produce teachers that are able to infuse technology and curriculum. A recent response to this challenge is Project PICT (Preservice Infusion of Computer Technology), a pilot project funded by the U.S. Department of Education, as part of the Preparing Tomorrow’s Teachers to Use Technology Program. This project employed a team approach to assist the infusion of technology in the teacher education program at Bowling Green State University and K-6 curricula. The primary goal of Project PICT was to provide future teachers with the knowledge to utilize technology to enhance teaching and learning. To promote the realization of this goal, a Technology Training Model was developed which established a collaboration between teacher education faculty, arts and sciences faculty, K-6 teachers, and preservice teachers and was designed to facilitate the infusion of national and state (Ohio) technology standards for teachers.

The Model

The Technology Training Model was designed in keeping with research findings on effective technology training. Studies involving technology training (Dyrli & Kinnaman, 1994b; Munday, Windham, & Stamper, 1991; Sheingold, 1991; Siegel, 1995) report that the success or failure of technology integration is dependent on teacher training. This training should occur throughout the teacher prep program (Byrum and Cashman, 1993; Thompson, Schmidt, and Hadjiyianni, 1995), should establish a vision of how to use technology in the
classroom (Wetzel, 1993; Sprague, Kopfman & de Levante Dorsey, 1998) and should be an active process with participants being exposed to hands-on instruction that establish how to use technology as a resource for instruction (Roblyer and Edwards, 2000). Further, training should be in-depth, and should include on-going support (Bruner, 1992; Thompson, Hansen, & Reinhart, 1996).

Accordingly, participants were involved, for four months, in a variety of whole group sessions (Kickoff session, training sessions, support sessions) and project and team meetings. The Kickoff session established a vision of how to apply technology in classroom situations as area K-12 teachers presented a variety of strategies for using technology as a tool to enrich curriculum. Successful lesson ideas were presented and student products were available for examination. The Kickoff was followed by a series of in-depth hands-on training sessions featuring the application of the Internet and multimedia as tools to enhance learning in elementary curricula. Support sessions were scheduled throughout the four-month training period to provide on-going support to participants, enhance skill levels and build confidence in participants. Bi-monthly meetings of teams resulted in team and individual plans for technology infusion. These meetings served as an additional source of support for team members. Team plans included team goals, a description of how (lessons plans) each individual would integrate technology throughout the semester to meet these goals and how the subsequent lessons would be used to complement teacher education courses. Team plans are presently were implemented in teacher education classes and K-6 classrooms as a part of the Technology Infusion Model.

The Study

There were 28 educators that participated in this pilot study. Of these 28 participants, there were eight university faculty, ten elementary teachers, and ten pre-service elementary teachers. Focus group interviews were held at the end of the pilot study to reveal participant perceptions of the Technology Training Model. These interviews were audiotaped. The questions were related to project outcomes. The data was analyzed with the participants being offered the opportunity to review the transcripts. In addition, pre and post surveys were also administered to all participants (Vannatta & O'Bannon, 2000).

Findings

Results from the focus group interviews revealed that participants had very specific notions about the Technology Training Model. Participants reported that all sessions were beneficial but having technology using teachers share successful lessons and student products provided the inspiration and vision for infusion. Further, the use of K-12 teachers, as opposed to university faculty, as training facilitators was instrumental in making them believe that they could be successful. The support opportunities provided by project personnel and the teaming process was a critical component in the success of this project.

Conclusions

The primary goal of Project PICT was to provide future teachers with the knowledge to utilize technology to enhance teaching and learning. Outcomes revealed that the Technology Training Model developed and implemented in this pilot project facilitated this
goal. In addition, there continues to be an increase in the level of technology infusion in teacher education classes at Bowling Green State University and in two of the schools that serve as professional development schools for this teacher education program. Project success has resulted in an empowered teacher education faculty with a dedication to expose preservice teachers to teaching methods that use technology as a resource for instruction. The findings in this pilot study provided a foundation for the design of the 3 year Project PICT Implementation that is now underway. Access more about this project at http://www.bgsu.edu/colleges/edhd/LPS/EDFI/PICT/

Coexistence of Technology and Healthy Active Lifestyles

Judy Oslin and Connie S. Collier, Kent State University
School of Exercise, Leisure and Sport
Kent, OH 44242-0001
Joslin@kent.edu/collie2@kent.edu

Computer use has significantly impacted the lifestyles of children, youth and adults in today's society. According to a major government report from the Centers for Disease Control and Prevention, the percentage of overweight children has doubled since 1980. The report warns of "...a new generation of young people who are in large part inactive, unfit and increasingly overweight." Much of the sedentary lifestyles are due to increase in computer usage and numerous technological advances that allow us to do more while moving less.

As physical education teacher educators we are faced with the dilemma of preparing teachers who will positively influence children to lead healthier more active lives and at the same time be able to infuse technology into their pedagogical practices. We must accommodate both of these issues by integrating technology in ways that substantively change the way pre-service teachers learn, so that we are not merely adding technology to an already full curriculum. The challenge is to create an environment in our teacher education program that allows for the coexistence of technology and healthy active lifestyles.

Our first step was to revise a traditionally taught fitness course, Lifetime Fitness, with a course focusing on healthy active lifestyle education (HALE). The intent of HALE is to: 1) Provide content that mirrors the situations in schools and communities. 2) Provide technological applications representative of resources available to preK-12 teachers. 3) And, infuse pedagogical strategies that reflect student centered learning practice. This curricular revision has taken considerably longer than we had first envisioned. First there were meetings and communications with PT3 group members, then selection and purchase of hardware and software, followed by hours of training and experimentation with set-up, application, and integration of hardware and software. We not only had to learn how to use the equipment and software, we had to design protocols for instruction. These protocols then had to be piloted with students to ensure viability in the instructional context.

Hardware included digital cameras, digital video camcorders, MAC iBooks® connected to an AirPort® base station, Qbe's® (personal computing tablets), scanncrs, and recording devices that included portable CD-RW and Zip® drives. Software included Dreamweaver®, Fireworks®, Flash®, Freehand®, and Adobe Photoshop®. Access to the wireless web, the availability of affordable digital video camcorders, and the portability and durability of this new hardware increased the feasibility of integrating this technology into a course occurring in a movement context. We have been able to capture teaching and learning episodes as they naturally occur in the complex environment of the gymnasium. The ability to construct instructional materials with such high ecological validity led us to focus on strategies emphasizing situated learning experiences.

We selected case method as our primary vehicle for educating students about HALE content and concepts. Physical education teacher education has traditionally used text-based-case-scenarios, however the digital video medium and other technological advances allowed us to enhance the case method. Certainly the value of the case method as a problem-based learning experience is well documented as it enables the learners to grapple with problems representing rich chunks of reality (Merseth, 1990). Never before has technology enabled teacher educators to so readily capture, manipulate and construct cases represented through digital media and publish them in user friendly, web-based environments. These learning experiences will allow pre-service teachers to examine the material outside of class at their own pace and reflect on the meaning of a healthy active lifestyle for themselves and their future students. Not only will students use case method to examine the material, they will be required to design and build their own cases and thereby learn to use this technology as a pedagogical application. Overall, HALE will allow physical education teacher educators to model technology integration and examine ways in which it can contribute instead of detract from the goal of a healthier, more physically active society.
[A digital video case demonstration will be used to illustrate the case method and related technology.]

Abstract: This presentation addresses some of the issues which one university encountered when it collaborated with 3 disadvantaged urban schools as part of a PT3 project. Using a case study format, we detail many of the obstacles which were faced by this partnership including hardware availability & maintenance, wiring in older buildings, threatened teacher strikes and work slowdowns, changes in delivery schedules, prioritization of schools within the district for various types of support, and levels of approval needed for changes to take place. What the university ultimately needed to supply and how this partnership became part of a larger outreach to the schools and community helps to describe the special challenges faced when working on technology partnership issues in social environments of this type.

Large urban school systems present many technology infrastructure opportunities. Size alone makes them promising markets for telecommunications companies, and cable networks are often eager to supply low cost or free internet access to schools in exchange for rights to offer commercial services in that locale.

However, these same urban school systems can present many special challenges. This is particularly true when the "digital divide" is also a factor. This paper describes some of the issues which one university encountered when it collaborated with three disadvantaged urban schools as part of a Preparing Tomorrow's Teachers to Use Technology (PT3) project. The level of support which was required for the schools exceeded anticipations, and while the end product was satisfying, it was quite different from what had been envisioned.

Inner-city schools are among the most vulnerable to both the "access" and the "information underclass" problems which are key dimensions of the digital divide (National Center on Adult Literacy & International Literacy Institute, 1999). Each of these phenomena can also be observed in other settings (e.g. rural schools in isolated areas) but urban schools have their own manifestation.

Access can be considered in terms of availability of internet services (e.g. whether internet connectivity is available in classrooms or labs) or in terms of quality of service (e.g. are computers capable of sustaining access to the internet at sufficient speed). Although we were initially told that the schools with which we were working had internet access, we encountered access problems of both types. At one school, for example, wiring had been completed throughout the building almost a year before we entered, but due to contract disputes with the installer the drops had never been lit. In other cases, basic access was available, but the computers in the classrooms were either outdated or not maintained at a level where they could be reliably used for instructional purposes.

"Information underclass" (IU) is a term which refers to the widening gap between technology haves and have-nots. It is a complex phenomenon where problems in one area exacerbate related problems. For example, when an older school with an outdated electrical supply is put on hold for computer upgrades until the entire school can be re-wired, the technology gap between that school and others which have adequate wiring grows larger. When the teachers in that school which is not upgraded are not given inservice training and/or do not attempt to use computers as part of their instruction because of the older technology which was not upgraded, the gap is further amplified.

Several case studies illustrate many of the access and IU obstacles which were faced by this partnership between a university and three disadvantaged urban schools. Two examples of these cases are:
1) Hardware availability & maintenance - In at least two of the schools, teachers had an opportunity to participate in a local inservice model through which they would be given a new computer and printer for classroom use if they completed a technology project. However, in order to complete the project they had to access available computers in the building, many of which were old and prone to breakdown. Once they did complete the project and received the computer & printer, many were unable to connect to the internet, which made the computer primarily a local-use device which had minimal use by students. Local technology support personnel (in one case, teachers who contributed time after school) were unable to maintain all of the hardware, and replacement was not a priority.

2) Prioritization of schools within the district for various types of support - A district-wide program to upgrade the electrical supply in most of the schools did not include these schools because they were so old that the administration agreed that a separate contract would be needed. That contract was delayed for various reasons, and that delay had an impact on other technology which could be installed in the building.

Ultimately, a partnership was able to be formed between these schools and the PT3 grant which supported teachers and student teachers in these buildings. However, the extra time and equipment which had to be provided greatly exceeded the time and equipment provisions for other schools which participated in the project.

InTime: A PT3 Catalyst Grant

Masha Plakhotnik
Univ. of Northern Iowa

Abstract: The purpose of InTime (Integrating New Technologies Into the Methods of Education) is to provide the necessary resources for methods faculty to revise their courses, model technology integration, and require preservice teachers to integrate technology, along with components of quality education, in their lessons and units. This project is developing online video case studies to be utilized in methods courses that include videos of best practices showing scenarios from PreK-12 classrooms where teachers are integrating technology in a robust educational environment. The participants will have a chance to view and critique one of the online case studies of best practice in technology integration and quality education via video streaming. The issues addressed in this session will be interesting for deans, administrators, faculty, and decision-makers of all expertise levels.

Statement of the problem:
Reports from the National Council for Accreditation of Teacher Education (NCATE) and the Office of Technology Assessment (OTA) have called attention to existing deficiencies in teacher preparation programs in preparing preservice teachers to use technology effectively in the PreK-12 classrooms. Technology and the New Professional Teacher (NCATE, 1997) reports that preservice teachers should be required to apply technology in their courses and should see faculty model technology use in the classroom. In addition, Teachers and Technology: Making the connection (OTA, 1995) suggests that in teacher preparation programs where faculty model technology use, students will adopt the use of educational technology in their instruction. In order for undergraduate students to learn to use technology when they teach, it is vital that university teacher education faculty change the way they prepare teachers to use technology.

Literature Review:
According to conclusions drawn by the OTA, it is not enough to tell students about what is possible. “They must see technology used by their instructors, observe uses of technological tools in classrooms, and practice teaching with technologies themselves if they are to use these tools effectively in their own teaching” (OTA, 1995, p. 185). It is far more common, however, for education faculty to discuss technology, have students read about it, or demonstrate technology, rather than model it or require students to incorporate technology use into their lessons or units (OTA, 185). Also, NCATE (1997) identifies five reasons for the lack of technology integration in teacher education courses: 1) teacher education programs lack sufficient hardware and software; 2) education departments lack sufficient technical support; 3) teacher education faculty lack the knowledge, skills, and training that support technology integration in their teaching; 4) teacher education faculty are out of touch with what is happening in P-12 classrooms, including the rapid introduction of technology; and 5) the academic culture rewards and recognizes individuality among faculty, rather than valuing a common version about technology and incentives to seek professional development. Therefore, the goals of InTime project provide direct solutions to each of the above five barriers that prevent teacher education faculty from modeling appropriate integration of technology in their courses and requiring students to apply technology in their lessons and units.

Project Goals:
InTime (Integrating New Technologies Into the Methods of Education) is a $2,397,594 Catalyst Grant from the United States Department of Education. The Three-year InTime project addresses deficiencies in teacher education programs in preparing preservice teachers to use technology effectively in the PreK-12 classroom. The purpose of InTime is to provide the necessary resources for methods faculty to revise their courses, model technology integration, and require preservice teachers to integrate technology, along with components of quality education, in their lessons and units.
This project is intended to produce change in teacher education programs in three ways. First, the project will generate new learning resources on the web to support new teaching and learning processes in education methods courses. New learning resources will include development of video scenarios of PreK-12 teachers effectively integrating technology, along with components of quality education, in a variety of grade levels and content areas. These videos will be stored on a video server already in place at the university of Northern Iowa and made accessible online nation-wide. Second, methods faculty will revise their courses to model technology integration using the video scenarios and online discussion forum, require students to apply technology, and implement the Preservice Teacher Technology Competencies as exit criteria for their courses. Finally, methods faculty will share strategies for integrating technology and course revision with other faculty involved in the grant through Faculty Online Discussion Forum and nation-wide through print and web publications of their findings as well as presentations at national conferences.

Participant involvement and outcome:
1) The participants will understand the crucial part of the project, the “Technology as Facilitator of Quality Education Model” used in this project which shows that technology is not at odds with the core values of the American educational system. The model includes several major dimensions:
   1. Students at the center of their own learning
   2. Principles of good learning
   3. Aspect of information processing
   4. Standards from content disciplines, and
   5. Tenets of effective citizenship in a democratic society
   6. Teacher knowledge and behavior
   7. Technology

   The seven dimensions of the model provides a way for educators to view the integration of technology related tools into a robust educational environment and thus answer the hard questions regarding support for the shift in our educational activities toward technology. It sets up a framework for this robust educational environment and identifies key points at which technology should be implemented and evaluated to determine its impact. It simultaneously allows for the integration of new research findings into the appropriate segments of the model while maintaining the structure to evaluate the impact of technology tools on these new findings as part of an ongoing evaluation process. In so doing it allows a variety of stakeholders to see the complex process that is education and how technology is affecting the process.

2) The participants will view and critique online case studies of best practices in technology integration and quality education in a P-12 setting via video streaming technology. They will consider what content standards were addressed, how technology was integrated and which other components of quality education were present in the lesson.

3) The participants will discuss the project as well as share their ideas about its goals, applications, strengths and weaknesses.

INTIME (Integrating New Technologies into the Methods of Education):  
A PT3 Catalyst Grant

Masha Plakhotnik  
Univ. of Northern Iowa

Purpose:

Reports from the National Council for Accreditation of Teacher Education (NCATE) and the Office of Technology Assessment (OTA) have called attention to existing deficiencies in teacher preparation programs in preparing preservice teachers to use technology effectively in the PreK-12 classrooms. Technology and the New Professional Teacher (NCATE, 1997) reports that preservice teachers should be required to apply technology in their courses and should see faculty model technology use in the classroom. In order for undergraduate students to learn to use technology when they teach, it is vital that university teacher education faculty change the way they prepare teachers to use technology.

Within this framework, the InTime (Integrating New Technologies Into the Methods of Education) project is developing online video case studies to be utilized in methods courses that include videos of best practices showing scenarios from PreK-12 classrooms where teachers are integrating technology in a robust educational environment. These video scenarios will help methods faculty and preservice teachers stay in touch with P-12 classrooms, thus breaking down time-worn distinctions between preservice and inservice teaching. This project will provide video scenarios from PreK-12 classrooms across the nation that will be made assessable to anyone at the project website. In addition, the methods faculty and students and PreK-12 teachers will utilize web-based instructional materials and an online discussion forum to foster reflective discussion about the methods of technology integration combined with best learning practices. Methods faculty will also revise their courses to include first-hand observations of technology integration in their partner PreK-12 classrooms.

Relationship to SITE 2001 Conference:

This project relates to SITE 2001 Conference because the online video case studies that will be available via video streaming from the project website feature best practices of PreK-12 teachers as they integrate technology in a robust educational environment. This environment, which is defined by the model, Technology as Facilitator of Quality Education (TFQE), currently being developed by the InTime project at the University of Northern Iowa. The model includes seven major dimensions:

1. Students at the center of their own learning;
2. Principles of good learning;
3. Aspect of information processing;
4. Standards from content disciplines, and
5. Tenets of effective citizenship in a democratic society.
6. Teacher knowledge and behavior
7. Technology

The seven dimensions of the model provides a way for educators to view the integration of technology related tools into a robust educational environment and thus answer the hard questions regarding support for the shift in our educational activities toward technology. It sets up a framework for this robust educational environment and identifies key points at which technology should be implemented and evaluated to determine its impact. It simultaneously allows for the integration of new research findings into the appropriate segments of the model while maintaining the structure to evaluate the impact of technology tools on these new findings as part of an ongoing evaluation process. In so doing it allows a variety of stakeholders to see the complex process that is education and how technology is affecting the process.

Abstract of Presentation:
InTime (Integrating New Technologies Into the Methods of Education) is a $2,397,594 Catalyst Grant from the United States Department of Education. The Three-year InTime project addresses deficiencies in teacher education programs in preparing preservice teachers to use technology effectively in the PreK-12 classroom. The purpose of InTime is to provide the necessary resources for methods faculty to revise their courses, model technology integration, and require preservice teachers to integrate technology, along with components of quality education, in their lessons and units.

This project is intended to produce change in teacher education programs in three ways. First, the project will generate new learning resources on the web to support new teaching and learning processes in education methods courses. New learning resources will include development of video scenarios of PreK-12 teachers effectively integrating technology, along with components of quality education, in a variety of grade levels and content areas. These videos will be stored on a video server already in place at the university of Northern Iowa and made accessible online nation-wide. Second, methods faculty will revise their courses to model technology integration using the video scenarios and online discussion forum, require students to apply technology, and implement the Preservice Teacher Technology Competencies as exit criteria for their courses. Finally, methods faculty will share strategies for integrating technology and course revision with other faculty involved in the grant through Faculty Online Discussion Forum and nation-wide through print and web publications of their findings as well as presentations at national conferences.

Participant Outcome:

Participants will understand the purpose of the Technology as Facilitator of Quality Education Model used in this project to illustrate that technology is not at odds with the core values of American educational system. This project will not just increase the use of technology but help teachers use technology to appropriately help children learn content, learn how to process information using technology, and practice the skills necessary to be a thinking citizen in a democracy. The participants will be provided with an opportunity to experience online video applied on the educational environment.

InTime (Integrating New Technologies Into the Methods of Education): A PT3 Catalyst Grant.

Masha Plakhotnik
Univ. of Northern Iowa

Objective:

The objective of this session is to consider how to utilize online video case studies of PreK-12 teachers using technology in a robust educational environment in preparing tomorrow's teachers to use technology.

Short description of the presentation:

During the session the participants will experience an online video developed at the University of Northern Iowa applied on the educational environment. This video as well as 49 more videos is a product of InTime (Integrating New Technologies Into the Methods of Education) which is a $2,397,594 Catalyst Grant from the United States Department of Education and which involves five Renaissance Group universities. The three-year InTime project addresses deficiencies in teacher education programs in preparing preservice teachers to use technology effectively in the PreK-12 classroom. The purpose of InTime is to provide the necessary resources for methods faculty to revise their courses, model technology integration, and require preservice teachers to integrate technology, along with components of quality education, in their lessons and units.

This project is intended to produce change in teacher education programs in three ways. First, the project will generate new learning resources on the web to support new teaching and learning processes in education methods courses. New learning resources will include development of video scenarios of PreK-12 teachers effectively integrating technology, along with components of quality education, in a variety of grade levels and content areas. These videos have been stored on a video server already in place at the University of Northern Iowa and made accessible online nation-wide. Second, methods faculty will revise their courses to model technology integration using the video scenarios and online discussion forum, require students to apply technology, and implement the Preservice Teacher Technology Competencies as exit criteria for their courses. Finally, methods faculty will share strategies for integrating technology and course revision with other faculty involved in the grant through Faculty Online Discussion Forum and nation-wide through print and web publications of their findings as well as presentations at national conferences.

The InTime project is developing the 50 best practice videos which will be available via video streaming on the project website http://www.intime.uni.edu. Every video has seven audio tracks, first of which is the live classroom audio. Also, each video is analyzed in six additional versions which will contain narratives about how the teacher is demonstrating one of the six elements from the technology as Facilitator of Quality Education Model (TFQM). Elements of quality education from UNI's Technology as Facilitator of Quality Education Model include:

1. exemplary technology;
2. democracy in the classroom;
3. rich content;
4. information processing;
5. effective principles of learning;
6. exemplary teacher knowledge and behaviors.

The above listed elements of quality education provide a way for educators to view the integration of technology related tools into robust educational environment and thus answer the hard questions regarding support for the shift in educational activities toward technology.
The edited videos of approximately 5 minutes in length are searchable at the project website not only by the elements of quality education but also by grade level, content area, teacher’s name, state, video title, and video code. In addition, these videos will be also available on CD-ROM and DVD.

During the session, the participants will have a chance to view one of the videos and its seven versions. Each of the seven audio tracks will appear on the left side of the screen with a written teacher’s narration running at the bottom of the screen. On the right side of the screen, the participants will see the full description of the classroom practice. This description includes the teacher’s name and the school location, grade and curriculum area. Further, they will see the detailed unit description which covers necessary preparations and procedures. Next, all necessary information about this classroom practice, such as tools and resources, assessment, timeline and course outline as well as the teacher’s personal comments on the implementation of this particular activity will appear on the right side of the screen.

**Participant Involvement and Outcomes:**

So, the participants will understand the purpose of the “Technology as Facilitator of Quality Education Model” as well as view and critique online case study of best practice in technology integration and quality education in a PreK-12 setting via video streaming technology. They will consider what content standards were addressed, how technology was integrated and which other components of quality education were present in the lesson.

**ABSTRACT:**

The objective of this session is to consider how to utilize online video case studies of PreK-12 teachers using technology in a robust educational environment in preparing tomorrow’s teachers to use technology. The participants will have a chance to view and critique one of the online case studies of best practice in technology integration and quality education in a PreK-12 setting, developed at the University of Northern Iowa, via video streaming technology. They will consider what content standards were addressed, how technology was integrated and which other components of quality education were present in the lesson. The issues addressed in this session will be interesting to deans, administrators, faculty, and decision-makers of all expertise levels.
Abstract: Today's schools must prepare students to use computer-related technologies well in a range of tasks. For K12 schools to prepare their students, colleges and universities must prepare teachers to integrate technologies well for learning. Thus, reform in teacher preparation must become a high priority. Research has shown that lasting reform must be systemic—in other words, the parts of an educational system must synergistically support one another. In efforts to reform teacher education at an urban public university, we have tried to ensure that policy, curriculum, field experiences, and faculty teaching practices all support the meaningful integration of technology. Our efforts to sustain systemic change along these lines have been greatly enhanced by a "technology and learning center" and a Preparing Tomorrow's Teachers to Use Technology grant. We show through a case study and vignette how these pieces fit together for reform towards the integration of technology in teacher preparation.

Introduction

The Need for Technology-Using Teachers

Today's workplaces are increasingly computerized and networked; hence, schools must better prepare students to use these technologies flexibly and creatively in their lives, for tasks ranging from problem solving to information gathering to communication (SCANS, 1991). In order for K12 schools to prepare their students, colleges and universities must prepare teachers to integrate technologies well for learning. But colleges, schools and departments of education have lagged to date in their integration of technologies for learning into teacher preparation. Thus, reform in teacher preparation must become a high priority if real change is to take place in schools (Darling-Hammond, 1993).
Historical and Theoretical Background: Change Studies

Research on educational change has shown that lasting reform must be systemic (e.g., Brown, 1992; Fullan & Miles, 1992). In other words, the various parts of an educational system must synergistically support one another. A sociocultural (Wertsch, 1998) perspective on human action provides some guidance as to how to explain and plan for systemic change. Wertsch shows how the multifaceted, interrelated aspects of human activity in complex social settings can be captured using Kenneth Burke’s “pentad”: the act, scene, agents, agency (or cultural tools), and purpose. The meaning of an act is simultaneously constituted by the scene or location in which the act occurs, the knowledge, role, and personal history of the agents involved, the properties of the cultural tools or mediational means used to accomplish the act, and the purposes which the act served. In our reform, we are making an effort to change the “scene” at the College of Education to include use of technology as a cultural tool for teaching as a normal matter of course. The relevant agents in our case have been the dean and faculty members, supported by staff working on a Preparing Tomorrow’s Teachers to Use Technology (PT3) grant. The scene began changing with policy and curriculum changes and the opening of a state of the art “technology and learning center.” Through a curriculum reform, the teacher preparation activities supported by faculty in their courses have been reexamined to more adequately integrate technology while simultaneously serving the many other purposes of individual courses. In this paper, we explicate how we have put these pieces together for systemic reform towards the integration of technology in teacher preparation.

Background at the College of Education

The College of Education at the University of Missouri-St. Louis prepares a large number of teachers for K12 schools in our region. Prior to 1995, technology was not an integral aspect of the college’s life. Although all faculty had computers in their offices and a few Educational Technology courses had been offered for years, few faculty members used technology for their instructional work. For instance, approximately 2% of our faculty was using email and online discussion groups with their students, and about that same percent referred their students to web resources and taught using technology. There was neither a technology course requirement nor an expectation of teacher education students demonstrating technology integration competency prior to certification.

A New Dean and a New Teacher Preparation Curriculum

With the entry of a new Dean and statewide certification changes in the second half of the 1990s, the situation changed. Paper copies of “The Dean’s Weekly Update” were banished upon the dean’s arrival in 1996—faculty members who did not use email before his appointment were forced to begin using it soon after. Innovations and grants involving technology were encouraged. A “futures” planning process resulted in a college-wide commitment to the importance of technology to the preparation of new teachers for the 21st century, and in a redesigned curriculum that required both a larger field component and technology integration in courses at all three “levels” (Level 1: Exploration, followed by Level 2: Analysis and Level 3: Professional). And finally, the state of Missouri instituted new performance-based (rather than course credit-hour based) standards for teacher certification, which included the need for all new teachers to demonstrate competence at integrating technology.

The Final Pieces: PT3 and the TLC

Our dean and development officer also envisioned and secured funding for a Technology and Learning Center (TLC) for our College and an Endowed Professorship of Technology and Learning. In the Winter of 1999, the Endowed professor and another full-time faculty member (the first author) were hired, and plans for the building of the TLC began in earnest.

At the same time, a group (headed by the second author) who had worked on technology integration with teachers in local K12 schools (the MINTs—Multimedia Interactive Networked Technologies—Project) submitted a grant proposal to the U.S. Department of Education’s PT3 program. We proposed adapting the professional development practices utilized in MINTs to support change towards technology integration in active teaching and learning projects among cadres of university faculty, and using the MINTs classrooms as fertile sites for future teachers’ field experiences.
During the Fall of 1999, the PT3 grant was awarded and the TLC plans were also finalized. The TLC was planned as a “hothouse” for educational technology, to mirror and model the possibilities for technology integration in K12 schools. It includes work clusters, a model classroom space, a seminar room with interactive whiteboard, and a “cyberlounge” with wireless networking (see Figure 1). The reconfigurable work clusters are set up to allow for solo work or collaboration on projects involving the Internet, standard office suites, and multimedia technologies including graphics and digital video. The classroom space is meant to allow discussion without computers between people as well as computer workstations and tables for discussion or work offline.

The pieces had all come together for the Winter semester of 2000:
- policy at the state and college level that encouraged technology integration,
- a new curriculum that allowed for introduction of new activities and tools in courses,
- requirements for field experiences as well as sites that integrate technology well,
- a PT3 grant to support university faculty in changing their teaching to incorporate technology, and
- a technology and learning center with staff and infrastructure to support technology integration

**Figure 1:** Floor Plan of the E. Desmond Lee Technology & Learning Center at the University of Missouri-St. Louis College of Education.

**Case Study: Introduction to Learners and Learning Course**

The new undergraduate teacher preparation curriculum at UM-St. Louis consists of three levels, the first of which is Exploration. At this level, there are three courses: Introduction to American Schools, Introduction to Teaching, and Introduction to Learners and Learning. In order to illustrate how the pieces of our reform efforts fit together, we describe the technology component of the latter course as implemented in the Winter 2000 semester.

The fourth author instructed this course, and groups of her students developed web sites about child development topics of their choice. The primary goal for the project was learning about psychological development, but secondary goals included gaining an appreciation of the range of resources available on the World Wide Web, learning how to find those resources, and beginning to learn how to make web resource pages (which we expect technology-using teachers at the K12 level to utilize to support learning activities in the classroom). The construction of a set of resource web pages about development, with
synthesis and annotated links to related sites on the Internet, was an ambitious project for an introductory education class, and many students began the process with considerable trepidation. As one student stated, “learning how to create a web page was very stressful to even think about” at the beginning. Student reactions to the technology were somewhat related to their level of experience with technology, with beginners feeling more overwhelmed at the beginning despite recognizing the relevance of technology skills for classroom applications.

In order to support the preservice teachers in the achievement of this complex, ambitious project, a variety of supports were utilized. During class meetings held in a computer classroom, two PT3 staff acted as guest facilitators along with the instructor. The PT3 staff introduced the class to web page editing basics using Netscape Composer (a free web page editor included with Netscape Communicator), and distributed a handout describing the basics. Using a web page template on disk, the facilitators assisted the groups in adding and modifying text, a digital photo of themselves, and links to resources on the Internet. Several classes were devoted to completing the assignment. The computer expertise and comfort in the class varied widely, from a couple with extensive experience including web page editing, to quite a few with word processing, email, and web browsing, to several with little experience and a good deal of fear. The instructor created groups of three or four students and made an effort to place at least one student with stronger technology expertise as measured by a skills survey administered online with a system called Profiler (http://profiler.scrtec.org). The in-class orientation and the handouts proved to be scaffolds of some use to the students, but more in-depth background and detailed written reference materials were desired by many. Not surprisingly, the people provided the most effective scaffolding: the multiple facilitators during class meetings provided by PT3 helped, as did the more expert peers spread among the groups. Nonetheless, many students wished for more in-class time with facilitators, and some lamented the difficulties of groups meeting outside class at a largely commuter university.

Several students wished for more staff support in the computer labs between classes. Frustration at the lack of support at the drop-in labs is notable, because at the time the assignment began, the College’s Technology and Learning Center had not opened (it opened mid-way during the semester). The staffing model of the traditional “computer labs” on our campus probably reflects the norm on most campuses—staff are hired mainly to control access into and out of the area and maintain the equipment. The staffing level is typically one “monitor” per lab. In contrast, the TLC’s mission is explicitly to support the educators—and all are future or current educators—who use the facility in their use and learning of technology for education. In addition to the scheduled workshops we offer to students and faculty, our staff “on the floor” offer as much assistance and guidance as they can give to our customers, although on-the-spot, extended individual tutorial sessions are not practically feasible with our large numbers of users (hundreds per month in the spring of 2000, thousands in the fall). We have worked hard to cultivate an atmosphere in which our customers feel free to ask questions and seek assistance. This is facilitated by having two staff on duty at most times we are open.

In reflection papers submitted after the assignment was complete, most students expressed agreement with the notion that teachers should be prepared to integrate technology. As one student said, “I believe it is very important for our class as college students and also as future teachers to be aware of and comfortable with the technology available.” But some expressed frustration at a technology assignment they did not expect in a psychology of learning class. This frustration may have been exacerbated by the fact that some sections of the introductory class during this period were not being offered in the new curriculum model, and thus did not include the technology work—therefore, students were aware that some of their peers were not required to complete the difficult work involved in a web site. As the new curriculum is more fully implemented, students who do not use technology in their courses will be more the exception than the rule.

Despite the frustrations, most students were pleased with their accomplishments. As one put it, “while I did have a hard time working on this website, ... I did learn a lot about the Internet, computing skills, and all the support websites that are available.”

In the Fall 2000 semester, the developmental web site project was repeated and extended to three sections of the new curriculum course, two of which are taught by part-time instructors. Most of the class meetings on technology were scheduled in the TLC classroom space, and facilitators were once again available for those meetings. Students during this second round had very similar reactions to the project as those in the second round—a mixture of excitement at using technology which is recognized as important for education and some trepidation at the newness and complexity of the task. Students have made more
considerable use of staff support in the TLC after spending time in the space with their class, and in reflection papers, no requests for additional supportive staff were made.

**Vignette: Technology Overcomes Achilles**

A vignette from early in the Fall 2000 semester serves as an example of the promise of readily available information technology settings such as the TLC as learning resources. One of the instructors involved in PT3, who we will call Ann, injured her Achilles tendon before the second class meeting of the semester, and was consequently unable to attend her Introduction to Instructional Methods class. On the day of class, Ann called up the PT3 project director, Ms. Mastin, and asked her to take over the class for the day by leading the group in an assignment Ann had prepared. Ms. Mastin asked the faculty member if they were using the new university online course material system, a version of CourseInfo’s Blackboard. The system had just been installed on campus in the summer, and many of the instructors and students, including Ann and her class, had not yet had training or experience using it. Ms. Mastin suggested they give it a try anyway. With Ms. Mastin’s help over the phone, Ann posted an announcement for her students, and posted the assignment document in the area reserved for that. Ms. Mastin met Ann’s class and took them to the TLC to read and work on the assignment. The class completed the assignment in the TLC, with Ms. Mastin acting as the facilitator, and also with the support of discussions with their neighbors about both technology and content.

The TLC and the technology infrastructure facilitated this successful adjustment of a class meeting in several important ways. Ms. Mastin’s availability to advise Ann on the capabilities of technology to enable work on the assignment was essential. The relative ease of posting announcements and assignment documents on the Blackboard system was also key—if Ann had wanted to post her ideas to a standard web site and had not yet attended a training session, she would have been unlikely to succeed in a timely enough fashion for class that very evening. And finally, the availability of a space in the TLC for individual class meetings to work with staff facilitation, a projector for display and walk-through of technologies for first-timers, and a classroom space that allowed for students comfortably working with one another all created new possibilities for successful technology integration into university coursework.

**Next Steps**

At this point in the implementation of our reform, we are expanding our scope in multiple ways. The new curriculum is being phased in at the same time new groups of faculty are being supported in technology integration. In the Winter of 2000, one section of the three Level 1 courses was offered. In the Fall of 2000, three sections of each Level 1 course is being offered, and one section of each new Level 2 course. In the Winter of 2001, Levels 1 and 2 will be offered in more sections, and new Level 3 courses will be offered. At the same time more introductory level courses are being offered in more sections, we are recruiting faculty members to participate in PT3 professional development activities in order to get extra support in integrating technology, and make use of the Technology and Learning Center. In addition, we are attempting to build in sensible articulation of technology competencies across courses and levels of the curriculum, but we have a great deal of progress yet to make. The change over the past year has been tremendous, however.

**Conclusion**

Researchers have demonstrated that the adoption of symbolic aspects of reforms such as trendy descriptors (“multiple intelligences”, “brain-based instruction”) or new textbooks can prove more symbolic than substantive (Ball, 1990; Fullan & Miles, 1992). At the University of Missouri-St. Louis College of Education, we have attempted to provide a whole new “scene” (Wertsch, 1998) where university instructors and students preparing to be teachers try out new ways of acting. Maybe this exciting new play they are constructing will have a longer run on the educational scene than other reforms.

Acknowledgements

We wish to thank our colleagues at the College of Education, especially the staff of the Technology and Learning Center, faculty participating in PT3, and Charles Schmitz. A Preparing Tomorrow’s Teachers to Use Technology grant from the U.S. Department of Education and a gift from E. Desmond Lee made this work possible.
Rethinking Teaching and Learning in the Age of the Virtual-Classroom

"Abstract:" The objective of this paper is to address the question of the changing conception of knowledge at present and the need for institutions of higher learning and educators to reconceptualize the notion of knowledge and learning in order to keep in line with the changes in the society. Furthermore, I will argue that it is necessary to develop teaching methodology that can function effectively in the new technologically-grounded paradigm that is evolving in the realm of the social and the economical on a global scale today. This paper is based on my experience in developing, designing and delivering a web-based Spanish Civilization course at the University of Arizona, Tucson.

Learning Environment

The Spanish Culture and Civilization course, Spanish 430 was taught during Summer Session I, 2000 at the University of Arizona, Tucson. It was unique in that it gave students the freedom to access class resources at any time, from any internet-connected computer in the world. Indeed, while many students in the Tucson area used the Web to read class materials, many others took part in class discussions and completed their assignments from Phoenix, Flagstaff, and Nogales, Arizona, San Diego and Los Angeles, California, and even from as far away as Spain and Italy.

The course lessons were divided into three broad categories: La Tierra y El Pueblo, Poetas, and Pintores (The Land and People, Poets, and Painters, respectively). Each of these categories was divided into subsections where class readings, practice quizzes, and discussion topics could be found. All class readings included images, photos, maps, audio and video materials along with text, and a dictionary feature that instantaneously provided word definitions at the click of a mouse.

One of the most innovative features of the course was a collaborative project. Students were required to form groups of three and read Spanish newspapers during the five-week period of the class, paying close attention to a particular news story and the manner it was presented in the Spanish news media. At the end of the course the groups presented their observations in the form of essays.

Student participation was facilitated principally through a section of the course called Mesa Redonda, but also through available chat rooms and e-mail. Mesa Redonda was a virtual round table where students were required to both post their thoughts on class lessons and read the postings of their classmates. During the five weeks of this course, there were over 500 postings. Students also had the option to use chat rooms to ask specific questions about class materials during the professor’s virtual office hours, or were able to have their technical questions addressed by the Technology Preceptor of the course. Chat rooms also provided for students who were in different areas of the world a means by which class readings and projects could be discussed in real-time. Students also made use of both the class e-mail system and their own e-mail accounts to discuss class topics and have their questions answered.

The designing, developing and delivering this experimental course presented me with several challenges and made me think about teaching and learning in the age of technology.

Technology and teaching

Technological innovation, the demands of global economy and the drive towards a cost-effective education are forcing educators, administrators and students alike to incorporate new and innovative technologies into education. Consequently, the virtual-classroom has emerged as an alternative to the traditional classroom as well as conventional distance learning courses. However, the virtual-classroom is yet to realize its full potential. Teaching and learning in a virtual-classroom cannot be conceived as a simple enhancement of the delivery of customary text-based materials, nor should it be thought only as freedom on the part of learners to access materials outside the confines of physical classroom and text. Technologically-oriented education in its present state continues to rely on traditional pedagogy. This approach will be unable to cope with the new paradigm that is redefining the society in hitherto unknown ways. The challenge for educators is to evolve new methodologies wherein the concept of teaching and learning has to be thought anew.
Knowledge in Information Age

The technological innovations and societal changes over the last fifty years have profoundly transformed the concept and utility of knowledge. Jean-François Lyotard in his book *The Postmodern Condition: A Report on Knowledge* characterizes knowledge in the postindustrial age as "payment knowledge" and "investment knowledge" (Lyotard, 1984, p. 6). While the "payment knowledge" is "units of knowledge exchanged in daily maintenance" the "investment knowledge" is "dedicated to optimizing the performance of a project" (Lyotard, 1984, p. 6). However the educational institutions—unaffected by changes in half a century—conceive knowledge as an end in itself. The academics envision the universities as places for pursuing whole body of human knowledge, therefore “research and the spread of learning are not justified by invoking a principle of usefulness” (Lyotard, 1984, p. 34). These two forms of conceptualizing knowledge today are the undercurrent of conflict witnessed between the communities and legislatures who demand greater accountability from academics on the one hand, and the universities that defend their freedom on the other. Wedding Internet technology and education as solution for this conflict is a losing proposition because these two groups views of knowledge are radically different. The possible resolution lies in institutions of higher learning reconceptualizing their idea of knowledge and its pursuit.

Teaching in classroom

Teaching in a traditional classroom takes place in a narrative framework: sender, receiver and referent. The teacher is the sender who stands before a class and transmits information during sixty minutes. The receivers are students who patiently wait for sixty minutes to pass, and the textbook, a bound volume of knowledge, is the referent. This narrative model does not have an inbuilt mechanism to foster teacher creativity and learner involvement. They are left largely to the personal initiative of senders and receivers. The anecdotal experience of most of those who went through colleges and universities demonstrates that they have had one or two teachers who inspired them to learn and one or two courses where they really learned.

The dissonance teachers experience between teaching and learning in the classroom is the reflection of the conflict between the two notions of knowledge I referred to earlier. The student body that enters academia is drawn from a society affected by the technological changes. They are exposed to a different form of information mapping and they process that information in a different way. Television and videogames, major sources of information and interaction, are episodic in nature, task-oriented and use-determined. However the narrative models of teaching and learning ensue an accumulation of large body of knowledge whose goals and utility may or may not be realized at a later date.

Challenges of a virtual-classroom

The Internet, so far, is the maximum achievement of the technological revolution. If web technologies are to be used in education, the concept of knowledge, how it is presented and for what purposes it is used has to be rethought. Without this reconceptualization of knowledge, publishing lessons and class notes on web with few added features such as note taking, search and visuals will be a mere translation of narrative model to Internet. Using the web as a delivery mechanism of traditional classes will be counterproductive because research has shown that students have not taken to reading on screens. Moreover, web learning eliminates the many benefits of live interaction in a classroom.

In a fixed classroom an innovative teacher responds immediately to evolving dynamics of the course through interaction with students and by evaluating students’ responses to the material and teaching style. However in the web-delivery such spontaneity is missing. The course cannot be redesigned or reoriented at such short notice. One potential solution is to incorporate as many scenarios as possible into course design and use the multimedia interactions. The teacher in a virtual-classroom has to forgo his or her role as transmitter of knowledge and become facilitator of learning. For this to occur the students have to be trained to play a new role, that is of active learner instead of passive listeners. My experience has taught me that both, the role of teacher and student have to be rethought and reengineered in adopting technology in education and creating virtual-classrooms.

Developing Techno-Savvy English Language Arts Teachers: from Blank Screens to Full Directories

Carol A. Pope, Judy Lambert, Amelia McLeod, & Julie Weber
Department of Curriculum and Instruction
North Carolina State University
United States
carol_pope@ncsu.edu, jlambert@lambert_corp.com, annie.v@mindspring.com, julicwcbcr99@hotmail.com

Abstract: This paper discusses the ongoing process of infusing technology into an English language arts teacher preparation program and includes an update of a longitudinal case study of a cohort of undergraduate students' development as teachers, learners, and users of technology and English language arts pedagogy. Principles and practices used to determine the degree and process of infusion are discussed in connection with teaching, learning, and technology strategies used by the methods professor and the preservice teachers. Also included are the perspectives of an instructional technologist specialist who works with the program, a middle school teacher, and the student teacher supervisor.

Introduction

The Middle Grades English language arts teacher education program at NC State University has in recent years committed to infusing technology in a seamless, constructivist way that simultaneously supports the building of students' confidence and competence as teachers, learners, and technology users. By merging the NC Technology Competencies for preservice teachers into the curriculum, the faculty and students have learned together the value of balancing and interweaving content, context, and technology. This process was catalyzed in 1999 by the reception of a PT3 grant from the US Department of Education. Through the grant the English language arts faculty received both technical and instructional assistance in boosting the degree of technology infusion in content methods courses.

Background

As a way to assure the infusion of technology into the program, faculty from English education and instructional technology created MIDtech, a web site specifically designed for preservice students in the middle grades program (http://www2.ncsu.edu/midtech/). The web site, developed with continuous feedback and evaluation by students in the program, contains interviews with middle school educators who infuse technology into their teaching in a thoughtful, successful way as well as numerous other useful resources. From the site NC State students, soon to become teachers, can locate exemplary lesson plans written by teachers, materials they can use in teaching, tutorials for technology use, and links to other courses and student work. They can also find the North Carolina required competencies for teachers (http://www.dpi.state.nc.us/tap/assess.htm#BASIC) as well as the matrix which shows how these competencies have been infused into the curriculum and courses for their program at NC State (http://www2.ncsu.edu/midtech/resources/preservice/msltables/matrix1.html).

Planning and Principles
The English language arts middle grades students take several pedagogical content courses that provide opportunities for technology infusion. Three classes which assume much of the technology infusion responsibility are ECI 307 Teaching Writing Across the Curriculum, ECI 430 Methods and Materials for Teaching Language Arts in Middle School, and ECI 454 Student Teaching in Language Arts. It is from these courses that the following examples were drawn.

Beginning in January 2000, we [the English language arts methods professor (Carol), with the assistance of an instructional technology specialist/graduate assistant (Judy) as well as the university supervisor (Amelia), and a middle school teacher/graduate student (Julie)], set as a goal the seamless infusion of technology into the Teaching Writing course. Carol was concerned about keeping content pedagogy, not technology, as the touchstone for the class; Judy was anxious to be of assistance and to bring her technology knowledge and skills to the planning; Julie was interested in connecting the preservice students with her middle school students to improve their writing; and Amelia referenced the state of technology in the area middle schools where these students would be student teaching.

Initial brainstorming and creation of the syllabus provided the jump-start for an active, challenging semester. Within the first week of class, Carol collected from the students a self-evaluation narrative of their computer competency, confidence, and present use. The students reported that they used computers primarily for writing papers (word processing), emailing, and searching the Internet. One student reported her ability to use PowerPoint for presentations while another reported using her computer for playing games. All of the students said they were comfortable when they knew the computer and the software but had little confidence in themselves as "experts" who could use technology in teaching. In short, they were blank screens about the infusion of technology into their teaching of English language arts.

In the months preceding the beginning of class, Carol had been working independently to add computer technology to her teacher preparation classes. Her refusal to make the technology just an "add-on" to the program and courses set into motion her struggles about the best ways to both use and infuse technology. Frequently Carol refers to content-specific methods instruction as a double helix—i.e., teacher educators are not just teaching the content but also the content pedagogy; adding technology to that duality created another element to an already complex challenge. Driven by that challenge, Carol worked with Jeffrey Golub at the University of South Florida to develop an article entitled “Preparing Tomorrow’s English Language Arts Today: Principles and Practices for Infusing Technology” (Pope & Golub, 2000) published in the new on-line journal, Contemporary Issues in Technology and Teacher Education (http://ww.citejournal.org). The purpose of this article, like the other content-specific articles in the first issue of the CITE Journal, is to stimulate a national conversation about the principles and the viability of their use in preparing English language arts teachers.

The following principles from that article guided the infusion of computer technology into English language arts pedagogy courses: 1) introduce and infuse technology in context; 2) focus on the importance of technology as a literacy tool; 3) model English language arts learning and teaching while infusing technology; 4) evaluate critically when and how to use technology in English language arts classroom; 5) provide a wide range of opportunities to use technology; 6) examine and determine ways of analyzing, evaluating, and grading English language arts technology projects; 7) emphasize issues of equity and diversity.

Place and Practice

Using the principles as guidelines for pedagogical decisions, Carol and Judy worked together and independently to explore ways of naturally infusing technology into the Teaching Writing class and then again in the Fall 2000 methods class—the two university-based English language arts pedagogy courses that precede student teaching. The Teaching Writing class was held in the computer lab so that Carol and the students had easy access to technology. By being in the room with the technology, Carol thought she would be much more likely to use the available technology for teachable moments that grew from the class interests and to have the technology waiting to be used. This decision proved to be a wise
At the end of the semester when we calculated the number of hours of technology use in the class, we discovered that over 50% of the class time had been spent using technology in the class context.

One of the most valuable technology infusion lesson cycles Carol used in the Teaching Writing class was the one in which she and Julie connected their students via technology. This E-PALS Project was one which Julie and Carol had tried before with limited success. This time they knew both the technological and communication hurdles they faced and were able to eliminate most of those problems. Carol’s students were matched one-to-one with Julie’s middle school students. The goal of the E-PALS project were that 1) the middle school students would get special attention from a university student to help them with their writing; 2) the university students would learn, through practice and guidance from Carol, how to respond to students’ writing and guide their revision to a final product. This process is discussed and outlined on an NC State web site (http://www2.ncsu.edu/ncsu/cep/ci/ci1eci307.html).

The E-PALS Project addressed all of the principles for infusing technology into teacher preparation. The preservice teachers were using technology to learn how to respond and guide middle school students’ revision, and they experienced the impact of language choice, audience, and voice when the “teacher” was communicating completely on-line. Because class time was spent on guiding the preservice teachers’ responses and guidance to the middle school students, the university students critically evaluated what was being lost and gained by e-communication as opposed to the face-to-face interaction they had with each other in the classroom. Questions regarding how to evaluate and how to grade technology products constantly emerged without Carol’s designating a “block” of time to consider grading and evaluating. As they worked with their E-PALS over several weeks, the preservice teachers had numerous questions about issues of equity and diversity--e.g., how to provide more-than-equal time to students who do not have access to computers at home and how to write grants to get more computers in classrooms for all students. They also experienced how to keep information in e-folders in the classroom and how to open each student’s file from the local server.

Most importantly, the students built relationships with middle school students via email. They learned both how to communicate openly with their own students and how to guide students’ writing; they learned how to revise and guide revision; they learned not to make assumptions about students unnecessarily; and they built their confidence as teachers. When Carol’s students went to Julie’s classroom across town at the end of the semester, the students immediately began talking and establishing the same bond in person that they had established through cyberspace. Both groups of students benefited greatly from this interaction.

More Applications - Teaching Writing

Following are a number of other ways in which Carol, with Judy’s assistance, infused technology into her Teaching Writing and Methods classes.

**Class Web Site:** The web site is an in-process location that changes as the class evolves. It is dynamic and reflects the class movement itself. Teachable moments become web links, and student work contributes to the site.

**Class Notes:** Each week one student keeps the class notes, which are posted by the students on the web site for both downloading and keeping a record of the class.

**Daily Writings:** Student have opportunities to write daily in the Teaching Writing class. They have a choice of writing on computers or by hand. Students often choose differently, depending on the day, as does Carol.

**Response/Chats:** Students respond to each other’s writing, ideas, questions, and views via email, Netforums, real-time chat formats, face-to-face, on e-cakewalks (by moving from computer to computer and responding), and by opening documents within their own and their peers’ e-files.

**Server:** One of the ways in which students get practice in how they can store and retrieve both their own and their future students’ work is to set up
and experience the use of a class folder and their own folders. From these folders (which are analogs to tangible class writing folders), students pull up assignments placed in e-folders by Carol and get a chance to post information in their peers' folders.

In addition to these larger activities, students also experience and reflect on the usefulness and application of such strategies as using split-screen response and/or note-taking/note-making, searching the Internet and taking notes on a word processing screen, doing "invisible writing" to break habits that block writing fluency (Strickland, 1997), evaluating and critiquing web sites in writing (then sharing their written results with their peers), and participating in videoconferences with other universities.

The critical element in the infusion of these technology activities in the Teaching Writing class is that before, during, and after the experiences, Carol and the students reflected on the value of the activity. Then they considered various ways of applying those activities in a real middle school classroom. Why, according to what we know from English language arts pedagogy research and informed theory, would these experiences benefit the learning of the middle school students? What would they gain from using computer rather than paper and pencil technology? How could the experiences be modified if the classroom had only one computer? three computers? no computers, but a computer lab down the hall? The incorporation of reflexive thinking assured that the preservice teachers were not only answering the "What" question but also considering the "So What" and "Now What" questions.

Building on Experiences

When the students from the Teaching Writing Across the Curriculum class entered the Methods class this fall, Carol and Judy sought to build on the students' skills and also stretch them a bit. However, the class was not scheduled in the computer lab. Instead, Carol, Judy, and the students used a mobile classroom cart which included wireless computers complete with Internet access via airports, a teacher computer with display capability, and a portable printer. The students quickly learned to set up the cart, hook up the Internet access, use both the MACs and PCs, and use the demonstration computer. They also determined how best to set up the classroom so that every student could participate and see both the front and back of the classroom, dual foci for projection and discussion. Even though students had valuable experience with this equipment and quickly made connections about how such wireless technology could be a tremendous advantages in schools, neither they nor Carol used the computers as readily as they did in the computer lab where there was no danger of batteries being dead or other quirks being encountered. Although that class has not yet ended, we project that Carol and the methods students will use the technology in class much less often than they did in the Teaching Writing class.

Besides using computer technology to critique web sites, do research on the Internet, and view various software programs, Carol and the students embarked this semester on a project to develop lesson plans appropriate for teaching Mark Twain's *The Adventures of Tom Sawyer* to middle school students.

After reading the novel and perusing web sites, the class visited Stephen Railton, an English professor at the University of Virginia who has created a series of digital archives that he uses in teaching his university classes on Twain. The preservice teachers visited his class on the day they were discussing *Tom Sawyer,* observed and participated in the class. Students are now creating lesson plans for teaching *Tom Sawyer* with middle school students by using the digital archives (http://etext.virginia.edu/railton/tomsawye/tomhompg.html).

These lessons, along with the preservice teachers' work from this semester, will be posted on web sites they are currently developing as part of their teaching and technology portfolios. The web sites will include an introduction, various types of lesson plans, student teaching unit plans, a teaching philosophy, and lessons which include technology infusion. [Although these web sites are not currently posted, web sites from former Methods students can be found at http://www2.ncsu.edu/classes/eci430001.]

Student Teaching and Beyond
Besides continuing to support and guide preservice teachers' infusion of technology in their exemplary English language arts teaching, we want the students to use materials from their own web sites in their student teaching and with their cooperating teachers. However, from our work in schools in our areas, we know the challenges our preservice teachers will be facing as they attempt to infuse technology seamlessly into their teaching. Many schools have computer labs halls away from the content classrooms, and often these labs are reserved for "computer classes" (keyed to the eighth grade computer competency test). This phenomenon was validated when the students went into area middle schools to determine what computer technology exists and what is actively used. By and large, students found few computers in classrooms and even fewer teachers using the computers in their own teaching. Rather, they found computer labs that had to be reserved far in advance and teachers who used technology at home but not as an active part of their teaching.

Amelia's observations and studies of area middle schools confirm that schools face challenges of equipment shortages, outdated or malfunctioning equipment, and often only one computer lab for a thousand students. She also reports that, although there are often highly committed technology resource teachers in the schools, they cannot take care of all the demands for both their time and the equipment. Teachers face the greatest challenge in that they have little time to learn and then figure out ways to use technology in their own teaching.

Student teachers who, as a result of the increased infusion of technology into content methods courses, view technology as a positive teaching tool and are ready to use technology in their teaching. If their cooperating teachers use technology and are not intimidated by the computer and/or computer lab, students teachers are much more likely to implement what they know in their teaching. However, one surprising variable we have discovered is that often student teachers' use of technology is stymied by middle school students' not having their "technology policy" permission slips signed by parents. If students do not have these permission forms filed at the school, they cannot fully participate in the class activities; teachers and student teachers are hesitant to use technology in such circumstances.

Research Update

To date, the cohort of students who are about to enter student teaching acknowledge that they will never know everything about technology because, according to Alice, "even the savviest technology people do not know everything." They believe they have "broken down [the] barriers of insecurity in using technology," (Rose) and will, as Paula suggests, continue to "work on those 'stumpers' "i.e., tools she is not yet completely comfortable using independently.

Encouraged to discuss ways in which they intend to use technology in their teaching, even the students who have philosophic concerns about technology interfering with the human touch acknowledge ways to "bridge" people across the world through technology. Barb says she will "embrace [technology], look at it and manipulate [it] as a tool for empowerment." She wants to have students learn about global issues and reach out to people who might not be reachable in any other way than through email. Her students, then, will "form relationships and establish bonds, which may open new dialogue" among groups. By examining the motivations and intentions of email, web sites, and technology, they will become critical users.

When these students are asked to list the kinds of technology tools they will use in their own teaching, they include student-created web sites, real-time chats, videoconferencing, digital archives, writing process through computers, E-PALS connections, global connections with other cultures, scavenger hunts, and numerous activities we have used in both classes. This list is a far cry from the blank screens of the students' first narratives. They see the potential for enhancing their teaching through technology, and they know they will be continuous learners as well as teachers.

Challenges to Technology Infusion
Judy, as a result of her work with Carol and other pedagogy content specialists at the university, notes that the initiative to infuse technology into teacher preparation poses special problems for pedagogical content specialists. Professors like Carol have been preparing preservice teachers for many years. Now they are called upon to prepare future educators to be technologically literate while they are also making the transition to new forms of instructional delivery. They face such obstacles as 1) insufficient personal knowledge and skills in technology, thereby creating anxiety and frustration that accompany any learning curve; 2) expecting themselves to model and infuse technology skills before they have mastered the skills themselves; 3) inadequate time to research underlying principles upon which successful practice can be based.

The challenges facing the pedagogical content specialists prompt equal challenges for instructional technology specialists who may, as graduate students, be paired with professors to assist them. Thus their collaboration time is limited because of the demands of both their roles. And, although individualized, just-in-time training may seem realistic and beneficial for personal growth, these teachable moments may not be sufficiently comprehensive. At the same time, the technology assistant's expertise may not be in the same area as the professor, thereby establishing the necessity for collaborative planning and learning. In such situations brainstorming ideas and strategies that are relevant, engaging, and successful for both the instructor and the students is critical.

Conclusions

The primary goal of teacher preparation should be that the infused technology appear seamless and be used only as it improves teaching and learning. However, basic computer skills are necessary before the learners (whether they be professors or students) can comfortably grasp and employ advanced processes. Both assistants and professors need to allow time for basic skill development through short lessons during class as well as applying the skills to the content pedagogy itself.

In our experience, the professor-assistant-student trio has been both rewarding and challenging. Every person in the triptych is both a learner and a teacher; therefore, each person serves several different roles. The teaching/learning field is level and shared; the preservice teachers then see an active model for technology infusion—one which requires an equal sharing of roles and responsibilities and one which honors the myriad opportunities to fill blank screens with full directories.

A Technology Consultant Model Implemented In A Project-Based Pre-Service Teacher Education Program

Anne Porter, Maria Cseh, Ledong Li, John McEneaney, James Quinn
Oakland University

Introduction

A recent national survey on the preparation of new teachers to use information technology (Moursund, 1999) reports that most college and university faculty do not model the use of information technology skills and most student teachers do not routinely use technology during field experiences. Topp's (1996) also revealed that recent graduates of teacher education programs felt that their preparation for using technology was inadequate because their programs did not include modeling of technology uses in methods and general education classes. Almost certainly related to the problem of limited faculty modeling of information technology in the university setting is the fact that faculty who adhere to a traditional professorial role may intentionally avoid using technology, fearing that it will reveal their lack of expertise and undermine their instructional authority. Moreover, the fear of appearing technologically inept is magnified by the familiarity and experience students frequently have using technology in other settings. Ironically, the very technology skills we hope to develop in students may undermine efforts to introduce new teaching technologies to classrooms by intimidating teachers. The traditional professorial model simply will not work under these circumstances and that, in part, seems to be the reason there is such widespread interest in alternative approaches to teaching with technology (Duffy, & Jonassen, 1992). The professor as a facilitator of learning is one particularly powerful example that has been used with technology-supported case analysis (Cognition and Technology Group, 1990; Risko, 1995) and problem-based learning (Savery, & Duffy, 1995; Barab, Hay, & Duffy, 1998).

The Project

This federally funded project (Preparing Tomorrow's Teachers to Use Technology, PT3) places digitally literate pre-service teacher education students and experienced, highly effective educators in a mutually supportive, collaborative environment. The ultimate goal of the project is to increase the number of in-service educators modeling effective integration of technology for our pre-service students both in classes across the university and in education field experiences.

Students participating in the grant (consultants) enroll in a 4 credit course, IST 464 Consultation: Technology Applications in Education which meets once a week for two hours and includes activities and guidance in the development of consulting skills and educational technology applications. This course is designed to help students integrate knowledge from any education major/minor with educational applications of technology.

Student consultants work for 10 hours per week throughout the semester in an applied field setting in either an urban or a suburban school system, or at Oakland University, with experienced educators (clients) who are interested in increasing the integration of technology in their classes. The consultants' goals are to help the clients learn technology integration skills that support the clients' teaching styles and curriculum needs. In addition, as they learn about what an already effective teacher actually faces in his/her efforts to integrate technology our students develop strategies to overcome these inherent challenges.

Major Activities and Findings

September through December 1999 was spent getting project personnel, systems, and preparation for the pilot offering of the technology consultant course in place. From January through April, 2000, primary
personnel hiring was completed, the project website was launched and the technology Consultant course was piloted with eight pre-service teacher education students (consultants). These student consultants were matched with five university professors and three K-12 teachers (clients). Many lessons were learned as a result of the pilot offering of the course and were implemented in the first full offering of the Consultant course which occurred in Fall of 2000. Eighteen pre-service teacher education students enrolled in the Consultant course and were matched with three university faculty members and fifteen K-12 educators.

As a part of the project evaluation, all consultants and clients were interviewed at the end of the Fall semester. Despite a number of challenges which will be identified below, all participants described the experience as extremely worthwhile, and all would recommend the experience to their peers. When asked of the likelihood of the project experience changing classroom teaching there was a unanimous positive response. Consultants were very strong in their certainty that the consultant experience will impact their use of technology in the classroom. In particular, consultants indicated that they had crossed a “confidence threshold”, a “competence threshold”, and had come across many ideas of how to integrate technology into the classroom. Without a doubt, fundamental mental shifts have taken place in the awareness of the project consultants. Clients expressed similar sentiments. Many commented that it was so different having on-going technology support as opposed to sporadic technology workshops. They felt that the support enabled them to work through some of the barriers that prevented them from actually implementing applications they had learned about.

Challenges encountered included: lack of technical resources in client environment, lack of time on the part of the client, adjustment to the role reversal between experienced educators and pre-service teacher education students in the client and consultant roles, potential role conflict when students were also doing traditional field placements with the same K-12 educator, and competing demands of work, family and other courses on time of student consultants. This last issue, busy student schedules, is the project’s greatest hurdle in recruiting students to enroll in the Consultant course. Our challenge is to create a “don’t miss” reputation for the course in the minds of our potential students.

In summary, we believe that the model presented in this paper, provides a long-term solution to the “lack of modeling and use of technology in pre-service teacher education” problem in university classrooms and in field placements. Essentially, in this model pre-service education students help university professors and in-service teachers create effective learning environments for them, and ultimately, for their own students.

PT3 Project InSight Develops Three Resources to Promote Visual Communications

M. D. Roblyer, Professor of Media & Instructional Technology
State University of West Georgia, College of Education, U.S.A.
(mroblyer@westga.edu)

William R. Wiencke, Assistant Professor of Media & Instructional Technology
State University of West Georgia, College of Education, U.S.A.
(wwiencke@westga.edu)

Abstract: As part of its activities funded by the U. S. DOE as a PT3 Implementation Grant, Project InSight, led by a consortium at the University of West Georgia, has three objectives to promote more visual communication of ideas and skill training among preservice students and faculty. These objectives include: (1) expanding a video-based school-to-university network link among six partner school districts and the university; (2) developing a series of video demos illustrating effective instructional uses of adaptive/assistive technologies; and (3) developing virtual reality and 3D environment examples to illustrate diagnostic applications and instructional uses of these emerging technologies in meeting special needs of students with disabilities. This presentation will describe the Year 2000-2001 activities and progress on accomplishing these objectives, and demonstrate the products developed to date for each.

Introduction

As the University of West Georgia developed a three-year Implementation Proposal as a follow-up to its Capacity-Building grant, it became evident that more visual communications were destined to play an increasingly greater part in our efforts to infuse technology into our preservice program. After considering our needs and the potential role of "face-to-face communications at a distance," we designed three different activities that would further visual communications and set the stage for similar activities in the future.

Expanding a Video-based School-to-University Network

One of the most successful efforts in the Capacity Building phase of our PT3 work was putting in place and testing a streaming video link between a local school district and the university. Evaluations of this activity reflected a high level of excitement shared by university and K-12 faculty about the link's potential. It became clear that many of us felt that more visual communications can improve the quality of teacher education in two key ways:

- By immersing preservice teachers into classroom activities at a distance; and
- By allowing teacher education faculty to include distant K-12 classroom activities into on-campus learning.
During the initial year of the Implementation grant (2000-2001) year, we are involving schools in additional partner districts in the network by accomplishing the following steps:

- Assisting our partner school districts (with funds and technical expertise) to obtain and implement high-speed connections between their sites and ours;
- Testing the links for each school/district site with a basic set of instruction-related activities we have designed to make use of the current link in classes and during internships;
- Initiating additional communications capabilities in schools to supplement our streamed video capability with additional video capabilities over the Internet (e.g., with EnVision); and
- Integrating the video activities as components in our teacher education program.

Developing a Series of Videos on Adaptive-Assistive Technologies

A need that has been identified and acknowledged by many preservice programs is additional training to prepare non-special education content area teachers to meet the needs of children with mental and physical disabilities. All too often, teachers receive substantially less training than they need in this area, not because they or their programs consider it unimportant, but because of limitations on the number of hours they can take in their programs. Courses in their content areas and in basic methods of teaching children in certain age groups must take precedence over other courses and skills.

To make it more feasible for faculty to provide training within current courses that will prepare preservice teachers to meet students' special needs, we are developing and providing training to faculty on a set of transportable, easy-to-manage materials they either can use in courses or have students use outside class. This set of materials would combine existing print and video materials with the video-based demonstrations we will develop. The proposed video demonstrations would make the content and delivery of this information more visual and, thus, easier to use outside class. They also would provide more graphic illustrations of how teachers can use technology-based tools to meet the special needs of students in inclusion classrooms. Special Education faculty will work with local teachers to develop these videos. Steps to accomplish this task include:

- Obtaining copies of existing materials on this topic;
- Developing video demos to illustrate technology uses and package it with print materials;
- Placing videos in our Support for Infusing Technology Center and disseminate them via our web site; and
- Providing presentations with infusion suggestions to teacher education faculty in all areas.

Developing Virtual Reality (VR)/3-D Examples That Meet Special Instructional Needs
Virtual reality (VR) technologies and other 3D environments have been talked about for years in terms of their potential for meeting needs of students with disabilities. As Roblyer & Cass (199) noted, “VR could allow students with disabilities to learn certain skills:

(a) with greater physical and/or emotional safety,
(b) in a more timely and cost effective way,
(c) in ways that do not highlight their disabilities,
(d) in a manner that does not interfere with the general public, and
(e) in a way that better meshes learning and learner characteristics.”

Yet this obvious potential remains largely untapped. Two primary reasons have accounted for this discrepancy. First, not many educators have skills required to design VR programs. Second, the cost of designing and implementing good quality VR capabilities has been relatively high.

However, recent developments in VR software have made it increasingly feasible to develop VR environments with relatively low levels of technical expertise and at a comparatively reasonable cost. In order to illustrate the uses of VR environments in meeting special learning needs, we are using SuperScape's VRT Development Software to develop two kinds of model VR environments with this lower-cost software:

- **Virtual Shopping** - Using video footage of popular shopping areas, we are developing an environment to train students with mild mental handicaps to learn and practice a series of shopping and purchasing activities. This training product is being designed and developed in conjunction with K12 special education faculty and teachers. Once in draft form, it will be field tested with students and evaluated for its transfer to real situations.

- **Spatial Mobility Training** - To help students with physical and mental challenges learn to negotiate spaces in buildings during emergency and non-emergency situations, we will design a model simulations in a school building, test it out with students with physical and mental challenges, and evaluate them for transfer to problem solving skills in buildings under real conditions.

**Summary**

All these activities are in keeping with our project's theme of “InSight” we have gained into the resources that are needed by preservice faculty and students if they are to infuse technologies into their instruction meaningful ways. During the presentation, we will discuss these needs, our insights about how to meet them, and the tasks we have undertaken thus far. Finally, we will demonstrate products we have developed to date under each objective.
Faculty Development as an Agent of Technology Change: Implementing a Shared Vision

Charles M. Savitt
Assistant Professor of Instructional Technology
Virginia Commonwealth University
United States
cmsavitt@vcu.edu

Abstract: This paper will describe first year efforts in reference to a PT3 Implementation grant. The grant promotes an alliance between two very diverse institutions of higher education. One university is a historically white public institution while the other is a small historically black private institution. Both institutions are implementing a series of initiatives to transform their respective teacher preparation programs. Using shared resources, these initiatives include an extensive program of faculty development in instructional technology for both arts and sciences and teacher education faculty. Significant changes to both institutions technology infrastructure provide faculty, preservice teachers, and classroom teachers with significant technology support, including individual assistance and a lending library of software and portable technologies. Using these support services, university faculty are modeling the use of instructional technology in their courses and increasing the use of technology into course assignments.

Introduction

A historically white public institution and a small historically black private institution partner in their faculty development efforts as part of a PT3 Implementation grant beginning the 2000-01 academic year. Through this grant, two diverse universities are jointly implementing a series of initiatives to transform their respective teacher preparation programs. Significant changes to instructional technology facilities at both universities are providing faculty, preservice teachers, and classroom teachers with significant technology support. Using these support services, faculty will help preservice teachers develop the needed knowledge and skills to infuse technology into content-based instruction.

As part of first year initiatives under the PT3 grant, one focus has been on ensuring that faculty receive training on the use, operation, and integration of technology into their respective curriculum areas. A recent survey of faculty (conducted during a 1999-2000 PT3 Capacity Building grant) at both institutions revealed a pressing need for improving faculty development and for providing assistance with infusing technology into teaching. Faculty also reported reasons for resistance to integrating technology throughout the teacher education curriculum. Approximately half the faculty identify classroom resources, costs of hardware and software, inadequate time for training, lack of motivation and knowledge, and costs of ongoing support systems as barriers to more use of technology. Other comments state that while training sessions are available, they may not be convenient or targeted to specific needs related to content and the skill level of each faculty member. This suggests that general training sessions need to be followed by opportunities for individual consultation to target training to meet specific needs. A primary need for both faculty and preservice teachers is enhanced availability of intensive training.

Solutions: A Starting Point

In an effort to respond to faculty needs for technology training and assistance with the use and integration of technology into curriculum, the following initiatives are currently being offered: Goal One: Offer technology resources, training programs, support and other opportunities to faculty at both universities.

To accomplish goal one, 16 faculty per year in teacher education programs and 14 faculty per year in Colleges of Humanities and Sciences at both universities are being provided with course release time.
This release time will provide faculty with opportunities to develop and infuse instructional technology into their courses and to serve as leaders in their respective disciplines. Because both universities require that prospective teachers earn a BA or BS in a Humanities and Science major, it is imperative that H&S faculty infuse their use of technology into their curriculum. While the release time initiative is just underway, a previous Capacity grant awarded during the 1999-2000 academic year has demonstrated the strong effect that release time can have on the use and integration of technology into instruction.

Faculty who have obtained release time over the 1999-00 year have actively learned about technology and incorporated it into their respective disciplines. Faculty represent a variety of program areas: elementary education, middle education, high school education, and special education. For example, a professor of science education has learned to use the new QX3 computer Microscope and then infused its use into his courses. His students, in turn, have used loaner microscopes to teach lesson in area schools.

A professor of special education has devoted time to learning about assistive technology and software. In his classes, the professor is demonstrating touch screens and other hardware devices that provide a variety of methods for inputting information. Second, he is demonstrating to preservice teachers how computer operating systems can be programmed to accommodate students with special needs. Humanities and Sciences professors have also actively learned about infusing technology into their classes. A professor of English is using Web Course in a Box to deliver instruction to her students and to model how technology can be used for instructional purposes. This same professor is also serving as a technology resource in the College of Humanities and Science, regularly visiting fellow professors to demonstrate the use and integration of technology.

These representative samples show how our Implementation Grant is allowing university faculty across disciplines opportunities to learn about new technologies; infuse technology into courses; share technology skills and strategies with their students; and serve as mentors to other faculty who wish to expand their knowledge about effective uses of technology for instruction. VCU and VUU faculty are also collaborating on technology infusion projects, technology conferences, seminars, and other activities that encourage faculty from both universities to learn from one another.

Faculty who have obtained release time, or are in the process of requesting a course release during the grant period require a great deal of guidance, training, and one-on-one assistance with technology. Hence, Goal Two: Improve the operation of the Department of Education Computer Lab at VUU and the Instructional Technology Center (ITC) at VCU.

VCU is expanding its collection of multimedia capable laptops and enhancing its collection of peripheral equipment such as scanners and digital cameras. At VCU the ITC has extended its capabilities by adding an “Infusio” Laboratory that provides "hands-on" assistance for faculty at both universities to incorporate technology into their classroom instruction. The Infusio Lab will also serve as a distribution system for the checkout of hardware and software technology resources.

The School of Education at VCU, for example, currently operates an Instructional Technology Center (ITC) that provides an initial base of technology support and equipment for students, staff, and faculty. The Center houses thirty computer workstations along with scanners and printers. Digital and video cameras, some educational software, and other technology-related resources are available for checkout. Some faculty assemble students in this facility to demonstrate the integration of technology into K-12 educational settings. In addition, workshops geared for faculty and staff provide opportunities to share ideas and technological innovations with peers.

The facility is often used as a classroom space by professors who utilize technology throughout their coursework. ITC personnel are also responsible for managing portable equipment and cataloging and checking out educational software programs. As a result of Virginia Commonwealth University’s commitment to infuse technology throughout its curriculum, the ITC has experienced a large increase in use and an increased demand for instructional support provided by ITC personnel. The growth in usage of the ITC has led to a need for more physical space and staffing. For instance, a multi-year grant awarded to us in Fall of 1999 has provided us with funds to purchase new educational software titles. Our growing software collection requires a significant time investment by current personnel. Titles must be cataloged, stored in a secure location, and checked out to faculty, students, and teachers throughout the greater Richmond area. The expansion of software selection has increased the checkout of the materials by faculty and students.

To accommodate the needs of our university faculty, preservice teachers, and classroom teachers, the current ITC is being enlarged by adding a Laboratory center known as “Infusio”. Three graduate
students are employed to manage and operate the facility. One of these graduate assistants will receive an increased stipend and be designated the lead director of the Infusio lab.

Personnel employed in this facility will have four major responsibilities: 1) Provide “hands-on” assistance for faculty to incorporate technology into their classroom instruction; 2) Offer training and support to student teachers and practicum students, with an emphasis on infusing technology into curriculum; 3) Provide technical assistance on the use of portable and handheld technology for faculty and students; 4) Provide greater access to and security for our expanding software collection.

Staff at Infusio will also be responsible for creating a Web site that will serve as a master information medium for all grant participants. The Infusio Web site will disseminate ideas, lesson plans and strategies for infusing technology into various curricula. Additionally, discussion forums will allow consortium partners to share ideas and concerns with others in the field. This model of asynchronous communication will foster the sharing of ideas across boundaries. Synchronous chat rooms will allow grant participants to share ideas, concerns, and general information in a “real-time” environment. Interested parties can discuss ideas without assembling a large group of participants from several geographic locations.

**Conclusion**

The central component of our project is that it allows us to provide systematic training and ongoing support for faculty to develop and apply technology skills to enhance their teaching and, specifically, to model effective technology-related instructional strategies. The development and implementation of cross-institutional experiences are fostering a sharing of ideas, resources, and technology expertise to accomplish a common mission – to use technology as one tool to meet the needs of diverse K-12 student populations.
Simultaneous Renewal in Teacher Education: Strategies for Success

Abstract: To adequately prepare preservice teachers to use technology in their own classrooms, teacher education programs must develop comprehensive models for technology integration that include meaningful uses of technology to improve and renew the teacher education curriculum. In addition, model K-12 sites must be fostered where preservice teachers can practice using technology to create active learning environments for students. Integrating technology effectively into teacher education courses and working collaboratively to create rich technology field experiences are both tremendous challenges for teacher education programs. Given the needs and challenges that both K-12 schools and teacher education programs face with respect to effective use of technology, it appears that both entities would benefit from collaborative work to address these needs. John Goodlad’s theory of simultaneous renewal for colleges of education and K-12 schools provides a useful framework for this type of collaboration. This paper describes several strategies that faculty at Iowa State University have used to successfully integrate technology throughout the teacher education program and in K-12 classrooms.

A primary focus of the majority of teacher education programs is to graduate teachers who have had meaningful experiences learning with technology in their courses and who have worked in technology-rich K-12 classrooms where children actively use technology to facilitate the learning process. Throughout their preparation program, preservice teachers must experience, observe, analyze, critique, and learn with technology. As a result, teacher education programs must develop comprehensive models for technology integration that include meaningful uses of technology to improve and renew the teacher education curriculum. In addition, model K-12 sites must be fostered where preservice teachers can study the integration of technology into teaching and learning. Integrating technology effectively into teacher education courses and working collaboratively to create technology-rich field experiences are both tremendous challenges for teacher education programs.

Given the needs and challenges that both K-12 schools and teacher education programs face with respect to effective use of technology, it appears that both entities would benefit from collaborative work to address the problems. John Goodlad’s theory of simultaneous renewal for colleges of education and K-12 schools provides a useful framework for this type of collaboration. Goodlad has observed:

“What comes first, good schools or good teacher education programs? The answer is that both must come together. There are not now the thousands of good schools needed for the internships of tens of thousands of future teachers. The long-term solution - unfortunately, there is no quick one - is to renew the two together. There must be a continuous process of educational renewal in which colleges and universities, the traditional producers of teachers, join schools, the recipients of the products, as equal partners in the simultaneous renewal of school and the education of educators.” (Goodlad, 1994, p. 2)
Iowa State University is using Goodlad’s theory to guide the effective use of technology for learning and teaching throughout its teacher education program. Technology as a tool to improve teacher education is the primary vision that drives the comprehensive technology in teacher education program in the College of Education at Iowa State University. This approach involves technology integration initiatives and strategies that impact the entire teacher education curriculum, including collaborative efforts with other colleges and K-12 schools. In recognition of these efforts, the American Association of Colleges for Teacher Education (AACTE) presented Iowa State University with the “Best Practice Award for the Innovative Use of Technology” for the year 2000.

This paper will begin with a brief overview that summarizes several technology integration strategies that have been used with Iowa State faculty and students for the past ten years. Then, the paper will describe additional integration strategies that have been designed as part of Iowa State’s Preparing Tomorrow’s Teachers Today (PT3) implementation grant.

Background: A Comprehensive Approach to Technology and Teacher Education

For over a decade, technology use and integration has been a major initiative for faculty and students in the College of Education at Iowa State University. Several technology integration initiatives have been designed that enhance faculty development, teacher education courses, field experiences, and extracurricular activities for students. These initiatives include a nationally-recognized technology mentoring program for faculty, a school-based technology integration model that creates technology-rich field experiences for students, a minor in educational computing, and teacher education courses in which faculty members model effective uses of technology.

The Department of Curriculum and Instruction in the College of Education has identified, designed, and implemented technology experiences that enhance teacher education courses, field experiences, and extracurricular activities for students. These experiences have been developed in the context of a large department (35 FTE faculty, 30 joint-appointment faculty, and 14 adjunct or temporary instructors) with approximately 1000 undergraduate elementary education majors and 450 secondary education students. In 1991, the college voted to include technology integration as a major initiative. Both the dean of the College of Education and the department chairs associated with teacher education provide leadership and commitment to the goal of effective technology use in teacher education. In this context, several programs have been collaboratively developed to support technology integration efforts in the College. The following sections provide brief summaries of programs that were developed to support this initiative.

Faculty Development: Technology Mentoring Program

A primary goal of the College of Education’s technology integration plan is to provide all faculty with the tools they need to make technology infusion a reality. In 1991, a mentoring program was established to assist faculty interested in technology integration, as well as to provide students with opportunities to develop individual, professional relationships with faculty members in their program. Cited as an exemplary national program in the 1999 CEO Forum Report, the mentoring program has resulted in successful professional development for more than 70% of the teacher education faculty.

Course and Curriculum Redesign: Technology Integration in Methodology and Content-Specific Courses

Not only are ISU preservice teachers required to design and use technology to complete course assignments, but they have many opportunities to observe faculty members modeling effective uses of technology in their courses. Some examples include:

- reading faculty members illustrate literacy assessment and diagnostic tools by using digital video case studies
- special education instructors use laptop computers to teach how preservice teachers can access and fill out electronic forms to document the progress of special needs students
- preservice teachers in social studies methodology courses use e-mail and discussion groups to communicate with preservice teachers at other universities to discuss themes and issues related to the social sciences
College of Education faculty members also work collaboratively with College of Arts and Sciences faculty and College of Engineering faculty to design courses that connect content and pedagogy using technology. For an introductory science course, meteorology and education instructors have created computer-based simulations designed to engage students in constructivist, inquiry-based learning activities. Faculty in the Colleges of Engineering and Education have implemented a “Toying with Technology” course that actively engages teacher education students in the design and construction of simple models of real-world systems.

Field Experiences: Collaborative Learning Communities

Based upon the faculty technology mentoring program, a similar program was extended into PreK-12 classrooms. This technology integration model promotes the collaborative efforts between preservice and inservice teachers. Participants include teachers and students from school districts, instructional technology consultants from an Area Education Agency (AEA), and faculty and students from the College of Education. This model provides school-based opportunities for preservice and inservice teachers to work together as mentors to examine methods for integrating technology effectively into classroom learning environments and helps to establish technology-rich field experiences for students.

In-depth Preparation: Educational Computing Minor

A minor in educational computing is offered by the College to provide in-depth experiences for students who wish to pursue leadership careers in technology. Established in 1984, this minor provides preservice teachers with comprehensive learning experiences that prepare them to use technology throughout the PreK-12 curriculum. Over one hundred students are currently enrolled in the minor. They take fifteen credit hours of coursework that includes classroom applications of technology, distance learning and the Internet, PreK-12 technological innovations in engineering, and field-based practicums in technology-rich schools.

Extra-curricular Activity: The Educational Computing Club

Undergraduate students are encouraged to develop leadership skills and pursue outside activities that contribute to their professional growth. Established in 1995, The Educational Computing Club (TECC) is an undergraduate student organization whose membership consists primarily of preservice teachers. Each year, TECC members organize and participate in a variety of activities. Examples of these activities include working with teachers and students in PreK-12 classrooms; assisting faculty, staff, and students in the College of Education with the use and integration of technology; writing grants to secure funding for technology; and sharing expertise by presenting ideas and projects at state and national conferences.

The technology in teacher education initiatives summarized here were designed to develop and define specific technology tools and instructional models that prepare teachers who can use technology in innovative and effective ways in classrooms. Even though this multi-faceted set of approaches has already positively impacted the teacher education program, additional strategies have begun to evolve from and expand upon these initial activities because of the PT3 support. In the next section, some additional integration strategies that have been initiated in the department will be described.

Additional Strategies for Successful Technology Integration in Teacher Education

The purpose of Iowa State's PT3 implementation grant entitled, Technology Collaboratives for Simultaneous Renewal in Teacher Education, is to create a strong collaboration between a school of education and K-12 school districts as both work simultaneously to infuse technology into teaching and learning. One goal of the project is to establish a collaborative learning community where there is a sharing of expertise and resources to rethink how technology can be integrated and used effectively in college and K-12 classrooms. Specifically, this collaborative effort embraces a vision of technology as a tool to facilitate renewal in both a teacher education program and K-12 schools. Because of this vision, several grant initiatives have significantly contributed to expanding and enhancing the use of technology throughout the teacher education program and in the partner...
schools. These strategies include: 1) establishing a cohort model preservice teacher program, 2) assisting 'technology scholars' (teacher education faculty) as they redesign their courses to infuse technology experiences for students, 3) working with a master teacher from the collaborating school district, 4) increasing the quantity and quality of K-12 field-based experiences using technology, and 5) providing collaborative activities to support K-12 teachers.

Technology Cohort Group of Preservice Teachers

Based upon the successful Project Opportunity cohort model developed at Iowa State University, a technology cohort of students in teacher education (TechCo) has been formed. Twenty-eight students were selected based upon their academic credentials, previous work with children, and technology interest and experience. This cohort group of preservice teachers will take their teacher education classes together beginning their sophomore year. During fall semester 2000, these twenty-eight students were enrolled in a field experience course that included twenty-four hours of field work in schools and a one-hour weekly campus seminar.

TechCo students will take each of their professional education and methodology courses as a cohort. As TechCo students progress through the teacher preparation program, they will enroll in the several courses (teaching strategies, methodology, field experiences, inquiry, and capstone) as a group. In addition, the TechCo students will take four courses required for the educational computing minor and will have the option to take the additional two courses to complete the minor's requirements.

To promote the use and integration of technology in courses and out in the schools, the ISU preservice teachers in this cohort were given the opportunity to purchase Apple iBooks at a discounted price. Twenty-one of the twenty-eight students purchased iBooks. Additional iBooks were purchased to provide access to students for checkout. The iBooks have wireless networking capabilities available both on campus and in the partner school sites. Having access to this technology has promoted and supported a 'wired learning community' where preservice teachers are observed using the iBooks in a variety of settings: classrooms, hallways, outdoors, and at home.

Teacher Education Faculty Technology Scholars

Iowa State's faculty mentoring program is well documented. For over ten years, teacher education faculty in the Department of Curriculum and Instruction have participated in a mentoring program that provides them with graduate and undergraduate student support as they learn to use technology. Even though the ISU mentoring program has been extremely successful, teacher education faculty members still need more time to learn about specific technologies and to develop technology integration ideas for their classes.

Building upon the existing mentoring program, teacher education faculty were given the opportunity to participate in a professional development activity designed to provide them with an extended period of time to focus on sharpening their own technology skills and to design technology experiences for students that would enhance their courses. So far, six faculty members participated in this activity. Each faculty member was given the option of a one-course release or one-month summer salary. These faculty members were soon nicknamed the 'technology scholars' because of their intense focus on developing meaningful ways to use technology that informs scholarship and practice.

In addition to providing faculty with time to work on these initiatives, other resources were available to support their efforts. A graduate student in curriculum and instructional technology provided additional support and one-on-one mentoring upon request. The graduate student was also available for course material and resource development. In addition, the 'technology scholars' met as a group with PT3 project directors for an hour each week to share their weekly celebrations. These sharing sessions were extremely valuable because the technology scholars gained ideas from each other as ideas were exchanged and discussed.

Master Teacher from Collaborating School Site

In order to facilitate communication between the university and the collaborating school sites, a master teacher from the participating school district was hired. The teacher was selected based on her interest in the position and because of her effective use of technology in her own classroom. The master teacher spends half of her time working in the schools and half of her time on campus at Iowa State. While at the collaborating school sites, the master teacher provides technology support for the inservice teachers involved in the project. The master teacher
conduces model lessons in teachers’ classrooms, facilitates workshops for teachers, and provides one-on-one consultation with teachers when requested. At Iowa State, the master teacher teaches one lab section of the required introductory instructional technology course and helps organize and schedule the collaborative project activities between the school sites and the university. Having a master teacher working as a liaison between the university and the schools has been an essential and a necessary component to successful project implementation.

Increase the Quantity and Quality of K-12 Field-based Experiences Using Technology

Other project goals include providing additional and extended field experiences for preservice teachers and creating model technology-rich field sites for field-based experiences. The school sites will provide opportunities for preservice teachers to use technology in K-12 learning environments for course practicums and field experiences. In order to increase the quantity of field-based experiences for preservice teachers, both teacher educators and inservice teachers have begun to redesign the structure of practicum experiences so preservice teachers can spend more time in classrooms while taking teacher education classes.

As indicated earlier, the twenty-eight TechCo students were enrolled in a field experience course that included twenty-four hours of fieldwork in schools. The primary purpose of this ‘early’ field experience was to begin working collaboratively with teachers in the partner schools and to observe teachers in PreK-12 classrooms (at times modeling technology use in classrooms). Instead of placing each preservice teacher with one teacher for the entire experience, each student was placed with a different teacher for a nine-week rotation. Using this format, the ISU preservice teachers observed nine different teachers teaching at different grade levels (PreK-12). Students appreciated having this field experience early in their preparation program. Next semester, the TechCo students will have another field-based experience that will be connected to a teaching strategies course.

Collaborative Activities to Support K-12 Teachers

For change to occur and be sustained, personnel from both universities and schools must work together to implement and support school reform efforts that impact instructional strategies and technology use. A variety of staff development activities were designed to assist and support teachers’ use of technology in classrooms at the partner school sites. These activities are delivered in multiple formats: traditional large group, classroom modeling, consultation and collaborative group settings. The most successful staff development strategy has been to schedule at least one inservice day per month at each school. Teachers are released from their classrooms for a 90 minute session, so they can work one-on-one with an ISU faculty member or an Area Education Agency (AEA) technology consultant. Prior to these sessions, teachers must submit a brief description of what they intend to work on during the session and how the activity is connected to curriculum standards and benchmarks.

Summary

Collectively, these integration strategies are positively impacting the use and integration of technology throughout the teacher education program at Iowa State University. Based in a teacher education program that is known for its work in integrating technology in teacher education, these combined efforts are providing the framework needed to sustain a technology-rich teacher education program. Using Goodlad’s theory of simultaneous renewal as a foundation, this teacher education program is continually working in partnership with others to develop a comprehensive model that uses technology to facilitate teacher education renewal.

Abstract. The teachers who graduate from our nation's teacher education programs will face an increasing professional challenge of accountability in their classrooms. Public schools are hearing an escalating call to arms to raise the standards of the performance of our students. Raising the standards for our students translates directly into raising the bar for our teachers. High stakes tests for college admissions of high school students are not the only major benchmark of student success nowadays. Middle and even elementary school teachers are preparing their students for high stakes benchmark exams. Under the microscope of political and public scrutiny, teachers are being held directly accountable for their students' performance in ways that did not previously exist. Pre-service teachers need the immediate attention and support of the mentors who are preparing them to enter this high stakes arena. How do technology and accountability intersect teacher education?

The teachers who graduate from our nation's teacher education programs will face an increasing professional challenge of accountability in their classrooms. Public schools are hearing an ever-louder call to arms to raise the standards of the performance of our students. Raising the standards for our students translates directly into raising the bar for our teachers. Under the microscope of political and public scrutiny, teachers are being held directly accountable for their students' performance in ways that did not previously exist. High stakes tests for college admissions of high school students are not the only major assessment of student success. Middle and even elementary school teachers are preparing their students for benchmark exams. Pre-service teachers need the immediate attention and support of the mentors who are preparing them to enter this highly charged arena.

To ensure academic success for all students, educators need a clearly-defined curriculum. What objectives does our state, district, and/or standardized assessment tool measure? How can we know that what's being taught is what's being tested? How can we know that all our teachers are "on the same page"? With accountability mandates voiced more and more publicly over the years, states and districts have responded at different rates and different levels of urgency, with varying implementation strategies, timelines for curriculum development, and methods of holding teachers and learners accountable. Districts with well-established curriculum teams have found themselves in a continual cycle of curriculum revision: once a curriculum has been developed, it is only a matter of time before revisions and updates require time-intensive modification or even overall restructuring. State guidelines change. Teachers or administrators who were not part of the original development team enter the district. Key supporters of a curriculum revision leave. A different norm-referenced test is designated as the new high-stakes assessment tool. Even without the "given" of such external changes, internal data from local assessment, standardized tests, and classroom assessment by individual teachers call for updates and changes in a dynamic curriculum.

Most states have done an efficient job in providing documents outlining the expectations for students to the school districts and their teachers. This monumental task of curriculum development and realignment has traditionally been accomplished during summer months and late nights, with state, district, and local personnel teaming up to correlate massive amounts of information by hand. Curriculum teams work like Sisyphus to integrate all of the "non-negotiables," to ensure no objectives were eliminated, to set ups naturally progressive sequences with one grade taking responsibility for mastery, and to reduce
redundancies to a minimum. The documents that result are often cumbersome and hard to implement. The sheer volume of a well-defined curriculum makes it hard to respond gracefully and swiftly to external and internal changes. And, if that weren’t challenge enough, the relationship between the curriculum document and high-stakes tests is often unclear to the very people who will be directly implementing the curriculum—classroom teachers.

With increasing demands on time and professional resources, many districts began searching for more efficient ways to manage curriculum development, revision, and alignment to ever-changing mandates. I was part of the curriculum development team in one of those districts. We wanted to produce dynamic curriculum documents that clearly related what was being taught to what was being assessed on high-stakes tests, both at the state and national levels. We found that such documents can be produced and implemented—and that technology can help keep them current. Technology equip pre-service teachers to engage in—and impact—this situation? Fort Osage School District, where I taught for <# of YEARS> before coming to EdVISION Corporation, used curriculum development software to create a fluid, working curriculum that helped increase student test scores up to 43%.

A Manual Curriculum

In 1996, I was working as a math teacher for a third year at Fort Osage School District in Independence, Missouri. Missouri had just sent out the “Show Me Standards” and, as part of the state review of school districts, required the integration of these standards into curriculum at the district level. I became involved in an intensive curriculum revision process as a member of the math curriculum team. Seven math teachers, ranging from grades K-12, met in the summer in a conference room. A lead teacher had been asked to guide the process in all areas to provide consistency. Because of my technical background, I was soon elected the “technical lead.” We cut and glued, we argued and protested, and after a week had a document that we called our “curriculum.” We soon realized that we needed a template in which to input all of the documents written. Somehow, I was chosen to design and implement a relational database for our curriculum guides. I spent the next 3 summers working on the writings and revisions of our curriculum.

Our curriculum team eventually involved almost 200 of the 350 teachers in the district in the writing process over those 3 summers. Teachers worked in content groups over the summers to develop documents that were consistent with the Missouri State Frameworks and had appropriate progression between grade levels. These three years were quite intensive, the culmination of a total of five years of developing and revising a curriculum by hand. The lead teacher and I were quite proud of what we had accomplished. Late in August 1997, we delivered seven 3-ring notebooks full of color-coded curriculum documents to each building principal and each board member got a complete set of the entire curriculum. The board members didn’t want to take theirs home (seven notebooks must have been too much to contemplate). This should have been our first indication that these documents would never be used.

Undaunted, we placed our hope in the expected response from grateful teachers. We had worked so hard to accomplish this massive output, and had involved so many of our colleagues in the decision-making process, that we felt teachers would enthusiastically embrace the new guidelines. A few weeks into the school year, the lead teacher and I admitted we’d been wrong. Documents sat on shelves and were not being used. Teachers continued to teach the way they always had. There was no change—except for the sag in the district shelves on which the notebooks sat.

The Electronic Curriculum

In August 1998, our Assistant Superintendent asked the lead teacher to sit in on a session of the Administrator’s Back-to-School Meetings. Because I had been leading the technological side of the District’s curriculum implementation, I was asked to sit in on the meeting as well. In this meeting, a representative from an educational software company presented a program that would design curriculum aligned to state standards electronically. We were reluctant to believe that a product could make alignments better than the teachers themselves in just a few clicks. We were even more taken aback when we were told that our district was going to purchase the program. Another shock came when the lead
teacher and I learned we would be the ones to implement the new software into the curriculum process. My understanding of the technical processes driving the software had, in short, promoted me to implementation management of a district-wide initiative.

In the fall of 1998, Fort Osage purchased Curriculum Designer software from EdVISION Corporation (formerly Tudor Publishing Company) and set up a hands-on training workshop on campus. Our initial skepticism turned into jubilation. We realized we could take our existing document, transfer it into the program's database, and compare our document to the state standards, standardized tests, and state test that we gave in the district. What an exciting thing to actually see the objectives students would be tested on!

We put the curriculum so lovingly and laboriously created by teachers into the product and ran comparisons, matching Fort Osage objectives to the Missouri state framework document, the MAP (Missouri’s state test), and the Terra Nova, ACT, and SAT (the national standardized tests adopted by the District). We started with our Math curriculum and matched all of our teacher-created objectives to the state objectives and national test standards in the Curriculum Designer database. Surprisingly—and despite the seven, color-coded 3-ring binders our long summers of curriculum building had produced—we found gaps and overlaps. Once the Math curriculum was aligned, we repeated this process for the other content areas, and then followed up by adding our non-core subjects to the program. Curriculum teams continued to discuss the movement of objectives when necessary or the addition of new objectives we did not have in our current document.

Next, alignment between grade levels became an issue: grade level teachers were no longer isolated. Grade level teachers discussed who would introduce, who would master, and who would reinforce specific content objectives. Grade levels with too much material were able to share objectives with other grade levels to balance the load. The teachers responded with great enthusiasm over the work we were doing. Suddenly, teachers and administrators did not have to “guess” what needed to be included in the curriculum. We had it in front of us. Teachers were free to focus on teaching.

We still had to face the hard fact that most teachers did not utilize print-based curriculum documents. Our assistant superintendent had had a vision years before of putting curriculum on “every teacher’s desktop.” What, we asked, if we disseminated the curriculum through a web-based application? Would teachers feel less overwhelmed? I spent that summer creating our district curriculum web pages. My concern was keeping the web-interface “point and click” so that it wouldn’t cause any stress on teachers to learn something new. We had over 240 courses entered and each of these had to have an Adobe .pdf file created for it. Link pages were set up so that teachers could view courses by grade level or content area. There were also links to allow searching the entire K-12 curriculum or each subject area in its entirety.

Fort Osage’s curriculum was ready for the Internet. Would teachers be willing to train to use the web pages to access their curriculum and other information? We decided to hold trainings the 2nd week of August on a voluntary basis. We sent a letter to every teacher with possible dates and times the trainings would be held. This was strictly voluntary and there was no compensation provided. I was given a voice mailbox and the teachers were told to call this number with their choice of time for training. I checked the box 3 days later and it was full. Over 40 teachers had called within a day’s time. The calls continued to roll in; I ended up training over 2/3 of the staff members that week. What made it exciting was that teachers stayed after the trainings to look at the curriculum documents, print them out, and discuss curriculum with each other.

This excitement continued throughout the school year. Teachers gave up their time voluntarily to learn more about using the curriculum website. Conversations in the halls started to include how to teach specific objectives to the students. Collaboration multiplied, and staff members began to share resources. Teachers became involved because they knew the written (or in this case, electronic) document was not guesswork, but an accurate reflection of what the students needed. There was a definite change of focus from the teachers’ standpoint. They were no longer having to wonder if they were teaching what the students would see on the test: now they knew what the students would see.

When testing came, there was not a panic two weeks prior to test time to “cram.” Teachers felt very comfortable that the students were prepared as best they could be. We took the state tests and waited for our scores.

When test scores came, they exceeded even our fantasies. In eight of the twelve MAP tests administered, we made gains greater than the state in moving students into the two highest achievement levels, Advanced and Proficient. Fort Osage also had fewer students scoring in the two lowest
achievement levels than the state average in seven of the twelve MAP tests administered. While the state increase was 20.27%, Fort Osage saw an overall 43% increase in all grade levels tested.

The software

Curriculum Designer software, designed by EdVISION Corporation, is a computer-aided design tool used by curriculum developers to quickly generate curricula that meets the needs of their district and state. A team of content and assessment experts reviewed state and national documents, identifying over 72,000 learning objectives for Mathematics, Language Arts, Science and Social Studies to develop a massive database of objectives. This database is correlated to national standards, state frameworks, state tests, and standardized tests.

This software does electronically what curriculum developers traditionally have spend hundreds of hours and thousands of dollars to do manually. The program sorts through testing and standards documentation in order to ensure alignment to state frameworks, tests and national standards. Curriculum Designer drastically reduces the time and money spent creating an effective curriculum, making this entire process much more efficient and manageable. Curriculum developers are no longer required to develop goals and objectives, arrange and rearrange instructional sequences, and write lengthy reports. This software efficiently automates these tasks, allowing for state mandated changes to be quickly enacted.

Electronic curriculum design is especially effective in crafting a clear plan of instruction that details what students are to know in a particular grade or course. Included in the final curricular documents from Curriculum Designer are "learner will" descriptions of clearly defined learning objectives. These statements are consistently written to allow for a unified language within the curriculum. Also included are Bloom's taxonomy codes for each skill which help to offer insight into the curriculum's goals.

Curriculum Designer's Instructional Hours feature projects a teaching time for every identified objective within its database. With this information, the user can organize the curriculum's objectives for each area and course by the hours needed to teach each objective, balancing the limited number of hours in the classroom with the required amount of time to teach the outlined skills. Such a check is valuable to ensuring there are enough hours to accomplish the teacher's task in the school year.

Other features of Curriculum Designer include sequencing, editing, entering resources, and printing the curriculum. The Sequence folder arranges units and objectives in the order to be taught, easily allowing for revision to reflect a change in the teaching sequence. The Editing feature is a multi-faceted tool used to create, include, remove or relocate any objectives, competencies or units within the curriculum. The ability to add instructional and assessment resources is featured in the software as well, which can provide teachers with a complete guide to district resources available to them. Finally, curriculum developers can provide printed reports in a variety of formats, including information for administrators, teachers, parents, and students as needed. A special feature allows the curriculum to be exported to the Internet to be published in HTML format on a web page.

Generating a curriculum electronically allows teachers to produce a dynamic curriculum that is responsive to change. New mandates, changes of personnel, or the adoption of different high-stakes assessments don't have to mean hours of painstaking rethinking and revision. Allowing the software to do intensive searches of massive amounts of data frees teachers up to do what they do best—teach our students. At Fort Osage, we found all these reflected in higher test scores.

Conclusion

A year after implementing the electronic version of their curriculum, Fort Osage students returned some of the best test scores ever seen in the district. In some areas, the gain was over 40%. Overall, scores improved in 45 of 72 areas. These gains were accomplished with just one year of focus on the curriculum. What changed? Aligning the curriculum and assessment electronically got the curriculum documents off the shelf and into the hands of the teachers. The electronic curriculum documents allowed Fort Osage to give teachers clear, current, readily updateable, accessible guidelines of what should be taught so that they could refocus their energies in addressing how to teach.
The adoption of an electronic curriculum at Fort Osage and many other schools around the country represents a paradigm shift in education. Systemic change is being sparked by the escalating urgency driving accountability mandates. As states and districts attempt to respond to the additional administrative demands placed on them, a great deal of administrative work is being shifted onto the classroom teacher. With this extra workload comes the (often urgent) opportunity to become change agents in their schools and their districts. Our pre-service teachers may soon find themselves involved in the implementation of system-wide change in the districts that hire them. This is especially true for those who have a technical background. Their ease and expertise in technological solutions such as the electronic curriculum described here can promote them into positions of leadership early in their careers.

What does that mean for teacher-educators, who are training teachers to move into this time of transformation in our public schools? The teachers and administrators in training now will be hired, at least in part, because of the technological background they're acquiring as pre-service teachers. New hires with technological backgrounds will tend to be relied on for specialized projects that their "non-electronic" colleagues won't. They can bring fast, cost-effective technological solutions to processes once done manually, at great time and expense. This ability will cause them to be put into positions of accelerated responsibility. In short, they will be required to be change agents.

Our technically-oriented pre-service teachers are much more likely to be listened to as problem-solvers than other workers just entering a profession. They are much more likely to be recruited into systemic reform projects or "administrative" roles (even if their job titles don't immediately reflect that). Because technology can accomplish the kinds of change I've discussed here, new hires with technical training come in with a "halo" effect. The district, at least initially, hopes their ease with technology can make them strong change agents within the district's own development strategies. The more pre-service experience these students have with innovative software solutions like the one I've outlined here, the more likely they are to transform this "halo" effect into solid career accomplishments.

More than ever, we are preparing the next wave of change agents for our schools—and the change they'll be involved in has a distinctly electronic face. As teacher trainers we can help pre-service teachers who will already be entering a district with great expectations placed on them to confirm those expectations. We can train them now to carve out solid positions for themselves within the district so that the initial "halo" of potential becomes a solid record of achievement.
Preparing Tomorrow’s Teachers to use Technology: Developments and Strategies of Ten Grantees

T. Colette Smith
College of Education
Arizona State University
United States

Abstract: There is a substantial demand to integrate technology into teacher education programs. Future teachers are not prepared to effectively integrate technology into the classroom. Emphasis is placed on the concept that effective programs are needed in order to produce technology-adept teachers. This paper describes project activities from 10 Preparing Tomorrow’s Teachers to Use Technology (PT3) grantees. Information was gathered from the PT3 web site, grantee web sites, and project members via electronic mail. Developments focus on revamping teacher education programs. Strategies include facilitating teacher and methods faculty workshops, and building interactive web sites and video based web instruction.

Introduction

Dialogue among educational scholars upholds the concept that future teachers are not equipped to properly integrate technology into the curriculum. “There is much rhetoric today about the inability of teacher preparation programs to fully prepare new teachers to use technology effectively in their professional practice” (Morsund & Bielefeldt, 1999). Computers are not utilized effectively in the classroom. The past two decades have proven the computer is no longer an additional tool in the classroom it is now essential (Puma, Chaplin & Pape, 2000). Teachers are hesitant to use computers because they lack training and are incapable of adjusting to technological evolutions. Research suggests that the traditional teacher preparation programs are not up to par in the field of integrating technology (National Center for Education Statistics [NCES], 2000). It is crucial to have teachers in the classroom who possess the ability to integrate and utilize technology. Once technology is effective in the classroom the teacher will become a facilitator of learning as opposed to a source of information (Office of Educational Research and Improvement [OERI], 1999). It will not be easy to re-educate existing teachers without professional development that provides the same technology literacy skills required of students (National Council for Accreditation of Teacher Education [NCATE], 1997; OERI, 1999). Teachers must perceive technology as interesting, not an added chore or a waste of time. Future teachers will not appreciate the value of the computer if their practicum experience is with a teachers who think efforts to integrate technology will hinder routine work (NCATE, 1997; Wang, 2000). In addition to teacher apathy, faculty members themselves are not fully aware of the evident demand. “Not using technology much in their own research and teaching, teacher education faculty have insufficient understanding of the demands on classroom teachers to incorporate technology into their teaching” (NCATE, 1997).

Currently, teacher preparation programs are undergoing several changes. Morsund & Bielefeldt (1999), emphasizes teacher education programs are not properly training teachers to implement technology into the classroom. Trainers in the field of educational technology should provide effective support to teachers; a simple additional course or a staff member who happens to know how to use a computer is not deemed adequate (NCATE, 1997; OERI, 1999). It is difficult to provide students with adequate training in technology, because special “technology funds” are not highly prioritized (NCATE, 1997). “In an effort to help schools, colleges, and departments of education meet the increasing demand for technology-proficient teachers, the U.S. Department of Education established the Preparing Tomorrow’s Teachers to Use Technology (PT3) grant program” (Planning and Evaluation Service [PES], 2000).

The PT3 program awards three types of grants: Capacity Building, Implementation, and Catalyst. Capacity Building grantees receive one year of support while Implementation and Catalyst grantees obtain funds for a total of three years. Capacity Building grants are awarded to institutions at the beginning phases of technology-based endeavors. Implementation grants focus on local initiatives to revamp existing teacher
education programs. Catalyst allowances uphold institutions that currently maintain commendable resources to make statewide, regional, or national improvements.

Selection of Grantees

Ten grantees were randomly selected from the PT3 web site (Error! Reference source not found.): one Capacity Building, four Catalyst, and five Implementation. The capacity building grantee is Southwest Texas State University. Catalyst grantees include The University of Northern Iowa, Louisiana Systemic Initiatives Program, Mississippi State University, and Maryland State Department of Education. Selected Implementation grantees include New Mexico State University, Bowling Green State University, West Virginia University, Boise State University, and Wichita State University. A database search was conducted on the PT3 web site by entering components of desired projects for review. Components selected were taken from the categories of grant type, content focus, and grade level. Project summaries were reviewed and web sites navigated. Grantees selected have distinctive information readily available and a site that is easy to navigate. Project members were contacted via electronic mail for project descriptions with no universal resource locator (URL) listed. The project members made reference to the project name and web site. Project activities, which encompass developments and strategies, were reviewed. Activities examined include goals and objectives, partnerships established (consortium), and project initiatives (local, regional, statewide or national).

Developments and Strategies of Grantees

Project overviews document consortia that consist of universities, schools, school districts, and partnering institutions. Grantee websites present goals, objectives, and project activities. Projects, URLs, and activities are described below.

Capacity Building Grantee
Southwest Texas State University

Southwest Texas State University facilitates workshops for faculty members demonstrating how to designing web pages, web quests, and web-based forms and tests. The project is called The Viewing and Doing Technology Project (VDT), which may be found at: Error! Reference source not found.. The overall goal is to nurture a university and school partnership to launch a new teacher education program. The project members work with 20 high school sites and approximately 300 students. The partnership is between Southwest Texas State University and Hays County Independent School District. The secondary methods courses serve as the focal point. The plan is to restructure the process by having education courses taught outside the college of education. Select faculty members receive training in areas of expertise. Professional Development workshops are an ongoing process. Practicing teachers take part in a summer course and secondary student teachers are assigned to them. Taking the summer course ascertain the placement of students with cooperating teachers proficient in technology.

Catalyst Grantees
The University of Northern Iowa

The University of Northern Iowa’s project is InTime, an acronym for Integrating New Technologies Into the Methods of Education at Error! Reference source not found.. This is a national initiative encompassing a consortium across five states. The consortium members include: University of Northern Iowa, Eastern Michigan University, Association for Educational Communications and Technology, North Central Regional Education Laboratory, Emporia State University, Longwood College, and Southeast Missouri State University. Universities assure that faculty members will have access to resources and technical support. Selected faculty members participate to gain information on how to revise methods courses. Each university hires a full time graduate student to trouble shoot on the web site and offer assistance to faculty members who want to learn about new software and equipment. Participating methods faculty receive a stipend. The best
practices in the classroom are taped and are posted on the website. Videos are displayed by descriptors such as content area, grade level, state, lesson title, and technology competency.

**Louisiana Systemic Initiatives Program**

Louisiana Systemic Initiatives Program is located at Error! Reference source not found. THE QUEST, Technology in Higher Education: Quality Education for Teachers and Students, is a statewide initiative. The consortium members include Louisiana Board of Regents, Microsoft Corporation, Louisiana Governor's Office, Louisiana Systemic Initiatives Program and the Louisiana Department of Education. THE QUEST provides assistance and professional development for faculty across the state of Louisiana. Faculty members involved teach introductory educational technology courses, other faculty members, and methods courses. K-12 teachers serve as mentors and supervisors. Two centers for professional development are strategically placed in the northern and southern parts of the state. Teaching, Learning, and Technology Centers (TLTC) are located in Louisiana Tech University in Ruston (northern area) and the University of Louisiana at Lafayette (southern area).

**Mississippi State University**

Mississippi State University's initiative may be found at Error! Reference source not found. The project is entitled Preparing Teachers to Deliver Technology-Rich, Problem-Based Learning Experiences. This is a statewide initiative. Consortium members involved are Jackson State University, University of Mississippi, Mississippi State University, and the University of Southern Mississippi. Technology rich problem based instruction is provide for faculty at the university and community college level. Hands-on projects take place throughout course work. Consortium members conduct all training workshops. Workshops are individually scheduled for faculty, teachers, and student teachers. As works shops progress, training materials are developed and serve as online references. A project web site is implemented to share information among students, teachers, and faculty.

**Maryland State Department of Education**

Maryland State Department of Education project is found on the web at Error! Reference source not found.. This is a statewide initiative, which includes a partnership between St. Mary's College of Maryland, Salisbury State University, Towson University, Bowie State University and Anne Arundel Community College. Additional institutions working on this initiative include, Wor-Wic Community College, Anne Arundel County Public Schools, Baltimore County Public Schools, Howard County Public Schools, Montgomery County Public Schools, Prince George's County Public Schools, Johns Hopkins University, and Maryland State Department of Education. Frostburg State University, University of Maryland at College Park, Maryland Higher Education Commission, and Human Resources Research Organization are included in the consortium as well. The primary goal of the project is to align future teacher experiences with the state objectives. Performance based standards and assessments are developed through efforts of the consortia. Future teachers are expected to achieve outcomes outlined by the Maryland Teacher Technology Outcomes. Students produce electronic portfolios demonstrating their performance.

**Implementation Grantees**

**New Mexico State University**

New Mexico State University focuses primarily on integrating technology into multicultural instruction. The project name is Preparing Tomorrow's Teachers Today. The purpose is to restructure the teacher education and bridge the digital gap by placing an emphasis on diversity. Information may be found at Error! Reference source not found.. Consortium Members include Scholarly Technology, CETP-Collaborative for Excellence in Teacher Preparation, Gadsden Independent School District, Pathways for Teaching Science for Understanding in Diverse Classrooms, and Las Cruces Public Schools. The project focuses on increasing the number of technology-proficient teachers in the surrounding area to increase achievement among students of diverse ethnic backgrounds.
Bowling Green State University

Bowling Green State University's project found at Error! Reference source not found. is entitled Project PICT: Preservice Infusion of Computer Technology. Consortium members are Woodmore Elementary, Crim Elementary, Conneaut Elementary, Napoleon High School, Perrysburg High School, and Toth Elementary. The members of Project PICT work with elementary and secondary schools. Plans involve restructuring teacher education programs by aligning the curriculum with Ohio curriculum models, International Society for Technology in Education (ISTE) standards, and National Educational Technology Standards for Students (NETS). Duties are assigned to preservice teachers, cooperating teachers, methods faculty, and curriculum facilitators. Efforts are to develop lesson plans and activities for implementation throughout the course of study. Faculty members have mentors in whom they meet with periodically to enhance technology skills and activities.

West Virginia University

The project developed by West Virginia University is located at Error! Reference source not found.. The project is called Trek 21: Educating Teachers as Agents Of Technological Change. Project members work with 21 professional development schools (PDS) which are primarily located in rural settings. Consortium members are Taylor County Schools, Preston County Schools, Technology, Teacher Education, Tomorrow (T3), Harrison County Schools, Marion County Schools, and Monongalia County Schools. The plan is to systematically place a five year program where practice and modeling takes place. The project produces 15 core courses with technologically-enhanced classrooms. Students are placed in learner centered classrooms that aid in providing experiences that are real. Mini conferences are held throughout the semester.

Boise State University

Boise State University's project is located at Error! Reference source not found.. This project is called the Bridges Project: Building Bridges With Technology. Consortium members are Meridian Joint School District, Middleton School District, Midvale School District, J.A. Kathryn Albertson Foundation, Weiser School District, Boise State University, Payette School District, Homedale School District, Kuna Joint School District, and Twin Falls School District. The teacher prep program has online components. The project will focus on three different areas: faculty development, student fieldwork and the development of an on-line pre-service. Faculty will be given extensive training and support in skills and integration of technology into the content areas they teach. Students and professors spend time in the field with teachers who have had three years of training and practice with integrating content-based technology activities.

Wichita State University

The project at Wichita State University, found at Error! Reference source not found. is entitled Models, Mentors, Mobility: Tomorrow's Technologically Astute Teachers (Project M3). This local initiative concentrates on middle schools and elementary schools. Consortium members include: Haddock Computer Corporation, Wichita State University Office of University Computing and Telecommunications, Wichita Public Schools, Wichita State University College of Education, Apple Computer Corporation, Wichita State University Media Resources Center, Wichita State University Center for Teaching and Research Excellence, and Wichita Catholic Diocese. The focus is to model teaching in the classroom, provide mentors to student teachers, and take technology to the classroom as opposed to taking the students to technology. Project M3 provides content area resources on the web site.

Conclusion

The developments and strategies described clearly accentuate, “effective change does not come without adequate planning, vision, professional development, evaluation measures, technology resources and new institutional modes of operating” (OERI, 1999). The projects focus on faculty members at universities and preservice and inservice K-12 teachers on local, state, regional, and national efforts. Activities varied according
to site needs including location and demographics. Some institutions promote modeling programs while others rely on training and workshops. Project efforts include giving stipends to participating faculty members. Some sites focus on elementary and middle schools while other focus solely on high schools. Some projects engage students in beginning years of their program with hands on activities along with regular course work. Other institutions simply construct lesson plans for others to implement. The International Society for Technology in Education (1992) affirms proper change will not happen without "restructuring education through the applications of technology." Formulating these developments and strategies prove to serve as the long needed wake up call to the field of education.

This paper provided limited information on PT3 efforts to revamp teacher preparation programs. However, an attempt to briefly describe activities in progress is well worth the effort. Possible future evaluations may perhaps report effectiveness and the impact on student achievement. Researchers might deal more accurately with adjustments surrounding administrative duties and policies. Further exploration should convey how administrators deal with modifications in school structure. Finally, more attention should focus on how teachers deal with the classroom and curriculum revisions.

With steady momentum toward incorporating technology into teacher preparation programs, the PT3 grant developments and strategies guarantee future technology-proficient teachers. The goal of producing talented and competent teachers who include technology into every day practice is now more attainable. As teachers (Puma et al., 2000) are prepared for this new way of teaching, they will no longer serve as the "sage on the stage" but the "guide on the side" where learning will take place by means of practical applications within a technology enhanced curriculum.

Abstract: This paper details the associated research endeavor of a technology program designed to integrate emerging technologies into the teacher preparation curriculum at Texas Woman's University. The objective of this study is to describe changes in behaviors and attitudes as well as changes in institutional processes. Specifically, the study addressed these questions: (a) How was the teacher preparation program adapted to support preservice teachers' technology proficiency; (b) to what extent did preservice teachers build technological skills and demonstrate understanding; (c) how did mentor teachers build technological skills and serve as guides of technology integration for preservice teachers; (d) to what extent did university instructors model technology proficiency in web-based curricular delivery; (e) what concerns were expressed, and how did they change over time; and (f) what early implementation lessons were learned to inform program improvement? The program as well as the accompanying research, is supported by a USDE implementation grant entitled Preparing Tomorrow's Teacher to Use Technology (http://www.pt3.org). Specific program information can be located at: http://www7.twu.edu/~f_snider/links/

Introduction

Learning and Integrating New Knowledge and Skills (LINKS) is a three-year technology project designed to integrate established and emerging technologies into the teacher preparation curriculum at the Texas Woman's University (TWU). The project is supported by a U.S. Department of Education, Preparing Tomorrow's Teachers to Use Technology implementation grant. The LINKS program redesigns the teacher education program within the Professional Development School (PDS) at TWU to address the technology proficiencies desired by the schools, recommended by the National Council for the Accreditation of Teacher Education (NCATE), and delineated by the professional associations. The project supports changes in university faculty involvement and roles, technology curriculum content and delivery, and preservice teachers' performance and responsibilities in field-based locations.

The objective of this study is to describe changes in behaviors and attitudes as well as changes in institutional processes. Specifically, the study addressed these questions: (a) How was the teacher preparation program adapted to support preservice teachers' technology proficiency; (b) to what extent did preservice teachers build technological skills and demonstrate understanding; (c) how did mentor teachers build technological skills and serve as guides of technology integration for preservice teachers; (d) to what extent did university instructors model technology proficiency in web-based curricular delivery; (e) what concerns were expressed, and how did they change over time; and (f) what early implementation lessons were learned to inform program improvement?

Perspective

Recent efforts in the nations' schools have centered on the infusion of technology into classrooms. Although a great deal of training has occurred at the school level, reports suggest that new teachers entering
classrooms are not well prepared to use technology (CEO Forum on Education and Technology, January 2000). Currently, the debate centers on the best means to integrate technology into teacher education programs. Approaches range from encouraging students to use e-mail to more advanced programs designed to infuse technology into all aspects of the teacher education curriculum. Recent innovations that have been implemented with varying success include electronic contacts via e-mail, listservs, and dialogue (Blake, 1998; McIntyre & Tlusty, 1995); virtual workshops, out-of-field certification, and add-on coursework (Simmons & Linnell, 1998, Veen, Lam, & Taconis, 1998), and more recently, comprehensive, integrated approaches (Dadowski, 1998; Parker & Farrelly, 1994, Schrum, 1998). Concerns about individual attitudes and perceptions that pose significant barriers to technology integration have been the focus of many recent research efforts (Blake, 1998; Buhendwa, 1996, Medea If & Davenport, 1999; Strudler & Wetzel, 1999). Though much research has been conducted, according to Shaw (1998) in his Report to the President on the Use of Technology to Strengthen K-12 Education in the United States, "a large scale program of rigorous, systematic research on ...educational technology...will ultimately prove necessary to ensure both the efficacy and cost-effectiveness of technology use within our nation's K-12 schools" (p. 115). Shaw further suggests that the rigorous evaluation of the programs we create is needed.

Project Overview
