The focus of the projects that the teachers created were around an integrated lesson that allowed the teachers to build on national standards in their own curricular area. The point of this focus was to have the teachers build a series of activities that would not only give their students the opportunity to construct their own knowledge, but also provide a interesting way to meet curricular standards. This allowed teachers to realize that alternative methods of assessment could be used to measure student learning, while still meeting the school district's objectives. Therefore, teachers could still feel they were "doing their jobs" -- in reference to Christopher Dede and Deborah Sprague's Question. For example, in an integrated lesson on the study of petroglyphs, students could learn about something of interest, while still achieving learning standards in math, science, and the language arts. This activity allows students to examine this interesting field of study through mathematical activities, scientific methods, and using language and communication skills to show what they learned.
Figure 1: A sample constructivist learning project on the study of petroglyphs

Feedback from Participating Teachers

On the final day of the workshop, feedback was elicited from the workshop participants in the form of a written questionnaire. The questionnaire was used as a substantive portion of the summative assessment of the workshop. A copy of the questionnaire is included in the appendix of this report. The questionnaire includes a summary of all comments given by the workshop participants. A brief summary of the feedback received from workshop participants will now be presented.

Numerical ratings given by the participants ranged from 3.86 to 4.93 (with 5.0 being the highest possible rating). The overall average numerical rating was 4.60. From these ratings it might be concluded that overall, the workshop participants were very satisfied with the workshop. Participants were asked whether they felt the goals of the workshop were achieved. Responses to this question clearly show that most participants felt that the goals and objectives were met, and in many cases, exceeded. In regards to the overall structure of the workshop, one participant commented "This was the 'best' professional development experience I have had in several years."

When asked how they intend to integrate what they've learned in the workshop into their own classrooms, participants indicated a definite eagerness to return to school and begin implementation of the new strategies. Several participants suggested that they planned to make better use of the web in their classrooms. In addition, one participant indicated that they would be making use of the constructivist approach as they work...
with and teach other faculty. Thus, the potential exists for other teachers at the participants' schools to benefit from the material shared in the workshop.

Comments from some participants indicated that they did not necessarily feel there was enough time for interactions to occur, especially between teachers from schools other than their own. The teams were structured such that most teachers worked with other teachers from their own schools. This was done to allow teachers to return to their individual schools and continue working together to further enhance what was learned during the workshop. In addition, these teams were encouraged by the workshop leaders to return to their own schools and share what they learned with other teachers.

Overall participants indicated that they felt the workshop was a valuable experience, worthy of being repeated in future summers. Some participants indicated that if the workshop were to be repeated it could even be extended to two weeks because of the amount of material presented.

Summary

Although many educators think that implementing the most high tech tools is the way to maintain successful educational practices, others bow to traditional theories. What is obvious is that many of the constructivist theories can be successfully implemented when intertwined with current Internet technologies. What seems to be needed currently is an understanding that the constructivist approach to learning can be implemented with the Internet, and if done so properly can be highly successful, taking educators and students where they have not been able to go in the past. For example, when teachers and students are actively engaging in Internet technology and implementing projects in such a domain (by building their own environments), they are simultaneously actively engaging in the learning of knowledge, within that domain. Students building artifacts on the web are creating creditable sharable externalization of their knowledge, which provides both motivation and opportunity to exercise meta-cognitive skills. As a result, students gain the ability to learn simply by applying the constructivist theory to their success factors when using the Internet. A passive view of integrating the Internet into education may only support instructions and techno-centrism (Papert & Turkle, 1993). Educational Internet resources will change this approach by allowing students some degree of autonomy in choosing their path of learning via computers. The Internet alone cannot produce “good” learning, however “good” learning can occur through successful implementation of the Internet (Papert & Turkle, 1993).

The goal of the “Constructing Knowledge Networks: Integrating Science, Math, Language, and Technology in the Middle School Classroom” workshop was to provide teachers with hands-on learning experiences and materials related to developing technology-based learning tools for use in Science, Mathematics, and Language Arts classrooms. Based on feedback from participants, the goals and objectives of the workshop were met and exceeded. In addition, participants encouraged workshop leaders to offer similar workshops in the future, focusing on a project-based approach to professional development.

Purpose

This study examines an often over-looked aspect of the implementation of computer technologies in schools, across Canada and elsewhere: we have sought to identify, describe and clarify "successful" models of teacher professional development.

As the number of computers accessible to students and teachers in classrooms and labs has increased, especially in the last ten years, there has been a corresponding emphasis on "integrating technology across the curriculum." Teachers' effective use of computers in their classrooms, however, remains an elusive goal. Researchers have identified numerous barriers to teachers' use of computers in their classes, such as limited equipment, inadequate skills, minimal support, time constraints and the teachers' own lack of interest or knowledge about computers (see, for example, Berg, Genz, Lasley & Raisch, 1998; Ertmer & Addison, Lane, Ross & Woods, 1998; Hadley & Sheingold, 1993).

Rightly or wrongly, teachers have come "under fire" as insufficiently skilled to make use of promising new technologies. Governments, faculties of education, school districts, schools, communities and individuals have begun to focus on helping teachers get access to training and development in required skills. While programs have varied widely, we have chosen to focus on three exemplary models of professional
development in Canada: a university-based model, a school-district model, and a
school-based model. In each of these examples, we elucidate the methods and
practices which support and hinder teachers in their technological professional
development, focusing on teachers' own stated preferences for "what works" and "what
doesn't work" as they attempt to make more and/or better use of computers in their
classes.

Methods
We have employed several methodologies in our work: documentary research, site
visits and interviewing. Through observations and semi-structured interviews with
teachers, project developers and administrators, and we have identified a common
range of issues that have been encountered when providing professional development
to teachers.

Models for Professional Development for Practicing Teachers

A university-based model
The Teaching and Learning in an Information Technology Environment (TLITE) is
a two-year post-baccalaureate program provided by Open School in collaboration with
Simon Fraser University (SFU) in British Columbia. Open School is a division within the
Open Learning Agency which provides programs (at a distance or in classrooms)
geared toward the K-12 curriculum for students and teachers using print, television and
Internet sources.
The TLITE program is designed specifically to aid teachers in using technology effectively in their classrooms; it is self-directed, collaborative and based on the mentor model. Over the two years, teachers meet face-to-face and on-line in their cohort groups (based on geographical area), with their "local" mentors, as well as university-based mentors (professors in the faculty of education) to design their course of study and interest. In most cases, school districts provide teachers with the incentive of a pay increase for completing the program.

The TLITE model is an excellent example of a self-directed program where teachers explore and learn to use technology in their own time and ways, setting their own goals for use and application of their skills in their classrooms. It further makes use of both face-to-face and on-line instruction and support. TLITE graduates are often found at the centre of innovative technology practice in British Columbia schools.

A school-district model

Integrating Technology in the Curriculum using Inquiry (ITCI) is a workshop-based, school-district model. Teachers and principals from five schools in the Peel District School Board in Ontario were brought together in for a four day summer institute on technology in the classroom. It has been followed throughout the year by workshops, site visits, and on-line mentoring. The program culminates in a final presentation to all teachers of the work they have done with students over the year.

The ITCI model combines workshop and skills oriented professional development with teachers' own subject-related interests for using technology with their students. It provides support for teachers throughout the school year, both on-line and face-to-face.
Even more uniquely, it mentors and supports the school principals involved in the project as they attempt to more fully commit their staff to technology-use.

This district is considered a "leader" in technology integration. Its teachers and principals are committed to helping other teachers and principals integrating technology into learning in their classrooms and schools.

*The School-based Model*

One individual working within a school, with the support of a principal, can do much to aid his/her colleagues in their use of computers with their students. Jane Clayburn (name has been changed), a teacher at an elementary school in British Columbia has developed a system in her school whereby all teachers have access to professional development and support in their use of computers. She offers, for example, skills-based workshops before and after school and during lunch as teachers request it, and each time the school purchases new hardware or software. She also talks to teachers about how they can use computers for different aspects of the projects they are currently working on. She then helps teachers the first three or four times they use the computers for their projects, working with them side-by-side with their class. She is able to provide what she labels "just-in-time" support for teachers in her school more easily because her principal gives her two hours of "release time" from teaching per day.

This model works best when teachers and principals cooperate to take advantage of the expertise of one or more individuals. While not a "large-scale" model, we found it to be the single most effect model we examined as it provided ongoing
support, on-site, and with flexibility. It depends entirely, however, on the good will of the actors, including a supporting principal.

**Implications**

As many districts and schools have discovered, professional development can be the Achilles heel of technology integration. Each of these models is described and critiqued in the paper in some detail. From the analysis, we have been able to describe key elements which should be considered when designing and implementing professional development programs for teachers. These include:

- The importance of self-motivation – a bottom-up approach to technology integration in the classroom;
- The importance of a facilitating environment – top-down support for innovation;
- The importance of play and discovery;
- The importance of incentives, financial and time;
- flexibility which makes allowances for all levels of competency and interest;
- just-in-time support for teachers as they begin to use computers in their classrooms;
- ongoing support, both on-line and in person;
- on-site workshops, where teachers learn on the computers they will be using with their students;
• activity-based emphasis – teachers don’t learn “stand alone” skills, but instead use computers in relation to the activities they design and will ask their student to do

• sustainability.

This list is not, of course, exhaustive but it is illustrative of those elements that teachers felt made their professional development experience with computers more successful.

Professional development for teachers cannot be ignored, nor can it be assumed that old models will work with new systems and technologies. In fact, some of the very characteristics of new technologies of computing and communication that make them so effective and challenging to use in the classroom also pose challenges and opportunities for teachers and their professional development. Our study provides some initial indications of best practice in the area, emphasizing the importance of sustainability, and reveals pitfalls to be avoided.

A Framework for Designing Professional Development Courses in Instructional Technology for Teachers

Colleen S. Kennedy
Department of Teaching & Learning
University of Utah
United States
Kennedy@gsce.utah.edu

Abstract: How do faculty in colleges of education gear their instruction in Instructional Technology courses to accommodate the varying levels of knowledge, skills, and abilities of practicing teachers? This presentation provides a framework for designing professional development courses in IT to meet the needs of individual practitioners. Key features of the course development model include: assessing the entry level of participants, based on ISTE standards and their levels of proficiency in using technology; determining the availability of technology and support for using technology in participants' schools; and the development of individualized learning plans that are aligned with ISTE standards and based on principles of effective professional development. The intent of the presentation is to stimulate dialogue on designing and delivering effective graduate level coursework in IT to practicing teachers.

Many colleges of education (SCDEs) are currently offering, or are planning to expand their graduate courses for teachers on integrating technology into their teaching. A preliminary examination of Instructional Technology (IT) courses in U. S. colleges of education suggests little agreement on a conceptual framework for designing graduate level coursework for teachers. Perhaps the International Society for Technology in Education Standards for Teachers (ISTE, 2000) will begin to exert more of an impact nationally; but, currently their influence is not yet reflected in coursework to any appreciable extent.

As faculty in SCDEs begin to develop new courses and revise existing ones to align with the ISTE standards, they are confronted with a variety of challenges. Individual teachers differ with respect to their knowledge and skills in using technology. Some teachers are more adept than others, or have had more experience than their colleagues in integrating technology into their classrooms. The settings in which teachers practice differ with respect to the accessibility and availability of technology. Some schools have new computer equipment, whereas others are using outmoded hardware, or have very few computers per classroom. Administrative and technical assistance to facilitate teachers' use of technology also vary among schools, ranging from excellent in some schools to little or no support in other locales (National Center for Education Statistics, 2000). Course designers must consider these differences among teachers as well as differences related to technological readiness and availability among participants' schools in planning appropriate graduate level coursework for teachers. In addition, given the public's expectations for teachers to become proficient in using technology, emphasis must be placed on designing coursework to assist them in achieving the desired outcomes.
This presentation provides a framework for designing IT courses for practicing teachers. The following key features guide course development. First, data from national studies such as the National Center for Education Statistics (NCES, 2000) are used to describe the varying levels of knowledge and skills teachers possess with respect to technology and differing degrees of availability to technology that characterize our nation's schools. These data illustrate the range of abilities and setting characteristics SCDE faculty must consider in order to meet the needs of individual teachers enrolled in IT professional development courses. Second, the ISTE Standards for Teachers are used as the basis for developing course objectives. Third, course content reflects the literature on stages of proficiency in using technology from novice to expert practitioner (Mandinach, 1992; Sandholtz, Ringstaff & Dwyer, 1997). Fourth, differences in availability and support for using technology within participants' schools is used as an impetus for planning ways to overcome barriers to implementing technology. Fifth, the literature on developing rigorous and professionally challenging graduate level coursework for practicing teachers (Little, 1999; WestEd, 2000) that actively engage participants in their own learning is an integral part of the course design. Finally, opportunities for college faculty to conduct research related to incorporating technology into teaching as well as encouraging practitioners to become reflective practitioners who study their own practice are discussed.

The presentation is best conceived of as a Rubik's cube, a puzzle of sorts, that is multifaceted and seeks to involve participants in examining the factors that are inherent in developing appropriate IT professional development courses for teachers. As faculty in colleges of education, we must be prepared to practice what we preach by modeling the use of technology in our own teaching and individualizing instruction to the maximum possible extent. This presentation seeks to make that point and stimulate discussion on the development and design of graduate level coursework for practicing teachers on instructional technology.

A Professional Development Model for the Use and Integration of Technology

Dr. Andrew D. Kitchenham
Faculty of Education
Malaspina University-College
Nanaimo, BC, CANADA
kitchenh@mala.bc.ca

Abstract: This paper outlines the preliminary results of a study that involved creating a professional development model for the use and integration of technology in an elementary school in Nanaimo, British Columbia, Canada. The 13 teachers and one support staff voluntarily attended professional development workshops on topics chosen based on pre-chosen professional growth outlines and specific action plans. The salient finding were threefold: (1) it is imperative that the participants feel in control of their own development; (2) there are specific motivators and inhibitors for the implementation of the action plan; (3) the respondents need to have a community of learners.

Introduction

Convincing teachers to use technology is not a difficult task; getting teachers to use technology is an extremely difficult task. The preceding statement has become the mantra of the research project outlined in the following pages as the writer found it very easy to discuss the advantages of using technology---specifically computers---in and out of the classroom. In other words, the teachers in this study, by and large did not need convincing to know that they could use Powerpoint presentations as an alternative to oral presentations, that the digital camera could open up possibilities that were endless, that transferring information to the school webpage could send out simple information to a potential audience of millions, as key examples. What they had, and some continue to have, a problem doing was actually getting around to using the technology. This writer believes that we have begun a journey that will allow the teachers to meld these two beliefs; philosophy will become fact.

The Study

In October, 1999, the writer and the grade five teacher at the elementary school, attempted to introduce the staff to a model of technology integration that he and the grade five teacher had designed. The research interest was to investigate the influences of technology on writing achievement. That is, do children write "better" when they are introduced to technological tools such as word processing (e.g., cutting and pasting; graphic importing), digital cameras, Powerpoint, and webquests? The project did not succeed. After a few debriefing sessions with individual staff members, the researcher realized that the project did not succeed primarily because it was moved too fast with a staff that was involved with so many other projects. More importantly, the answer lay in the issue of ownership; the teachers needed to choose what they wanted to learn, how much they wanted to learn, and when they wanted to learn. It is clear that most staffs would also need to have this type of ownership in order to implement technology in the classroom. From these revelations came this project and the Continuum of Technological Literacy (see Fig. 1).

The continuum that was designed for this project was adapted from the literacy (i.e., reading and writing) research from the last 10 to 15 years. Indeed, technological literacy is not any different than reading or writing literacy; however, the writer has not come across any researchers who have designed such a graphic representation. Subsequent to designing the continuum, the researcher has found a similar study (CEO Forum, 1998; 1999; 2000) on a much larger scale. As this study progresses, it may become more appropriate to adopt the CEO Forum (1998; 1999; 2000) descriptors: entry, adoption, adaptation,
appropriation, and invention; however, the strength of this continuum and the descriptors laid in the key questions that teachers ask themselves as they progress along the continuum.

According to the Continuum of Technological Literacy, the participant might ask one of five questions depending where he or she begins. The first question, at the beginning of the continuum or the pre-literate stage, asked whether or not technology could help the person. In answering this question, the respondent is forming a habit of mind that assists him or her to move along the continuum. The second question asked what the effective tools would be for particular tasks or goals. The person would be at the emerging stage at this point. The third question queried, at the developing stage, when the participant could optimize learning so that he or she examines the conditions in the classroom, the attitude of the students, and the aforementioned tools. The fourth question, when the person is at the competent stage, asked how to use strategies effectively. The last, at the end of the continuum and the literate stage, questioned why the person is using technology strategies, in general and, in particular.

Critical to this study is the fact that the site school is a recipient of a Network of Innovative Schools (NIS) grant and was the first elementary school in the province of British Columbia to receive the prestigious recognition from the Canadian government. As the school was so open to technological innovation, in June of this year, the researcher circulated a personal growth plan questionnaire that had been created in consultation with the principal and two staff members. All teaching staff, including three new teachers, and one support staff member completed the questionnaire. The results of the Likert-scale questionnaire were collated and a meeting with the principal was set up to discuss these results before presenting it to the staff. When the overall results were presented to the staff, each of the fifteen participants completed an action plan that outlined on what he or she would like to receive professional development, who would be involved in the delivery of the Professional Development, when it would start and end, and how would “success” be measured. Respecting the fact that many of the teachers in this school have been recognized, at various levels and by various organizations, for their outstanding contributions to the education of students, the researcher asked them to outline what they felt would be roadblocks and easy access, to use a highway metaphor, for the success of their action plans.

In conjunction with these action plans, the Continuum of Technological Literacy was presented to the staff as an artifact on which they could measure their personal growth. That is, much like when students

Figure 1: The Continuum of Technological Literacy that all participants will use to map their journey.
learn to read and write, teachers started at a particular point of this continuum and as they reached each "stage" on the continuum, they asked themselves questions about what was happening at that point in their movement along the continuum. In short, a teacher might have moved from being "pre-literate" (Can technology really help me?) to the end of the continuum and be "literate" (Why do I use the technology that I am using?). It should be noted that the continuum is recursive in that teachers may need to move back to a previous stage or stages in order to understand a particular concept or technological tool and that some teachers may have to begin at the first stage for some concepts or tools but may begin at the last stage for other concepts and tools. It also acknowledged that some teachers may choose to master only one computer software or hardware concept or tool in the course of one year; however, by encouraging teachers to "take it slowly" and by providing support when needed, the personal growth (action) plans will be sure to be completed.

Approximately half of the participants (n = 8) attended the initial Professional Development workshop on how to use a digital camera and how to import those files into word processing (e.g., Word) and multimedia presentation (e.g., Powerpoint) programs. After this workshop, each of the participants were given a questionnaire that pinpointed the pros and cons of that particular workshop as well as general information that would assist in further workshops. The key questions asked on the questionnaire revolved around three areas: (1) the utility of the workshop (i.e., on a scale of 1 to 5, what the usefulness, for the success of the individual personal action plan was); (2) the next layer for the scaffolding (i.e., what is needed now that the participant has this new knowledge); (3) the sense of community (i.e., has there been an opportunity to discuss the information with a colleague or to implement in the classroom).

At the time of writing, three to five more workshops will be conducted. Questionnaires will be conducted at the conclusion of each workshop. In addition, a short interview will be conducted with randomly selected participants in January and March of 2001.

The Findings

The findings to date are minimal in data but plentiful in trends and patterns to come. Even at this early stage of data analysis, it is apparent that three salient findings are evident. Firstly, it is critical that the teachers and support staff have a sense of autonomy. Secondly, there exist a number of characteristics that promote or motivate success as well as characteristics that inhibit or prohibit success. Lastly, the participants need to belong to a community of learners.

The researcher has noted that the participants in this study need to know that they, themselves, are in control of, and responsible for, their learning and movement along the Continuum of Technology Literacy. These particular teachers and the support staff member are exceptional in many fields within and without the school community and it would be insulting and detrimental to the success of their development and of the research study to treat them otherwise. They know what are their timelines for completion, they know what they want to know, and they know what they want to use in the classroom. As common sensical as the preliminary finding is, it appears to be critical that each teacher knows that he or she has direct "ownership" of his or her learning and professional development.

In the informal discussions with teachers before and during the study and gleaned from the literature (see CEO Forum, 1999 "Principles for successful technology professional development," pp. 17-21 and U.S. Department of Education: NCES, 2000, pp. 89-100), the researcher generated a list of "motivators" and "inhibitors" for the successful completion of individual professional development action plans (see Tab. 1). In other words, if a school district, particular school, or individual teacher wanted to know what conditions needed to be present for successful professional development, this inexhaustive list would be a place to begin. This paper is too brief to expand on each list item but two motivators will be discussed in the next paragraph; two inhibitors are worth mentioning at this point in the paper: "cliques of learners" and "locomotive staff member." The former inhibitor is an integral component for the success or failure of professional development in technological literacy. If a group of learners get together with each other in the school and share their knowledge, there is direct benefit for the school (as will be discussed in the following paragraph); however, if that group only seeks to keep its learning and knowledge within the group, those learners become a clique and, by definition, a clique, rather than a community, of learners. The latter inhibitors, "locomotive staff member," refers to the person in the school who does know a great deal about technology and believes that everyone in the school should also be at this philosophical and/or technical level of expertise. This person shows others how to use technology by doing rather than by
teaching; he or she might demonstrate the construction of a webpage by creating the page in front of his or her colleague without allowing that learner to attempt the task from a participant rather than observer point of view. It should be noted, on the other hand, that this person is rarely acting in the capacity of “computer coordinator” who would be beneficial to a staff (Becker, 1998). At his or her worst, the “locomotive” also sees him- or herself as superior to those who cannot or choose not to be at his or her level.

The last preliminary finding, and a corollary to the preceding trend, is the notion that the professional development participants must belong to a community of learners. A community of learners is a group of like-minded individuals who believe that their learning goes beyond the group and should be shared by others outside of the group. It is also dynamic so that, unlike the “clique of learners,” the composition of the learners changes from topic to topic. The researcher has witnessed several instances of this community of learners at work. Particular teachers have spent time attending a workshop, practicing the newly-acquired skills independently or with others and then teaching those teachers who did not or could not attend a specific workshop. At the core of the community of learners is the idea that these participants are teachers and the concept allows them to do what they are best at: teaching. The idea of community of learners will be an interesting one when the data---especially the interview data---begin to come in later in the study.

Table 1: Motivators and Inhibitors for the Success of Personal Growth Plans

Conclusions

This paper has outlined a small-scale study of 13 teachers and one staff member who volunteered to participate so that they could learn more about the use and integration of technology. The school is innovative in its use of technology but the number of teachers who use technology in the class is low. In fact, the principal of the school completed the STaR and the school was “mid tech” in hardware, connectivity, and content; however, in professional development and integration and use, it was “low tech.” In other words, there are few hardware barriers in the school but the level of expertise and confidence is low. This study has helped the participants to understand that the opportunity for the use and integration of technology is present but they, themselves, need to take the next step to achieve success.

The three preliminary trends of the need for autonomy, the identification of motivators and inhibitors, and the notion of a community of learners will be interesting and informative to follow as the study progresses over the next stage. This researcher hypothesizes that the participants will move along the Continuum of Technological Literacy and will feel empowered to continue that journey until each teacher
has reached his or her comfort zone for that set period of time. It is also apparent that the teachers will need more than one year to unanimously agree that they are a “high tech” school. Time will tell.

An In-Service Methodology Course via the Internet: A Designer's Perspective on the Learning Potential of the Delivery System

Esther Klein-Wohl
English Unit, The Open University of Israel
esterk@oumail.openu.ac.il

Abstract: This presentation describes a model of an in-service Methodology course for teachers through the Internet which not only aims at teaching a content area but also represents a model of instruction. While focusing on the content of the course, the participants are exposed to a delivery system which includes features they can easily adapt to their own teaching environment; while expanding their personal horizons regarding the use and potential of the technology. Knowing how to transfer pedagogical skills and strategies from one context to another is essential to help teachers solve problems and reach students more effectively. We intend our training programme to serve as a model of teaching which the participants may transfer to their own teaching contexts. The design of the course is based on a Presentation, Practice and Production (PPP) model.

We are in a period when strong efforts are being made to develop a new kind of professional community in education - one whose ethos is built around the continuous study and improvement of teaching and learning, and the direct application of knowledge to real life situations. Educators are attempting to design environments conducive to the construction of knowledge which have relevance to learners' authentic needs.

In such a constructivist view of education, we aim at developing a learning environment which facilitates the enquiry of learners but also emphasizes the practical implications for production, both in the immediate setting and in the long term. Within the general framework of constructivism, knowledge is emerging rather than static, learning means seeking meaning within one's expanding frame of reference, building knowledge and checking it against the concepts of others, and connecting what is being learned in the instructional setting with real life demands (Richardson, 1997).

The theoretical underpinnings for such a view are that new concepts can change ways of organizing knowledge, provide new material for associations and problem-solving (Ellis, 1993), and that meaningful learning is likely to go beyond the classroom and provide skills and strategies that will impact future actions. A further underlying assumption is that the design of a useful instructional model must incorporate a computer environment of some kind, since we strongly believe in the increasing importance of computer literacy for functioning in the real world. Indeed, one of the ways of bridging the gap between the instructional environment and life outside the classroom is learning and knowing how to function with the technology.

Rationale: The rationale behind the design of this Open University in-service methodology course for teachers of English as a foreign language is based on the construction of teachers' knowledge, an awareness of the importance of a teaching paradigm that models teaching and learning, and the development of the capacity to face the real world both within and outside of the instructional setting. We have created a course based on a task-based syllabus (Long & Crookes, 1992), which is teacher-directed in its conception but highly learned-centered in its actualization (White & Weight, 2000).

A salient feature of teaching is that it requires continuous adaptation and demands new learning in order to solve the problems of each moment and situation. Therefore the process of knowing how to transfer pedagogical skills and strategies from one context to another is essential to help teachers solve
problems and reach their students more effectively. Horizontal transfer refers to the conditions in which a skill can be shifted directly from the training situation. When the work and training settings are very similar, a skill can usually be transferred "as is" with little additional alteration and learning. On the other hand, if the two contexts are very different, vertical transfer is needed. Vertical transfer refers to conditions in which the new skill cannot be used unless it is adapted to fit the new conditions wherein an extension of learning is required before the skill can be applied. Such transfer is more likely when there is a greater gap between the context of training and the conditions of the new situation: the newly learned skill being different and thus not easily fitting into the new situation. The distinction between horizontal and vertical transfer refers to the amount of adaptation and reinterpretation that is necessary if the skill is to be effective in the new situation. Familiarity is the key. The greater the degree to which a new skill fits into already familiar patterns, the less adjustment will be needed.

Because English is the subject that our experienced teacher trainees teach, we have been able to take advantage of the globalization of English and the fact that it has become the main medium for international communication and technology. English provides us with a window to the real world as well as with additional opportunities for accessing information. As a result, we have created a framework which links pedagogical perspectives on teaching and learning to elements of Internet input in order to achieve our particular desired educational outcomes.

Design of the Course: The 15-week course is transmitted via the Internet. It consists of weekly readings from selected professional journals provided to the teachers in a printed anthology, and of questions related to these readings delivered through the Internet. Some of the questions focus on the theoretical principles discussed in the articles while others are application tasks which the trainees are required to think about, plan and implement in their own teaching context. The trainees' reflections and reports about the practical tasks, the presentation of individual and of collaborative projects among participants, the discussions, as well as all other interactions are asynchronous and occur on-line. Depending on the nature and the purpose of the communications, some involve the trainees only while others include the trainees and the instructor.

The participants are responsible for finding and sharing Internet sites and articles which are topically related to the subject matter at hand and which they feel will enhance their knowledge and increase their teaching repertoire. In addition, three areas which may be problematic for teachers are selected on the basis of negotiation with the trainees. Each chosen area serves as a topic for on-line discussions for a period of four weeks, with the specific aim of finding appropriate solutions that will emerge from sharing ideas and drawing applicable conclusions. At the end of the course, trainees submit an individual portfolio which includes some of the above and a journal in which they are asked to reflect on their experience of the course and its practical relevance to their teaching context.

The design of the course is based on a Presentation, Practice and Production (PPP) model (Willis, 1996). Planning the presentation of the content, getting the participants to practice and execute the required tasks, and eventually take what has been learned beyond the framework of the immediate environment into a wider world seems to reflect a sensible definition of an educational mission. In other words, we take the view that one of the secrets of successful learning lies in the process of transfer – the effect of learning one topic or skill on another situation.

In this context, the teacher trainer presents the course content, encourages the teacher trainees to practice what is being learned within the framework of the course, and hopes that eventually some of the elements of the course, including the strategies and skills presented, will be utilized (in horizontal transfer) adapted and perhaps even reproduced (in vertical transfer) by the trainee in his/her professional world (as a teacher) and personal world (as an Internet user).

Similarly, the teacher prepares and presents materials in class, encourages the pupils to practice what is being learned in the school, and hopes that in the future some features of what has been taught and learned will be useful in the pupils' lives outside the classroom. The presentation and practice stages feature mostly in the school setting while the production stage is expected to first occur in the instructional environment, and eventually filter through beyond that environment into the pupil's big wide-world. In other words, pupils will operate first on the basis of horizontal transfer and then proceed to a vertical transfer of the skills and knowledge they have acquired.
How is this model of teacher training for a Methodology course for teachers different from others? The method of delivery via Internet not only teaches a content area – Methodology for teaching English as a foreign language – but it also represents a model of instruction for their own use in their classrooms. While focusing on the content of the course, the participants are exposed to a delivery system which consists of features they can easily adapt to their own teaching environment; at the same time they are expanding their personal horizons regarding the use and potential of the technology.

Abstract
An experimental course offered at The George Washington University (GWU) is specifically designed to assist teachers in meeting the technology standards and performance indicators developed by the International Society for Technology in Education (ISTE, 2000). Eleven teachers representing three school systems participated in the first offering of the course in Fall 2000. Teacher reflection through journal writing focused on how teachers perceived themselves as learners of technology and the ways they were able to transfer those perceptions and new understandings to their instruction of secondary students. Several common themes emerged relative to learning and using technology to enhance student learning.

Introduction
The formulation of National Education Technology Standards for Teachers or NETS (ISTE, 2000) reflects what many participating national education affiliated associations (i.e. National Education Association, American Federation of Teachers, National Association of Secondary School Principals, Council of Chief State School Officers) as well as corporate (Apple, Milken Exchange on Education Technology, Microsoft Corporation) and government (U.S. Department of Education, National Aeronautics and Space Administration) organizations believe is an urgent need to elevate the technology proficiency of PK-12 teachers. Added to the list of other national, state, and local standards created for students and teachers in all curriculum areas across all grade levels the standards movement is propagating at a dizzying rate. At the center of it all is the classroom teacher who must assume considerable responsibility for implementing standards to improve students' learning.

How do teachers meet the multiple demands of standards? In the case of technology, the options for learning can be limited when schools are underserved or when the folks with the “know how”, the technology specialists, are forced to spend their time connecting wires and trouble-shooting. At GWU, we offered an experimental course to assist area teachers in learning about and learning to use new technologies for instructional purposes. The course was tailored to assist teachers in meeting the performance indicators outlined in NETS. Six standards encompass what teachers should know about and be able to do relative to technology. In brief, they are: understanding technology operations and concepts; using technology to design effective learning environments; applying technology to maximize student learning; effectively using technology to facilitate assessment and evaluation strategies; enhancing productivity and professional practice with technology; and, understanding social, ethical, legal, and human issues surrounding technology (ISTE, 2000).

In the course, computer technology was the primary medium. Learning experiences ranged from simple to complex. Teachers learned to create newsletters, develop presentations using MS PowerPoint, evaluate and use various software, explore and evaluate Internet resources, critique listservs, complete a scavenger hunt to in order to uncover the technology resources available to them in their schools and school systems, design webquests, and develop a website to showcase their technology portfolios. As teachers encountered new content, they were encouraged to consider how they learned, what strategies were most
useful for them, and what, if anything, made learning technology unique. Reflections were captured through journal writing.

Promoting Reflection Through Journal Writing

John Dewey (1933) believed that there are three primary sources for student knowledge: beliefs based on emotions, beliefs based on authority, and reflective thinking. He believed that reflective thinking involves active, persistent, and careful consideration of any belief or practice in light of its supporting evidence and its eventual consequences. Dewey implied that both content and process are components in reflective thinking. Han (1995) distinguishes between the two: “While the process element of reflection emphasizes how teachers make decisions, content stresses the substance that drives the thinking” (p 228).

Reflective teachers think about their behaviors and experiences in the context of the educational environments in which they work. They then make work related decisions that are more informed. While reflection is a source of personal and professional development essential to effective teaching, it’s often a difficult process for teachers. Two reasons for this difficulty are: 1) lack of time and structured opportunities for reflection and, 2) teachers’ inability to view their school based experiences objectively and thereby benefit from them (Black, Sileo & Prater, 2000).

One method for promoting reflective thinking is journal writing since it engages the writer “… in making beliefs and knowledge explicit and provides an internal dialogue between feelings and thoughts” (Han, 1995, p 229). Simply requiring that they respond in writing to experiences in the course and their classrooms, does not guarantee that teachers’ professional development will be enhanced, or that changes in professional practice will occur. My experience has taught me that reflective writing is most useful for the writer and for me as instructor when it has an organizing structure. This structure can take the form of specific questions that the writer responds to, a descriptive or expository writing that the writer critiques, or a step-by-step process in which the writer describes an event, then reacts and analyzes the event in order to determine a course of action.

In the GWU course, three central questions prompted teachers to reflect on both content and process. The table below describes the structure of their journal writing.

<table>
<thead>
<tr>
<th>React</th>
<th>What thoughts, responses, perceptions, and/or attitudes were generated as you learned and used technology presented in the previous class?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Extend</td>
<td>In what ways can you use this technology to promote students’ learning and/or enhance your instruction?</td>
</tr>
<tr>
<td>Transfer</td>
<td>Given your experiences as a learner in the previous class, what have you learned about teaching technology to your students?</td>
</tr>
</tbody>
</table>

Table 1: Organizing Structure for Journal Writing

Eleven teachers submitted thirteen journal entries representing continuous reflections on their experiences during class and between classes. Between classes experiences were those that teachers had while practicing and applying what they’d learned in class. These included developing new lessons or revising existing lessons to include a technology component, creating a technology-based assessment or using technology to manage teacher work. Continuous reflection refers to the expectation that teachers would cycle through previous entries before writing so that they could reinterpret and articulate their understandings and beliefs in light of new experiences and knowledge. A description of the course design provides a context for understanding the text of the journal entries.

Course Design

Class sessions were generally divided into three main segments. The initial time was spent reviewing what was learned in the previous class then introducing new or less familiar material, equipment,
and skills. This was followed by guided practice and finally lab time to begin applying new learning in an activity linked to a course assignment. Assignments in the course were designed for use in teachers' classrooms and allowed for individualization based on interests and needs. Skills and knowledge required to successfully complete the initial assignments were folded into successive assignments.

Research Questions

The purpose of this study was to describe professional growth evidenced in the journal writing of eleven teachers participating in a course on technology applications in educational settings. I was particularly interested in identifying common themes that emerged from the entries. Three questions guided this investigation: Do reflective journals demonstrate heightened awareness of technology standards and applications? Do reflective journals validate that course assignments linked to classroom practice actually lead to transfer of new knowledge and skills to secondary students? Do reflective journals aid teachers in identifying the conditions necessary for effective classroom implementation based on their own experiences as learners?

Data Analysis

A total of 143 journal entries were analyzed in a multi-step approach described by Huberman and Miles (1994). Using the organizing structure for the journals as a framework for initial analysis, the entries were sorted into three categories: react, extend, and transfer. A second step in the analysis involved selecting entries from each category that demonstrated reflective thinking in three cluster areas: awareness, transfer, and teaching. The data set was reduced to 104, and analyzed to determine themes common in each of the cluster areas. Excerpts from the journals represent a partial sample of quotes.

Findings

Heightened Awareness

Of the eleven teachers participating in the course all had experience with word processing and communicating using e-mail. None of the students had used a word processing program to create a newsletter, 3 had some experience with presentation software, all had attempted Internet searches at some level, none had any prior knowledge of webquests and none had ever developed an electronic portfolio or published a website. The range in technology related knowledge, skills, and experiences among the group was extensive. One teacher had used a computer for the first time only six months before the course began, others varied in their abilities based on the technology and only one teacher had advanced skills in communication and productivity applications. Evidence of heightened awareness was found in at least three journal entries for all teachers. Themes that emerged are awareness expressed as excitement, as anxiety, as recognition, and as realization.

Excitement

Most of the narratives expressing excitement refer to responses to technology tools or applications introduced in class, to instructional uses for familiar technologies, or to students' responses when the teacher implemented technology use in his/her middle or high school classroom.

I feel like a student again. I find myself discussing what I have learned in this class with my students. I ask how many would be interested in learning how to do some of the things we do. Even the young man who yearns to be out of my class wants to be a part of a computerized classroom.

A webquest works by taking a group of learners on an inquiry-based exploration of real-world facts and ideas that result in a collaboratively-mediated authentic learning experience. Eureka! Who could ask for anything more?
Anxiety

Increased awareness doesn't always produce pleasant thoughts and feelings. Sometimes, tension results when one initially become aware of something that has direct implications for her or him. This was the case for many of the teachers in this course as they learned about new technology standards for teachers and as they were introduced to some of the course material and expectations. As teachers added to their knowledge and skills feelings of anxiety were reduced or eliminated.

My head is starting to reel from the wide array of technologies that can be used by teachers. All of these tools and resources are to be used in a way that complies with technology standards, which are tossed on the pile to complement the content and pedagogy standards that are also to be complied with. I wonder when I will find time to actually teach!

In the last session we were introduced to creating a web page. The guest speaker...was very knowledgeable. She did a remarkable job on her own web site. I felt somewhat overwhelmed as I listened to her presentation. [The speaker's] website seemed to be so much more than what I felt I could accomplish.

I feel very much like my students must – overwhelmed and anxious. Sometimes I count the sessions until the end of the course. Other times I cannot wait to get to class.

Recognition

Several of the teachers expressed heightened awareness as recognition of their abilities and predispositions as learners.

To confess, I was a victim of my own creative process. I like to re-do things, exploring the alternatives, trying to take it a notch higher. I took this one a notch too far, though, and ran out of stick! The first effort was simple but it had a nice effect to it. As the days and nights passed, I reworked the newsletter so much that on the way to creating The Best Thing I Could Do, I nearly snuffed out all the original spark.

My week was spent thinking about my electronic portfolio. I feel like I have so much to do that I don't want to start anywhere. I can tend to be a perfectionist and that is why it takes me so long to get started.

As for technology, I think that my use of technology fits with my personality type as well. A person can communicate, create and organize on the computer with out ever directly talking with another soul.

Realization

As teachers' awareness of technology applications in classrooms expanded, they all wrote about experiences or thoughts that I characterize as being “Ah-hahs”. By that, I mean they came to realizations about broader issues related to technology than they had written about previously.

We must be selective in our use of technology tools in our classrooms. As educators, we must always have the primary goal of effective learning and cannot become so impressed with what technology can produce. We must always consider different strategies and be sure to use the best one to do our primary job, which is teaching.

I just wonder how much input the students have in the planning, process[ing], and implementation of technology. It bothers me that we seem to be “doing technology” to the students. Most of the decision-making power resides at the top of the pyramid...and the students are down there at the base.

Transfer

An important indicator of professional growth is the transfer of knowledge and skills gained in the course to other experiences or environments. In this case, my concern was whether the reflective journals validated that course assignments linked to classroom practice actually lead to transfer of new knowledge and skills to secondary students. Three themes surfaced in the analysis as critical influences in transferring knowledge and skills: overcoming barriers, managing time and gaining confidence.
**Overcoming Barriers**

As teachers explored the opportunities to introduce the computer-based skills they’d acquired to their students many frequently encountered barriers to technology use in their school sites. Their reflective writing describes their frustration, but also highlights their creativity, persistence, and success.

When I think about my school and my class, I’m not very excited about integrating technology. I feel like there is so little access to computers for our students. Because of this course, I’ve spoken with our principal and will be getting a computer in my classroom soon which will allow me to implement some of the projects I’ve mentioned in my journals.

Our technology coordinator told me that I would not be getting a new computer. I was livid ...but, sometimes bad news makes you work a little harder. Since our discussion, I have secured two more computers with Internet capabilities. This brings me to a grand total of six. I am currently designing in-class fieldtrips using computer technology. My students are responsible for producing a newsletter and will help maintain a course-related website. This course has turned a flame to my classroom operation.

**Managing Time**

One of the issues that teachers raised regarding technology use was time. If using technology saved them time, they were wholeheartedly in favor of it. If it required more time than some other approach, they were less inclined to use technology.

Creating newsletters to communicate with students and/or parents is a perfect example of how classroom practices can be improved by a very simple application of technology. A common complaint of teachers as well as other professionals is that new technology consumes rather than saves time. This is an example of the opposite being true.

[The presentation on searching the Internet] made me realize I was not using the information I learned about searching the web and how much time I could save by simply implementing some of the research tools I had previously learned. I want my students to be equipped with the necessary knowledge that will make searching the web a good experience rather than a burden.

**Gaining Confidence**

In order to transfer skills and knowledge to their students, teachers needed to feel confident in their ability to both use and teach a particular technology.

It is not enough to have teachers “technology certified” on paper. Teachers need to be given the confidence in order to get them to want to implement the technology in their classrooms. I had never truly used PowerPoint as it’s designed to be used before last week. As it is, I used it effectively twice in one week.

This weekend I have been going back and forth between hating this course (it entails so much work!) and loving it (I have learned how to use more technology in this course than I have in the last ten years!). Despite my frustration, I am confident the webquest I developed is one my students can really use and learn from.

**Teaching Technology**

Reflective writing encouraged teachers to identify the conditions necessary for effective classroom implementation based on their own experiences as learners. Empathy and effective teaching are two themes that captured what teachers had learned.

**Empathy**

As teachers encountered challenges in learning to use technology some made references to having a new appreciation for how their students must feel in similar situations.
I feel like I'm all alone! I am sympathizing with my students BIG TIME. While I am usually not afraid to ask if I have a question, many students are; they may frequently feel as I do: LOST.

As I reflect on my feelings toward creating my website, I can relate to some of the grumbling my students do when asked to do certain projects. I need to help them get started and express their thinking. I need to be there to help them move forward rather than see their reservations as a refusal to participate.

My experiences have also informed me in terms of using and teaching technology with my students. Just like I did, students need the proper equipment, time to investigate the web, and time to struggle with the software.

**Effective Teaching**

Teachers identified clear instructions, planning, organization, sufficient time, pacing, instructor patience and support, and differentiated instruction as key elements of what they'd learned about teaching technology while sitting in the “student seat”.

Technology based instruction needs to be carefully planned out in advance. This is no different than instruction that does not utilize technology. As teachers, we must always carefully map out activities, noting potential pitfalls and be prepared for potential detours.

A good practice for my classes is to have them do a brainstorming activity before getting started on their projects. The brainstorming will give the students time to think through and work cooperatively to come up with ideas. I do a lot of brainstorming but I'm not good about writing them down.

**Discussion**

Reflection was an essential aspect of teachers’ professional growth. This study found that reflective journals allowed teachers the opportunity to (a) become more aware of what and how they were learning and make connections to broader educational issues, (b) transfer what they had learned to secondary classrooms, and (c) examine how their experiences as learners revealed conditions necessary for effective technology implementation. The organizing structure of the journals helped to focus writers’ thinking. Revisiting earlier entries as the first step in writing each new entry pushed teachers to reconsider their feelings and thoughts in the context of newly acquired skills and knowledge. Reflection assisted teachers in making informed decisions about their classroom practices.

It was not surprising to find that teachers often cycled between feelings of excitement, frustration, acceptance, and satisfaction as they encountered new technologies since much of what must be learned required “doing”. The movement from seeing the possibilities to creating a usable product fit within Einstein’s description of genius as one that primarily requires perspiration and a modicum of inspiration. Learning technology requires practice, practice, and more practice. Many of the problems teachers encountered (a sudden error message, or a frozen screen) aren’t solved by referring to written text and don’t usually lend themselves to easy solutions. A heightened sensitivity to their students’ feelings resulted from teachers’ encounters with challenging situations. Further study on effective strategies for teacher infusion of technology in schools with highly defined content standards is needed. Since, for all teachers in this study, transferring skills and knowledge to their students required they spend class time teaching technology rather than math or English content, teachers were selective about when and how much technology they integrated in their classes.

Puzzling Over the Missing Pieces:
The Real Practice of Technology Integration

Judy Lambert
Department of Curriculum and Instruction
North Carolina State University
United States
jlambert@lambert-corp.com

Abstract: This paper is a report on the findings of a pilot study conducted on novice technology-using teachers. Although emerging technologies have significantly impacted much of society, they have not yet and to any large degree, transformed the practice of many educators in the classroom. Findings indicate that several strategies may assist these teachers in learning to use technology. Provide them with a logically sequenced curriculum guide that identifies specific computer objectives and methods of including these in content areas. Encourage administrators to establish concrete guidelines to promote teachers’ regular planning and practice of technology integration.

Introduction

Recently emerging technologies are presenting dynamic instructional opportunities for educators such as they have never before experienced. Through the use of these technologies, some teachers are providing students with powerful classroom experiences that will significantly enhance learning. These teachers, who are still few in number, have eagerly welcomed the opportunities technology offers and are moving forward in acceptance of these new learning resources. On the other hand, a large number of computers still sit in the back of classrooms collecting dust or on a teacher’s desk being used only for classroom bookkeeping. Teachers in these classrooms have experienced enormous uncertainty and anxiety at the restructuring they foresee as a result of technological reform. Use of technology has yet to make a significant impact on the way they teach or in the way their students learn (Parr, 1999). Roblyer (2000) reminds us that the mere presence of technology will not guarantee its use (p. 29). In either case, teachers are keenly aware of an inescapable fact—technology has made its impact on society and if they are to effectively prepare students for tomorrow’s world, they will have to adjust their thinking and their methods of teaching to incorporate its use.

Society has been experiencing this technological transformation for some years now but only, due in part to increased funding and connectivity, has the field of education begun its transformation at the same rapid pace. Trying to find ways to prepare our educational institutions and personnel to make the needed changes can be likened to putting together the pieces of a puzzle. When putting together a puzzle, the framework is usually connected first, consequently making it easier to assemble the inside of the puzzle. The rest of the puzzle is arranged until the last piece completes the picture. Throughout the process the box cover provides the picture, or illustration of the final goal. Herein lies part of the problem with technology integration—no one knows what the final picture of this reform will include. It is easy to fit the outer edges together because each of these pieces can be identified by at least one straight side. The framework for integration has been identified and many of these outer pieces have provided a preliminary framework.

An enormous infrastructure has provided many of our nation’s schools with the equipment and connectivity needed to ensure computer integration in the classroom. Integration models have described successful characteristics needed for the overall planning and implementation of technology use as well as for teacher training (Grant, 2000). Professional organizations, government agencies, and private sponsors have expressed a general consensus that one of the most important steps in effectively incorporating technology into education is preparing teachers. They have provided the funding and mandated that a percentage of their allocations go toward teacher training. Universities have implemented programs to
equip preservice teachers with the skills and knowledge to use technology in their classrooms. State, district, and local levels of education have increased technology spending and revised their technology plans to implement a variety of educator training programs such as in-service day workshops, after-school workshops, conferences, seminars, and “train the trainer” models to accommodate the requirement to train inservice teachers. Yet despite the general framework provided thus far, to a large degree teachers have not shown any sudden shift in wanting to integrate technology. If technology is to reform education the way it has the rest of the world and teachers are to become motivated and energized with new ideas, then their voice needs to have an impact in the shaping of the reform where it ultimately counts—in the classroom.

In an attempt to learn what teachers had to say, a pilot study was begun by a beginning doctoral student. This study was conducted at a middle school situated in a rural, low socioeconomic county of North Carolina. Some very simple, yet important pieces emerged in how to assist teachers in learning to use technology and in providing a school with concrete steps to encourage this technology integration. This school was chosen for the study because of a prior ongoing relationship the doctoral student (trainer) had with the school in technology training. In June of 2000, the teachers of the participating school were trained in many aspects of computer skills and technology integration during a two-day workshop. Another invitation was received for teacher training and in August 2000 teachers reviewed what had been learned in the previous workshop. In addition to a review, teachers were introduced to a web site designed by the trainer to test an online method of technological support that would provide ongoing communication and resources. A half-day workshop was offered without cost as reciprocity for the school’s willingness to participate in the research. This workshop was given to twelve of the teachers in late August.

A major concern throughout the study was how to maintain objectivity since the trainer designed many of the materials being used. Some of these materials and ideas were found to be ineffective while others worked extremely well. The ultimate goal of the study was to find some practical strategies or “pieces,” that would provide teachers with effective tools to begin arranging their picture of technology integration. Would an online support system offer help in this process? And if what teachers still need are the basic technology skills, how can they be presented so that teachers will begin to use them in the classroom? Throughout the study great effort was made to listen to what teachers had to say in their attempts to use these resources.

The Research Study

In June 2000, teachers were trained in various aspects of technology integration. The goals of the workshop were to:

- Familiarize teachers with each of the major competencies and objectives of the state technology requirements for teachers and students, and provide background knowledge of how each of the objectives is built upon skills learned as early as kindergarten.
  
  Example: 6th grade Objective 2.2: Create/modify a database relevant to classroom assignments. (North Carolina, 1998).

- Break the objectives into individual and manageable skills or chunks that could be practically integrated into classroom instruction.

- Practice brainstorming lesson ideas and spend time creating lesson plans that integrate content areas with the individual computer skills.

- Provide further understanding of technology integration by modeling effective lessons.

- Schedule time to practice, implement, and record personal development in technology integration in a portfolio.

Before the workshop in June 2000, teachers completed a survey that identified the types of technology used, how often it had been used with students, and their beliefs about technology integration. Teachers were asked, “Do you think that you should be using technology in the classroom more?” and “If you were told that your use of technology in the classroom should become part of your yearly evaluation as a teacher would you be positively motivated to learn it?” On a scale of 1-4, with 4 being “yes, to a large degree,” most teachers answered 3 or 4 on both questions.

Prior to beginning the workshop in August, the survey results were shared with the new principal. During this workshop, teachers reviewed what they had learned in June, reviewed the integration materials, and planned their technology goals for the school year. Teams of teachers were partnered and together they
planned a schedule in which they would write a technology lesson and practice it together. During the following month, they would teach the lesson. At the workshop teachers were also introduced to a commercial web site at Blackboard.com (http://www.blackboard.com) that was set up by the trainer to test the idea as an online form of ongoing support and access to technology resources. They expressed much enthusiasm about using the site and because of their enthusiasm it was thought that this could be a vital method for providing the much-needed support usually lacking in technology training (Schlager & Schank, 1997). Leaving teachers with concrete plans and enthusiasm about using the web site were thought to be significant steps in getting the teachers to begin their efforts in using technology. After this workshop, a letter was sent to the principal explaining what was seen as the current state of technology in the school and to encourage further development in this area.

In a half-day workshop in late August, teachers were to be introduced to the many features of the Blackboard web site that could be helpful in encouraging their technology growth. Having only used locally installed software on the school’s computers in previous workshops it was not anticipated how incapable the outdated equipment would be for this workshop in which the Internet was needed. Trying to explore the web site on these computers was futile. However, it proved to be a great opportunity to model for novice users how to handle the frustrations that so often accompany the use of technology. Because of the mounting frustration and lack of time, the focus of the workshop (and consequently the research inquiry) was changed from testing an online support system to technology team planning. Teachers chose partners and spent the next hour in technology planning. Before the teachers moved to separate rooms they were provided with an agenda of what they should accomplish during this planning time and reminded to take the materials they had previously received in workshops.

The agenda included five steps: plan your lesson, practice the lesson with the group, schedule a date to teach the lesson, schedule the next planning meeting, and record personal technology growth in portfolios. Teachers had received a template, “Technology Mini Lesson Plan” during their previous training. This template was created as a simple guide to assist teachers in the thinking process of including a manageable chunk of technology while planning a classroom lesson in their own content areas. Teachers had received step-by-step instructions for completing the lesson plan and during the June two-day workshop each teacher wrote five lesson plans using the template. Before using the plan on this particular day, the lesson template was amended and further explanations added as a guide for filling in each section. This same template was also used successfully during a graduate class in technology integration with inservice teachers. With this prior success and the previous training the teachers had received on the use of the template, it was assumed that the same success would be observed. From recording this planning session, several emerging pieces became very clear. Teachers did not clearly understand the various technology applications and their uses. Because of this they were unable to choose a specific skill or objective within an application to make the technology component of the lesson manageable. Although, in several workshops the teachers had been introduced to computer applications and breaking computer skills into chunks, they had not remembered this and did not refer to the notebook materials that may have provided direction. They also skipped around while filling out the form when logically one section should progress to the next. This only seemed to add confusion to the process and prevented the teachers from getting the lesson completed.

On an optimistic note, teachers were focusing on their content area and even trying to expand the lesson in a variety of ways. Their desire and suggested ideas for enhancement of the lesson would have added variety in both content and technology. The vocational teacher monitored the practice sessions and this proved to be a great benefit to the teachers in understanding specific problems. By monitoring the team planning sessions, she identified a fundamental obstacle with most teachers—they did not know how to choose small chunks (or objectives) from the computer applications to include in their lessons. Teachers completed surveys after the workshop that added some optimism for the outcome of the team planning sessions. Survey results were corroborated on questionnaires and through formal interviews:

Question: How did you feel about working in teams to learn how to integrate technology? Answers:

- “Great! Two heads are better than one and working together may allow me to get different ideas,”
- “It helped me out just by watching someone else go through the motions and explain every step.”
- “Teams are always helpful; sharing different teaching strategies you’re more inclined to use them.”

Question: How do you feel the meeting itself will influence your learning to use technology in your classroom instruction? Answers:
"I will be more apt to try it since I know I can run down the hall for help!"
"It will help with thinking of strategies when planning."
"You're more inclined to teach the skill as a team project rather than individually."

"The technology team gave me the boost of confidence and assurance that I could have successful as well as meaningful lessons using technology."

"It was fun, their input...you know if you have three people looking at a problem you might get three different solutions or three new ideas, three different ways of doing it and to me that's important that maybe there are some other ways, and somebody might benefit from it."

After the workshop an impromptu meeting took place with the principal and the vocational teacher. The principal shared, "I want you to know that your letters keep me focused, and that's what I need in technology. It's an area that's easy to overlook. I agree with you that the teachers will not grow if this is all that they get. They need something that will make them continue to use it." She then asked for feedback on some ideas she was considering for her staff: (1) Teams were to make technology planning a part of their regular weekly team-planning times, (2) they were to write one technology lesson and schedule a date to teach the lesson and provide this information to the office, (3) and they were to be evaluated monthly during the teaching of a technology lesson.

Brainstorming began and through further discussion other ideas were developed to encourage the use of technology within the school. After the workshop a letter was sent to the principal to outline the ideas discussed, share the workshop survey results, and to offer support for her efforts:

"These answers lend more credibility to the ideas you shared after the workshop about requiring teachers to include technology as part of their planning. I believe if you will implement the ideas you mentioned you will see more conscious effort among your teachers to include technology."

Part of the team-planning meeting was to practice the lesson but the teachers did not have time for this. A return trip was scheduled a few weeks later to observe the teachers during their practice. In the meantime, the teachers had revised their lesson plan with the help of the vocational teacher and had already practiced the lesson on several occasions. They were eager to share their results and proud of what they had accomplished. One of the teachers commented on a questionnaire completed after teaching the lesson, "I feel very confident and proud I used technology with my lesson content...I now feel even more comfortable using technology in my class lessons." Upon examination of the revised lesson plan, it was evident that they now had a much better understanding of the technology application and how to choose a specific skill to teach. However, during the practice session another important piece of the puzzle emerged.

The teachers had chosen a clear objective, "Students will enter information about mythical gods and goddesses into a database." After a short review of mythology, the teacher went to the computer to demonstrate what students would do on the database. The trainer, acting as a student raised her hand and asked, "Teacher, what is a database?" At this point the teachers found that they still did not have enough background knowledge to support the use of this application with students. A mini-lesson in database was provided and teachers expressed how much more confident they felt having this knowledge. Encouragement and praise was offered for their efforts and a date scheduled for observing the lesson. A formal interview with the vocational teacher later that afternoon confirmed what had been observed during the practice session, "Yes, at the planning sessions teachers chose whatever computer skill they wanted to use in a lesson and they didn’t choose what should have been taught first, “an introduction to database.” Teachers needed a sequence of skills to follow. Then they would’ve had this background knowledge." This piece, which should have been reinforced, was another false assumption that the process of learning to sequence in one curriculum would transfer to another. This did not appear to be the case when learning to teach lessons that include computer skills.

The following week each of the teachers taught their lessons and was again observed. Documents used during the lessons were collected and examined. The trainer, in order to measure the components of an effective technology lesson, created a formative evaluation instrument. This instrument was a combination of measures borrowed from other evaluation measures and the personal knowledge and experience of the
trainer. Therefore, the instrument could only be considered an informal means of gauging the use of certain technology components.

One class had 9 students in 6th grade. This teacher was in her 9th year of teaching and this was not her first lesson using the integration of technology. The other class had 7 students in 8th grade. This teacher, while not a certified teacher, was a full-time tutor at the school. She was in her first year of teaching. These two teachers taught their lesson in the same room that housed only one computer and one printer. Students in both these classes were performing at grade level. The third teacher, in her 3rd year of teaching, taught her lesson in a room with 8 computers. In this class, there were 11 special education students who were performing at a 3rd grade level. During each of the lessons the teachers used the same strategy of pairing two students at the computer while other students worked on seatwork in the content area. Following is a brief summary of the observations recorded during the lessons:

Strengths:
- 2 of the 3 teachers provided adequate background information for database; 1 provided exemplary knowledge of the subject; 2 of the 3 provided a review in the content area.
- 2 of the 3 had the objectives clearly written on the board for both content and computer areas.
- All teachers had materials ready and they effectively managed the instructional time with both the students at the computer and those at their seats.
- All teachers were exemplary in explaining to students the process they were to follow: what they were to do at the computer, at their seats while waiting their turn, and how they would take their turns at the computer.
- Effective strategies were used to account for the available equipment and needs of the students.
- All teachers maintained a focus on the content area rather than on the technology.
- Technological problems occurred with 2 of the 3 teachers and it was adequately handled and the lesson was continued.
- All students in 2 of the 3 classes were able to participate at the computer during the lesson. Only in the special education class were all students not able to take their turn. In this case, it would be more realistic and effective to continue the lesson for several days.
- Collaboration among students working at the computer was encouraged in 2 of the 3 classes. In the special education class one student was to mentor the next student in what they were to do.

Areas for Improvement:
- 2 of the 3 teachers did not provide for students a real connection from the content area to the use of the database. This may have been due to their lack of knowledge, adequate practice, or simply being new to using technology.
- Only one teacher completed the lesson with enough time for closure and assessment of learning.
- Seatwork was adequately used as a strategy in a one-computer classroom for a beginning technology lesson. However, in time and with more practice it would be anticipated that a diversity of strategies would be used to actively involve more of the students in the lesson by using a computer presentation device which the school has available.

After the process of planning, practicing, and teaching the technology lessons these teachers answered a questionnaire about their experience. The following is a summary of some of their answers:

- Training or staff development and practicing helped them the most to prepare and perfect the lesson.
- The lesson plan template was helpful as a guide and to provide step-by-step instructions.
- The team planning session boosted confidence and helped in knowing what to expect.
- The in-house technology expert was a valuable resource in planning. “She gave technology hints and advice; showed them what was wrong and how to correct it; and helped them narrow the lesson.”

Surveys taken by twelve teachers appear to confirm some of these findings. When asked, “What do you think teachers mainly need in a personal way to be able to integrate technology?” Ten out of twelve had common responses, “more training, more time to plan for it, and more knowledge of computer skills.”

Before the study was officially completed a formal interview was conducted with the principal. She shared that her team leaders had been informed that technology planning was to be a part of their weekly team meetings and that they would be evaluated once a month during one of these lessons. She described how her function as an administrator was to communicate with her teachers that technology was to be one of their major goals. Again she insisted, “You keep me focused; I need you to keep communicating and sharing with me about technology, to keep us on track.”
Conclusions

Some of these simple technology "puzzle pieces" have already been identified through other studies and this paper tends to confirm what has been already found. Because of the rapidly changing nature of technology, much of the literature seems so quickly outdated or has been extended beyond the initial stages of technology integration and does not address the needs of beginning technology users. Many educators have not even yet begun to include technology in their instruction so this study could be most useful in reminding administrators, technology specialists, and trainers that there are still teachers who need the basic skills before they will be eager and able to use technology in the classroom. Training and materials for inservice teachers should combine technology instruction for personal use and strategies for using the technology as an instructional resource. Although many states provide a computer skills curriculum for the vocational teacher or computer lab instructor, this comprehensive curriculum may offer much more than any classroom teacher could begin to process when combined with their other responsibilities. Even so, classroom teachers need some type of guidelines if they are expected to integrate one curriculum with another. This curriculum, as in the case of any good curriculum, should be a logically sequenced method of including computer objectives in the content area curricula but possibly in a condensed or simplified form that could be easily referenced by the classroom teacher. Regularly scheduled planning and practice sessions may increase in-house technology support, peer collaboration, and comfort level of teachers. As much of the literature before has indicated, most teachers will probably only grow in their desire and ability to integrate technology in their classroom instruction if it is strongly supported and encouraged by an administrator. More administrators may be receptive and enthusiastic about providing this support and encouragement if they were kept "focused," or given ideas by technology resource personnel. Further study would be useful in identifying an effective, but simplified version of a computer curriculum for classroom teachers. In addition, as more educators learn to integrate technology, administrators will need more appropriate and valid instruments to evaluate instruction of integrated lessons. In order to be qualified as evaluators of technology instruction, administrators will also need further training in the use of technology, methods and strategies that prove most effective, and characteristic differences in learning environments when technology is used as a resource. Finally, even though an online technology support system was not fully developed in this study due to inadequate equipment and time constraints, its potential should be further examined.

The Unique Impact of Internet Instruction on Future Teachers: A Qualitative Study of Delivery Systems and Their Impact

Douglas Lare
Professional and Secondary Education
East Stroudsburg University, PA
United States
Dlare@po-box.esu.edu

Abstract: Recent teacher shortages and the growing popularity of teaching as a viable career change has led to a blossoming of many graduate teacher education programs. Distance education is especially attractive to these students since many have families and must maintain jobs. However, many teacher educators are still suspicious. This paper summarizes a qualitative study, which looked at two required courses in the graduate teacher certification program at a teacher training university. Two groups of students participated in these courses in the traditional manner of traveling to the university and attending classes. Two other groups of students took the identical courses over the internet. The same two instructors instructed all four courses. This study followed these students not only while they took the courses, but also as they continued their studies and in some cases, when they started teaching in their own classrooms. The results suggest that while the instructional delivery models may have impact on course objectives, the greater impact may be upon a future teacher’s attitude toward the effective use of technology in the classroom.

Introduction

Recent teacher shortages and the growing popularity of teaching as a viable career change have led to a blossoming of many graduate teacher education programs. Distance education is especially attractive to these students since many have families and must maintain jobs. In fact, as distance education becomes routine at even the most established universities, future teachers are able to take a significant number of courses through distance education.

At this time, there appears to be at least two models of distance education that are becoming popular. There is the classroom distance education model, and an emerging model of instruction being presented over the internet. In the classroom model, students sit in a specially designed room and view a projected television image while their image is beamed back to the instructor via television cameras. These facilities are usually fairly high in cost to establish and operate and requires students to travel to a specially equipped facility, not much different than current educational practices of having students attend classes at the university.

The internet model can be broken down into two variations- asynchronous and synchronous instruction. Asynchronous instruction, meaning students view materials posted by the instructor or by other students at any convenient time, is readily supported by most institutions by making available various pieces of template software that allow a faculty member to create course materials fairly easily. This type of course support is necessary for any internet instruction, but lacks the interaction of a live class. Many students report feelings of isolation and find it difficult to remain motivated using this type of instruction.

The synchronous internet model, gaining popularity with business and industry for training, allows the instructor to be in one location and students in different locations, their schools, homes, offices, or a computer laboratory, for example. The instructor is similarly in another location. Instruction takes place using streaming video, audio, white boards, and similar technologies. Students and the instructor can see and participate with one another, much like in a regular classroom. Students no longer need to travel to a central location for a class, and there is live communication and interaction taking place. This type of instruction is less expensive in terms of facilities, but does require expenditures for special software and some hardware on the part of the student.

The advantages of either type of delivery system have been celebrated on numerous occasions.
Disregarding the financial issues, the positive potential for instruction cannot be denied in certain circumstances (Teh, 1999). Berger (1999) has justifiably pointed out the potential for global learning over the internet.

However, many teacher educators are still suspicious that web based instruction, while adequate in some situations, still falls short when teaching future teachers the skills necessary to function in current classrooms. Many anecdotal studies have taken this more cautious approach to web based delivery systems. (see Dewald, 1999; Waters, 1999; Sullivan, 1998). While there may be advantages in terms of convenience, the pedagogical advantages might be limited and need to be explored in more detail.

This paper summarizes a qualitative study which looked at two required courses in the graduate teacher certification program at a teacher training university. Two groups of students participated in these courses in the traditional manner of traveling to the university and attending classes. Two other groups of students took the identical courses over the internet, one using the synchronous model and one class utilizing asynchronous web based instruction. All four courses were instructed by the same two instructors. This study followed these students not only while they took the courses, but also as they continued their studies and in some cases, when they started teaching in their own classrooms.

The Study

Since the university has a carefully monitored curriculum process, both courses had to offer similar content. One class was an introduction to the internet for teachers. This course had traditionally been offered in a lab classroom at the university and relied heavily on project based instruction. The other course was an overview of schools and their place in the community. This course had included internet components in the past, but had not required extensive use of web based resources.

Students were interviewed in focus groups prior to taking the course and upon completion of the course. In addition, follow up interviews were conducted based on a willingness to participate. Surveys were also administered at the end of the course which focused on instructional issues. The instructors then interviewed each other focusing on the common experience of offering courses at the university and over the internet. Taken all together, this interview and survey data from instructors and students gave a good picture of the issues involved in this type of teacher education.

Findings

As might be expected, the variety of responses suggest that the learning style of the students is a consideration, but not to the degree as might be expected. There was no general pattern which emerged which suggested that those students with a certain learning style were more suited to internet or classroom instruction. This might suggest that a wide range of students may find internet instruction, in certain situations, a viable option. Students in the "Internet for Educators" course clearly gained additional benefits by having the class conducted over the internet. They felt they were more self-reliant, better able to solve technological problems, and had a better understanding of the capabilities of internet instruction for their own classrooms. Students who took this course at the university felt the course was valuable, but did not report these positive trends in their own learning to the degree reported in the internet only course. The fact that this course was offered in the synchronous mode turned out to be of limited importance. The course evolved to the point that the project based approach really did not require the entire class to be on line at the same time.

The instructor for this course had taught internet based courses in the past and was technologically skilled enough to answer all technical questions. Also, having taught internet based courses in the past, he was concerned that the amount of instructor time would be far greater when so many individuals demanded increased attention. His experience has suggested that internet based courses were far more work than regular, classroom based instruction. However, since this was a project based course relying on internet resources, he documented that this course did not take any additional time than the lab based course.

In short, the data suggests that as long as the course is project based, internet based instruction in this particular course, "Internet for the Teacher", is superior to lab based instruction on site. The course did not require additional instructor time, and the students reported that they became more skilled in their use of internet resources than those in the lab classroom. The key, however, seems to be that the instruction was project based. Whether the course was offered in synchronous or asynchronous mode did not seem to be an
issue with this particular course.

Students in the “Teacher and the School Community” had a very different reaction. Those taking the class at the university felt that they had been exposed to new issues, had interacted with their colleagues in new and meaningful ways, and had a better understanding of where they might fit into a community once they became teachers. The course content allowed frequent field trips and the opportunity to question guest speakers in person. Students who took the course on site repeatedly commented that these opportunities were the best learning experiences the course had to offer.

Students who took a portion of this course over the internet felt they had gained valuable technical experience, but did not feel that they had significantly grown in these same areas. They felt that the spontaneous interaction was lacking, since this course was offered in the asynchronous mode. Chat room discussions or conferencing on particular topics was useful, but “slowed down” the process by which students might clarify and synthesize ideas. Many commented on the fact that they felt disconnected from the instructor. Several mentioned that they did not exactly understand the role of the instructor in that he only seemed to “worry about setting up activities on the web.” The web based assignments were group projects, which seemed to have potential with this type of delivery system. Unfortunately, many commented on the difficulties of interacting with each other which led to frequent frustration and an exclusive focus on technology issues.

Conclusions

Follow up interviews indicate that those students taking these courses over the web gained useful technological skills which they have been able to apply both in other courses and in the teaching field. In retrospect, those who took the “Teacher and School Community” course over the web do not feel they have “missed a significant opportunity.” Many commented on the fact that the limitations of web based instruction has proved to be a useful lesson in that they can critically analyze the benefits and pitfalls of internet based instruction.

One of the most useful products of this study was the dialogue established by the two instructors. The “Internet for Teachers” course had a distinct advantage in requiring individualized work and instruction. The “Teacher and School Community” course, relying on web discussions in chat rooms and group projects, suffered. The instructors learned from each other in that future courses will make appropriate modifications to explore more effective ways to promote instructional strategies other than project based learning. The issues involved in web based delivery seem to cross disciplines and what may work with one content area may cause problems in another. Helmi, Haynes and Maun (2000) noticed that the experiences and potential solutions to this type of instruction may in fact create useful bridges between disciplines which may lead to interdisciplinary instruction. This is exactly what happened in this particular case.

On Integrating IT into Teaching of English in Taiwan Junior High School

Greg C. Lee and Yu-Jen Lo
Department of Information and Computer Education
National Taiwan Normal University
Taipei, Taiwan
{leeg, viviane}@ice.ntnu.edu.tw

Abstract: The goal of this study is to investigate the support and training needed in integrating information technology (IT) with teaching of English as a foreign language. Two junior high school English language teachers were given 20 hours of basic computer software training along with 15 group discussions on how to integrate IT into classrooms. Teaching experiments were then conducted in 8 class periods. The major findings of the study are: (1) training of computer skills needs to focus more on the short-cuts of operating a software; (2) CAI titles that facilitate IT induced instruction is yet to be improved; and (3) full support from the school, both administrative and technical personnel are necessary for the long term implementation of IT integration into classrooms.

Introduction

K-9 curriculum in Taiwan has undergone major changes in the last few years. With the advance of information technology (IT), not only are information technology courses being taught in the K-9 schools, the new K-9 curriculum calls for full integration of information technology into teaching of all subject areas. Thus, not only will the students be IT informed; teachers also need to be IT trained to be qualified educators of tomorrow.

Although the newly graduated teachers are most likely IT trained, most of the teaching force are educated from yesteryears; thus lacking suitable IT training, making integration of information technology into teaching a difficult task. The Taiwan Ministry of Education sponsors many on-the-job IT training courses to teachers through colleges and universities in Taiwan. These courses range from introductory hands-on courses to theoretical advanced network management course. Furthermore, special funding was appropriated to all K-9 schools to training teachers of their respective schools. Thus, it is safe to say that most teachers are at least aware of the inevitable changes brought on by the advancement of information technology.

Taiwan's new K-12 curriculum guideline has now mandated that foreign language courses be offered to all students beginning at the 5th grade. With the government's will to push ahead the use of IT in the educational sector (Lee & Wu, 2000) and the requirement for studying foreign languages by all students, the need for effective teaching of foreign language is more pressing now than ever before. In this study, we invite junior high school English teachers to join us on learning to integrate IT tour. By experimenting with using IT in their classrooms, it is hoped that the experience learned can be shared among all teachers in Taiwan.

Related Research

In this day of information age, teachers are increasingly under pressure to use technology as a learning tool and to integrate technology into classroom instruction (Scheffler & Logan, 1999). In many ways, integration strategy is often guided by different factors including equipment accessibility, educational objectives, students' needs and the teachers' technical know-how (Halpin, 1998). In a report by OTA (1995), a number of common barriers exist among the teachers in using technology in classroom instructions. For one, many teachers lack a clear understanding about what resources technology can offer them as they try to meet their instructional goals. Yet another is that teachers need extra time to experiment with new technology and plan lessons using new methods that incorporate technologies. In terms of integration IT into teaching and
learning, Roblyer (1997) classified the efforts into 6 categories. On a more abstract level, we can also categorize the experiments in the literatures into 2 categories based on who is required to operate the IT equipments in the learning process.

**Student-centered IT induced activities:** Many of the experiments reported in the literatures involve the students using the IT equipments in fulfilling the assignment given by the teachers. For example, in “Project with Teeth” exercise by Roblyer (2000), teachers use e-mail to connect K-3 students with “Keypals” around the world. The students interchange how many teeth the children lose during the year. Thus the students must practice their writing via email message to their keypals. Another example also by Roblyer is to let students use word-processing tools or crossword puzzles generators to develop several test items over the learning contest. It was argued that this hands-on approach helps students retain more because they themselves generate the questions. In both cases, the teaching or learning is student-centered. Furthermore, students must have adequate access to computing equipments. Thus activities such as those are only possible in a learning environment where students and teachers alike have ample computer access opportunities.

**Teacher-centered IT induced activities:** In contrast to student-centered IT activities, a teacher-centered IT activity is one in which the teacher is in charge of operation of the IT equipments. Here IT equipments are used merely as a teaching aid as oppose to self-learning facilitator. For example, a teacher may use PowerPoint as a delivery-metaphor technology. In Saye (1998) group of 10 teachers experienced with transforming teaching material into digital forms. So instead of chalk and board, teachers used computers and LCD monitors/projectors in class. However, if not carefully planned, teacher-centered IT induced lesson can cause many classroom management problems (Mason & Hlynka, 1998). A different use of IT is exemplified by the “Project Essay Grade” (Jones, 1999), in which English teachers use computer and essay analyzer to help grading students’ writing. The analyzer can look at five specific traits, namely content, organization style, mechanics and creativity and provide feedback to the teachers. Thus saving teachers’ time in grading essays.

**Experiment Setup**

This study was carried out at a municipal junior high school where the principle has agreed to allow schoolteachers to try out new teaching methods as would be required by this study. The procedure of the study is as follow. First, participating English teachers were gathered through a general call for participation. No pressures from the school principal were exerted on any of the teachers, so all joined were on voluntary basis. Bi-weekly meetings with participating teachers were then held to give the teachers a sense of the current state of IT and of how teachers in other parts of the world are using IT in their instructional activities. More importantly, the meetings allowed the teachers to express their opinions on how IT can be integrated into their classrooms and allowed us to formulate the necessary training courses for those teachers. After the training, the teachers began to practice integrating IT into their teaching. Students were asked to fill out questionnaires, with both Liker-scaled questions and open-ended questions, at the end of the teaching experiment, which the teachers have post-experiment interviews. In addition, teachers were asked to keep a teaching journal detailing their thoughts on the experiment. After analyzing all the data gathered during this study, one last meeting was conducted with the teachers to resolve any unanswered question at the data analysis phase. Timetable of this study is outlined in Table 1, and a brief account of each stage of the study is given below.

1. **General preparation:** Ten teachers volunteered for this study at the outset. However, only 2 made it through the teaching experiment. The other 8 dropped out of the study when it comes time to design their own IT integrated teaching plans. The most often cited reason for dropping out was heavy teaching duties and not having enough time to do the extra work. The two remaining teachers all have 3 plus years of teaching experience and are casual users of computer even before this study. Three discussion sessions were held to let the participating teachers be acquainted with the research team and to gather information about the school. Thus, topics of discussion range from school’s computing environment to how the teaching of English language is being conducted.

2. **Learning about IT integrated teaching:** Four discussion sessions were held with participating teachers to discuss possibilities of integrating IT into teaching and into classroom activities. During these four meetings the research team show the teachers the teaching resources that are available on the Internet and
discussed about other IT integrated teaching projects reported in the literature. During these discussion sessions, it was determined the type of IT trainings those participating teachers needed the most.

3. Preparing for IT integrated teaching: There are two objectives during this stage: participating teachers’ IT training and design of teaching plans for use in the experimentation stage. Twenty hours of computer usage training were provided to the participating teachers to ensure they have enough IT background to conduct IT integrated teaching activities. The topics of the training were results of the previous discussion sessions and the trainings were all conducted at the school’s new multimedia computer PC lab. The training covered the topics of Windows 98 (2 hours), Word (8 hours), Power Point (4 hours) and Internet basics (6 hours). Class notes and exercises were all specially prepared to ensure quick learning results. Upon completion of the computer usage training, teachers were asked to design teaching plans to include classroom activities that involve usage of IT equipments. Although only two participating teachers remain at this point, both were very enthusiastic about the opportunity to experiment with new teaching methods. Over a period of 4 weeks, those two teachers refined their teaching plans and prepared the necessary teaching aids (e.g. Power Point slides, scanning of pictures) all by themselves.

4. Experiment: Eight hours of teaching experiments were carried out in two different classes toward the end of the semester (actually 2 weeks at the end of the semester, 2 in the summer). All the experiments were done in a classroom equipped with LCD projector. The teachers had to bring in their own notebook computer and setup it up on their own. Each lecture was tape-recorded for future analysis. The two classes were chosen for the simple reason that their schedule matches with that of the research team. As it turned out, the first class (Class A) is a model class in which all the teachers praise about the good study habits of the students in the class. On the other hand, the second class (Class B) is a complete opposite of the first class in which the motivation to learn is non-existence among the students in the class. At the conclusion of the experiment, students in both classes were asked to fill out a survey to give their thoughts on the new teaching method. The questionnaire focused on whether IT integrated teaching will better attract and retains attention and on its effect on learning. The questionnaire and the results are given in Table 2. The teachers were also interviewed after the experiment with questions relating to teaching preparations and classroom management.
Experience Learned and Discussions

Thoughts from the Students on IT-Integration

The students’ questionnaire and summary of their responses are given in Table 2. From the table, several observations can be made. In general, Class A (the model class) gave more favorable response than Class B in all questions by a large margin. Furthermore, majority of the Class B responses fall into the indifference category, meaning that the students do not care much about the new teaching/learning method. This can be attributed to the fact that students in Class B are less motivated to learn. Anything the teachers try is probably fruitless. Looking at Questions 7 and 8, although only 30% of students in Class B liked the IT induced classroom activities, 42% favored the use of CAI software to ease the pressure of learning (English). This observation raised an issue for future study. That is what type of classroom IT activities can help bring about students’ desire to learn foreign language, or any school subject for that matter.

As for Class A, it is interesting to know that although only between 41% and 60% (questions 4 to 6) of students think that IT aided teaching method facilitated their learning, 71% liked the new teaching method over the traditional mean (question 8) and that only 6% of the students dislike the IT induced classroom activities (question 3). Again, a future in depth study of the correlation between IT induced classroom activities and students’ learning progress is warranted.

Thoughts from the Teachers

At the outset of this study, both teachers were having doubts about the feasibility of integrating IT into classroom instruction, let alone that the ever presence of the National High School Entrance exam makes any
deviations from routine teaching/learning method susceptible to challenges from parents. However, after one semester of experimentation, both teachers have outgrown their initial skepticism and now embrace the idea of integrating IT into their teaching. From this study, we are also able to conclude that teachers are like students in terms of installing new teaching method. At first, they need to be guided. With a few IT integrated teaching sessions under their belt, they will be more enthusiastic and be able to design and implement IT integrated lesson plans on their own. The following is a brief summary of the experience that the two teachers have shared with us.

Teaching preparation

As can be expected, preparation of IT integrated classroom activities takes more time than the non-IT activities. However, besides shortage of ideas for IT-integrated activities, unfamiliarity with the operations of IT equipments is also a major factor. For example, one of the teachers encountered scanner problem. After running around for help for a couple of hours, the problem was finally resolved, thanks to the school technician. However, an impatient teacher would likely have given up on it if the equipment fails to work properly. Thus it is important to have the teachers properly trained to not only use computer software, but also routine operations of the commonly used IT equipments.

Classroom management

Although neither teacher experienced additional classroom management problems other than those common faced, they did brought to our attention that it is better to prepare additional contingency activities for use during unexpected equipment failure. One of the teachers ran into an unexpected problem during one of her classes. The LCD projector apparently got too warm and it triggered the automatic shut-off and cool down function. For about 10 minutes, the teacher had to do without the projector. Once the “power” was restored, it went off again after only a short while. Students often can get too hyper when unexpected event occurred. Fortunately, the teacher had a contingency plan and the class went on smoothly.

Administrative support

During the course of the experiment, the school administrative support was critical. Since IT integrated teaching is still in the experimental stage in Taiwan, the classrooms were not equipped with the necessary IT equipments. Our teaching experiment was carried out at a make-up IT classroom, equipped with the necessary IT equipments. However, the first few teaching sessions went on with routine calls to the schools maintenance staff to make better the teaching environment. For instance, window blinds or curtains of the class need to be added because the LCD projector was not bright enough. However, the curtain problem was never resolved in a satisfactory way. If it weren’t for the teachers’ persistence, setbacks like these could discourage teachers from using IT in their instructions.

General comments with regard to IT integrated instruction

Though there were some setbacks at the beginning of the teaching experiment, both teachers were quick to point out the advantages of using IT in the classroom. Though it takes more time and effort to design IT induced teaching plan and that some class time may be lost due to equipment failure, both teachers agreed that the IT integrated activities are more compact than the non-IT activities. As a result, students seemed to concentrate better through out the whole activity. The teachers also pointed out that many of the CAI titles are not suitable as a teaching aid in the traditional classroom setting. The current titles are suitable only for individual viewing only. When it is projected onto the white screen for the whole class, the characters on screen are generally too small to be visible for students sitting in the back of the classroom. The teachers also noted that during our training sessions, we have taught them many ways of accomplishing a task (e.g. copy and paste operations) for reason of completeness. However, they found that during teaching, they often use only
one of the many ways, the fastest way! It was recommended that future training courses should include a "short-cut" sessions in which the teachers learn the fastest way of operating around a piece of software.

Concluding Remarks

Teaching of English as a foreign language is very suitable for IT integration because repeated practices on the same content is the major teaching method. With multimedia computer being capable of replacing many of the equipment currently in use in teaching foreign languages, including word cards, audio tapes, situation diagrams, a trivial form of IT integration would be to transform all the material currently in use into digital form so that students can have access to the same material for practicing at home. With the suggestions of the experienced English teachers, we are currently working on a word card system for which the teachers can easily create electronic word cards for use in IT equipped classrooms.

Abstract: This paper reports on professional development approach, used in an Indiana-based Technology Innovation Challenge Grant, for middle and high school teachers designed to promote problem-centered uses of technology. As an initial activity, in-service teachers, pre-service teachers, and grade 6-12 students took part in a two-day modeling activity using technology to investigate and report on a local community problem. This allowed teachers to experience problem-based learning and understand the elements of the process. Evaluation of the modeling activity showed positive reactions from both teachers and students. Subsequently, teachers took part in a semester-long, school-based course involving a number of problem-centered activities. Teachers developed their own problem-centered projects that contained appropriate elements of problem-based learning. These findings suggest that the professional development approach used in this project was effective.

Introduction

Fast-paced life in the 21st century will demand adaptability, problem-solving, and continual learning. A recent Presidential panel report (Panel on Educational Technology, 1997) stated that 21st century workers must possess "the capacity to readily acquire new knowledge, to solve new problems, and to employ creativity and critical thinking in the design of new approaches to existing problems" (p 6). Because of these demands, there is growing emphasis in educational reform efforts on learning models based on students' active construction of knowledge and skills. Learners must learn how to learn if they are to be successful in a rapidly changing world.

Two similar learning models, problem-based learning (Torp & Sage, 1998) and project-based learning (Krajcik, Czerniak, & Berger, 1999), embrace this perspective on students' construction of understanding and show great promise for helping learners acquire knowledge and skills while using technology as an authentic tool. Although the specifics of problem- and project-based learning vary
somewhat, they share an emphasis on situated learning (Brown, Collins, & Duguid, 1991) in authentic contexts (Stepien & Gallagher, 1993). Authentic problems anchor the curriculum and provide a vehicle for both problem-solving and content learning. In general, this approach is characterized by: (1) use of an ill-structured problem or driving question that provides opportunities for student investigations and problem-solving; (2) student analysis of the overarching problem or question to identify a specific problem for investigation (e.g., identifying what is known and unknown); (3) student-conducted investigations or actions that typically result in the development of artifacts or products; (4) collaboration among students, teacher, and community; and (5) student presentation of a final report or solution that summarizes the process and findings. Technology can play an integral role throughout this process as a tool for acquiring relevant information, gathering and manipulating data, and producing and presenting the culminating presentation in multimedia format.

For teacher educators, a key issue is how to best help in-service and pre-service teachers learn to apply problem-based methods that effectively integrate technology. Little (1993) argued that traditional models of professional development are not adequate to the task of preparing teachers for the challenges of teaching in the climate of reform. Because of the complexities of pedagogies demanded by learner-centered approaches, deeper and more meaningful professional development experiences are needed. One-shot technology workshops will not work today (if indeed they ever did). The Indiana Education Policy Center (1996) suggested that, to provide for continuous growth, effective professional development must: be school-based, use coaching and follow-up techniques, be collaborative, focus on student learning and be evaluated at least in part on that basis, and be embedded in the daily lives of teachers. Hill (1999) suggested that teacher technology development can rely on the same problem-centered and activity-based methods that are suggested for students in problem- or project-based learning.

This paper reports on the initial professional development activities of an Indiana-based Technology Innovation Challenge Grant project. These professional development activities, launched in the fall of 2000, were conducted by university faculty working in collaboration with teachers from the lead school district. Activities relied on problem-centered approaches to introduce problem-based learning with technology. The goals of the in-service professional development were to: (1) promote teachers' understanding of problem-based learning, (2) facilitate teacher's development of technology integration skills and knowledge, and (3) facilitate teachers' development and implementation of their own problem-based learning activities incorporating technology. The process consisted of an initial problem-based learning modeling activity, designed to show teachers the problem-based method in action, followed by a semester-long, on-site course focused on technology integration and problem-based learning approaches. The process and preliminary outcomes are described here.

Project Background and In-Service Professional Development

Tech-Know-Build: Indiana Students Building Knowledge with Technology is a Technology Innovation Challenge Grant project, funded by the U.S. Department of Education, which deals with problem-based learning approaches integrating the use of technology. Initiated in August of 2000, this five-year project focuses on the development and implementation of a learner-centered and problem-based curriculum, beginning in the sixth grade, involving collaborative construction of knowledge in authentic contexts using technology. Naturally, professional development is an important element of this process. Additional elements of the project include the use of portable technologies, electronic mentoring of K-12 students by university pre-service teachers, and electronic links among project partners and with the larger community. Project partners include the Crawfordsville (Indiana) Community Schools, Indianapolis Public Schools, Purdue University, and Indiana University Purdue University at Indianapolis (IUPUI).

The university partners, working closely with school personnel, direct the teacher professional development component of the project. Purdue University (main campus) has a long history of cooperation with the Crawfordsville Community Schools, the lead school organization. In addition, the Purdue campus is located relatively near (about 30 miles) to Crawfordsville, a small rural community in central Indiana. IUPUI has a similar long-term relationship with, and proximity to, the Indianapolis Public Schools. Hence, Purdue University works primarily with the Crawfordsville Community Schools, and IUPUI works primarily with the
Indianapolis Public Schools on the professional development aspects of this project. Because of funding patterns, grant activities involving Indianapolis teachers will not formally begin until summer of 2001, but activities involving the Crawfordsville teachers began during the fall of 2000.

The professional development activities involving Purdue faculty and teachers in Crawfordsville actually pre-date the grant by several years. In 1997, the Crawfordsville Community Schools launched a project to provide all district teachers with laptop computers. To receive a laptop, teachers had to acquire computer competencies through one of several available means. One of these was completing an on-site introductory educational technology course offered through Purdue University. Since this collaboration began, over 150 teachers have elected to take an introductory and/or advanced educational technology course through Purdue to satisfy the requirement to obtain a laptop computer.

During the fall of 2000, twenty-four Crawfordsville middle and high school teachers enrolled in the advanced educational technology course (EDCI 564, Integration and Management of Computers in Education) as the first group of grant participants. These teachers had already completed the introductory level course, which concentrated primarily on basic computer applications for teacher productivity (e.g., Word, Excel, Powerpoint), or an equivalent alternative. While the first course dealt with learning fundamental computer applications, EDCI 564 focused on integrating educational technologies in the classroom.

As a kick-off activity, we wanted the teachers to see and experience first-hand a problem-based activity involving the use of technology. So, we designed a modeling activity—a short-term problem-based learning activity. Early in the semester, participating teachers along with eighteen students from grades 6-12 and six pre-service teachers from Purdue took part in a two-day problem-based learning activity involving a significant environmental problem (water quality) in the local community. The purpose of the activity was to help the teachers understand the problem-based learning process, the roles of teachers and students, and the use of technology as a supporting tool. We involved pre-service teachers because 1) they brought a high level of technology competence, 2) they could benefit from the experience themselves, and 3) this provided a vehicle for initiating collaboration between the university students and the K-12 teachers and students. We involved K-12 students because a growing body of literature suggests changes in teacher-student relationships can accompany technology integration (e.g., Ertmer & Hruskocy, 1999; Ringstaff & Yocam, 1994). We wanted teachers to work with students as co-learners in this process.

During the two-day activity, mixed teams of participants first were presented with the driving question on water quality, "What's in our water, why is it there, and what does it mean to us?" Teams designed their own investigations within the framework provided by the overarching driving question and conducted their investigations. In most cases teams traveled to field sites to collect water samples and used available water test kits to assess what was in their samples. Finally, each team produced a multimedia report of their investigation and findings, which was then shared with the other teams on the second day. Rather than teaching about technology, the emphasis in this approach was on using technology as an authentic tool to gather background information (e.g., Internet searching), collect data and artifacts (e.g., digital camera photos of field sites, Excel graphs of data), and assemble and present multimedia reports of the investigations (e.g., Powerpoint presentations). Results of an evaluation of this activity are presented below.

Following the modeling activity, the teachers participated in a semester-long in-service development program that consisted of a specially tailored version of the EDCI 564 Purdue course. The professional development course focused on development of participants' knowledge and skills to integrate technology within a problem-based context. Several activities involving the use of technology in a problem-solving context were employed during the course. For example, early in the course, participants engaged in a spreadsheet activity involving prediction of the medal times/distances for track events in the 2000 Summer Olympics in Sydney, which took place during the course. A Webquest activity was used to introduce concepts related to evaluation of websites. A web-based discussion board was utilized to give participants the opportunity to reflect on class topics and interact with peers. A history-based activity required teams of participating teachers to research and develop multimedia presentations to convince their peers of the historical significance of one decade of the 20th century. These activities were designed to demonstrate additional ways that technology could be integrated into the classroom in a problem-centered context. As a culminating course activity, participating teachers developed their own problem-based learning activities, incorporating technology, to be implemented in their own classrooms during the spring of 2001. As a means of sharing their project plans, teachers also produced websites describing their projects.
Outcomes

The two-day modeling activity was viewed as a key element of the professional development approach, because in a relatively short time it allowed teachers to experience the process, understand the roles of teachers and learners in the process, and see effective ways to utilize technology. At the end of the activity, a short evaluation form was administered to all participants. This evaluation form consisted of eight Likert-type items, five semantic differential items, and five open-ended items. Table 1 presents the mean ratings by participant group for the Likert-type and semantic differential items.

<table>
<thead>
<tr>
<th>Evaluation Item</th>
<th>Mean Rating</th>

<tr>
<td>8. Because of this project, I am more confident in my ability to do investigations.</td>
<td>3.93</td>
</tr>
<tr>
<td><strong>Semantic Differential Items</strong></td>
<td></td>
</tr>
<tr>
<td>1. Boring ... Exciting</td>
<td>1.79</td>
</tr>
<tr>
<td>2. Challenging ... Too Easy</td>
<td>3.43</td>
</tr>
<tr>
<td>3. No Fun ... Fun.</td>
<td>1.57</td>
</tr>
<tr>
<td>4. Worthwhile ... Waste</td>
<td>4.43</td>
</tr>
<tr>
<td>5. Best ... Worst</td>
<td>4.29</td>
</tr>
</tbody>
</table>

Table 1. Mean Ratings of Evaluation Items from the Two-Day Problem-Based Modeling Activity

The Likert-type items were rated by participants strongly agree (5 pts), agree (4 pts), undecided (3 pts), disagree (2 pts), or strongly disagree (1 pt). Therefore, a mean of 3 indicates undecided, while means greater than 3 indicate agreement and means less than 3 indicate disagreement. Semantic differential items were rated by participants closest to the word on the left (5 pts), closer to the word on the left (4 pts), undecided (3 pts), closer to the word on the right (2 pts), or closest to the word on the right (1 pt). Therefore, a mean of 3 indicates undecided, while means greater than 3 indicate preference for the word on the left and means less than 3 indicate preference for the word on the right.

The data for the Likert-type items in Table 1 indicate agreement with positively worded items and disagreement with negatively worded items. The strongest reactions were disagreement with item #4 and agreement with item #5. This indicates that participants did like the hands-on activities, and they liked the problem-based activity compared to what they usually do in school. Reactions to the semantic differential items indicate that participants thought the activity was exciting, challenging, fun, worthwhile, and the best.

In response to the open-ended question, "What did you like most about the activity?" participants' most common responses were working with others and learning about technology. In response to the open-ended question, "What did you like least about the activity?" responses were scattered but lack of prior knowledge and the short time frame were the most commonly mentioned. In response to the open-ended
question, "What was your favorite part of the activity?" participants cited working with others, going outside, and learning about technology. In response to the open-ended question, "List something you learned in the activity," participants mentioned science content, information about the community, and technology. Finally, in response to the open-ended question, "List some words that describe how you feel about the activity?" the most commonly cited words in order of frequency were: fun, interesting, exciting, and worthwhile. The results suggest that participants had positive reactions toward the problem-based modeling activity while learning about science and technology.

The in-service professional development course that followed the initial modeling activity was designed to adhere to principles of good professional development practice. It was school-based; classes took place each Tuesday after school, a time that was generally convenient for participating teachers, in a computer laboratory/classroom in Crawfordsville High School. It took place over an extended period of time, a whole semester. This gave participating teachers the opportunity to practice what they learned and hence grow under the coaching and guidance from the university faculty and project staff. The emphasis in the course was on integrating technology for student learning, not on learning about technology devoid of context. The course was highly collaborative; most of the problem-centered activities throughout the semester involved teams of teachers working with one another. We hoped that this course collaboration would carry over into collaboration in the classroom when teachers implemented their own problem-based learning activities.

As a culminating activity in the course, teams of participating teachers developed their own problem-based learning units for implementation in the classroom during the spring of 2001. The components of these projects included: a driving question, curriculum objectives and links to curricular standards, possible student investigations and other activities, materials and resources, and assessment. The driving questions that were developed by the teachers to guide their projects were:

- Why should we care about deforestation of the rain forest? (interdisciplinary middle school unit)
- What makes the good life? (high school English, social studies, and elementary special education)
- What is conformity and how does conforming / not conforming affect our society? (high school English and music)
- What good is math and science? (high school mathematics and science)
- What makes something strong? (middle school technology and physical education)
- What would it take to live off planet Earth? (middle school interdisciplinary unit)

Websites describing the teachers' projects are available online at: http://research.soe.purdue.edu/challenge.

Conclusions

Problem- or project-based learning is a promising approach that involves students investigating complex problems in authentic contexts. Technology can play an important role in this process as a tool for gathering information, analyzing and representing data, and communicating results. How can teacher educators best prepare teachers to utilize this methodology in the classroom? This project utilized an approach that involved modeling problem-based learning via a realistic activity involving in-service teachers, pre-service teachers, and students. Evaluation data showed that teachers and students alike viewed this modeling activity positively. In a short period of time, this activity was able to convey the nature and components of problem-based learning to the participating teachers. Following this activity, a semester-long in-service course that was collaborative, school-based, and focused on integration introduced additional examples of problem-based learning and allowed participating teachers to build the conceptual and skills framework necessary to construct their own problem-based curricular units. This appears to be a promising approach for helping teachers to integrate problem-centered applications of technology in their own classrooms.

Multimedia in the Classroom With PowerPoint and VBA

David M. Marcovitz
Education Department
Loyola College in Maryland
United States
marco@loyola.edu

Abstract: This paper describes the results of a pilot project to use PowerPoint and Visual Basic for Applications with a class of teachers taking Multimedia Design in the Classroom. Most participants in the class were enrolled in a masters program in Educational Technology and had completed Introduction to Educational Technology in which they learned basic multimedia functions of PowerPoint and HyperStudio. Few participants had more than beginner-level computer programming background but all were able to use and modify a limited number of Visual Basic for Applications tricks to create fully interactive multimedia projects.

Introduction

Interactive multimedia needs a mechanism to facilitate interactivity. Most basic tools, even modern word processors and spreadsheets, support the incorporation of a wide range of media, such as graphics, sound, and video. But few tools support interactivity, and of those, even fewer are within the reach of classroom teachers. Professional tools are cost-prohibitive, and many tools require technical skills that are beyond the level of even technology-savvy teachers. A graduate-level class in multimedia design that is geared to classroom teachers must strike a balance between sophisticated technology and accessibility; i.e., we want to stretch the teachers but not to the point that they cannot use in their own classrooms what they have learned.

PowerPoint is a tool that is widely available in schools because it is part of the Microsoft Office suite of tools. The basics of PowerPoint are very easy to use, and many teachers are already using PowerPoint in their classrooms. With the advent of PowerPoint 97/98 (and with little change in PowerPoint 2000), PowerPoint supports the basic tools of interactivity. PowerPoint slide shows no longer are limited to linear presentations. With buttons and hyperlinks, they can be full hypertext documents that provide links to multiple paths (Cavanaugh & Cavanaugh, 2000). This is a start, but it is not enough.

The true power of interactivity comes with scripting. Fortunately, PowerPoint comes with a sophisticated scripting language: Visual Basic for Applications (VBA). With VBA, the possibilities are endless. VBA is a complete object-oriented programming environment. VBA can provide interactivity with buttons, textual input, variable feedback, and much more.

"Wait!" I hear you cry. VBA is a sophisticated programming language. Can teachers become programmers? Certainly, many teachers can become programmers—and Galloway (1999) even argues that all teachers should have a foundation in programming—but the goal is not to create programmers but to create scripters. A programmer learns all the subtleties of a computer language in minute detail. A scripter might learn some of the details of the language but, more importantly, learns a few easily-modifiable scripts that can perform important tasks.

Scripting might not be a useful technique when used with a stand-alone programming language, but VBA can be built around PowerPoint. Content, media, and some basic interaction are already built into PowerPoint. Knowing a few simple VBA tricks, teachers can add more interactivity. By building the project around PowerPoint, teachers can use as much or as little VBA as their knowledge permits. Every VBA script is built on a framework of PowerPoint, so the basic structure of the project can be built with tools that all teachers can master easily.

This paper describes a pilot project to use VBA to enhance teacher-created PowerPoint projects in the context of a multimedia design class. The class consisted of teachers of various backgrounds, including: computer teachers, general elementary teachers, a middle school science teacher, a high school math teacher, a special education teacher, and a media specialist. Ten of thirteen of the teachers were enrolled in the class as part of a
masters program in educational technology. The teachers were asked to report on their experience with computer programming when entering the class. On a scale of zero to five (with zero indicating no experience), none of the teachers reported above a three, and almost all teachers reported a zero or one.

The pilot project was set up to study the feasibility of this approach to a multimedia design class. The basic question was whether or not teachers could successfully learn enough VBA to add a significant level of interactivity to PowerPoint projects. The paper describes why the answer was "yes" in this case, and it describes the methods the class used to make this a successful experience for the teachers.

Multimedia Design in the Educational Technology Program

Multimedia Design in the Classroom is a required class for the Loyola College in Maryland masters program in Educational Technology (see http://www.loyola.edu/education/EdTech/). Additionally, it is used as an elective by other programs in the Education Department. The Educational Technology masters program is geared toward classroom teachers in the K-12 environment who are interested in expanding their use of information and communication technology within their own classrooms or becoming technology specialists on the school or district level.

Loyola College is currently undergoing review by the National Council for Accreditation of Teacher Education (NCATE). To this end, the masters program is aligned with International Society for Technology in Education (ISTE) Standards for Advanced Programs in Educational Computing and Technology Leadership. These ISTE standards are used by NCATE to judge advanced programs (any program beyond initial certification) in Educational Technology. Multimedia Design in the Classroom is largely responsible for addressing standard 4.2 (International Society for Technology in Education, 1996):

4.2 Instructional Design and Product Development.

Candidates will evaluate authoring and programming environments for use in the classroom. They will apply instructional design principles to develop, implement, and test interactive multimedia instructional products using authoring environments.

4.2.1 use and apply more than one computer authoring and/or programming environment.
4.2.2 describe the characteristics and uses of current authoring environments and evaluate their appropriateness for classroom applications.
4.2.3 describe the characteristics and uses of current programming and scripting environments and evaluate their appropriateness for classroom use.
4.2.4 apply instructional design principles to the design of screens, text, graphics, audio, and video in instructional products under development.
4.2.5 describe and practice strategies for testing and evaluating instructional products designed.
4.2.6 apply instructional design principles to develop substantive interactive multimedia computer-based instructional products.

The goal of the class is to provide K-12 teachers with a firm grounding in multimedia development to create their own multimedia projects for use in their classrooms and to help their students create multimedia projects. Additionally, as per the ISTE guidelines, this class gives a basic introduction to instructional design principles. Since the goal of the masters program is not to create professional instructional designers or professional multimedia designers, the above ISTE guidelines can be met within the context of a one-semester class. However, the class covers a wide range of topics, so the appropriate selection of a textbook and supplementary materials is crucial.

Textbooks

Several textbooks provide a good foundation in Multimedia Design, including Ivers & Barron (1998) and Agnew, Kellerman, & Meyer (1996), which both concentrate on multimedia uses in the classroom. Ivers and Barron (1998) was chosen because of its strong emphasis on an instructional design model that easily can be applied to the
classroom. While the text mentions specific technologies, including software and hardware tools, its strength is its emphasis on general principles of instructional design and multimedia design, and how these principles can be applied to the K-12 classroom. The next challenge was to supplement this text with material that can help the teachers use specific technology (in this case VBA) to create working projects.

This is a hands-on technology class in which teachers are not only required to understand general principles but also apply those principles to the design and development of a significant multimedia project. This left the dilemma of technical reference material for the programming/scripting/authoring environments used. As per ISTE standard 4.2.1 (see above), the class was required to "use and apply more than one computer authoring and/or programming environment" (International Society for Technology in Education, 1996). Previous versions of this class had used HyperStudio as the authoring environment with HyperLogo as the scripting language within HyperStudio. For this class, PowerPoint was added as an additional authoring environment with VBA used as the scripting language.

Reference books, at the level of the beginning programmer or scripter, are available for HyperLogo (see for example, Smith & Yoder, 1998; Lynn, 1995). However, no comparable books were available for VBA. VBA is a very sophisticated programming language, and reference books treat it as such (see for example, McFedries, 1999). HyperLogo is also a sophisticated programming language (which is based on the Lisp programming language used for artificial intelligence), but HyperStudio and HyperLogo were designed for schools and reference material has been developed that addresses the needs of teachers and students. Due to this gap in material for VBA, the author chose to develop his own supplementary material that brings the sophisticated power of VBA to a level that a classroom teacher can grasp without a background in computer programming.

This supplementary material, entitled An Introductory and Oversimplified Guide to Using Visual Basic for Applications for Scripting PowerPoint Slideshows, gave some background information but concentrated on specific practical applications of VBA for adding interactivity to PowerPoint. The next challenge was to create an environment in which teachers with differing technical backgrounds could learn from each other and learn to use a difficult technology (VBA) that was different from anything that most of them had ever used.

Partners and Templates

One premise of the class was that teachers would work together, if not throughout the entire class, at least when working on a significant final project. To this end, the first project (completed in class on the first day) was titled the Pick-A-Partner PowerPoint Project. This project served several purposes:

(1) It introduced some of the potential of PowerPoint as an interactive tool.
(2) It served as an icebreaker by allowing the teachers to meet each other using the technology.
(3) It introduced the concept of templates, an important concept in a multimedia design class.

All teachers in the class had some familiarity with PowerPoint. On the first day, the basics of PowerPoint were reviewed with careful attention being paid to incorporating media, buttons, and hyperlinks (to other places within a PowerPoint slide show and resources outside a PowerPoint slide show). These skills were then used to fill in the media and links in a PowerPoint template. The template included places for personal information, technical skills, and final project ideas. Although this was done at the very beginning of the semester, teachers were immediately encouraged to think about topics for final projects.

To start the second day of class, each teacher went through all the other projects. As they went through a project, they were asked for certain information, including their names, whether or not they were interested in working with the project's creator, and any project ideas they had. This information was added to the slide show in such a way that only the show's creator could access it. When everyone had gone through everyone else's slide show, each teacher returned to their own show to peruse the comments made by potential partners. This acted as an icebreaker and as a mechanism for choosing groups for final projects.

The power of this template project was not merely that the teachers only had to concentrate on the media and content. This, in itself, was a powerful introduction to the template concept. But even more powerful were features that were built into the template that the teachers could not, at that point, do themselves. All interactive features were added with VBA, providing a powerful example of the use of VBA in PowerPoint. The VBA code was made available to teachers and studied as part of the class.
Programming Concepts

VBA is a programming language. To fully understand it and take full advantage of it, one must understand basic programming concepts. While the goal of the class was not for teachers to fully understand VBA or take full advantage of it, introducing certain programming concepts was beneficial. This was always done in the context of performing a specific task. With the emphasis on scripting, the theme was script first; ask questions later. That is not to say that questions were not welcomed at any time, but that each VBA script that was introduced was introduced to either be useful in and of itself or with only minor modifications. Without understanding the programming concepts, teachers could use the script unchanged. Significant programming concepts, such as variables, loops, and if-then statements were then introduced as part of the working scripts. As teachers gained more knowledge about these concepts, they could modify the scripts to tailor them for their own purposes.

Some teachers left the class with only a vague understanding of key programming concepts. These teachers were only able to make minor modifications to scripts that were given to them. Others were able to grasp many programming concepts and were able to make significant modifications to scripts to do new and interesting things with VBA.

Simple Script Examples

The scripts that were introduced to the class started out simply. To start with, teachers put simple message boxes on the screen:

```vba
Sub SayHello()
    MsgBox("Hello")
End Sub
```

This quickly advanced to scripts that could ask for user input:

```vba
Sub YourName()
    userName = InputBox(prompt:="Type your name", _
        Title:="Input Name")
End Sub
```

The input was then used in a message box:

```vba
Dim userName As String
Sub YourName()
    userName = InputBox(prompt:="Type your name", _
        Title:="Input Name")
End Sub

Sub DoingGreat()
    MsgBox("You are doing great, " & userName)
End Sub
```

Along the way, the concept of variables was discussed.

By tying YourName to a button on the first slide (possibly adding to that a simple script to advance to the next slide), the DoingGreat feedback could be placed anywhere in the slide show. This feedback would include the user's name.

With simple scripts, like the ones above, and more complex scripts that were introduced throughout the semester, teachers learned how to add objects (such as drawn shapes and text boxes) directly to PowerPoint slides, how to add slides, how to modify the text on a slide, how to keep track of right and wrong answers in a quiz, and how to provide feedback on a menu slide to indicate which topics had been visited by the user. All the while, issues
of instructional design, graphical design, interface design, student-created multimedia projects, assessment, and much more were discussed.

Projects

Teachers demonstrated their skill with two VBA projects. The first project required the teachers to use a few of the VBA tricks they had learned. This was a technical project, where they were to show that they had mastered a few tricks. They had to include at least four tricks from this list:

- Student inputs a name which is used in feedback.
- Student answers some questions and is given feedback as to the number of correct answers.
- Objects are added to slides.
- Text is added to or modified on slides.
- Text color, font, size, or style is modified.
- A menu gives feedback as to what topics have been visited.
- Timed functions are used (with VBA, not standard PowerPoint timing).

For the most part, the VBA code for these tricks could be taken directly from class handouts. If this were a computer programming class, simply taking code from a handout would be discouraged. However, with the emphasis on scripting, mastering four or more of these tricks leaves a teacher with a limited but powerful set of tools to add interactivity to PowerPoint slide shows.

The final project was the most significant accomplishment for the class. Teachers worked alone or in groups of two, three, or four. In the final projects, teachers applied what they had learned about interactive multimedia and VBA to a significant educational project. Some groups chose to create templates for their students; other groups chose to create interactive projects that were complete, and others chose to do both. Teachers had a choice of using HyperStudio with HyperLogo or PowerPoint with VBA for their final projects. All groups chose PowerPoint because it was more accessible to them at home and in their schools and because the older version of HyperStudio we had available in class was not as stable as PowerPoint on the Windows platform.

Work on the final projects included discussions of how to create and assess a group project, instructional design, and storyboarding (a storyboard was required in advance for each final project). The class emphasized learning while doing and tying important concepts like these from the textbook to real projects.

In terms of VBA, the amount and complexity of VBA used varied from group to group. The goal was to have everyone comfortable with a few basic tricks. This was clearly demonstrated in the final projects as each group used at least a few basic tricks. More advanced teachers took VBA to the next level and were able to modify scripts used in class and write a few original scripts to create powerful interactive effects. The most common uses of VBA were for users to add their own feedback to a presentation and for quizzes.

For example, the Canada group created a template for their students about the provinces of Canada. They modeled their use of VBA after the Pick-A-Partner project. Each group of their elementary students would fill in the information about their chosen province into the teacher-created template. Other students would then have the opportunity to go through their slide show and give feedback about the information they learned about that province.

The Economics group created a project with several parts, including a tutorial and quiz for elementary students. The tutorial used VBA to keep track of menu selections, insuring that the students had visited all sections of the tutorial before proceeding to the quiz. The quiz used VBA to keep track of individual scores and provide feedback about numbers of right and wrong answers.

While these projects based their VBA on the tricks presented in class, the teachers expanded these tricks and demonstrated an ability to do a limited amount of original programming.

Conclusions

For the professional multimedia designer, PowerPoint is probably not the right choice. However expensive and complicated tools are not common in schools. Using PowerPoint as a framework, teachers are able to add as much or as little interactivity as their skills allow and their needs require. Thus, PowerPoint is an appropriate multimedia tool for teachers.
The goals of the Multimedia Design in the Classroom class included providing skills that teachers could use to create their own multimedia projects and provide skills to allow them to have their own students create multimedia projects. The first goal clearly was met. All teachers in the class were able to master a few basic VBA tricks that they could use to add true interactivity to their PowerPoint slide shows.

The second goal was partially met. The teachers learned to create multimedia projects that students could use. They also learned to create multimedia assignments in which their students could create multimedia projects. However, none were confident enough to try to get their students to script with VBA. The largest extent to which VBA would be used by these teachers' students was to fill in templates with VBA already scripted by the teacher. Perhaps as the teachers use VBA more on their own, they will gain the confidence to allow their students to create their own interactivity with VBA.

Overall, the class was a success. The emphasis on interactivity allowed teachers to think beyond media to make projects that engaged students and were more than page-turners with pictures.

Reflections on the Impact of ICT on Teacher Education

dmckibben@eircomlearning.ie

Abstract

"New ideas of any worth to be effective require a in-dept understanding and the development of skill and commitment to make them work" (Fullan, 1993)

The attitude of the teacher has been identified as a crucial factor in the successful integration of ICT in education as has the role of teacher education. This paper reflects on the learning experiences of a group of teachers - two in particular - during the first year of a Masters programme in the area of ICT in education. Supported by data gathered from the class mailing list, video taped reflection, face-to-face interviews and informal discussion this paper focuses on how student-teacher attitudes to the role of technology, and perspectives on their own learning, changed over the course of the first year.

Background

The course in question is a masters degree in the area of IT in Education run jointly by the Departments of Computer Science and Education in Trinity College Dublin. The first two authors are students on the course the second two instructors. The stated aim of the course is to enable graduates "to play a leadership role in the area of IT in education". The degree is offered on a part-time basis over two years and is structured as a taught component followed by a substantive research dissertation leading to the degree of Master in Science.

The first cohort of twenty-eight students started in October 1999. Students were selected on the basis of academic qualifications, teaching experience and some by interview. They were characterised by a mixed ability skill set in terms of technical proficiency. Most of the students on the course were returning to formal education after many years. Assessment of student learning during the first year was via nine assignments, some done in groups, some done independently. Four assignments were given at the end of term one, four at the end of term two and one at the end of term three. The final assignment consisted of a capstone, or meta-assignment, and required a ten thousand-word dissertation and an IT artifact which was either a piece of educational multimedia or a website to present the findings of the meta research. A strong sense of community is one of the hallmarks of the class and students in the class refer to themselves as mite99 after the name of the class mailing list mite-99 (Masters in IT in Education class intake 1999). The second intake are referred to as mite00.

The research reported here focuses particularly on three snapshots of the class taken in October 1999, June 2000 and October 2000. (It is from these sources that most of the student, and staff quotations, used in the rest of this paper are taken.) We attempt to identify positive and negative learning outcomes and how learning changed over time. The course aimed to provide an environment where students learned with and about technology and we explore how this changed not only the learning outcomes but also more fundamentally the learning process itself.

Summary of Findings

It was found that there was a marked contrast between the students’ learning and the attitude to learning at undergraduate level and that on the Masters course. Overall the learning experience on the Masters was a more positive one than that at undergraduate level. The reasons for this are explored fully in the body of the paper but a contributing factor was certainly the smaller class size which allowed the development of interpersonal relationships among the entire class not possible at undergraduate level, where up to five hundred students took some courses.
As elaborated upon below the use of ICT had a significant effect. In particular the use of a simple asynchronous communication medium, i.e. a class e-mail list, contributed significantly to the development of a learning community as it allowed students to engage in anytime, anywhere communication with their peers and thus helped learning to take place in a scaffolded environment of peer support and support from lecturers.

Teaching strategies were significantly different from those at undergraduate level, where the didactic model was the norm. On the course the "lecturer as learner and learner as lecturer" model was the norm. This was evidenced through the use of video for lecturer self-analysis and reflection in an effort to learn more about teaching through and with ICT. Course lecturers acted as learners by auditing courses given by other lecturers. This allowed lecturers to experience the course as a learner and is typified by a remark made by one of the course lecturers on being interviewed as part of the reflection process at the end of the first year - "I think I've learned more as a learner than a teacher". Students often acted in the role of lecturer themselves by giving classes to their peers and to the lecturers. The group dynamics and the fact that a thriving learning community existed allowed students the confidence to do this. This confidence further allowed students on the course to make even greater strides in the fields of education and business. One student on the course is now currently lecturing on this year's first year intake, while two other students have left teaching and taken up jobs in ICT/Education companies. Still others have taken career breaks and become involved as researchers in the University's Center for Information Technology in Education (CRIE).

The body of this paper argues that different learning and teaching strategies facilitated by the use of Information and Communication Technology characterised this positive learning experience.

October 1999 Snapshot

At the outset the class were highly committed with one student commuting from a distance of over 200 km away twice, and sometimes three times, a week to attend lectures. There was a mixed ability skill-set among students in relation to technical proficiency. This proved daunting and some students felt intimidated by the high level of experience and skills of their peers. There were students who were familiar with Java programming or had completed degrees in computer science while others were just mastering Microsoft Word! Many students were returning to learning after a long period of time and were motivated to learn because of the commitment they had made in terms of time and money. There was a willingness to use new learning tools in the quest for IT knowledge. The high attendance at lab sessions was an indicator of this willingness. Students on the course, as educationalists and parents, wanted to equate their IT skills with those of their counterparts in the business world and with those of their own students and children. Both of these aspects emerged clearly when students introduced themselves to the class at the first lecture.

At this early stage one of the main problems experienced by students was the originality of the type of learning process. Students were faced with the prospect of engaging with new technology, not just the internet but MOOs (Multi User Object Oriented), MUDs (Multi User Domains), SMART boards, digital video etc. More fundamentally students were faced with new types of learning involving collaboration, communication, presentation, publication, sharing and above all reflection on their own work and learning process. For most it was a new way of learning which was initially frightening, and off-putting, and there was some reluctance on the part of students to engage with this new methodology.

"We were exposed to completely different ways (of learning)."

"We were coming from this drastically different learning environment to this new learning environment which was totally alien. I was frustrated by it."

This reluctance was exemplified at the beginning of the year when it was noted that there was very little engagement in the mite99 e-mail list. In October 1999 there were approximately eleven e-mails sent and these came mainly from the lecturers. This stood in marked contrast to October 2000 when forty nine e-mails were posted. This was also shown in students' lack of enthusiasm with regard to the use of digital video in first term assignments.
This reluctance to engage with this new type of learning was further exemplified by the lack of participation in the online debate which the class was invited to participate in. Students were required to obtain a login name and password by filling in an online form and submitting it to the debate organisers. It was a course requirement that students participate, however only 15% of the class did so. When the class was queried as to why they thought the participation rate was so low some responded that the debate took place on a Saturday and they wisely (in their opinion) chose to remain in bed! More seriously it was remarked that this type of activity was too daunting and ambitious for those who had little or no experience of using the Internet, in particular engaging in online debate with people who had done so before.

One particular lecture in October 1999, introduced the concept of MOOs. Students had no prior knowledge of using MOOs for learning and it was introduced without much scaffolding. Instead the focus was on discovery learning which as not well received at this point in the year. It was later discovered that the reason for this was because students did not fully understand the meaning of the task or the concept of MOOs. Students became increasingly confused and their desired learning outcomes were not achieved. Reference to a log of this particular MOO session is testament to this. There were lots of jokes and chit chat unrelated to the lesson objectives with the reflective comments being of the form “These (MOOs) are dumb”.

June Snapshot

At this stage of the year students had completed the taught component and were completing their end of year capstone, or meta, project. As was to be expected the quality of the contents, and production, of assignments was of course higher than that found during the year1. By now students were using more sophisticated tools and experimenting with programming. Netscape Composer, so highly prized in the first term, was left for dust with students using tools such as Dreamweaver or Flash to produce their artifacts which ranged from presentation of research assignments in the form of websites to the development of educational software.

June also witnessed the development of higher expectations and motivation to continue experiencing success on the part of students. This was borne out by a readiness to become involved in ICT related projects outside the realm of the course. In particular some students became involved in research projects being carried out by CRITE which led to one student from the course sharing a stage at a conference in Dublin with Nicholas Negroponte, the Director of MIT's Media Lab. Motivation and commitment was also borne out by students initiative to learn the Dreamweaver package even though it was not taught on the course. This was done through peer tutorage and independent learning. By August the motivation had still not waned and many students embarked on commercial courses to further develop their web authoring skills.

There was far greater participation in online discussions at this stage with over 90% being active participants. Many of the emails at this point expressed support and sympathy because of the stress and strain being experienced by students in relation to the meta assignment. (“Don't mention the meta” was a common response to queries about work in progress.) The email list offered an important support structure to students, particularly at this stressful time. “Keep up the good work” and “Nearly there” were common messages to the list. “Where's the barbecue happening” was the question on everyone's lips after the “meta madness” had ended!

There was a willingness to share resources both in class and online particularly because the meta assignment was proving so time consuming and stressful. People used the class mail list to share resources, found online, with fellow students. As soon as someone learned a new skill it was passed on to the class, the mastery of digital video editing being a case in point. Books, journals and feedback on individual assignments were offered. Most students felt more confident and had better self esteem. This resulted in even more access to assignments and work in progress as people wanted to share and reflect and had the confidence to do so in a safe learning environment.

1 So high in fact was the standard that the external remarked that many of the Meta assignments were the equivalent of Masters dissertations, such was the amount of work that had gone into them.
October 2000 Snapshot

At the start of the second year of the program a number of career changes took place among the original cohort. The first two authors had left formal teaching and embarked on new career paths. Others had extended career breaks to focus on research, while others are considering the possibility of pursuing PhD degrees. Most interestingly, a number of the original cohort are now engaged in lecturing course modules to the first year students.

Enthusiasm has not waned, evidenced by the fact that more than half of the mite99 class turned up on the first night of lectures for mite00, to welcome the new class and share their experiences of learning over the past year. It was remarked by mite00 students and one of the lecturers that the enthusiasm and motivation of mite99 was an inspiration to mite00. Immediately a system of mentoring was fostered between the mite99 class and the new incoming class. ICT facilitates this process as the main communication method is via email. A sharing of resources and assignments has also begun to emerge. Data from the mite00 web discussion reveals that the new intake are experiencing the same fears and anxieties as their predecessors.

"I feel overwhelmed with unfinished tasks & wonder when I will post the uncompleted strands - which are now on Floppy disc. While many of my peers appear to achieve this, my difficulty is not getting set tasks completed on the given night".

"I feel that I am lacking in technical ability compared to some people on the course".

It is our intention to map the impact ICT has on the learning of this group and to compare it with the ongoing reflections of the mite99 group. We hope to monitor the interaction between the two groups with particular emphasis on the use of email list facilitates and a virtual learning environment.

A New Type of Learning & The Role of ICT

As argued in (Margaret Riel and Kathleen Fulton, 1998) computer technology can be viewed as an effective vehicle "to transform classroom learning into learning communities with students, teachers and community members all playing a vital role in directing the course of education." The experiences described here exemplify this type of learning model with its emphasis on collaborative group based learning, lecturer as learner and learner as teacher, as alluded to earlier. Electronic communication, peer tutoring etc. have contributed to the development of a community of learners in which learning flourishs in a non-threatening, supportive environment.

Learning at undergraduate level was the antithesis of this experience. It stressed isolated, competitive endeavor in an environment where failure was not a valued learning experience.

The students' own perceptions on how ICT has impacted on their learning experiences are informative. Initially many students began the course with the perception of ICT as a 'scary' subject, e.g. "I was afraid to be left alone in a room with the computer for fear it might blow up". "I don’t know the first thing about technology. I am hearing words like operating system, ftp, ASDL, broadband and I haven’t a clue what they mean!" while some were even unconvinced as to the value of ICTs in education. "I don’t see what a computer can do that a blackboard and chalk can’t, and with far less hassle." In addition, many students had little experience of integrating ICT into the curriculum. "I have never used a computer with my students before. Number one, I have never had the opportunity and number two I would not know how to".

Students found however that their perceptions changed when they experienced success in learning and grew more confident in using ICT as a learning tool themselves. "We can see how children can benefit from our experience and that’s been very motivating". Student fear of ICT and group work was overcome by experiencing early success in learning through and about ICTs. "I remember when fellow students arrived at my house to do the first assignment. I was terrified. I had never worked in a group before where I shared my work with others and displayed it for them to comment on!" "Having received a good grade and enjoyed the experience of working collaboratively I was ready to do so again but this time without the anxiety" (A positive view towards ICT is not universally shared. "I felt there was no reward because by
the time I had finished coming to terms with the technology I was so exhausted that I couldn't enjoy the success.

Early success was crucial to the development of a positive attitude to ICTs and being motivated to continue learning. The course created a range of learning opportunities and environments, which addressed the needs of multiple intelligences and provided a framework for successful learning outcomes. Riel & Fulton (1998) argue that people of multiple intelligences working collaboratively makes a learning community interdependent i.e develops peoples strengths and competencies which leads to empowerment. "I really felt that we brought out the best in each other" one student said about collaborative learning.

A particularly interesting observation on the course to date is that students with a moderately successful experience of learning at undergraduate level are achieving higher results than many of their peers who excelled in the traditional undergraduate and even postgraduate system. Many factors may be contributing to this but one possibility is that those who are most dissatisfied with the traditional learning paradigm may feel more motivated to fully embrace a new learning environment characterized by self-direction, collaborative learning, peer tutoring and experimentation with new technology.

Motivation, combined with competence and confidence in learning with and about ICT led to increasingly successful learning outcomes as the course progressed. This development of competency in ICT was invaluable in motivating students to become involved in the transfer of learning to the global community. This was evident when an interest emerged among mite99 students in participating in conferences and projects outside the realm of the course. Fullan (1998) views this "connection with the wider environment as being critical" to successful learning.

A steep learning curve was recorded during the course. Students' learning began with Netscape Composer and PowerPoint progressing to Macromedia Flash, Dreamweaver and Java Script. Research, presentation (both orally and written), communication and collaboration skills were enhanced. Keeping pace with regular changes in technology necessitates lifelong learning. A specific example of this related to the constant revisions of software and applications used on the course. In particular web-authoring tools changed at a rapid pace.

Finally and perhaps most importantly the students stressed the importance of reflection in the learning process and how ICT facilitates this. Students revisited assignments and used their reflections as a catalyst to construct new learning situations. ICT enabled this process by facilitating rapid revision and review of learning. For example the use of video allowed immediate review of reflections on learning and thus the reflection became an integral part of the learning process itself.

Summary

This paper has briefly explored some of the reflections of students on the affect that ICT and broadly collaborative, or social constructivist, approaches to learning have had upon their own learning. The reflections are for the most part very positive. It is still however early days and we aim to continue to monitor and reflect upon the learning experience as we endeavor to construct knowledge on how to learn with ICTs.

Abstract: The second year of the professional development project was designed to facilitate the integration of instructional technology in the classroom. Twenty-five teachers in grades 3-5, from 9 different schools, participated. The project consisted of four workshop modules on technological training and five modules on development of interdisciplinary thematic units for integrating materials to achieve the Mathematics, Science and Technology, and English Language Arts New York State Learning Standards. Effectiveness of the project was determined by giving all participants a General Pre-test to determine baseline measures for each of the aspects of the Project and a General Post-test. In addition, participants in the original project were contacted one year later and were given a General Post Follow-up measure. Results indicated that the both years of the project was highly successful. The Post Follow-up showed that the positive changes achieved during the first year, endured one year later.

Introduction

The original Targeted Instructional Staff Development Project took place during the spring semester of 1999. Its major purpose was to facilitate integration of technology in the classroom. The ultimate goals were: to empower students to use technology in all phases of their education, to facilitate teachers as learners, and to achieve the New York State Learning Standards in Mathematics, Science and Technology, and English Language Arts, and to facilitate integration technology into the curriculum. The one-semester project consisted of nine separate workshop modules.

The Targeted Staff Development Project was renewed for the 1999-2000 academic year. In the second phase of the project, seventeen teachers from six different school districts participated in seven workshop modules. Four of the modules were specifically designed to facilitate integration of technology into the classroom.

The purpose of this paper is to describe the evaluation procedures used to determine the effectiveness of both phases of the project. A review of the literature suggests that the major limitation of evaluation research is the research design employed. In 1997, Bauder, Carr, Mullick & Sarner reviewed research techniques employed in evaluating effectiveness of programs and found that few employed sound research designs. As a result, the authors developed a set of guidelines for researchers that were adopted for the current study.

A pre-post test design was employed. This design is particularly appropriate for assessing both formative and summative information. Because each subject acts as his/her own control it minimizes any random influences of extraneous factors and determines the effects of the project on changes between pre and post-measures.

Previous research by Ely (1990) and Bauder (1993) has shown that there are a number of conditions that facilitate or impede implementation of educational technology. Questions were included in the questionnaires to determine if changes of perceived barriers to integration of educational technology into the curriculum occurred as a result of participating in the project.
The Evaluation of the Project

The participants in both phases of the project were given a general pre-test to determine baseline measures for each of the aspects of the project. Upon completion of the workshop modules, a general post-test, consisting of many of the same items, was administered for both phases of the project. These questionnaires provided summative information regarding the overall impact of the various modules on teachers’ responses. Pre-test and post-test questionnaires were also administered for each of the individual modules. These results were used for formative information to refine or modify the procedures and information being presented in each of the modules, if required. A post-follow-up questionnaire was also administered to the participants of the first phase of the project. Only the results of the general pre and post-tests and the post-follow-up test are considered in this paper.

The Questionnaires

The pre and post questionnaires had four common parts. Part I examined frequency of use of hardware and software, perceived importance of these technological aspects in achieving the New York State Learning Standards, and the teachers’ degree of comfort in using each of the items. Part II examined teachers’ experience with technology including the use of technology in the classroom and the specific activities for which students used technology. Part III examined the extent to which teachers integrated technology into the classroom and Part IV tapped teachers’ perceptions of barriers that impeded integration of technology into their classroom instruction. The post-test included a final section that asked teachers to rate each of the modules on three dimensions. These responses provided an overall summary of the teachers’ experiences throughout the project.

Results

Pre-Post Changes to Determine the Effectiveness of the Development Modules

Part I: Frequency of Use and Degree of Comfort Working with Hardware and Software

For summary purposes, total indexes were developed for both phases of the project and for the post-follow-up by summing the ratings for the subsets of items related to frequency of use of hardware, frequency of use of software, comfort in using hardware and comfort in using software. The average scores for each Total Index is displayed in Table 1. In both instances, teachers rated the items higher on the post-test than on the pre-test. The only exception was average comfort in using the hardware items in Phase I. The average on the pre-test (52.00) was higher than on the post-test (49.96).

Table 1: Mean scores for the indexes for total frequency of use and total comfort for hardware and software items in both phases of the project.
An analysis of variance for repeated measures using overall indexes from the pre-test, post-test and post-follow-up as the within-subjects variables for Phase I was conducted. The results of the analysis for Total Index of frequency of use of hardware and Total Index of comfort with hardware yielded one non-significant results (see rows 1 and 3 columns 3 through 5). This finding is not surprising in light of the fact that teachers continue to use the hardware they used previously. However, significant F values were found for Total Index of frequency of use of software (F = 6.72, df = 2.28) and Total Index of comfort in using software (F = 16.51, df = 2.28). Post-hoc comparisons indicate that the pre-test scores are significantly less positive than both the post-test and the post follow-up while the post-test and post follow-up scores did not differ significantly. Taken together, these results suggest that positive changes occurred as a result of participating in Phase I of the project, and remained positive even after a year had elapsed.

To examine the data for Phase II more fully, t-tests for dependent (paired) samples were performed to compare changes in the Total Indexes to determine whether or not significant changes in teachers’ responses occurred as a result of their participation in Phase II of the project. The findings from the analyses of the t-tests for the Total Index for frequency and Total Index for comfort in using hardware and software are displayed in Table 2.

</tbody>
</table>

** p < .01

Table 2: Summary of the t-tests for dependent samples on changes in total index for frequency of use and total index for comfort in using hardware and software for Phase II.

An examination of column 5 in Table 2 shows that two of the analyses yielded significant changes from pre to post testing. Rows 2 and 4 show that frequency and comfort ratings for using software were significantly higher at the completion of the project than at its onset. However, two of the t-test failed to achieve significance. No significant changes occurred in the teachers’ overall ratings of frequency of use of hardware or level of comfort in using the hardware at the end of Phase II of the project. This finding is not surprising in light of the fact that the types of hardware used tended to be the same types that teachers reported having experience with prior to the project. It appears as though the frequency and comfort levels in reference to hardware were not impacted by participating in Phase II of the project.

Part II: Changes in Experience with Integrating Computing into the Classroom

Teachers were asked to rate their experiences in dealing with technology in the classroom. For Phase I of the project, teachers responses yielded a pre-test mean total index of 42.40, a post-test mean total index of 59.47 and a post-follow-up mean total index of 61.73. A repeated measures analysis of variance on the total index for use in the classroom achieved significance. The post-hoc test indicated that the significant difference was caused by the lower scores on the pre-test while no significant differences occurred between the post and the post-follow up evaluation. These results show that teachers tended to integrate computing into the classroom significantly more after participating in Phase I of the project. In addition, these significant changes endured one year later.

Changes in responses to items dealing with experiences involving technology in the classroom for participants of Phase II of the project yielded similar pattern of results. The results of the series of t-tests
Part III: A Comparison of Perceptions of Teachers use of Computers in the Classroom Compared to Students.

Part III of the pre and post-tests obtained during Phase II of the project compared teachers' perceptions of frequency of various activities involving the use of technology in the classroom by the teachers themselves and by their students. Teachers believed they used computers more frequently compared to their students for organizing and storing information, for e-mail and for retrieving information from the Web. However, no significant differences were perceived between teacher and student use on text editing, creating non-visual graphics, performing calculations, and performing any of the Web related activities. In examining the ratings on each of these individual items it becomes clear that no differences occurred for one of two reasons. Teachers tended to see their level of use of computers for text editing, to support individualized learning and for remediation as similarly high. Mean ratings for these items ranged from 7.7 to 6.5 on a nine-point scale. However, teachers perceived activities associated with the development of Web pages and performing calculations as equally low for both themselves and their students.

Part IV: Changes in Perceptions of Barriers to Integrating Technology into the Curriculum.

Part IV of the post-tests was designed to re-examine the teacher's perceptions of some of Ely's (1990) and Bauder's (1993) factors that impede their ability to integrate technology into the classroom. Results from Phase I of the project indicated that teacher's perceptions of degree of impedance of integration of technology into the classroom significantly decreased for all but one perceived barrier. A Total Index of Perceived Barriers was also developed and was used as the dependent measure for a repeated measures analysis of variance for the three time periods of Phase I. The mean Total Index for Perceived Barriers was 71.13 for the Phase I Pre-test, 63.07 for the Phase I Post-test and 39.47 for the
Phase I Post-Follow up. The significant F value of 7.74, df = 2.28, p = .002, shows that the ratings changed over the time periods. The post-hoc test indicated that teachers perceived the factors as significant impediments to integrating technology into the curriculum prior to participating in the project. In addition, the perceptions of degree of impediment on the post-test were significantly higher than on the post-follow-up. One explanation for this continued reduction in perceived impediments over the three time periods is that as teachers continue to work with the hardware and software and gain additional confidence, external factors are perceived as less of an impediment to integrating technology into the curriculum.

T-tests for dependent samples were performed to examine whether or not changes in perceptions occurred during Phase II of the project. The results of these analyses displayed in Table 4 show the same pattern of results as was found during Phase I. Teacher’s perceptions of the extent to which the factors act as impediments to integrating technology into the curriculum significantly decreased after participating in Phase II of the Targeted Staff Development Project.

Table 4: Changes in perceived barriers after completion of Phase II of the project.

Part V: Overall Evaluation of Each of the Modules of the Project:

In order to obtain summative information for the impact of each of these individual modules, rather than reporting the analyses of each individual module, the last part of the Post-test asked teachers to evaluate each of the models by: giving an overall favorability rating to each, indicating the extent to which they believe that each Module would be beneficial in achieving the NY State Learning Standards and indicating the extent to which they expected to apply information from each of the modules in their future classes. These responses provide an overall summary of the teachers’ experiences throughout the project.

The results of the analyses show that teachers had a favorable impression for each of the modules for both Phase I and Phase II of the project. On a nine-point scale where a rating of 9 indicates high favorability, the average rating ranged from 6.48 to 7.88 on modules in Phase I and from 6.00 to 8.00 on modules in Phase II. The average ratings of the extent to which teachers’ believed each of the modules would help to achieve the NY State Learning Standards were also highly favorable with mean ratings ranging from 5.84 to 7.6 on Phase I and 6.00 and 7.87 on Phase II. Ratings of the extent to which the teachers expected to apply information from each module in their future classes showed a similar pattern of results. The mean rating for each module ranged from 6.4 to 8.0 on Phase I and from 6.0 to 7.93 on Phase II.

An analysis of variance for repeated measures using teachers’ overall ratings for the eight modules as the within-subjects variable, failed to achieve significance on all three of the sets of ratings. These
findings indicate that teachers' overall ratings of the modules were not significantly different from one another and tended to be consistently high.

Conclusions:

The results clearly indicate that both phases of the Targeted Instructional Staff Development Project were highly successful. There were three major sets of findings. First, the teachers' responses for both phases indicate that as a result of participating in the project they were using software more frequently in their classrooms than they had prior to the project. It is interesting to note, however, that there were no changes in frequency or comfort of using hardware. It appears as though the project required teachers to use only the types of hardware with which they already had experience and felt relatively comfortable in using. Second, teachers believe that these activities helped them to learn new ways to integrate technology in the classroom and they felt more confident in using technology themselves and in guiding their students in the use of technology at the completion of the project. The third major set of findings showed significant change in perceived barriers to the integration of technology in the classroom. Factors that had been perceived as barriers prior to participating were seen as significantly less of an impediment as teachers gained new experience and knowledge about technology and learned new strategies for integrating technology into their curricula. This finding is particularly interesting since few of the activities within the project addressed the perceived barriers directly. The one year post-follow-up of teachers who had participated in Phase I of the project indicated that the significant changes that resulted from participating in the project maintained one year later.

Participants did identify several limitations of the project in their post-test comments. Specifically teachers felt that the activities were too concentrated and there was too little time to deal with the material adequately. They also indicated that a severe limitation to integrating technology in the classroom is the lack of technical support when they returned to their schools. Future projects should therefore attempt to address these difficulties.

Abstract: In order to meet the challenge of teacher education responsive to the integration of the newer electronic technologies, the Integrating Technology in Schools (ITS) Program leading to a Masters of Education in Curriculum and Instruction was developed. The ITS Program is structured around a cohort process that supports students finding common ground around a shared set of experiences, knowledge, readings, activities, and support systems. This paper presents a summary of data obtained during the 1999-2000 ITS Program and examines 1.) changes in participants' stages of concern, 2.) changes in participants' self-reported frequency of technology use, 3.) changes in participants' self-report concerning collegial interactions, 4.) changes in participants' summary of assigned technology use in their classrooms, and 5.) conversations with participants. Examining these changes enabled the authors to discuss the relationship between changes in attitude and classroom practice.

Meeting the Challenge: The ITS Program

In order to meet the challenge of teacher education responsive to the integration of the newer electronic technologies, the Integrating Technology in Schools (ITS) Program leading to a Masters of Education in Curriculum and Instruction was developed. The ITS Program is structured around a cohort process that supports students finding common ground around a shared set of experiences, knowledge, readings, activities, and support systems. Each group shares a common area of inquiry – one that centers on models, methods, and processes that support the incorporation of technology into educational practice. As teachers enter the Program, their most pressing goals center on learning to use the newer electronic technologies. Participation in the ITS Program, however, leads not only to technological expertise but to a consideration of the social, cultural, political, and epistemological impacts of these technologies. Participants are encouraged to wrestle not only with how to use these technologies but also with their meaning for the practice of education (Norton, 1994).
Since its inception, the impact of the ITS Program on the attitudes of participants has been repeatedly studied. Sprague (1995), for instance, used an ex post facto survey/interview design to investigate the effects of the ITS Program on participants' self-reported use of a variety of instructional strategies as well as their stages of concern related to the integration of technology as a change or innovation. She reported a significantly higher self-reported use of technology in their classroom for ITS participants over a control group. Additionally, those who had completed the ITS Program expressed concerns related to understanding the consequences of technology and collaborating with peers related to the integration of technology as opposed to higher concerns among the control group about basic awareness and information. Norton & Sprague (1996) reported similar changes. Using a pre/post design, they reported that ITS participants significantly changed their perceptions of the role of technology to support teaching and learning as well as shifting from awareness and information concerns to concerns related to consequences and collaboration. In addition, open-ended questions revealed a self-reported increase in leadership activities related to technology integration.

Examining the Relationship between Attitudes and Practice

Research suggests that the ITS Program plays a significant role in attitude. Yet, no data exists to examine the impact of the Program on actual classroom practices of participants beyond those self-reported on surveys. In the past, collecting such data was difficult because of the unpredictable nature of access to technology. In the early years of the ITS Program, many participants had no access to technology. In later years, many teachers were limited to computer labs in their schools with difficulties in regular or sustained access to these resources. Because of these irregular and unpredictable access problems, it was difficult to assess the relationship between attitude changes reported on surveys and actual classroom practice. In August, 1999, a group of 24 teachers began their participation in the ITS Program. Unlike any previous group, this group of teachers was teaching in a school district that had implemented a major technology initiative. ITS participants were teaching in schools where all classrooms had four, Internet connected computers. The time had come to ask the question: when attitudes change, do changes in practice follow?

Of the 24 original participants, all remained in the program. At the beginning of the program, four of the participants were assigned to schools as Technology Resource Teachers (TRTs). A fifth participant assumed this role during the course of the program. In addition, two participants were specialty area teachers – one in art education and one in music education. These seven teachers were eliminated from the research pool because they did not have regular, sustained classroom responsibilities. Thus, the final subjects for this study were 17 classroom teachers. Seven participants were elementary classroom teachers; four were middle school classroom teachers; and six were high school teachers. The subjects’ averaged 12.3 years teaching experience, ranging from 1 to 28 years.

In order to answer the question – when attitudes change, do changes in practice follow, a pre/post survey was administered to the 1999-2000 participants. The pre survey was administered at the group’s first meeting in August, 1999. The post survey was administered 10 weeks before completion of the Program in October, 2000. The survey was divided into two parts. The first part asked about frequency of technology use and the frequency of collegial interactions related to technology planning. The second part of the survey asked participants to complete the Stages of Concern Questionnaire (Hall, George, and Rutherford, 1998). A third section was added to the post survey asking two open-ended questions: what are obstacles you experience in using computers to support teaching and learning and what are some of the enabling things that support you in using computers to support teaching and learning. Finally, participants were asked to summarize assigned classroom use of computers each Friday for two four-week periods. These teacher summaries were collected during a four-week period in October, 1999 and again in October, 2000.

Changes in Attitude: The Stages of Concern Questionnaire

Participants’ responses to the thirty-five items on the pre and post Stages of Concern Questionnaire (SoCQ) were grouped by relevant stage, totaled and converted to percentile scores using guidelines in the SoCQ manual. The stage reflecting the highest percentile score for each participant was identified. The stages of highest concern are presented in Table 1, and averaged percentile scores for the group are presented in Figure 1. Upon beginning the ITS Program, the largest number of participants expressed personal concerns followed by those participants who expressed information needs. In addition, expressed concerns about consequences for
students, collaboration with peers, and refocusing were lower. This profile illustrates normal, interested nonusers who are somewhat aware of and concerned about the role of classroom computers integrated with teaching and learning. This would be an expected profile for those entering the ITS Program. Post survey scores indicate unchanged awareness, information, and personal concerns as well as demonstrating increased concerns relevant to consequences for students, collaboration with others and refocusing, that is, concerns that reflect ideas about seeing their ideas put into practice, tried out, or ideas to improve the use of classroom computers to support teaching and learning. As demonstrated in the figure reflecting group percentile score averages, this pattern holds true for the group as well as for individuals.

**Table 1. Highest Stage of Concern by Number of**

It is clear that the concerns of participants changed over the course of the ITS Program. Intuitively, one would expect awareness, information, and personal concerns to lower as participants shift from a nonuser to a user profile. However, it is not uncommon for the Stage 0 concerns of established users to rise. Experienced users tend to be more concerned about other things in their lives. Examining the individual Stage 0 items may identify one reason for this. Item 21, for example, which was rated as "somewhat true of me" by all participants, states "I am completely occupied with other things." Individuals who are more experienced, comfortable, and confident users tend to shift their concerns to other aspects. They therefore report very directly that things other than integrating technology with teaching and learning are of concern to them. After looking at self-reported use of technology, participants' logs of assigned computer activities, and conversations with participants, we will return to discuss what might have replaced integrating technology in schools as a concern.

**Changes in Practice**

**Participants' Self-Reported Use of Computers**

To determine if participants' changes in concerns were reflected in their use of classroom computers, the first part of the survey asked participants to respond to four questions: 1.) student use of a variety of
computer applications, 2.) frequency of discussion with other teachers, 3.) student use of computers, and 4.) primary goal for classroom computer use. Results from the questionnaire are reported in Table 2. As reported in the table, self-reported use of a variety of applications shows a consistent shift toward more frequent use. There are, however, several notable exceptions. At the beginning of their program, 70 per cent of the participants reported frequent use of word processing. On the post survey, this declined to 39 percent with a rise to 46 per cent from 12 per cent in the occasional category. Similar shifts can be noted for use of the Internet and for the Other category. While not inherent in the raw data, it is likely that two factors influenced this shift. One, participants became more aware of and able to use a larger variety of applications and, thus, were not dependent on one or two applications. Second, participants became more realistic about the benefits and limitations of particular applications and their role in supporting teaching and learning.

Participants' self-reported student use of computers also shows an important shift. On the pre survey, 35 per cent of the participants reported their students' daily use of computers while only 27 per cent of participants reported daily use of computers by their students, suggesting no change. However, in the 2 to 4 times a week category, participants' students' use of computers shifted from 18 per cent on the pre survey to 60 per cent on the post survey. It is possible to interpret this as an important shift toward both more frequent use of computers and more realistic and planned use of computers rather than use of computers just to be using them. Participants also reported increases in conversations about hardware, software, curriculum, and issues. Eighty per cent of the participants reported frequent or occasional conversations with colleagues.

Participants' Logs of Assigned Computer Activities

In October of 1999 at the beginning of the ITS Program and again in October of 2000 nearing the end of the ITS Program, participants were asked to submit a log of computer activities assigned to students. Upon examination of the data, it became clear that all participants had not submitted complete sets of weekly assignments. However, thirteen complete sets were available. The most remarkable aspect of these reports was that six of the thirteen participants reported no computer use during the four-week period in October of 1999.

Table 2. Self-Reported Use of Classroom Computers
Thus, nearly half of the participants were not using the four computers placed in their classroom at all. Of the remaining seven, one participant reported only teacher/administrative use of the classroom computers. Of the six who reported student use of computers during the four week period in October of 1999, three reported that their students had used the Integrated Learning (skill building) System mandated by the school district, three reported Internet use, one reported using PowerPoint, and two reported using word processing or desktop publishing programs. Things were very different during the final four-week period in October of 2000. All thirteen participants reported weekly computer use. Use during this period included one participant who used a computer simulation, one who used Logo programming, one who used HyperStudio, one who used a web-based editor, one who reported using a graphics program, one who used digital cameras and scanners, six who reported using PowerPoint, and all thirteen reported using word processing programs and the Internet. Clearly, patterns of use had changed.

Responses to Open-Ended Questions: Obstacles and Enablers

On the post survey, participants were asked to respond to two open-ended questions. Their responses to these questions are reported in Table 3. When asked what obstacles they experienced in using computers to support teaching and learning, 47 per cent of the participants mentioned challenges associated with the management of classroom computers and 41 per cent mentioned challenges associated with software including inadequate software availability and disagreements with software decisions made at the school district level. When asked about things that enabled their use of computers to support teaching and learning, 88 per cent of the participants mentioned peer support including building TRTs and fellow ITS participants and 41 per cent mentioned educational opportunities including staff development and the ITS Program. Although only mentioned by 18 and 12 per cent respectively, participants also mentioned their own personal confidence, success, and desire as well as recognition of student successes and enthusiasm for computer supported learning.

Table 3. Reported Obstacles and Enablers in the Use of Computers to Support Teaching and Learning

Conversations with Participants

In their final semester, the group focused on issues related to leadership and change. Participants studied and discussed strategies for creating change, for promoting learning communities within their school and school division, for coping with criticisms related to computer use, and for advocating changes consistent with their emerging vision of teaching and learning. During the course of these discussions, a number of concerns arose. Participants expressed concerns about the decision-making process within their school division, particularly as related to who made decisions about software purchases and policies, why the use of Integrated Learning Systems was mandated without teacher input, how Internet access was managed, and how hardware was configured in classrooms. The general feeling among participants was that much decision-making was done at the district level with little attention given in that process to teachers’ needs and visions or even to students’ learning needs. A second area of considerable concern among participants was the difficulties associated with implementing teaching and learning that capitalized on the power and possibilities of technology within a district and state culture that mandates Standards of Learning and high-stakes, multiple choice testing. Finally, while participants recognized the need for planning and collaborating time in order to implement needed curricular and instructional change, they believed that the reality of institutional and systemic structures made such time minimal or nonexistent. Participants felt that their ability to implement innovative practices would not drastically improve until provisions were made for collaborative planning activities. Concerns such as these may well account for the continued high scores on the SoCQ in Stage 0 – Awareness.
and Stage 2 – Personal. While nonusers have concerns about the integration of computers with teaching and learning and “self” concerns related to impacts on their own practice, the high awareness and “self” concerns have, for these participants, become different in nature. Participants have shifted concern to the impact of issues like district decision-making, standards, and time (continued high Stage 0 - Awareness concerns). Additionally, these systemic concerns are reflected in continued high “self” concerns, increases in concerns for consequences for student learning, and identification of hardware, software and time obstacles. Thus, continued high personal concerns have shifted from personal practice to issues related to systemic concerns and their role in promoting needed system-wide changes and the impact of their efforts on student learning outcomes.

Conclusion

We asked the question: when attitudes change, do changes in practice follow? As reflected in the pre-post SoCQ comparison, participants’ attitudes did change. The group profile shifted for one of typical nonusers to one more consistent with users. This newer user profile suggests a shift to concerns related to the impact of computers on student learning, collaboration with others to promote change, and clear ideas they are interested in trying and promoting. Continued high scores on Stage 0 – Awareness and Stage 2 – Personal coupled with concerns expressed in the Conversations with Participants section can also be interpreted as demonstrating shifts from basic awareness concerns and the impact on participants’ classroom practice concerns about other issues and with concerns about their personal role in promoting change related to systemic as opposed to classroom issues. In addition, changes in attitudes are reflected in changes in practices, such as, more frequent and realistic use, primary use as an integrated part of teaching and learning, and increases in discussions with colleagues as well as increases in both the number of assignments and the variety of applications used. Clearly, there is a positive connection between changes in attitudes and changes in practice. As attitudes become more positive, there are positive changes in practice.

This positive relationship between changes in attitudes and changes in practice is not, however, as dramatic as one might hope. Although results of this research show positive shifts in actual classroom and professional practices related to the increased integration of computers to support teaching and learning, the results do not indicate a transformation in practice. Based on results of this study, it seems evident that no matter the extent of attitudinal change, there are system-wide obstacles that create a climate that is less than conducive to change. Thus, no matter how much participants profit from their educational experiences, there remain systemic issues that impede their progress toward substantial transformations in educational practice. It may well be that questions related to the effectiveness of teacher education to impact the use of computers to support teaching and learning can only be answered in the broader context of public policy. If we, as teacher educators, hope for a transformation in teaching and learning, we must become active advocates in the public arena as well as skilled teacher educators.

Abstract: Few would argue that teacher education is a central factor in realizing the potential of educational technology to influence teaching and learning. Understanding the impacts of a variety of teacher education options on teachers' concerns, self-reported uses, and self-reported collegial activities related to technology can play an important role in deciding what opportunities are most appropriate. This paper examines two graduate level options: a 12 graduate credit hour certificate program and a 36 graduate hour Master's of Education degree program. Using a two-part questionnaire, 44 teachers from the Master's of Education degree program and 247 teachers from the Certificate Program were surveyed. Responding teachers in the Master's group were matched with a responding teachers in the Certificate group using grade level/subject taught and years of experience. The resulting matched groups are compared and discussed in this paper.

Lack of teacher training is one of the greatest roadblocks to integrating technology with curriculum. Yet, most school districts spend less than 15 percent of their technology budgets on teacher training and development (Office of Technology Assessment, 1995). Yet, teachers must have substantial time if they are to acquire and, in turn, transfer the knowledge and skills necessary to effectively and completely infuse technology with the curriculum and into classroom practice (Hawkins & MacMillan, 1993; Kinnaman, 1990). However, Harvey and Purnell (1995) suggest that there is an overwhelming sentiment that schools have yet to create the kind of training and practice time teachers need in order to learn to effectively integrate technology with the curriculum. Opportunities for teachers to learn about the role of technology to support teaching and learning must do more than simply help them embrace technology; it must also anticipate classroom changes that must accompany technology's widespread use (Guhlin, 1996; Stager, 1995). If teachers are going to be convinced to change their practice and integrate technology into their teaching, they must come to understand the relevance of technology to what they do in the classroom (Shelton & Jones, 1996).

The need to provide meaningful contexts for effective teacher learning is clearly evident. When there is substantial effort and interest in learning to use technology as an integrate part of teaching and learning, teachers are supported to grow and change. As teacher educators, school systems, and universities wrestle with appropriate strategies, incentives, and content for effective teacher education, they must also confront the question - how much is enough?

Two Educational Options

In the Winter Semester, 1998, faculty in the Graduate School of Education implemented two new programs. The first was a 12 graduate credit hour ITS Certificate Program – 180 contact hours or the equivalent of 30 inservice days. Although offered as an on campus option, the ITS Certificate Program was primarily offered in collaboration with school divisions throughout Northern Virginia who were seeking to provide educational opportunities for teachers as part of a state-wide initiative for teacher technology competency.
Faculty worked with leaders in these school divisions to organize and deliver the Certificate Program to groups of 24 teachers, kindergarten through twelfth grade including specialty areas. Generally completed in about 18 months, those who chose to complete the Certificate Program with sponsorship from their school division completed five one-credit hour courses focusing on teaching and learning with telecommunications, databases, computer graphics, TV/video, and educational software. They then completed two two-credit hour courses focusing on teaching and learning with desktop publishing and hypermedia. As a capstone class, students completed a 3 credit hour capstone course, Principles of Integration. This course built on knowledge about the individual applications from previous coursework and focused on methods and models of curriculum and instruction that incorporate a range of technology tools. Some school divisions paid all tuition costs while others shared costs with those seeking to complete requirements for the Certificate. Teachers were required to apply to and meet entrance requirements established by the Graduate School of Education and were awarded a Certificate at the completion of the program.

The second program implemented in the Winter Semester, 1998 was a comprehensive, 36 credit hour Master's Degree Program emphasizing Integrating Technology in Schools (ITS) – the equivalent of 440 contact hours with no inservice equivalent. This intensive cohort program consists of four consecutive semesters of study. Cohorts are comprised of 24 practicing teachers. The curriculum for the Master’s Degree includes four, three credit hour courses that focus on teaching and learning with a range of technology tools. In addition, teacher-students take two courses that focus on social issues related to technology and education and learning and teaching. They enroll in a Web-Based Learning course, and, like those in the Certificate Program, complete Principles of Integration. Finally, teacher-students complete a course focusing on leadership and technology, a course focusing on action research, and a 6 credit hour Practicum. The practicum culminates in the presentation of an action research project to Graduate School of Education faculty. Table 1 summarizes the curriculum for each Program.

Table 1. Comparison of Courses for Certificate and Master’s Degree Program

To compare the impacts of the two programs on teacher attitudes and self-reported practices, questionnaires were sent to 247 teachers enrolled in the Certificate Program. These teachers had either just completed the Certificate Program or were nearly finished with the capstone course. Of those sent a questionnaire, 153 returned a completed questionnaire (62%). Questionnaires were also sent to 20 teachers who had completed the Master's Degree Program three months previous to receiving the questionnaire and to 24 teachers who were in the final semester of the four-semester Master’s Degree Program. Of the 44 teachers who received the questionnaire, 32 were returned (73%).

The questionnaire was divided into two parts. The first part asked about frequency of technology use and the frequency of collegial interactions related to technology planning. The second part of the questionnaire asked participants to complete the Stages of Concern Questionnaire (SoCQ) (Hall, George & Rutherford, 1998). On the SoCQ, respondents are asked to respond to 35 items on a scale of “not true of me at all” to “very true of me.” The items are grouped into seven stages (Awareness, Information, Personal, Management, Consequences, Collaboration, and Refocusing) of concern related to an innovation. In this case, the innovation was defined as the integration of technology with the curriculum to support teaching and learning.

It was determined that the most appropriate way to insure that the two groups were comparable, Certificate respondents were matched with a Master’s Degree respondent using grade level and subject taught as well as years of teaching experience. Since the number of questionnaires obtained from the Certificate respondents was so large, it was possible to match respondents fairly closely. Demographics for the two groups

1155
are, therefore, similar. 46.9 percent of the Master's group and 43.8 percent of the Certificate group were elementary teachers. 18.8 percent of the Master's and the Certificate Group were Middle School teachers. 21.9 percent of both groups were high school teachers. 12.5 percent of the Certificate group and 15.6 percent of the Master's group were technology resource teachers. Average years of teaching for the Certificate group and the Master's group was 12.25 years and 11.97 years respectively.

Summary and Discussion of Questionnaire Results

Participants' responses to the thirty-five items on the pre and post Stages of Concern Questionnaire (SoCQ) were grouped by relevant stage, totaled and converted to percentile scores using guidelines in the SoCQ manual. The stage reflecting the highest percentile score for each participant was identified. When an individual had percentile scores on two stages that were equal, both stages of concern were counted. The stages of highest concern are presented in Table 2. This table reflects a marked difference between stages of concern ranked highest by individuals in the group. The largest number of individuals (10) in the Certificate Program ranked information concerns – general awareness and interest in learning more detail – as their highest concern while 16 in the Master's Degree Program ranked collaboration – a focus on coordination and cooperation with others – as their highest concern. Clearly, respondents in the Certificate Program still felt they needed to learn more while respondents in the Master's Program felt knowledgeable and confident integrating technology to support teaching and learning and had shifted their attention and concerns to collaborative efforts to expand and implement the innovation in broader contexts.

Table 2. Highest Stage of Concern by Number of Participants

Percentile scores for each stage were averaged for each group and graphed. This strategy diminishes the diagnostic and prescriptive potentials inherent in individual profiles but provides the ability to better compare the two groups. Results are presented in Figure 1. Information concerns are highest for the Certificate group while awareness – little concern or involvement - and consequences – a focus on the impact of the innovation on students in the respondents' immediate sphere of influence – are lowest. For the Master's Degree Program respondents, the highest group concerns were collaboration with others and personal – uncertainty about the demands of the innovation and inadequacy to meet those demands. The Certificate and Master's Degree groups were most different in the Stages 4, 5, and 6 categories. The high scores in these stages for the Master's Degree group are typical of more experienced users, confident in their knowledge and ability to cope with the innovation.

Two aspects of this figure are particularly interesting. The first is the group score for the Master's Degree group on Stage 0 – Awareness. Intuitively, one would expect awareness – little concern about or involvement with the innovation - to be lower for experienced users. However, individuals who are more experienced, comfortable, and confident users tend to shift their concerns to other aspects. They therefore report very directly that things other than integrating technology with teaching and learning are of concern to them. The second is the high group concern score on Stage 2 – Personal for the Master's Degree respondents. Given the higher concerns in Stages 4, 5, and 6, the high Stage 2 – Personal concerns, like the continued Stage 0 – Awareness concerns, would not be expected.

Since half of the respondents in the Master's Degree group were still actively involved in their final semester, we took the opportunity to ask them to tell us more about their "other" and personal concerns. Participants expressed concerns about their school division's decision-making process, particularly as related to who made decisions about software purchases and policies, why the use of Integrated Learning Systems was mandated without teacher input, how Internet access was managed/blocking, and how hardware was configured in classrooms. The general feeling among participants was that much decision-making was done at the district level with little attention given in that process to teachers' needs and visions or even to students' learning needs.
A second area of considerable concern among participants was the difficulties associated with implementing teaching and learning that capitalized on the power and possibilities of technology within a district and state culture that mandates Standards of Learning and high-stakes, multiple choice testing. Finally, while participants recognized the need for planning and collaborating time in order to implement needed curricular and instructional change, they believed that the reality of institutional and systemic structures makes such time minimal or nonexistent. Thus, high personal concerns of those in the Master's Degree Program are actually reflective of challenges in designing appropriate responses to their concerns about consequences for student learning, collaboration with others, and refocusing – the need to explore more universal benefits including the possibility for major changes – not about their roles or ability to integrate technology with in their own practice.

![Figure 1. Average Group Percentile Scores by Stage of Concern](image)

To determine if differences in concerns were accompanied by differences in practice, Table 3 presents responses of the two groups to three questions: 1.) use of a variety of computer applications, 2.) frequency of discussions with colleagues, and 3.) primary goal for classroom computer use. The data reflects no substantial difference between the two groups in the frequency of use of a variety of different applications. There is a slight tendency for those in the Master's Degree group to use a wider range of applications. There is, however, a marked difference in the respondents' self-reported frequency of conversations with colleagues about hardware, software, curriculum, and computer issues. Frequent discussions were reported almost twice as often for respondents in the Master's Degree Program as for those in the Certificate Program. This is consistent with the groups' reported collaboration and refocusing concerns and suggests that those in the Master's Degree group are acting on their concerns. A difference in the percent of respondents reporting integration as the primary goal of their use of computers for instruction is also evident in the data. Fifty-three percent of the Certificate group reported integration as their primary goal while 75 percent of the Master's Degree group reported integration as their primary goal. Only 6.3 percent of the Master's group reported learning a skill as a primary goal while 31 percent of the Certificate group stated learning a skill as their primary goal. Fewer of the respondents in the Certificate group appear to have become integrators of technology.

How Much is Enough?

In the opening section, we asked the question: how much is enough? Given the data for the Certificate group, it is possible to conclude that their participation in the Certificate Program has supported them in their efforts to use a variety of computer applications as part of their practice. It has encouraged most of them to have at least occasional conversations with colleagues about hardware, software, curriculum, and computer issues. Fifty-three percent of them report integration as their primary goal for classroom computer use. Participants in the Certificate Program have made important strides. One might consider this "enough." Yet, despite these positive advances, one third of them still report only occasional use of all varieties of applications, and forty-
seven percent of them still have teaching about computers and teaching skills as their primary goal. In addition, the highest concern for the group is Information – an interest in learning more. They do not seem to be satisfied with their level of knowledge and skills related to integrating technology. If the goal of professional development is for teachers to learn about the role of technology to support teaching and learning and to help teachers anticipate necessary classroom changes (Guhlin, 1996; Stager, 1995) as well as to convince teachers about the relevance of technology to what they do in the classroom (Shelton & Jones, 1996), the Certificate Program was not "enough."

Table 3. Self-Reported Use of Classroom Computers

Those participating in the Certificate Program were more invested in learning to integrate technology to support teaching and learning than most. Although the school divisions of those in the Certificate Program provided partial or full financial support for their participation in the Program as well as providing the benefit of 12 credit hours of graduate credit, this was not mandatory professional development. Participants volunteered to participate in the Certificate Program and gave up precious after school time to attend class as well as the time it took to complete reading and written assignments. Despite their commitment, the data does not reflect that all their learning needs were met or have they finished the process of transforming their practice to integrate technology with teaching and learning even after 180 contact hours or the equivalent of 30 inservice days.

This is particularly disturbing when compared with common professional development practices. Trotter (1999) reports that when

As asked how many hours of basic technology skills training they had received within the past 12 months, the largest group of respondents—31 percent—said one to five hours. Next came the 27 percent of teachers with no training. The figures are worse regarding training on integrating technology into the curriculum: 36 percent of teachers received one to five hours, and another 36 percent received none.

So, is the more robust Master’s Degree option “enough.” Certainly, data obtained from participants in the Master’s Degree Program suggests that they have become established users who have matured to concerns about implementing and revising practices based on their consequences for student learning as well as
collaborating with others to further the goal of integrating technology to support teaching and learning. Their reported actions further support the notion that these respondents are not only thinking about these concerns but acting accordingly. They report higher incidences of conversations with colleagues than the Certificate participants. More of them report integration as their primary goal for student computer use. Their higher group score for Stage 6 — Refocusing suggests that they are interested in exploring more universal benefits, the possibility of major changes, and that they have definite ideas about alternatives. They are concerned about seeing their ideas put into practice or at least tried out. These respondents are well on their way not only to being established integrators of technology but also to leadership roles. They appear confident in their ability to implement the innovation but remain concerned and feel unprepared to cope with external pressures that impede their progress. Participants in the Master's Degree group still have high personal concerns about their ability to implement their vision within the context of system-wide structures.

Certainly, more appears to be better, but is it "enough?" Probably not. Although results for the Master's Degree group show positive shifts in actual classroom practice and in professional activities related to the increased integration of technology to support teaching and learning, the results do not suggest that these respondents recognize that a transformation in teaching and learning is still a vision on the horizon. And they remain concerned that they may not be able to achieve that vision within the confines of existing systemic structures.

Conclusion

For us, there are two lessons to be taken from this research. One, professional development activities designed to promote changes that fully integrate technology to support teaching and learning must be extensive, consistent, and long term. Short term or one shot professional development activities do little to advance the power of inherent in the newer technologies to change teaching and learning. Those who are in teacher education must understand that they are in it for the long haul. Second, teacher educators must listen carefully and take to heart the message sent by the Master's Degree group. That is, their ability to translate their learning into system-wide practices depend not only on what they learn or what they are able to implement in their practice but on the ways in which their learning and practice interact with broader, systemic issues. No matter how much participants profit from their educational experiences, there remain systemic issues that impede their progress toward substantial transformations in educational practice. It may well be that the answer to the question, how much is enough, can only be answered in the broader context of public policy. Teacher education may never be "enough." "Enough" may well depend on teacher educators' ability to merge teacher education and advocacy in the public arena.

Engaging Learners with Technology: 
An Innovative Professional Development Model

Margot T. Williams, Van Andel Education Institute, USA, margot.williams@vai.org
Mathew B. Burns, Van Andel Education Institute, USA, matt.burns@val.org
Dick Oostenink, Van Andel Education Institute, USA, dick.oostenink@vai.org

Abstract: This paper will describe an innovative professional development initiative where teachers, administrators and curriculum development specialists assume the role of students as they explore how the engaged learning environment can be supported by technologies in meaningful and authentic ways. The purpose of this paper is to share a replicable, instructional, technology-integration model designed to help educators (pre-service and in-service) develop and implement learning experiences that invite and engage students to construct knowledge and to make meaning of their world. Additionally, details and particulars of the supporting professional development program will be outlined and discussed.

Learning comes naturally. It's what humans do intuitively. The need to understand, to bring order and create patterns to new ideas and concepts, to share this new learning, and to feel empowered to act using this new understanding speaks to the very foundations of learning in today's classroom. Within a classroom, there are observable and measurable indicators which signal that learning is taking place. What does that look like? What are students doing? How are they accomplishing the tasks? How and when does technology support the learning process? How do you know the learning "stuck?" Did this process happen accidentally or was there a deliberate plan and scheme to develop such a context for learning. These questions are at the foundation of "engaged learning".

The following treatise will:

- Define engaged learning
- Explore how the engaged learning environment can be supported by technologies in meaningful and authentic ways
- Describe the steps of the Van Andel Educational Technology School (VAETS) project-based instructional model including the infused strands of problem-solving, collaboration, and technology
- Describe the technologies and curricular materials selected in this project
- Explain how technology can become transparent in this engaged learning environment
- Highlight the particulars of the one-week Van Andel Education Institute (VAEI) Teacher Academy

What is Engaged Learning?

Exemplary teachers have always known that their students are at the center of the learning in the classroom. Learner-centered awareness can be observed in classrooms where students are encouraged to build upon their experiences and strengths, are provided with realistic options and choices about their learning, are given opportunities to share with fellow learners, are provided with opportunities to assess their progress, are engaged in internal and external reflective dialog to monitor self-learning, and are given appropriate access and use of the necessary tools to support the learning process.

Because learning is a process, not a product, research and its authors such as of Dewey, Vygotsky, Feuerstein, Diamond, Caine, Bransford and others, suggest to us that what students do, what teachers do, what learning
tasks students perform, and the type of assessments associated with those tasks are essential factors in achieving engaged learning. Identifying these variables as dimensions of learning helps us, as educators, to document that engaged learning is indeed occurring. These dimensions, as listed and described below, form a clearer picture of an engaged learning culture.

- **Passion for learning**: In a classroom where engaged learning is honored, the learner is involved in the learning process from the beginning. Developing this passion for learning comes from being responsible for setting goals, choosing tasks to accomplish those goals, and developing assessments to monitors one’s progress in achieving success. In short, the learner must understand the “big picture” and enlist a cadre of thinking and learning strategies to accomplish the tasks.

- **Challenging, authentic tasks**: Challenging learning tasks need to address issues in the real world by integrating a variety of disciplines to solve problems. A blending of content in a multidisciplinary context provides opportunities for sustained, authentic learning. When deliberate and thoughtful choices are made about the use of specific technologies, strategies and resources to support their learning, the engaged learner becomes resource savvy.

- **Performance-based assessment**: As an essential part of the instructional process to improve learning, assessment is ongoing, equitable, and purposeful. In an engaged learning context supported with technologies, assessment comes in the form of performances, demonstrations, and products that have meaning and purpose for the learner. These examples of evidence should match the goals of the curriculum, represent knowledge and essential skills, and provide authentic contexts for assessment. Tools of assessment such as self, peer, and teacher assessments should evaluate both individual and group efforts.

- **Generative, multi-contextual environments**: The classroom culture must be engaging and responsive to learner needs by providing multiple contexts for learning. In order to assist the learner in constructing meaning and understanding, this enriched classroom environment will support strategies whereby the learner can actively solve problems, conduct meaningful inquiry and discovery, and function effectively in a variety of diverse contextual settings.

- **Collaborative, flexible grouping**: Classrooms that encourage and support engaged learning allow students to learn collaboratively. Flexible learning communities build upon the diversity of their members and create a more empathetic environment which encourages the pooling of knowledge and experiences of the group. Engaged learning environments challenge the learner to ask complex questions, define the problems, and seek out information and knowledge from professionals. Diverse grouping strategies will provide opportunities to differentiate goals for all students.

- **Reflective, metacognitive dialogue**: Within the culture of an engaged classroom, metacognitive reflection is ongoing. As an essential component of the learning process, learners are consistently engaged in activities that encourage and rely upon reflective dialog with peers in order to bring clarity and focus to their thinking and learning. Metacognitive opportunities provide each learner with a context for reflection and articulation about his/her individual learning strategies, successes, and growth potential.

These dimensions of learning are at the very foundation of a constructivist instructional model that is currently being implemented with the goal of identifying the most effective ways to integrate current instructional technologies into existing curricular frameworks.

### VAETS Engaged Learning Model: Project-based Learning

In an attempt to provide an instructional schemata whereby technology becomes an intuitive part of the learning landscape, this model combines a 5-step process with three interwoven strands of problem-solving, collaboration and technology. Using the collective wisdom of cognitive science, as well as the emerging field of brain-research, this 5-step model helps to create a framework where learning occurs naturally and with purpose:

1. **Curriculum Planning** – This model speaks to the needs of accountability and assessment with the beginning step of curriculum planning. Great care and detail is given at this first step as the teacher provides the curricular framework using existing standards and benchmarks. The teacher clusters standards or objectives, defines project content, identifies general and specific goals and objectives of
content, instructional technology, and collaborative learning skills, identifies prerequisite skills, plans a strategy for creating teams, sets general project timelines and identifies resources and materials.

*Three strand examples: Teacher planning always involves problem solving and teachers are encouraged to collaborate with colleagues. The Internet, spreadsheets, Inspiration® and other organizers are a natural part of planning.

2. Project Focus – The teacher outlines and presents the general project topic to the students, sets timelines, milestones and assessment options for students, lists resources available, identifies prerequisite skills and competencies, and forms teams.

*Three strand examples: Teachers must cultivate a project-based culture by modeling and demonstrating problem-solving and collaborative techniques and sampling the technology resources available to students. Teachers should use organizers and a variety of technologies in modeling for students.

3. Project Planning – Students begin preliminary planning, pool their knowledge of the topic, narrow their focus and identify their specific team projects, complete a project planning chart which might include assigning individual roles and responsibilities, confer with the teacher, receive feedback and revise their plans.

*Three strand examples: Students, of course, will be working collaboratively and should be using some type of graphic organizers such as Inspiration® and they must be required to problem-solve and make decisions about their particular approaches to the project.

4. Project Implementation – Students use a three-story intellect model which involves gathering activities, processing activities and applying activities. (Fogarty, 1995) They create a timeline with one milestone for each task involved, refine their project definition and procedures, decide on the product to be produced, continue to collaborate and cooperatively problem-solve, seek and receive feedback and move toward completion.

*Three strand examples: Working collaboratively, the students should employ a division of labor. The gathering process should involve the use of electronic encyclopedias, web searching, interviews, textbooks, etc. and some method of electronic recording using word processing, database, spreadsheet, filming, etc. Processing should involve imagination, problem-solving, and manipulation of data to bring clarity and focus to the project. Applying involves the creation of a final product in the form of desktop publishing, an electronic presentation, movie, etc. Students typically use: Inspiration (organizing), Appleworks® (word processing, spreadsheets and slideshows), Hyperstudio® (interactive presentations), Presswriter® (desktop publishing) or iMovie® (movies).

5. Completion – Students do their final revising, polishing and presenting. The teacher and students assess, celebrate, and bring closure to this project by reflecting and discussing where it fits in the big picture and how it leads to further investigations.

*Three strand examples: Assessing and celebrating may be combined with students collaboratively making their presentations, presenting their documents, playing their videos, etc., explaining their methods and receiving feedback.

This model serves as scaffolding for an engaged learning culture by providing a student-centered vision for learning. This engaged, collaborative learning environment stimulates a passion for learning with authentic, challenging tasks, meaningful opportunities for reflection, and assessments that reflect purposeful learning. As confidence and proficiency increase over time, this scaffolding becomes transparent and the use of technology becomes natural and intuitive.

Van Andel Education Institute: Teacher Academy

The focus of the academy is to explore current cognitive research as it relates to the development of the VAETS Project-based Model. Using the tools of technologies, the participants identify the instructional standards and plan, develop, implement, assess, and evaluate a project using productivity, research, and multimedia resources.
Specific topics such as process writing, research strategies, cognitive mapping and multimedia development are used as focus areas to connect the learning in a project format. Methods used in the academy include direct instruction using short lecture segments, demonstration and hands-on practice of selected technologies. These methods are complemented with modeling of collaborative group activities, independent writing, reflective dialoging, assessment, and evaluation.

The VAEI Teacher Academy is a 1 week, 30 hour immersion into the VAETS Project-based Model. Designed for pre-service and in-service educators in grades K-12. This workshop environment provides the participants with:

- An overview of the latest cognitive and brain-based research as it relates to the educational setting
- The project-based learning model, its components, and its foundations in constructivist theory
- A state-of-the-art technology-rich environment designed to engage learners by focusing attention appropriately in multiple contexts
- Just-in-time training on appropriate educational software and hardware
- A curricular framework document for planning and implementation including curriculum and project planner resources and multimedia design considerations
- Modeling procedures of engaged learning strategies such as cognitive mapping, process writing, collaborative problem-solving strategies, etc.
- Assessment rubrics and guidelines for developing rubrics for student projects
- Sample vignettes using the project-based model and supporting technologies
- Hands-on opportunities to experience the process and resources of project-based learning (Each participant is a member of a team which experiences a complete project from planning to completion.)
- Sampling and discussion of pertinent professional articles and publications supporting engaged learning
- Replication scenarios in diverse educational settings

After a successful trial program for 25 participants in the summer of 1999, the VAEI program was expanded in the summer of 2000 to three Teacher Academy sessions. Information about the Teacher Academy offerings was disseminated to area schools and area college and university departments of education. Announcements were placed in a statewide technology newsletter, and invitations were distributed at professional education conferences. With a participation limit of 25, the three sessions were filled in advance and a waiting list was begun. The teachers were drawn from school districts across the midwest and Canada, representing public, private, and charter schools. Some districts sent teams of teachers to create self-supporting networks while others sent individuals. Participants were charged a nominal $50 registration fee. Because the Teacher Academy was funded as an outreach activity of the Van Andel Education Institute, it was possible to return that value to them in the form of curricular materials, workshop notebooks, and support resources. Graduate credit from two local universities and professional development credits from some local school districts were available. The three members of the VAETS staff served as the facilitators for the Teacher Academy.

Conclusion

When learner-centered education is at the heart of today’s classroom, we honor the naturalness and intuitiveness of the learner. In his/her quest to bring order and understanding to the world, the learner becomes responsible for the learning process and claims ownership of the process. This ownership of the learning process empowers the learner to gain confidence in his/her ability to think creatively, solve challenging problems and make sense of powerful ideas. Ultimately, this is the purpose and goal of education.

Preparing Teachers for the School of the Information Society in Greece

Georgios Papdopoulos
Michalis Karamanis
Barbara Ioannou
Eleni Houssou
Hellenic Pedagogical Institute
Athens, Greece
{gpap,mkaram,bioan,ehous}@pi-schools.gr

Abstract: Hellenic Pedagogical Institute is implementing a large-scale national teacher-training project. The project aims to expand teachers' understanding in Information and Communication Technologies (ICT) and to equip them with the necessary knowledge and skills in order to support their efforts in utilising ICT effectively to teach particular subjects. Central issue of the design of the project is its flexibility to accommodate the various professional needs, background knowledge and skills, learning styles and inclinations of the teachers. The training process is totally decentralised, transferring to the schools the responsibility for the selection of the training model and the training providers. Final target of the project is the establishment of a life-long training mechanism based on the operation of sustained learning communities around the country. In this paper the design principles as well as the implementation process of the project are presented.

Introduction

As our society changes from an industrial one to an information society, dealing with information is becoming a key element for people. Educational systems of the third millennium face the challenge to reconsider their educational beliefs and teaching routines, in order to be able to effectively prepare the future citizens of the information society.

A central issue of the changes occurring in today's educational systems is the integration of Information and Communication Technologies (ICT) into subject teaching. The educational community has recognised the value of ICT as a teaching tool since the early 80's. However, in a world crossed by the information super-highways, ICT plays a more significant role than just that of another teaching tool. ICT can perform as the vehicle for the reform of the educational strategies towards a student-oriented learning model, transferring part of the responsibility of the learning process to the students, implying at the same time new roles for the teachers and changes in their classroom performance.

The effective integration of ICT in teaching and learning is directly dependent on teachers' knowledge, skills and abilities to make decisions about when, when not and how to use ICT in teaching particular subjects. Therefore, supporting teachers in this direction is one of the most critical factors for the successful integration of these technologies in daily school practice. Helping teachers in integrating ICT into their teaching process has little to do with helping people operating machines. It has to do mainly with supplying teachers with a powerful educational toolkit, which can enhance their own expertise and professional practice, redefining at the same time their profession's core practices and requirements.

Since learning takes place in a social context, teachers' communication and collaboration with each other as well as with experts, is of major importance in extending their knowledge base and skills. In this perspective, ICT can perform both as the motivation and the platform for the creation of the required communication and collaboration channels for the establishment and operation of learning communities.
In the last four years the Greek Ministry of Education has been working through various actions and projects to introduce ICT technology into the Greek primary and secondary schools. Towards meeting this target, new and flexible curricula have been developed capable of accommodating ICT based activities and new educational material that has been produced (books, CD-ROMs, Web-based material). All schools will have an Internet connection by 2001 providing all teachers and students with e-mail addresses. Additionally, the schools' network is being established offering access to educational content and services over the Web.

However, the key figures for the introduction of any innovation introduced in schools are always the teachers. In this context, many pilot teacher-training programmes have been taking place around the country, making use of various teaching and delivery methods.

Project Design

Recently the Ministry of Education announced a project to train 75,000 primary and secondary teachers (80 percent of all the schoolteachers in Greece) in ICT as an educational and professional tool. The project -managed by the Hellenic Pedagogical Institute (HPI) (http://www.pi-schools.gr)- is the largest and most comprehensive national investment programme ever to be implemented as far as education is concerned. The scope of the project -entitled "Preparing teachers of the Information Society"- is to integrate ICT technologies into daily school practice, in an attempt to provide students with the knowledge and skills required by the Information Society. Within this framework, the project aims to expand teachers' understanding in ICT and to equip them with the necessary knowledge and skills in order to support their efforts in utilising ICT effectively to teach particular subjects.

Central issue of the design of the project is its flexibility to accommodate the various professional needs, background knowledge and possible difficulties of the teachers around the country. Thus, training process makes use of various models as far as the delivery methods and training activities are concerned. In this context, the schools are designated as decision-making units as far as the training model and the training providers are concerned.

One of the main principles of the project is the presumption that teachers themselves will take personal responsibility and create opportunities for their professional development in a self-learning approach. In a continuously changing world, learning should be a life-long process, taking place in all the situations, in which people live and work. From this point of view, the project focuses on providing the teachers' community with the appropriate environment in order to be able to make out their own learning and professional development paths (Rogers, 1977).

The final target of the project is to develop a non-intensive and life-long training mechanism through the establishment of learning and communities around the country capable to support a peer-to-peer training model (Wilson & Ryder, 1998).

Training Programmes

Within the framework of the project various training programmes are organised across the country involving all the Greek primary and secondary teachers as well as local administrative heads and school masters.

The programmes targeted at the teaching staff, are structured under three main axes:

- **Axis-1: basic skills in the use of ICT:**
  These particular training programmes aim at improving self-confidence, knowledge and skills of the teachers as far as the use of new technologies is concerned. The curriculum of the programmes is tailored to the particular needs of the Greek teachers determined through the various pilot projects that have been implemented during the last four years. The main principle under which the programmes are structured is the belief that helping teachers in using ICT is more than training people in operating machines (Wild, 1996). Thus the training material and the activities designed for the programmes derive from the schools' daily programme and the particular needs of various teaching subjects.

- **Axis-2: use of ICT in subject teaching:**
  In the context of these training programmes teachers are expected to participate in activities relating to the use of ICT as a teaching tool. The curriculum of the programmes is structured over various special activities. The
activities include the development of lesson plans as well as the teaching process using educational software titles as well as common applications (browser, e-mail, word processor etc.) used in subject teaching. The effective use of ICT in the classroom implies new roles for the teachers, who are expected to act as facilitators of their students' approach to learning (Bickmore-Brand, 1996). In an attempt to promote and articulate new roles in teaching and learning process, during the implementation of the activities, teachers play the role of the student, having an expert as an instructor.

- **Axis-3: design and production of educational activities, lesson-plans and scenarios concerning ICT exploitation in classroom.**

  The programmes of this axis concern teachers who feel confident in using ICT. The programmes will be implemented within the school or on a co-operative basis among a number of schools. Within the context of the programme, work groups are established with the active participation of both teachers and pupils.

  The important issues in these programmes are peer-to-peer interaction among teachers as well as the active participation of the members of the group. Each work-group will implement an interdisciplinary project with the participation of the students. The programme encourages project themes, which are of interest to the local societies of the schools, in an attempt to bring schools in touch with the real world. Additionally, schools from remote locations collaborate-using the facilities of GroupWare tools - in developing projects of common interest. In that way, the programmes are expected to perform as the kick off activity for the establishment and operation of the learning communities.

  There is no defined curriculum for these particular programmes, as work-groups make use of the educational material provided by the Greek Web for Schools (GWfS). In this context, participants are neither expected to have the same starting points nor to achieve similar outcomes. The target here is to provide teachers the opportunity to improve their understanding and to extend their knowledge base about the effective use of ICT as a learning tool (Underwood & Cavedish, 1996).

  The general target of the three above programmes is to provide the teachers the skills and abilities needed to evaluate ICT applications and resources, to be able to chose the appropriate for teaching, assessment, school management as well as self-learning and professional evolution. Additionally, teachers are expected to be able to determine the abilities required from their students in order to construct their knowledge model through the use of new technologies (Davis, 1998).

  Additionally, the following training programmes are organised:

  - **Head-teacher and administrative staff training**, so that those involved will then serve as mentors and facilitators for their colleagues. The role of head-teachers is rather critical in the integration of education innovations into the school environment as they are in daily contact with the teaching staff, managing and encouraging their efforts (Lawson & Comber, 1999).

  - **The trainers who are going to facilitate group-work at schools** will participate in special seminars organised by the HPI. The scope of these seminars is to equip the trainers with the expertise gained by Institutions in Greece and abroad from various projects. Additionally, the seminars will inform trainers about the alternative resources, which will be used during the training process.

Due to landscape peculiarities, too many isolated small schools -basically primary schools- exist in Greece, which are served by only one or two teachers. Especially for this kind of schools, a pilot training programme is going to operate, in the project's framework. Specifically, these schools are supplied with special equipment and fast Internet connection, in order to be able to participate in on-line training programmes, using synchronous multimedia communication. The additional outcome expected from this pilot programme, is to bring the students and the local communities of these areas in touch with human and digital resources from around the country, removing in that way their isolation.

**Support Activities**

The training process will be facilitated and supported by a number of actions and activities aimed at firstly making the life of the participants easier and secondly helping them articulate the knowledge offered to them. Additionally, the support activities aim to enrich the existing infrastructure in the domain of teacher training.

The teachers participating to the training programmes are supplied with a multimedia PC and Internet connection for home use. In that way teachers will have the opportunity to practice as well as to prepare their lesson plans and material.
Local training support centres are established across the country. The role of these centres is to function as a reference place for trainers and trainees. The centres are staffed with expert scientists and are equipped with state-of-the-art laboratories and updated libraries.

A 24/7 help desk centre operates in the HPI in an attempt to solve the various problems that occur during the training process.

The educational environment implemented within the context of the project “Added Value Services to the GWfS” will perform as the virtual reference and meeting place for the participants of the training process. (Papadopoulos et al, 2000)

**Evaluation-Quality Assurance**

The quality of the training process is firstly going to be ensured by the quality of the educational material. The HPI has developed a specification framework as far as the educational material is concerned. Additionally, the HPI has developed curricula for all the training programmes describing the targets of the training process and outlines the skills and abilities expected to be acquired (Fleischman & Williams, 1996).

Universities and Institutions from all over the country participate in the process of developing material.

The training material consists of activity-based lesson plans for subject teaching using ICT, trainers' guidelines, educational software titles as well as web-based material.

As a second level of quality assurance, the abilities and the skills developed by the teachers are going to be evaluated through an assessment mechanism compatible with the European Union Initiatives. Finally, external evaluators will evaluate the whole project as far as the effectiveness of: the training mechanism, the training centres and the training material.

**Implementation**

The HPI has developed the curricula for all the programmes included in the project. Additionally, the HPI has produced a specification framework as far as the training material is concerned. Both the curricula and the specifications' framework have been published in the GWfS and have also been distributed to all the schools around the country.

The training material varies depending on the training programme as well as the training model and includes lecture notes, multimedia titles, web-based material, interactive tutorials etc. The HPI has produced sample-training material while, already existing material is being evaluated. Additionally, Universities, Teacher Unions and other Institutions around the country produce material.

The training programmes concerning the axes 1 and 2 are offered through three alternative models. The models differ mainly on the delivery method adopted:

- **In-school training**, which includes face to face training seminars. The trainers can be either members of the school's teaching staff (e.g. the IT teacher) or external trainers. Whenever possible, the training process takes place with the participation of students.

- **Seminars organised by training providers**. Teachers sit in seminars organised at the premises of the training providers. The later have to ensure that the computer lab will be available for practice purposes, for at least six months after the end of the seminars.

- **Distance training**, provided both by the training providers and the HPI. The training process will make use of both web-based and conventional distance training methods.

A call was made addressed to all the organisations, institutions etc. intending to participate in the training process as training providers. The training providers have to meet a number of prerequisites concerning the equipment and the services they can provide. Only approved training providers are allowed to deliver training. These providers had to demonstrate a track record of expertise and experience in providing successful training, advice and materials. Additionally, the call was addressed to individuals who have expertise in ICT use as a teaching and learning tool. The individuals who meet the prerequisites are going to be used as training staff by the training providers or to perform as independent trainers in in-school training programmes.

The approved training providers and individual trainers are included in a list published by HPI. The training providers and the trainers can cover all the axes of the training programme or just one of them.
The training process will be facilitated and co-ordinated by the local support training centres, which are founded in all the regions of the country. The training support centres are managed by training committees (consisting of administrative staff, facilitators, scientists/experienced teachers), which are responsible for the implementation of the project at the local level and the communication process with the schools of the region as well as with the HPI.

Seminars, concerning the scopes and the design principles of the project, are organised for school head-teachers and the local administrative staff. Additionally, special trainer's training is organised around the country. The participants in these seminars are going to perform as facilitators of the group work in schools (axis 3). The training content focuses on the trainers' role as tutors to colleagues and aims to support them in successfully co-ordinating the teamwork as well as to stimulate the participating teachers. The seminars are held by the HPI in all the capital cities of the regions of the country with the contribution of the local Universities and municipalities.

The teaching staff of the schools decides how they will be trained. Schools are asked to fill in and submit to the local training committee an application form describing the training models and the resources required for the training. It is possible for a school to choose more than one training model according to the particular needs of its staff. It is also possible for a teacher to choose different training models for the various programmes in which he/she participates. Depending on the members of the staff seeking training and the chosen training model the schools receive a fund to cover the training expenses.

The following training programmes are being implemented:

The training programmes under axis 1 concern teachers with minimal or no previous experience in the use of ICT. They include seminars focusing on the achievement of basic ICT skills. The teachers work in computer labs (one person per computer) in groups of 10-15 people with the presence of one or two trainers. At the end of the seminars the teachers are asked to sit an on-line exam in order to receive accreditation for their training.

The training programmes under axis 2 concern teachers who have attended axis-1 programmes or already have the basic knowledge and skills in the use of ICT. The teachers are expected to work in groups (three persons per computer) in the computer lab. At the end of the training programmes the teachers have to carry out assignments concerning the production of teaching scenarios and lesson plans, exploiting ICT use in subject teaching.

The training programmes under axis 3 concern teachers who have either successfully completed axis 2 or have already adequate previous experience in using ICT.

The teachers participate in work groups consisted of the members of teaching staff of the same or different schools. The work groups carry out projects with the participation of their students and under the co-ordination of facilitators. The content of the projects implemented by the work-groups is a synthesis of individual interests and inclinations pointed out by the participating teachers.

Each facilitator may be involved in up to five work groups. The facilitators' contribution to the work group concerns among others:

- the determination of the subject and the methodology of the group work
- the planning and the documentation of the methodology followed to implement the project
- the definition of the learning targets
- the encouragement of the work group
- the facilitation of communication and collaboration among different work groups.
- the technical support of the work groups
- the synthesis, the presentation and the publishing of the results of the group's work.

The facilitators also organise seminars/meetings, for the members of work groups they facilitate. During these meetings, the groups will present the interim results of their work and receive feedback by their colleagues.

The results of the work of the groups are published in the GWIS and are expected to perform as reference material for other groups.

Conclusions-Further Work

First of all, the project aims in supporting teachers to overcome their feeling of insecurity in dealing with new technologies. Moreover, a serious attempt was made in order to bring teachers in touch with the
potential and features of the use of ICT in teaching and learning. Teachers' perceptions about innovations in
teaching and learning are continuously revised according to the feedback they receive from their students as
well as by the changes in society and the evolutions in technology. Under this prism, the project aims in
establishing a training environment capable to accommodate different perceptions derived from different skills
and inclinations.

The project spends a lot of efforts in transferring the responsibility for the selection of the training
model, the training providers and the training rate to the teachers. Furthermore -through the teamwork
organised in schools- the project makes an attempt to involve schools in research activities concerning the cross
curriculum utilisation of ICT. In that way, schools are expected to develop the abilities to investigate, evaluate
and finally integrate into the classroom the innovations in technology and society.

One of the main issues of the project is the establishment of a human network of experts around the
country. The human network is going to use the infrastructure of the GWfS in order to create the required
communication and collaboration channels. Additionally, the members of the network are expected to facilitate
the enrichment and management of the educational content available over the GWfS. The human network will
be facilitated by the existence of the local training centres, which are expected to perform as local training
institutions, covering not only the needs of the project, but also acting as a permanent support mechanism for
the professional development of the Greek teachers.

At the beginning of the project HPI was concentrated in the development of the training curricula as
well as in the training material specifications. The training curricula describe the targets of the training process
and outlines the skills and abilities expected. It is for the training providers to decide the teaching methods and
strategies in order to achieve the described targets. Furthermore, the whole national curriculum is being
reconsidered in order to be able to accommodate ICT based activities.

Final target of the project is the establishment and operation of sustained learning communities, which
can not only perform as a peer-to-peer interaction environment for the Greek teachers but also to bring in touch
all the members of the educational community towards a life-long training approach.

Abstract: A series of case study-type interviews were conducted with selected K-12 teachers on their perceptions of technology integration in-service activities in which they had participated. Teachers were selected to represent rural and urban, small to large schools, and a variety of disciplines. The primary goals were to determine the depth and breadth of in-service activities teachers experienced such as variety of computer applications, utility applications versus instructional applications, Internet usage, degree of expertise, and degree of successful implementation developed from the experiences. Teachers reported positive results of in-service in terms of awareness of the technologies available. Often, recent in-service activities were focused on administrative/utility functions rather than instructional applications. One major concern mentioned was that during the in-service activities, teaching strategies and 'hands-on' time were seldom included. Many teachers expressed frustration with the limited time allocated to the topics/skills being taught in the in-service activities.

Background and Rationale

In the recent past, the Wyoming State Department of Education has mandated the integration of technology in the classroom. There have been a number of initiatives by the State Department of Education to encourage technology use. Along with the Wyoming School University Partnership's Staff Development Academy (a consortium of school districts, community colleges and the University of Wyoming), school districts have been required to develop and initiate Technology Plans. The State of Wyoming and QWest have provided Internet access to all its schools. With the introduction of the WHEN (Wyoming High School Equality Network), compressed video has been brought into all the high schools in the state, community colleges and the College of Education. Regional technology training centers have been put into place in order to contend with the vast distances that separate the state populations to provide local staff development centers. And, within the University, the College of Education has had a strong mandate to raise the level of technology use in the pre-service program for both student and faculty. Obviously with an influx of this much technology into a state, there is a need to know how well our teachers are coping. Are they using these technologies? Do they have access? Are they being trained effectively to use these technologies? Are they receiving support?

This situation is not unique to Wyoming. Nationally, Internet use has been on the rise in all public schools growing from 35 percent in 1994 to 78 percent in 1997(Bare & Meek 1998). We are now rapidly approaching a level of 95 percent use of Internet use in Wyoming schools in the year 2000. Another major trend is in the arena of standards based assessment for both in-service and pre-service teachers. Both are
now required to begin to meet technology standards on a national level. ISTE’s (International Society for Technology in Education) National Educational Technology Standards for Teachers quite clearly states, “All candidates seeking certification or endorsement in teacher preparation should meet educational technology standards” (ISTE, 2000). NCATE (National Council on the Accreditation of Teacher Education) has responded with a similar standards requirement (NCATE, 2000). Several states have responded with commitments to implement these standards. For example, Utah has fulfilled its commitment to public schools to provide access to educational technologies that promises to enhance teaching and learning (Tyner, 1998). Missouri has begun investigations to determine the status of technology integration in schools as well as provide laptop computers to all College of Education majors (University of Missouri, 1998).

In spite of all of the efforts to improve the quality of education and integrate new technologies, it has been suggested that most teachers continue to teach the way they have in the past (Sparks & Hirsh, 2000). The argument has been well documented that purchasing new technology equipment and software alone does little to cause effective change in the classroom (Hite, 2000). Recent investigations, indicated that this influx of technologies into the educational system has caused many teachers express high degrees of frustration and bewilderment as how to integrate these technologies into their classroom instructions. At the same time, the school districts have established technology integration and staff development as primary goals (Reynolds, 1999). Given that school districts have established technology integration and staff development as primary goals, and recognizing that teacher participation in both these areas is increasing, the question that we must ask is, “What are the teacher’s perceptions as to the effectiveness of these efforts?”

Objectives of the Study

The intent of the study was to determine the answers to the following statements, which also served as the interview questions for the study:

1. What technology do you currently use in your classroom? How often?
2. To how much technology do you have access?
3. How does the technology that you access suit your needs?
4. What recent in-service activities has the district provided to you?
5. What have you implemented as a result of these in-service activities?
6. What barriers exist that prevent you from integrating technology?
7. How would you integrate more technology if it were available?
8. What should the district do to enable you to integrate more technology?

Procedure

A naturalistic inquiry approach was used to conduct this study. This approach was selected in order to facilitate on-site observations while schools were in session and to enable unsolicited answers to be followed by additional inquiry during the interview (Lincoln & Guba, 1895, Reynolds, 1999). Selected high schools were contacted throughout Wyoming in the fall of 2000 and the researchers obtained permission to interview various teachers within the school districts. Teachers were sought out that were users of technology in the classroom rather than the technology professionals enlisted by the school districts to improve technology use. However, it should be noted that on at least two occasions, the latter individuals did find their way into the interview process. The questionnaire was designed to elicit responses in an informal setting. Each interviewee was given a questionnaire and free flowing discussion took place, using the lead questions as a guide. The data developed in these discussions was extracted from the taped conversations and the extensive field notes taken by the researchers during the interviews.

Results

The intent of the interview questions was to obtain teachers’ perceptions as to the availability of technology, and to what extent and how often they use technology in their classrooms. Moreover, the
primary focus was to determine recent in-service activities, their effectiveness, and how well the in-service prepared them to integrate technology into their instruction. We were also interested in determining how much support they receive as follow-up to the in-service activity. And, we were also curious as to the identification of barriers that prevented them from using technologies, whether they would integrate more technologies if they were made available, and in what way their respective school districts could assist in the process of more integration of technology.

In response to the first question, "What technology do you currently use in your classroom? How often?" the majority of teachers used computers with the basic Microsoft Office package for word processing and presentations, email, and the Internet and WWW. A limited number of teachers indicated they used spreadsheets with their students to teach problem solving. On two occasions, with foreign language and the Schools to Careers program, we saw teaching computer centers with a wider focus on various software packages that supplemented the subject matter. Very few teachers indicated they used peripheral technologies such as; presentation equipment, computers, digital still and video cameras, video editing, scanners, and CD writers.

Responses to the second question, "To how much technology do you have access?" included a wider range of technology was in fact available for use: presentation equipment, computers, Internet, digital still and video cameras, video editing capabilities, scanners, CD writers and a fairly wide array of software. In almost every case, teachers reported that the district provided a wide array of the latest technologies but because of location, complications with scheduling, or lack of expertise, they often perceived it as having limited availability. One teacher stated that there were CD-ROM writers however they were on a teacher's desk as part of their personal computer and it was uncomfortable to ask to use the equipment. Another teacher reported that they had presentation equipment on carts but one had to move up and down stairs or across to another building in order to use it.

In response to question three, "How does the technology that you access suit your needs?" the overall responses were that there was not enough equipment in the necessary places. Most computers were located in the labs and not always accessible because of scheduling conflicts. Several teachers expressed that there was not enough money in the district to purchase the needed items. Limited access to existing computers seemed to be a problem in that certain computers were often dedicated to special groups because of grant purchases. There was a need for more varied and interactive software and a need for presentation hardware in the classroom. One teacher noted that their particular Superintendent liked to see technology and supported the purchases of such things but getting training to support that technology integration was next to impossible.

In response to question four, "What recent in-service activities has the district provided to you?" in-services were related to the needs of the district and not the individual curriculum needs of the teachers. Recent in-services had provided information on how to use the new grading systems in order to meet the needs of the new standards based requirements. One high school however was out of the norm in that they had organized more effectively and had begun a 'mentor to mentoree' program with Apple Computer and their in-service was growing in a different direction. A third predominant idea that surfaced was that several districts relied on in-service needs being fulfilled by sending certain teachers to conferences. Basically, the notion that going to a conference some how provided the necessary in-service training for a teacher was the model. The individual rather than the group was the focus and teachers felt like this was granted to the "privileged few."

In response to question five, "What have you implemented as a result of these in-service activities?" most successful implementation was directly related to the needs of the district. "We were taught how to use the grade book on the computer (in some cases the paper grade book was actually taken away) and now we use the grade book on the computer." Another example was the implementation of attendance software. One exception, in the case with of the school district using the mentor program, teachers were the most satisfied with this implementation strategy. One teacher would learn a topic and mentor it to a variety of other teachers, including teaching strategies as well as develop expertise in using the technology. The practice of sending selected teachers to a conference was not perceived as being a very effective model unless the 'mentor-mentoree' approach was implemented as a follow-up.

In response to question six, "What barriers exist that prevent you from integrating technology?" the responses were overwhelmingly lack of money, lack of knowledge, resources in the labs, software and equipment, and greater need for time to learn to use and implement technologies into the curriculum. Also, access to technical support and follow-up were often mentioned as major barriers.
In response to question seven, “How would you integrate more technology if it were available?” the answers were more curriculum specific. For example, math teachers wanted graphic calculators and programs such as Geometry Sketchpad. Most teachers expressed the need to make the technologies more mobile or having more of them concentrated in the classroom. Rather than having computer labs which are often generic in nature and are often overbooked, teachers prefer that those technologies were available in the classroom. This change would create the feeling of ownership and the opportunity to realistically make the technology part of the everyday curriculum.

The responses to question eight “What should the district do to enable you to integrate more technology?” were oriented toward a variety of concerns. Having greater access to technologies and providing more time and money for training and integration were prevalent. The teachers voiced the position that the development of a more responsive management team was necessary. Overall, a technology team, which included a technology director, repair crew, integration specialist and data specialist complimented by a strong technology plan, was suggested. Also, the technology plan should reflect the need for planning of obsolesce and rotation of equipment. Better staff development, with more hands on in-service experiences, more follow-up, and creating a cadres of student assistants, were also expressed as primary needs.

Implications

It was enlightening to hear most teachers express that they would like to integrate more technology in their classrooms. But, most of the barriers they expressed pointed toward insufficient or inadequate in-service. Also, it was frequently expressed that the approach by districts to select the ‘chosen few’ to attend regional and national conferences had limited in-service value. It seemed to be a common theme that in-service to integrate administrative functions i.e. electronic grading and attendance software, was usually quite adequate and had continued technical support. The most commonly expressed frustrations were with instructional software applications where the in-service activities did not include enough ‘hands on’ time and follow up support. Strategies for ways to integrate instructional software in teaching were frequently mentioned as lacking as well. One positive finding, the process of establishing expertise among a few teachers, who in turn taught their peers, was seen as being one of the more effective types of in-service to aid in the integration of technology.

To effectively integrate technology in classroom instruction, school districts must involve teachers more in the in-service planning and delivery process. Second, school leadership needs to be aware of more “user friendly” ways to make the existing technology accessible. Another strategy is that a continued support system needs to be put in place to aid teachers, for example, when technical assistance is needed, it needs to be easily accessible. The message came through very clear that without the technical support; it was unlikely that much integration would occur.

It was also made clear that too many in-service activities were planned for the large groups where ‘hands-on’ activities were limited. This approach worked well to develop awareness of technology, but it wasn’t very effective for integrating the technology. Smaller group activities in which teachers have the opportunity to practice using the software must become the norm as opposed to the traditional “show and tell” presentation approach. Finally, teachers prefer the in-service activities to be taught by those who can relate to the classroom climate. Teaching strategies, and subject matter related examples must be a part of the technology in-service process. Follow-up support as well must contain a teacher-oriented component.

Multimodal distance learning: A personal cooperative video on-line asynchronous experience.

Dorothy Sammons
A.W. Strickland
Charles Zimmerly
Idaho State University
Sammdott@isu.edu

Introduction:
Idaho State University’s College of Education serves an area of nearly 40,000 square miles. Three major cities are the loci of economics and higher education in this region. Pocatello, where ISU is based, lies approximately 50 miles west of Idaho Falls and 110 miles east of Twin Falls. Idaho Falls is home to a large federal research facility, as well as to a higher education satellite center and a nearby private college. Twin Falls, whose main source of income is agriculture, also has a well-known state junior college. A few small towns dot the desert landscape between these larger communities. Though rural and sparsely populated, southern Idaho does have a strong emphasis on education, as witnessed by the junior colleges, college centers, and university. Many of the inservice teachers of the 55 school districts within southeastern Idaho participate in graduate degree programs through ISU’s College of Education. These graduate programs have, in the past, been supported by faculty who commute from Pocatello to teach night or weekend classes in Idaho Falls or Twin Falls. However, in order to coordinate graduate cohorts in the three cities, to save faculty from the inconvenience (sometimes danger!) of commuting long distances late at night or in extreme weather, and to follow through on its commitment of making graduate courses available to all students in its service area, the College of Education seeks innovative means of delivering graduate courses, including compressed video and web-supported classes.

This paper describes one distance learning class that utilized compressed video and supplemental web-based material to reach students at six different cities and towns. This class was a master’s level class on learning theories, with a combined enrollment of 73 students. Besides the larger groups of students located in Pocatello, Idaho Falls, and Twin Falls, smaller groups of students also attended the class from Blackfoot (20 miles east of Pocatello), Malad (60 miles south), and Soda Springs (50 miles southeast). The primary means of delivery was a weekly 3-hour broadcast from Pocatello to the other six sites. During the weekly broadcast, the instructors and students delivered presentations which incorporated compressed video feed, computer, videotape, and Elmo technologies. The broadcast sites in Twin Falls and Idaho Falls also had Elmo, videotape, and computer facilities for transmission. The smaller sites could receive and send audio and compressed video signals, but were unable to send computer-based applications, videotape, or Elmo images.

The class met one night each week over a sixteen week semester. A different learning theory was presented each week by the instructor, during the first half of the class. The following week, that same learning theory would be presented in greater detail by a group of six to eight students, during the second half of the class meeting. Groups were assigned during the first week of the semester and did not begin their reports until
the third week of the semester. Each presentation was required to include an overview of
the learning theory, discussion of a research article, and a class activity which
demonstrated the principles of the particular learning theory. Group members came from
all the class sites and so, in order to cooperatively develop the different components of
their presentation, the group members had to communicate over long distances. Brief
"meetings" during the evening breaks, asynchronous messages on the WebCT bulletin
board, personal email communication, and long distance phone calls were the primary
means of communication.

Outside of class, students utilized on-line components of WebCT to access
additional information, quizzes, and examinations. The WebCT sections of the course
included course contents, quizzes, and communication. The syllabus and calendar, as
well as chapter reviews, were posted under course contents. The course contents section
also contained the instructor's and students' electronic presentations, converted to .pdf
files and posted for downloading. This was an economical way to distribute hand-outs
and class notes to all the students without photocopying and sending them to the sites.
Also within the course content section were chapter quizzes linked to the chapter reviews.
Chapter quizzes and two examinations were created and posted, using WebCT's
capabilities to create objective and short-answer assessments. Ten quizzes assessed
students' comprehension of the text through 15 multiple choice questions. At the mid-
term and at the end of the course, multiple-choice examinations (50 items) were posted
which tested the students on content knowledge of both text and lectures.

On-line communication included a bulletin board which supported asynchronous
conversations. The bulletin board was organized into a main forum to which all students
had access, and eleven subject-specific forums. Weekly study questions were posted to
the main forum by the instructor; all students were expected to discuss the question via
the bulletin board. The eleven forums were reserved for discussions between members of
a presentation group. These discussion groups were limited in their membership; only
those students who were part of that presentation group could see the messages posted to
that forum. The bulletin board group fora were central to the cooperative groups'
communication and planning of their presentation. The students' cooperative groups
posted on the bulletin board: messages to each other, drafts of electronic presentations
and hand-outs, and research articles to be read. The student groups also used the
chatrooms in WebCT for synchronous planning sessions as they coordinated their
group's presentation on a specific learning theory

Method:
A survey of the students was undertaken to determine which of the various
distance learning technologies was used most frequently by the students in the
preparation and delivery of their group presentations, and whether particular
technological components facilitated or hindered their learning experience. The survey
consisted of four parts, only three of which are touched upon here (demographics, student
assessment of technological components, number of distance learning/WebCT classes).
The first part collected demographic information about the students, including the site
from which they took the class, their age, their gender, and which their area of
concentration within the Master's of Education program. Of the 73 students enrolled in
the class, 67 attended the night the survey was delivered. Table 1 summarizes the class
demographics of these 67 students.
This paper reports the students' responses to the second part of the survey, which examined three major constructs. The students were asked to rate specific technological elements of the class relative to (1) how well the technology supported the class objectives; (2) how well the technology supported the group presentations and (3) how well the technology facilitated their learning as individuals. As can be seen in Table 2, the questions dealt with technological components of the compressed video broadcast, as well as elements of the WebCT supplement.

Components 1-4 are those which were used during the compressed video broadcast during class. The instructor and the presenting groups used these components to varying extents. Students at the remote sites did not have all these technologies at their sites, but they interacted with them to the extent that the instructor or other students used them. Components 5-7 refer to elements of the course content available at WebCT site, including chapter summaries and overviews authored by the instructor, articles and handouts which were available in PDF format on the web site; and quizzes and exams. Components 8-11 deal with electronic communications through WebCT, especially the bulletin board and chatrooms. Each component was rated on a Likert scale of 1 to 4, from Strongly Disagree to Strongly Agree.

Table 2. The constructs and components rated by the student survey

Table 3 indicates the average rating and standard deviation for each construct.
Results:
As indicated in Table 3, most of the response to the various technological components of the course was positive. Students found that the compressed video format was the most used and most useful in supporting the class objectives and their group presentations; they also indicated that the compressed video format supported their individual learning more successfully than did the WebCT components. The table further suggests that there is a greater variation in some scores than in others. For example, while the standard deviation is similar for four out of the six constructs, the use of WebCT components to support the group presentations was rated from strongly negative (1) to strongly positive (4). This is due in large part to the students’ use and perception of the two functions of WebCT—presenting content and communication. Those portions of WebCT which conveyed content (overviews, articles, handouts, quizzes; components #5-7) were rated mostly negatively by the students (average score of 2.5). Those elements of WebCT which dealt with communication, however, were rated highly by the students, especially for planning and presenting their collaborative group projects. The use of the bulletin board (components #8-9) for group presentations (construct II) had an average score of 2.9 (SD = 0.9; mode = 3); the use of chatrooms had an average score of 2.83 (SD = 1.06); and the use of email had an average score of 3.3 (SD = 0.9).

Student valuation of either the compressed video broadcast or the WebCT supplements to the course does not appear to be related to their experience with these formats. As Tables 4 and 5 indicates, there is no clear increase or decrease in students’ assessment of the technological components relative to the constructs over time. Students for whom this was their second distance learning course tended to rate the constructs at a slightly lower level than their counterparts with either more or less experience with distance learning (Table 4). Students for whom this was the third (or more) class supplemented by WebCT which they have taken, tended to rate the WebCT components slightly more negatively than their counterparts who had had only one or two previous
web-supplemented classes (Table 5); however, there is no real trend in the students’ assessment of either the compressed video or the WebCT components related to their experience with these formats.

Conclusion:
Students' high rating of the video compressed broadcast and the incorporation of videotape, electronic presentations, and other technologies in the weekly broadcast is not surprising. These elements were incorporated into most of the lectures and group presentations, so all students interacted with these technologies on a regular basis. However, the use of the WebCT supplements to the class was determined by the individual students. Class participation, including participation in the WebCT site, was incorporated into each student's grade, but it contributed only a small fraction to the student's overall score. Therefore, students had only weak external motivation for using the WebCT site. Intrinsic factors would be the primary motivators for the students' use of the WebCT resources, bulletin boards, and chatrooms. It appears from the survey results that students tended to use the WebCT site primarily for communication rather than for additional content. Further study is required to determine what factors may have limited or enhanced students' use and value of the chapter summaries, topical overviews, and articles which were available as part of the course content.

</table>
The most highly rated components of the WebCT resources were those dealing with communications. Most students strongly agreed that the bulletin board and email contact with instructors and fellow students were very important to supporting the class objectives, planning and preparing group presentations, and facilitating individual learning. In some ways, the bulletin boards, chatrooms and email communication created a new community consisting of students and instructors. This electronic community gives names and personalities to the otherwise anonymous faces that we saw each week over the compressed video. The combination of on-line communication and weekly visual contact was a unique element in the distance learning experience.
Course Design Overview of a Web-Based M.S. Program

Abstract

This poster presentation will provide an overview of the course design of the Master of Science in Agronomy Distance Education Program at Iowa State University. The presentation will share experiences of the course design and formative evaluations of the courses provided by the program. In the fall of 1998, the Masters of Science in Agronomy Distance Education Program at Iowa State University (ISU) started providing interactive multimedia courses in which most course materials and resources were accessed and delivered through the WWW and CD-ROM. Most of the students enrolled in this program were professionals working in industry and government. Several interactive multimedia activities were developed in the courses. Those activities included Study Questions, In Detail, Try This, Check This Out, and FYI. Various formative evaluation activities related to the course design have been conducted and actions have been taken to improve the courses and program. Lesson maps, glossaries, and calculation examples have been added to the courses. Additional multimedia presentations have been developed. Links to previous and subsequent lessons have aided with navigation. A search function for topics and words within each course has also been tested.

Overview of the Program

Distance education has a long history of applying technologies in delivering instruction to those who are not able to participate in a campus-based curriculum. Many people involved in distance education are professional individuals who are seeking to pursue advanced degrees and empower themselves with knowledge that is relevant to their career field.

A Masters of Science in Agronomy Distance Education program began in the fall of 1998 at Iowa State University (ISU). The program introduced interactive multimedia courses whereby students could access most course materials and resources through the WWW and CD-ROMs. A major goal of this program was to provide an alternative educational program for professionals working in industry and government to gain an advanced degree in Agronomy without having to attend the campus in person.

The curriculum consists of 12 courses, a one-credit workshop, and a three-credit creative component, totaling 30 semester credits (Iowa State University, 2000). The courseware integrates content material on WWW/CD-ROM with the interactive tools of WebCT (WebCT, 2000) located on an ISU server. The WebCT tool allows students to electronically interact with their instructors and classmates by utilizing a course calendar, discussion board, chat room, student homepage, assignments, emails, and student records. The program began with an enrollment of fifteen students in a fall, 1998 pilot program. In the fall of 2000, 51 students are enrolled in the program. The program has admitted 81 students.
Several interactive multimedia activities were developed in the lessons. Those activities included a) Study Questions, b) In Detail, c) Try This, d) Check This Out, and e) FYI.

a) Study Questions generally provide immediate feedback to the students concerning how well they are grasping the concepts of a particular lesson. They may be simple questions about concepts, or may ask the student to think beyond a particular concept. These questions are not assessed for a grade.

b) An In Detail activity probes a concept further without interrupting the flow of a lesson. After the In Detail window has been closed, the student returns to the lesson at the same place they left off. This is required information for the lesson and could involve activities like assignments, Study Questions, or Check This Out.

c) Try This activities allow students to try out or practice tasks, further clarifying concepts to the students. These are usually followed by Study Questions.

d) Check This Out links are connected to external WWW websites aiming to provide additional information to the students on particular subjects. It is a great opportunity to put other well-developed sites to work for our program, especially extension sites from Iowa and other states.

e) FYI activities further explain topics and impart tidbits of interesting information. The information is interesting but is intended to be remedial.

Various formative evaluation activities related to the course design have been conducted. Faculty members and students were the primary target groups of the evaluations. Results of these evaluations indicate: a) students believed they were learning as much in the distance environment as they would on campus and b) they liked the interactive multimedia presentations and asked for clear navigation structure. Based on the evaluation results, improvements have been made to the courses and program. For example, lesson maps, glossaries, and calculation examples have been added to the courses. Additional multimedia presentations have been developed. Links to previous and subsequent lessons have aided with navigation. A search function for topics and words within each course has also been tested.

This poster presentation will provide an overview of the course design of the Master of Science in Agronomy Distance Education Program at Iowa State University, and share experiences of the course development and formative evaluation results of the courses. Brochures with detailed information regarding this M.S. in Agronomy Distance Education Program will be available during the poster presentation. The multimedia interactive lessons will also be demonstrated.

Abstract: The only way to make changes in the pedagogical practices of teacher’s work is to influence the whole school community in collaborative way. Also the background organizations like the whole commune should actively give the frame of reference and financial resources to make it possible to all students to participate in the information society. Based on these findings ICT Learning Centre of Helsinki University has been developing the practices for in-service training that includes methods like collaborative learning, research based learning, computer assisted team work and distance learning on the net. It is easier to make a change in a school community when there is a team of teachers to adapt new pedagogical skills to use. In this article we present the authentic case: Information Strategy for the Educational Use – Done by Collaborative Work.

Background

In the middle of the first period of the Finnish national information strategy, Committee of the Future (established by the Finnish Parliament) started an extensive evaluation project the goal of which was to devise an up-to-date and well-grounded evaluation of the impact of ICT (Information and Communication Technology) on instruction and learning. The Finnish National Fund for Research and Development (Sitra) carried out the evaluation project which was divided into five sub-projects. One of these sub-reports was an evaluation of institutions of general and vocational education and kindergartens. According to the evaluation, only one fifth of the educational staff extensively applies new technology to support teaching. The new Information Strategy for Education and Research for period 2000–2004 devised by the Finnish Ministry of Education is based largely on the results of this evaluation project and the recommendations made in it. At the same time the city of Helsinki started to equip comprehensive schools and high schools with computers and networks (LAN) and the training ICT for teachers. ICT Learning Centre grounded a research group to study and evaluate the comprehension and ICT skills of teachers, students and parents. One major part of that research was to study teachers’ technical skills and pedagogical thinking and relationships between them. In the research it was proved that those teachers who use ICT actively showed to have a more mature insight of the use of ICT in education and generally more sophisticated pedagogical thinking. They also valued ICT more than the others as a tool for collaborative learning and emphasized the active role of the learner in information constructing process. These teachers also believed that it is possible to develop human intelligence. (Hakkarainen 1998b).

The only way to make changes in the pedagogical practices of teacher’s work is to influence the whole school community in collaborative way. Also the background organizations like the whole commune should actively give the frame of reference and financial resources to make it possible to all students to participate in the information society.
The Modern Model of Teachers In-service Training

Based on these findings ICT Learning Centre has been developing the practices for in-service training that includes methods like collaborative learning, research based learning, computer assisted team work and distance learning on the net. In all our courses we use multiform teaching containing face-to-face lessons, learning tasks and collaborative team work as project work. We use open learning environments so that all teams can access and make comments to others workspaces. In all of our courses we presume that there will be a group of at least two teachers from a single school and they will work together during the course. It is easier to make a change in a school community when there is a team of teachers to adapt new pedagogical skills to use. Learning tasks are done within the whole school community. In this way we try to guarantee that almost the whole school community will be involved in or at least will be conscious of the learning process.

The basis of all our in-service training is that all the methods and models used are transferable to the student level. When teachers learn to use these methods as a student they have a better ability and willingness to implement the methods into practice with their students. Dissemination of these pedagogical practices facilitate to form modern learning culture.

Open Learning Environments Support the Modern Model of In-Service Training

The use of Open Learning Environments (OLE) supports in an excellent way the modern model we are using in teachers' in-service training. As a matter of fact, several applications of learning could not be realized or they would be very difficult to carry out without ICT or open learning environments. The fact is that the demands of teacher's work and the pressing nature of it may often limit the possibilities to attend face-to-face training. OLEs make it possible to study and work with projects without the limitations of the time or the place. The training that is not limited to time nor place is however not the main reason to the use of OLEs. The most important reason is the method of learning, examples being collaborative learning and research based learning which can very easily be implemented with OLEs.

The traditional working model of the school has not supported the demands of the Information Society. It is necessary to move on from the traditional working model towards the culture represented by real world (living life). The construction of new information, the evaluation of information and sources and the use of information as a tool will be the most essential part of education. In several professions the modern expertise and know-how presuppose an ability to use ICT and ability to construct new information and to use information. Open learning environments and proper use of them offer schools very good possibilities to develop the education all-inclusively.

Most of the OLEs have a property to make thinking and the problem solving process visible. Thinking can be made visible by writing texts, drawing schemes or charts. It is possible to present ones ideas and hypothesis and other users can comment on them and ask questions. After that the second version of the text can be written based on the comments, and be published on the OLEs and the writer can have even more comments. The whole developing or problem solving process will become visible and also other users can learn by observing it. Interaction with colleagues, instructors, experts and the whole community of the school plays a significant role in development of education.

The open learning environments and their pedagogically meaningful use are the key factors to the challenges and demands of Information Society and open classroom. The use of OLEs facilitates the transformation of learning (and thinking) into a profound process and to a collaborative activity. The direction is from traditional working models towards research based learning and the real development of dynamical expertise. OLE is not restricted only in the classroom or the school, it openly extends to various fields of science and to the whole society and the world.

Case: Information Strategy for the Educational Use – Done by Collaborative Work

The Finnish Ministry of Education presumes that every Finnish school creates its own strategy for the educational use of ICT. The National Board of Education is funding training programs to guide this work. In the ICT Learning Centre we have planned a training program in which a group of teachers from a school creates the strategy collaboratively with other teachers of their own school and other groups of teachers in the same training program. It is expected that the head master, IT-teacher and one to three other teachers participate from a single
school. The team will work together on face-to-face lessons and during a distance period they are responsible for taking their own school community to work with them by informing and dividing tasks and duties. At the same time there are eight to ten other teams from other schools working on the same subject. There is an open learning environment to use for all those teams. In the open learning environment all the material the instructor has done is available (for example tools for the development process), as well as plans, ideas, learning tasks and etc. from each team. Every participant is able to access all workspaces and comment on the work of other teams. It means that every team can use and improve the ideas of the others and so the teams don’t have to invent things that another team has already developed.

Figure 1: Collaborative model of constructing Pedagogical Information Strategy for the Educational Use

The course of three credit weeks consists of three parts: four day face-to-face lessons, learning tasks done in advance and during the course and the project work: planning of the strategy and its execution plan. All the work is done on the open learning environment by the team. There are no individual tasks; work is done collaboratively and the whole team is responsible for the results. The first task is to map the situation of the school at this particular time. It means that the team or its authorized group at school have to collect the facts about the ICT equipment and personnel’s knowledge about software and its use in teaching. Because there are some teachers who wouldn’t like to use computer in their teaching, it is important to discuss also about the attitudes, fears and threats and to give everyone a possibility to be heard. That way it is easier to make a big change in working community.

First there must be a discussion of values; what is the information and the skills of ICT the students need in their future. It is also important to discuss and agree on the concepts like ICT, the pedagogical use of ICT, open learning environment etc. that are needed to create the ICT strategy. After the discussion the school community needs to decide what are the visions and the goals of using ICT in education. All this can be done in an open learning environment or as an open discussion. The most important part of this work is to write down all decisions and inform everyone.

To get new ideas of using ICT in education during the course every team plans an ICT project to implement with students, carries out the plan and describes the experiences on the open learning environment. Many of the teams have planned a project where students study some new entity using learning environment. This way teachers also get an idea of how to guide and tutor on an open learning environment when they themselves are students in the course using an open learning environment.

The most essential matter in this kind of training is the collaborative process. When every member of the school community has a possibility to take part in creating the strategy and all work is done together,
everyone is motivated to carry out the strategy in their own teaching. In the strategy there must be plans on how to train ICT and its pedagogical use to teachers, how to organize the technical and pedagogical support in a school and how to apply an open learning environment to teaching and learning. It is not so important to emphasize an individual teacher and his knowledge but the knowledge of the whole school community. The point is to facilitate all students to get the ICT skills needed in the future and the possibilities they have in improving their learning.

Abstract: This paper describes an educational technology online Master's degree program at Florida Gulf Coast University. The Curriculum & Instructions M.Ed. graduate program provides both educational and technology experiences for educators who are interested in using technology to support the learning process. A rationale is provided for distance learning. The target audience is defined. A rationale for the selection of courses is provided, faculty support, selection of student, and features of the program. Student and program evaluation techniques are discussed.

Introduction

Florida Gulf Coast University, founded in 1991, is the tenth institution in the Florida State University System. The approximate enrollment is 2,700 with a faculty and staff of 500. The campus is located in Southwest Florida on 760 acres of land. The mission statement of the University encourages the use of distance learning, and the Strategic Plan of the University states that FGCU will develop 25% of its enrollment using distance learning.

The M.Ed. in Curriculum and Instruction with a specialization in Educational Technology program (EdTech) began in 1997 when the University opened. The EdTech program offered 50% online courses and 50% face-to-face courses. The two three-week summer Tech-Ins offered 18 hours of course credit. Students completed the program as a cohort in 13 months.

Evaluation of the existing program demonstrated that students are successful with the online courses. Faculty in the college have experienced success with online learning, and the university supports training and support for online delivery of instruction. In order to support the Strategic Plan of the University and to provide more students with increased opportunities and flexibility, the current program will be offered as a 100% online program.

Online Distance Learning

Online distance learning courses have become an important facet of curriculum at many universities (Robertson & Stanforth, 1999). Schools are increasing their distance learning opportunities through the use of web-based technologies (Moran & Myringer, 1999). Colleges and universities are embracing online distance learning as a means to increase accessibility to many of their courses and programs (Phillips & Peters, 1999, Blumenstyk & McCollum, 1999). The increase in home computers and access to the Internet has expanded the potential student population (Dunn, 2000). If increased accessibility is the goal of colleges and universities,
it is important to ensure that they are meeting the needs of all learners through online distance learning, and not excluding large portions of their potential population.

Some of the reasons to support the ETOL program at FGCU included:
- Online/distance leaning is one of the major missions of Florida Gulf Coast University.
- One of the goals of the EdTech program is to learn about distance learning.
- EdTech students have the necessary skills and computer power to successfully learn online.
- The hardware and software technology for distance learning is improving and becoming more affordable.
- Software packages such as WebCT support higher quality distance learning activities.
- FGCU's support system for distance learning is in place and is improving.
- COE has faculty who are knowledgeable and supportive of online learning.
- Online programs have the potential to earn significant FTE.
- Research exists to support quality learning online.
- Thousands of courses exist using WebCT. Some courses are at the pre-college level.

Some of the issues facing the College as an online program is developed include:
- Online courses require careful planning for a quality experience.
- The content of technology courses changes often and requires frequent updating.
- Some students require face-to-face learning and live social interaction.
- Live classes may be more fun for both instructor and student.
- Some courses are more appropriate for distance learning than others.
- Intellectual property rights and faculty load issues need to be addressed.
- Faculty need to be trained to provide quality online experiences.

Target Audience

Students enrolled in this program fall into four broad categories:
- Classroom teachers who want a Master's degree that emphasizes technology.
- Classroom teachers who want to become Ed Tech Specialists at school or county level.
- Computer trainers who want to increase computer and pedagogical skill.
- Those with undergraduate degrees who want to learn about technology in education

Sub categories include:
- Level - kindergarten through college.
- Subject area - mathematics, art, elementary education, business
- Physical location – Anywhere in the world.
- Computer background – Minimum computer skills to computer science degree
- Intensity - part time to three courses per semester.

Student Learning Styles

Researchers in the field of distance education examined effectiveness, student motivation, student attributes and traits, student perceptions and attitudes, and interaction. Most of the research did not examine online distance learning, but focused on other forms of distance education (Russell, 1999). Clow (1999) and Sonner (1999) discovered that courses delivered by distance yielded greater effectiveness than traditional courses. Russell (1999) found no significant differences in the effectiveness of distance education compared to traditional education.

Locus of control refers to a student's perception about who is responsible for, or has control over, the events in his or her life (Baynton, 1992; Jonassen & Grabowski, 1993). Tests measuring locus of control
provide students with a type of either internal or external locus of control (Dille & Mezack, 1991; Jonassen & Grabowski, 1993). Students with internal locus of control tend to believe that academic success is due to their own abilities; responsibility for learning has been internalized (Dille & Mezack, 1991). Individuals with an external locus of control attribute their academic success to external factors or luck (Dille & Mezack, 1991). Dille and Mezack (1991) found that students defined as having an internal locus of control completed more in telecourses and performed better than students with an external locus of control. The implications for instruction include providing activities that "capitalize on the external student and challenge the internal student" (Jonassen & Grabowski, 1993, p. 360). These activities include teacher-controlled highly structured instruction, highly cued information gathering, and deductive activities all supported by praise and positive feedback from the instructor (Jonassen & Grabowski, 1993).

Kolb's Learning Styles Inventory (LSI) ranks students on four modes of learning, concrete experiential, reflective observer, abstract conceptualizers, and active experimenters (Dille & Mezack, 1991; Jonassen & Grabowski, 1993; Kolb, 1984). The modes of learning yield four learning styles, converger, diverger, assimilator, and accommodator (Dille & Mezack, 1991; Kolb, 1984). Implications for instruction include providing learning opportunities for all four types. Convergers prefer technical tasks to interpersonal issues, whereas divergers prefer activities of information gathering and imagination (Dille & Mezack, 1991; Kolb, 1984). Kolb (1984) stated that assimilators learn best when directed by theory, and accommodators work best while carrying out plans and being involved in challenging experiences (Dille & Mezack, 1991; Jonassen & Grabowski, 1993; Kolb, 1984).

The Student Learning Styles Scale (SLSS) was developed and refined by Grasha and Riechmann (Grasha, 1996; Jonassen & Grabowski, 1993). The SLSS classifies students in six categories, competitive, collaborative, avoidant, participant, dependent, and independent (Grasha, 1996; Jonassen & Grabowski, 1993). Grasha (1996) suggested that the six categories represent three dichotomous relationships, competitive-collaborative; avoidant-participant; dependent-independent. Grasha's research (1996) discovered that learning styles may be dependent on or influenced by course structure. Implications for instruction include providing a variety of learning opportunities to meet the learning styles of all learners (Grasha, 1996; Jonassen & Grabowski, 1993). Extensive research on learning styles shows some correlation between particular styles and success in different classrooms, with different instructors, and in different majors (Dille & Mezack, 1991; Grasha, 1996; Jonassen & Grabowski, 1993). Much of this research has been conducted on distance learning involving telecourses (Dille & Mezack, 1991; Institute for Higher Education, 1999; Russell, 1999). Online distance learning research is limited in scope and depth (Institute for Higher Education, 1999; Russell, 1999), due to the limited history of online technologies.

Student motivation has been studied on two levels, motivation to enroll in the class and motivation to complete the course. Motivation to enroll in distance learning courses included all-hours accessibility to learning, choice and variety of classes, and flexibility of location (Rodrigues, 1999; Rowntree, 1992; Saba & Shearer, 1994). Internal motivation for course completion was a key factor in successful completion of many distance courses (Ehrman, 1990; Kinzie, 1990; Schrum, 1998).

Verudin and Clark (1991) examined several traits and attributes that affect student performance in distance learning courses. These attributes include values, attitudes, and self-concept of the learner. Dille and Mezack (1991) evaluated additional factors that impacted student performance in telecourses. They discovered a positive correlation between grade point average and earned credit hours and final course grade. Dille and Mezack (1991) also discovered that older students received better final grades than younger students received, and married students fared better than divorced students did. Several researchers examined student perceptions and attitudes. Most research found that students completing the distance learning courses were satisfied with their learning experience (Inman & Kerwin, 1999; Phillips & Peters, 1999; Teh, 1999). Inman and Kerwin (1999) found that lack of direct interaction with the instructor did not negatively impact student perceptions or attitudes regarding course effectiveness and delivery. Dillon, Gunawardena, and Parker (1992) concluded that distance education students were positive about their interaction with the instructor and other students. Researchers reported that students preferred greater control and responsibility of their learning (Schrum, 1998).
Electronic Portfolios

The portfolios are developed and maintained in an online format, making them available to professors, students, and employers for the duration of the program. Portfolios are employed as a capstone project, an alternative to comprehensive examinations. The portfolios are developed throughout the program, and the final product is used to evaluate student knowledge gained in the coursework. The students have FTP access to their portfolios throughout the program. They can update the portfolios anytime, and faculty can examine the contents and page design and layout. The students can use the online portfolio as a professional resume. The university can use the portfolios for marketing the ETOL program.

Program

The EdTech program is designed to provide students with a theoretical foundation and the practical skills required for developing curriculum and instructional materials, in a specific area of concentration and for a variety of settings, from pre-school through adult education. The EdTech program concentration is designed to enable students to (a) provide leadership in applying information technology to a variety of educational systems; (b) provide in-service education and basic technical support to teachers and instructors who wish to use technology in curriculum and instruction; (c) assist in curriculum development that integrates technology as a tool for learning; and (d) design and implement courses in computer applications, literacy, and programming.

Degree Options

The M.Ed program is specifically designed for those who already possess Florida teacher certification, while the M.A. program is designed for those who are neither currently seeking nor intending to seek Florida certification.

Entrance Requirements

Students entering the program are required to have a Bachelor's degree from a regionally accredited university.
GPA and GRE or MAT are considered for admission. Letters of recommendation, an e-mail interview, and a self-assessment will determine student qualifications for DL.

In order to compete with other online programs, we will have to build QUALITY.
We need to shift from "experience-based" learning to "performance-based" learning.
Online focus group for feedback

Schedule

Nine courses are offered only once a year, but three courses are offered each semester.
The Social Foundations/Research/Special Projects block would be taken during the student's last semester.
This Foundations/Research/Projects block of 9 hours could be an integrated online synthesis with a team of faculty working with the students. Online teaming with WebCT is a natural. Multiple instructors could interact with students. Online faculty teaming would be a unique feature of the program.

Abstract: Can faculty views about internet-based online courses and degree programs change from skepticism to acceptance, and from opposition to cooperation in less than two years? This paper reviews the development and institutionalization of two 100% online teacher education degree programs at Webster University (St. Louis, MO, USA). The number of course offerings grew from one pilot online course in Spring 1999 to 14 in Spring 2001. This success is attributed to program developers' efforts to understand the institutional climate, select suitable program directions, and design online instructional methods congruent with those program priorities. The applicability of Webster University's solutions to online program development efforts at other colleges and universities are discussed.

Introduction

Two years ago, 100% online (Internet-based) courses were non-existent in the School of Education at Webster University (St. Louis, MO). Faculty were skeptical about offering online courses or degrees. The University's administration was also unwilling to commit new funding or resources to the online initiative. Today, the School of Education boasts two successful online Master of Arts in Teaching degree programs. Increased faculty interest in teaching online and high expectations about these courses have supplanted the skepticism. With the online programs now integrated into the University's operational infrastructure, administrative support for online programs is now a given. This paper traces the development and institutionalization of the School of Education's online programs. The successful institutional integration of Webster's online programs may be attributed to the program developers' attention to three dimensions: (a) the organizational climate, (b) curricular and program directions and (c) instructional methodologies. The innovative strategies for each dimension are discussed. With many other institutions starting online programs, Webster's case narrative here may be instructive in their efforts to chart a meaningful program development direction there.

Webster University / School of Education overview

Webster University is an independent, comprehensive, multi-campus University with an enrollment of 17,000 students worldwide and a home campus in St. Louis, Missouri. Its extended campus network
consists of 80 locations in the U.S., Europe, and Asia. The School of Education is one of five academic units within the University, with an enrollment of 1,100 in St. Louis, River Heritage & Kansas City, Missouri. Eighty percent of enrollment is in the graduate programs, including the Master of Arts in Teaching and the Education Specialist degree programs. The School also offers the Bachelor of Arts degree. In addition to the degree programs, it offers programs that lead to Missouri Teacher Certification and Missouri Administrator Certificates.

**Progress of online School of Education Programs**

The School of Education began offering 100% Internet-based graduate courses in the Spring 1999 semester. New online courses were added each semester. The coursework for two Master of Arts in Teaching degree programs, ("Educational Technology" and "Multidisciplinary Studies") may now be completed entirely online.

The School of Education was a pioneer for Webster University in offering among the first 100% online courses and was the first to receive approval for entire degree programs to be offered online. The instructor and student experiences in a pilot course in Spring 1999 were used to assess whether to proceed in further online program development. The pilot course was a success for the instructor and the 15 students alike. Student evaluations of the course was superlative, and the instructor assessed that course objectives were fully achieved in the online format.

*Table 1: Number of online courses, sections & instructors (SP 99 – SP 01)*

Subsequently, the online offerings have increased (See Table 1.). New courses have been added every semester since the pilot. Some courses had multiple sections. As new instructors are added each semester, there are now 21 different instructors teaching 39 different courses online. The enrollment total has exceeded 600 students.

**Faculty Concerns**

There were several reasons for the prevalent campus-wide faculty skepticism and opposition: (1) Many believed online courses were impersonal simply because the familiar face-to-face interactions were not present. Online courses were hence viewed to be in conflict with Webster University's mission statement that emphasized "student-centered" approaches and "personalized learning." (2) Faculty did not know how effective online courses were: Would students learn as much in online courses as they do campus courses? (3) Faculty were concerned that teaching online would be too taxing on individual instructors and on other campus programs or projects. They believed the time required to learn how to teach using this medium and extra time needed to teach the courses were unreasonable. They were concerned that online effort would take greater importance than existing programs, and therefore compete for money, time and other resources. Some faculty feared that online teaching would become a new criterion for evaluation. Some opposed it because they themselves were not interested in teaching online.
It was important to recognize the intensity of the faculty opposition to the online initiatives. The motivations and reasons for the opposition were both philosophical and emotional. Advocates and developers of the online courses were outnumbered. This meant that a cautious approach was necessary. In this climate, the potential for a devastating backlash was ever present.

**Priorities in Program Development and Instructional Methods Development**

The intense faculty skepticism necessitated planning and development strategies that did not compete with existing programs and University resources, and did not threaten faculty interests. It would be ideal if both the program development process and the results and products were beneficial to all involved, especially faculty and students. The program developers even hoped that the experimentation and development process itself would eliminate the threats, uncertainties, and problem issues. If the experimentation and development proved successful, additional faculty support was still required for faculty curriculum committees to approve the online courses and programs for the curriculum. The faculty concerns played a significant role in shaping the online program development priorities. These priorities in turn supported the development of the new online instructional methods. (See Table 2.)

Table 2: Relationship between faculty concerns, program development priorities, and instructional methods

**A. Too Impersonal for Webster's mission?**

Like the faculty skeptics, the online course developers were committed to advancing the university's mission to provide "student centered" approaches and "personalized learning." The online initiative should cease if the format or instruction in these courses did not lead to more personalization. Program development efforts were therefore shaped by this guideline. Resulting curricular and program directions included:

- **100% Online Courses:** Courses taught entirely online, and without any required on-campus classes increased flexibility for students in both time and geography. Students could participate in the course within wider time frames from home, school, office, or from a hotel room if they are traveling.
- **Asynchronous:** Removing any specific meeting time for classes also increased time flexibility for students.
- **Rejection of self-paced tutorial format:** It was important to keep the instructor involved and "visible" throughout the online course experience as a means of increasing the sense of personal contact.
Instructional methods that resulted from the attention to personalization include the following:

- Threaded discussions: Students value the interaction in campus-based class discussions. This is mirrored in online courses through threaded discussions, and occasional "chat" sessions.
- Peer critique: Students appreciated the peer critiques online because the record of the written feedback allowed for later review and reflection.
- Self-reflection: The written format of online course enabled students to review the material and reflect on the value of the process as well.

Online courses may be viewed as more personalized when it increases convenience for the students and affords them more flexibility in time and place. Some students find the online experience itself highly personalized because there may be greater opportunity to share one's experiences, read about others' and be heard in the threaded discussions. Others may not value this in the same way because they do not experience the written communication as personal enough.

B. Are Online Courses "Effective?"

How much learning occurs in online courses compared to campus-based courses? Are online courses merely "watered-down" seconds? Aren't students too passive in online courses to learn much at all? These questions reveal the importance of (a) choosing instructors, courses and instructional methods that have the greatest potential for success and teaching-learning effectiveness; (b) documenting how students experience online courses that our faculty teach; (c) assessing learning in both campus and online course; and (d) communicating the results of these assessments to faculty. Regularly updating the faculty is also beneficial in raising awareness about what are online courses and in correcting misconceptions or faulty assumptions about them.

These program development guidelines had the following effects on instructional methods:

- Instructors known for their effective or excellent campus teaching are among the best candidates for online teaching. "Excellent" instructors are likely work conscientiously to shape their teaching methods to also be effective online.
- Instructors seemed more motivated to develop new teaching methods when they or their courses were selected for online delivery because of the potentiality for teaching-learning effectiveness.
- Instructors have observed improved writing among students within the semester in online courses.
- Instructors report the quality of student assignments to be comparable to that in campus courses.
- There may be a stronger norm in online courses to produce quality work when the instructor requires some assignments to be shared among class members.

How much learning happens in an online or campus course is contingent on many factors including the instructors and their aims, priorities, skill and experience, as well as the course topics selected and the teaching methods employed. It appears unlikely that the online medium per se is the most significant factor in learning effectiveness. Finally, it may be just as important to communicate this conclusion to faculty in the department and across campus.

C. Too Taxing to Faculty and Other Programs?

Opposition to the online initiative may have been strongest when it was viewed as competing for priority, personnel, time, and resources. The absence of extra or special funding for the online initiative may have helped reduce the perception of inequitable distribution of resources. For the online initiative, it did mean experimentation costs could not exceed existing operating budgets. Given strong faculty sentiments, it was not possible to redirect funds already committed to departments and programs. There was some flexibility in some small grant (soft money) projects to multi-purpose some of the project objectives. For example, in a funded project to develop professional teacher networking across several school districts, the electronic
communication tools designed for use in the teacher collaboration could also be used for collaboration and teaming activities in the online courses. Many of the experimental instructional designs for online courses could be supported in this manner.

It was important to reassure faculty that online teaching was voluntary. No new expectation or requirement for faculty to teach online was being advanced. Evaluation of those who teach online involved the same criteria as those who teach campus courses. The impact of a voluntary online faculty, meant involvement of highly motivated instructors, which contributed to the strength of the courses. Also, with reluctance among full-time faculty to teach online, a strong pool of adjunct faculty teaching for online courses emerged.

Faculty concerns about significant learning time and preparation time for online courses were addressed by: seeking new instructor stipends for online teaching and providing specialized training and instructional design support for instructors. Instructors participate in a short-term training sequence to introduce them to the online tools and to course design issues. The tools and templates are especially helpful in shortening the time instructor might spend preparing the course, organizing activities, and grading assignments. Technical support is available to instructors throughout their course development period and through the duration of their course delivery. The strength of the support is its quick turnaround and response to problem solving provided by two staff members assigned to the online programs.

The threat that the online courses would "steal" students from existing programs was not realized. There was an immediate increase in new student enrollment when the online courses were launched. Also, it was possible for students in current campus programs to enroll in an additional online course, because of the time flexibility, whereas they would not have been able to schedule another campus course. This pattern also validates the program developers' decision to increase time and place flexibility.

As more instructors volunteered to teach online, and benefited from the support, the time-saving tools and templates, and new stipends, many realized the personal value of the experience. Teaching online, for most first time instructors, was an opportunity to learn about the technology, about teaching, and about their own teaching skills. Instructors have expressed the value of discovering new ways to organize a course, and how valuable this is in teaching both campus and online courses. Many faculty now view teaching online as an arena for their own learning and professional development. For them, these results are well worth the extra hours spent developing their skills.

Discussion

Two kinds of generalizations may be made from the School of Education's successful launching of its online programs: (a) Other institutions starting online courses may benefit from Webster University's case; (b) Some elements of the process may be instructive for other program innovations at Webster University or other institutions.

Like the Webster faculty, other university and department faculty are likely to be divided in their views about establishing online courses and program. Strategies used at Webster that not only reduced opposition, but also won the cooperation of faculty colleagues are probably applicable to many situations. Expanding the employment of qualified adjunct faculty when full-time faculty opt not to teach online (or whatever is the program innovation) is effective in building the programs and minimizing unwanted pressure on full-time faculty to participate.

While few universities share the multi-campus presence and organizational infrastructure, many departments, colleges or universities face similar budget and human resource limitations that the School of Education faced. It may be helpful for advocates of any innovation to view some lack of funding as an asset in reducing the resentment, sense of inequity or even hostility toward the innovators. “Multi-purposing” special projects appears to be an effective strategy when used for other program development goals in the context of frozen or restricted budgets.
When faculty have misconceptions or strong negative bias about other innovations, concepts or change being advanced, it makes good sense to document and collect assessment data, which can then be distributed to begin clarifying incorrect assumptions and biases.

Conclusion

It is likely that exploring any innovative curriculum such as this online initiative inevitably begins in a context of skepticism and opposition, as it did at Webster University's School of Education. Some of the strategies in program development and instructional methods employed in this case seemed unexpected or counterintuitive when taken out of context. In retrospect however, the choices made and the process followed were sensible and meaningful. We do not know if the association between these decisions and the success of the online programs or the change in the faculty climate was coincidental or germane. It is also speculative whether applying these factors to other situations would lead to similar success. Perhaps the more important lesson lies behind the individual factors discussed above. The underlying process may be more essential. This process was: to listen carefully to the voices of opposition; to understand and acknowledge them; and to provide creative but genuine and meaningful institutional responses to them. The resulting program directions and instructional methods will differ in every case where this process is used, but they are likely to be the most appropriate and, let's hope, successful direction for that innovations.

Abstract: A graduate level specialty track in learning technologies was approved in 1998 in the College of Education at Florida International University. It is offered as a track under the Master of Science in Urban Education degree program. The first group of students enrolled in the program during the Spring 1999 semester. This paper provides an overview of the
Introduction

The College of Education at Florida International University in Miami, Florida has been offering a Master of Science in Urban Education degree program for a number of years. In response to a perceived need, a specialty track in learning technologies was proposed in 1998, and was approved and added to the urban education degree program in the same year. The District Director of the Division of Instructional Technology and Media Support Services of the Miami-Dade County Public Schools (M-DCPS) provided a letter in support of proposal to start the program. A majority of the graduates of the College of Education teach in the Miami-Dade County Public Schools, which is the fourth largest school district in the United States. Many of the students enrolled in the learning technologies specialty track teach in the M-DCPS. The purpose of this paper is to provide an overview of the learning technologies specialty track. Excerpts from written comments submitted by students who were enrolled in the program at the time this paper was written are also included.

An Overview of the Specialty Track

The College of Education at Florida International University places a great deal of emphasis on learning technologies, as indicated by the following statement that appears in the strategic plan developed by the faculty of the College:

The teacher of the 21st-century must be as comfortable with technology as a learning tool as he/she is with the chalk board, textbooks, etc. Teacher education institutions must therefore play a vital role in the preparation of such kinds of teachers and other school personnel (Florida International University, College of Education, 1996, p. 11).

As stated in the document Technology and the New Professional Teacher (National Council for Accreditation of Teacher Education, 1997)

Classroom teachers hold the key to the effective use of technology to improve learning. But if teachers don’t understand how to employ technology effectively to promote student learning, the billions of dollars being invested in educational technology initiatives will be wasted (p. 1)

The purpose of the specialty track in learning technologies is to make educators, especially classroom teachers, comfortable with the idea of using various technologies to facilitate learning, teaching, and professional development. As their comfort level grows, students in the program also become capable and knowledgeable about how to use various technologies in their own classrooms, and to further their own professional development. Extensive knowledge of or proficiency with technology is not a prerequisite for admission into the program. However, by the time students are ready to graduate from the program, they will have developed sufficient technological expertise and gained adequate knowledge to enable them to use various technologies in educational settings.

The beliefs upon which the master’s degree program is based are as follows:

1. Technology is not an end in itself, but a means to an end, the end being learning.
2. All students, irrespective of their social, economic and ethnic backgrounds can learn with the help of technologies such as computers, CD-ROMs, videodiscs, the Internet, and the World Wide Web (WWW).
3. Given adequate experiences and opportunities, all students (males and females) can learn equally well with the help of various learning technologies.
4. A ‘hands-on’ approach to preparing teachers to teach with technology will better equip them with the skills to facilitate learning in technologically rich classroom environments.
5. Teachers who are encouraged to reflect upon and continuously improve their practice will discover better ways to use learning technologies to facilitate learning in the classroom.

The beliefs upon which the proposed program is based, are in turn based on the following
assumptions:
1. Technologies will continue to change at a rapid pace.
2. The availability of learning technologies in K-12 schools will continue to increase.
3. The potential that advanced technologies have for facilitating learning will also increase.
4. Learning technologies will be used in schools in fair and equitable ways.
5. Newer and better technologies will become available in the future.
6. Teachers will have the freedom to experiment, explore, and discover new ways of facilitating learning using technologies.
7. Teachers who are taught using a 'hands-on' approach will develop positive attitudes and become more confident in utilizing technologies to facilitate learning in their classrooms.

In order to graduate from the program, students have to complete 36 hours of coursework, including 18 hours of coursework in the area of learning technologies. The other 18 hours of coursework consists of core courses that are a part of the Urban Education master's degree program, and consist of courses in research and foundational graduate level courses in education. If students take two courses a semester, they can complete the program in six semesters or two years, including summer sessions. In addition to making students more comfortable with technology, the program also provides them with a strong foundation in research.

A Hands-on, Project-Based Approach

The learning technologies courses in the track are taught using a hands-on, project-based approach. All the learning technologies classes have so far been taught in computer labs. Assuming that computer labs are available in the future, such classes will continue to be taught in computer labs where each student has access to a computer. Students work individually or with others to complete various projects, that sometimes involve creating products and at other times result in presentations. They are also given the option of gearing the content of their projects towards the grades and the subject areas in which they are interested. A student stated, "I have engaged in many hands-on projects that I was able to create specifically for my teaching discipline. I feel the major advantage has been the ability to actually complete projects using technology and take them back to the classroom." Another student noted, "Creating projects gave me a clearer picture of what I should be doing with my students to help increase their motivation and learning. I have seen that there is so much available to help teachers and students. Participating in this learning technologies track has helped me see how important it is to expose students to a tool that will enhance their learning, and how I can become a change agent in helping other teachers to integrate technology in their classrooms as well." According to a third student "The most important skill I have received from this unique program is the project-based learning, the hands-on experiences."

Instructor is a Facilitator

The theme that defines the College of Education (COE) at Florida International University (FIU) is stated as follows: "The Professional Educator and/or Related Professionals as Facilitator of Learning and Change Within Diverse Populations and Environments" (Florida International University, College Of Education, 1996, p. 28). The theme implies that "the graduates of any program in the College should be disposed to view teaching as the act of being a facilitator of student growth rather than a source of information to be learned" (Florida International University, College Of Education, 1996, p. 28). The College's stated theme suggests that the emphasis of proposed master's degree track should be on a facilitative approach. The learning technologies courses that are a part of the specialty track have been taught up to this point in time using an approach that can be best described as a facilitative approach. The instructor acts as a facilitator, setting the stage for learning. The instructor plays the role of a 'guide on the side' rather than the so called 'sage on the stage.' In this approach, the instructor is in charge and in control of the course at the beginning of the semester. Slowly but surely, students begin to get more involved in the course and in their own learning. Students are encouraged to share ideas and resources with each other in all the learning technologies courses. According to one student "The courses are designed to build confidence, allow for
sharing of information and knowledge regarding practical applications for the use of technology in the classroom."

**Some Challenges**

Adequate technology resources are not always readily available. Even when such resources are available, they are not available for use during class. Since many of the students in the program are teachers, the learning technologies classes for this program are generally offered in the evenings. Since the offices on campus that provide technology support services usually close at 5:00 p.m., it is sometimes difficult to get access to the necessary resources during class hours. It must be pointed out that many of the staff members who work on campus in offices that provide technology support services, have been extremely helpful to and supportive of students enrolled in the learning technologies track. On a couple of occasions, the university support personnel have even stayed in their offices a little late and taken the time to demonstrate technologies to students.

At this point in time there is only one full-time faculty member who is responsible for teaching many of the learning technologies courses in the track. One or two other faculty members have occasionally taught courses in which students from the track have enrolled. However, such help cannot be taken for granted since these faculty members have other responsibilities and may not have the time to teach learning technologies courses every semester. Since the learning technologies program is relatively new, and the student numbers are growing at a slow pace, the college cannot justify hiring more faculty members until the program grows some more and becomes larger in terms of student enrollment. This situation will hopefully improve as more teachers become aware of and enroll as students in the learning technologies program and as the college hires more faculty members.

**Future Plans for the Specialty Track**

A few prospective students have called and expressed a need for online offering of some of the courses within the specialty track. When more resources, especially personnel resources become available, some of the courses will be offered partially online. This will make it more convenient for teachers in M-DCPS and other nearby school districts to pursue the program.

It would also be nice to have dedicated lab space for use by faculty and students in the learning technologies specialty track. The availability of such space and equipment would make it possible for students to learn more about various technologies that can be used to facilitate learning, teaching, and professional development.

**Conclusion**

The learning technologies specialty track is a small but steadily growing program. It is also a relatively new program. Initial indications are that the program is beginning to make an impact, albeit on a small scale. One student stated "After two years in the LT program I have gained valuable information on how to use technology not only in the classroom but also for my own personal use. When I first started I only thought of my computer as a $2,000 deck of cards . . . . Two years later I now feel extremely comfortable using different programs. I am also no longer afraid to try different programs in my computer. While I still use my computer to play cards that is only while I’m waiting for my information to be downloaded." As another student put it, "In my first class, I had to ask the professor how to save a file on a PC Disk. I was a Mac person who had always dragged and dropped files. I had no idea that a mouse had a left side and a right side. Two years later, I can edit movies, create charts, graphs, PowerPoint presentations, Hyper Studio presentations and Web Pages. I have set up an entire distance learning class and a database." There is a need to monitor the effectiveness of the program on an ongoing basis.

Abstract: The current model for mentoring doctoral students is based on apprenticeship; but this process may result in the insufficient development, application and spread of knowledge. Other mentoring models have been proposed, but none have addressed online professional development. Communities of practice (CoP) have the potential to be conducive to mastery of new knowledge. Several successful reform projects have supported this concept. This paper describes a CoP model that combines on-line and face-to-face (FTF) elements designed to enhance mentoring and professional development strategies. The goal is to evolve a sustainable CoP for the graduate education of professionals, learning the intricacies of their profession, implement practices, and apply new content knowledge. This study demonstrates how a CoP model supports doctoral students' learning. It concludes with a discussion of the attributes of CoPs and guidelines for construction of effective mentoring models for learning reforms.

Introduction

The current model for mentoring doctoral students is based on apprenticeship; but this process may result in the insufficient development, application and spread of knowledge. Other mentoring models have been proposed, but none have addressed online professional development. Communities of practice (CoP) have the potential to be conducive to mastery of new knowledge (Lieberman, 1996; McMaster, 1999; Renyi, 1996). Several successful reform projects have supported this concept (National Science Foundation, 1997; Stokes, Sato, McLaughlin, & Talbert, 1997). This paper describes a CoP model that combines on-line and face-to-face (FTF) elements designed to enhance mentoring and professional development strategies. The goal is to evolve a sustainable CoP for the graduate education of professionals, learning the intricacies of their profession, implement practices, and apply new content knowledge. This study demonstrates how a CoP model supports doctoral students' learning. It concludes with a discussion of the attributes of CoPs and guidelines for construction of effective mentoring models for learning reforms.

Communities Of Practice

Quintessentially, "communities of practice are groups of people who share similar goals and interests; and, in doing so employ common practices, work with the same tools and express themselves in a common language. Through such common activity, they come to hold similar beliefs and value systems (Collaborative Visualization (CoVis) Project, 2000)." These groups of professionals are informally bound to one another through exposure to a common class of problems, a common pursuit of solutions, and
embody a store of knowledge (Peter+Trudy Johnson-Lenz, 2000). A common sense of purpose and a real need to acquire the knowledge of each other holds these professionals together. Members of CoP collaborate directly, use one another as sounding boards, and teach each other. They are not merely peers exchanging ideas who share and benefit from each other's expertise, but members committed to jointly develop better practices. Thus, developing a "community that learns" rather than just a "community of learners." In fact, many CoPs have occurred naturally in learning and/or working environments.

Three Dimensions of CoP

Three dimensions of CoP, knowledge, community, and integration, are proposed by McDermott (1999).

CoPs, whether spontaneous or intentional, share both knowledge and information. CoPs have both individual and community relationships, and integrate the individual's work in many different ways. They vary a great deal concerning how much they focus on each of these dimensions. Some focus more on sharing tacit know-how and others on explicit information (knowledge dimension). Some build relationships among individuals; others build a common identity (community dimension). Some are tightly tied into people's everyday work; others are distinctly separate from it (integration dimension). By understanding these dimensions, one can determine the kind of learning community that will likely be most effective for a given situation. None of these dimensions are mutually exclusive.

Knowledge

There are many different kinds of knowledge, data, information, tools, procedures, know-how, and understanding. Some knowledge can easily be written down or drawn and made "explicit." Tools, procedures, templates, are examples of explicit knowledge. Other knowledge is "tacit," things known by people, but not documented anywhere. The know-how, understanding, mental models, and insights of an individual or discipline are examples of tacit knowledge. Since explicit information is written down, it can be organized, distributed, and managed. Know-how, on the other hand, includes a vast store of knowledge that people are unaware they possess. To become aware of this knowledge, people often need a problem or issue to draw it out, such as problem-based knowledge building. Know-how is difficult to communicate in a way that is useful to others. It rarely translates well into explicit procedures. In fact, it is often shared through "war stories," observations, reflective discussions, and other person-to-person connections. Understanding which kinds of knowledge a community needs to share is key to selecting the forums, structures and systems that will be most effective.

Community Identity

The second dimension is the strength of the community's sense of identity. This identifies how people participate socially in the community and the boundaries that hold the community together. In a strong community people interact frequently, both individually and as a unit, and share a common identity and purpose. This is a community of practice. In a weak community there is very little interaction, common identity, or purpose. Both extremes and the variations between them can be useful in disseminating learning.
Integrated with the Work

Documenting and sharing knowledge with other communities often feels like an imposition on "real work." Problem solving and applying insights form the core of the work of most communities. It is usually hard for them to step back and document their insights for others or break to solve another communities' problem. Requiring documentation is not a resolution. Even when required, documentation is often seen as an afterthought and frequently does not contain the richness, subtlety, and meaning of the communities' thinking.

When sharing knowledge is naturally integrated with work, people often naturally share ideas and insights without thinking of it as separate from their normal work. When sharing knowledge is seamlessly integrated into work it is unobtrusive.

CoP And Learning

CoP has a strong influence on pedagogical designs (Collaborative Visualization (CoVis) Project, 2000). The concept of CoP can enhance learning in a social interaction environment (Brown & Duguid, 1996; Lave & Wenger, 1991; Wenger, 1998). This concept is familiar to most educators and is based on several educational theories. The focus on learning through "participation" in CoPs is reminiscent of John Dewey's learning by doing. The underlying assumption is that people gain new abilities and knowledge through efforts to attain goals. The second focus on learning through participation in the community is reflective of many efforts, past and present, to bring the social learning and doing, so often found in the workplace, into the classroom. Learning in CoPs includes efforts to integrate collaborative learning, apprenticeship, mentorship, and tutoring as a part of classroom education. The concept of CoP suggests that it is the combination of these endeavors, rather than the isolated application of any one of them, that will allow students the widest access to opportunities for learning (Collaborative Visualization (CoVis) Project, 2000).

When CoP is applied to academia, novices in the CoP must participate in and must be assisted by the community to acquire the goals, values, language, and techniques of practice. Novices and experienced-members are constantly acquiring complex abilities and knowledge through their regular participation in professional, recreational and daily living CoPs (Collaborative Visualization (CoVis) Project, 2000). A key component of becoming a member of a CoP is that learning takes place through working with others toward a common goal. One must have a commitment to continuing learning to be a part of the community. One exceptional technique in learning is to be engaged in teaching others and in developing new approaches to old challenges. Fully participating in a CoP increases the ability to learn individually and also increases the knowledge of the whole community (McMaster, 1999). Debates and contentions are key components that drive community activity and the evolution of that activity over time.

Building Informal Communities

Although CoP is naturally created, it can be fostered. Sharp (1997) suggested several factors to facilitate the development of informal communities. Members of the community should work together, train together, and stay together long enough to provide a fertile environment for the development of CoPs. However, just being together is not enough; personality, judgment of competence, and style need to be included, as well. Therefore, trust, cooperation, friendship and community are essential to community discourses.
FTF interactions increase the likelihood of a CoP developing among members; but they are not required to foster CoPs. Generating occasional social interaction is the key to advancing a CoP. Computer-mediated communication (CMC) is able to deliver social interaction and is, therefore, a viable means to construct CoPs. In building social interaction, trust and mutual recognition of competence, developed over time, are critical to supporting professional groups (especially using CMC) and CoPs. According to Sharp (1997), frequent reassignment or promotion of professionally skilled people may inhibit or degrade CoP development.

Sharp (1997) argued that improved learning would often come from encouraging development both of CoPs and CMC Communities of Discourse. Both FTF meetings and CMC forms are critical to foster CoPs. A CoP can be maintained through supplemental non-FTF forms of communication. Arranging a time, place, and agenda for a FTF meeting can be cumbersome. However, the informal nature of communities and the possibilities of modern technology make the formation of communities easier to accomplish. CMC can help professionals sustain and deepen relationships that they initiate through more conventional channels.

Technological designs exert a strong influence on CoP (Schlager et al., 2000). Several guidelines are proposed to foster CoP through the use of CMC forms: (a) Facilitate and publicize "Schelling Points": Enhance and widely publicize the ability to easily create mailing lists, Web pages, phone lists, online bulletin boards, real-time discourses, and other communication facilities that can support communities of discourse; (b) Seek active support from one or more CoPs when using CMC forms: The more "water-cooler" CoPs using a particular CMC form, the greater the likelihood of a successful sharing of information; (c) Explore the use of "Agent" technology to enhance signal-to-noise ratio, giving participants more relevant messages: Use cognitive (content) and social (rating) systems of intelligent agents to filter information.

Method

Participant observation method with a dramaturgy perspective was used to understand the building CoPs from the student's point of view. The community was composed of eight students enrolled in the Distance Education Seminar, a doctoral level course offered by a university in the Southwest United States, were the subjects. Students were allowed to take from one to three credits. All eight students were enrolled in the course continuously over two years. One instructor served as the coordinator. The group met once a month for two hours. FirstClass, a computer conferencing system, was used for group communication. It provided e-mail, bulletin board, and real-time chat functions.

The data were collected over two-semesters through casual conversation, in-depth interview, direct observation, and document analysis. At the twelfth week of the second semester, four semi-structured in-depth interviews were conducted with students to explore particular concepts in the CoP. Document analysis included all messages delivered on FirstClass and outside e-mail received by group members.

RESULTS & DISCUSSIONS

Several guidelines were generated from the qualitative data analysis.

Determine Community Knowledge

If the community which shares tacit knowledge has a strong sense of identity and needs to integrate new knowledge related to their work, FTF meetings and many opportunities to link together one-
on-one via CMC are necessary. The sharing of explicit information (documents already written) that is not vital to the community identity and that does not need to be immediately integrated as new knowledge for the work of the community can be accomplished by the development of community databases that are managed by a select group of community members, such as web-based databases.

Build Important Topics

Organizations frequently cast "too wide a net" and ask teams to share or document too much information. As a result, they end up building stockpiles of underutilized information. To leverage knowledge effectively, communities of practice need to understand what knowledge is strategically important to the communities.

Build Background Context

Sharing insights is not simply a matter of transmitting information from one to another. To be useful, information needs to be translated from the context in which it was developed to the context in which it will be applied. It is in the human interaction that people build enough common contexts to understand each other, enough trust to be willing to share ideas, and enough initiative to draw out the "tacit" knowledge.

Most CoPs have many different kinds of knowledge to share. Since data, information, and know-how travel best in different media, most CoPs need multiple ways to connect and share knowledge. When a community relies too heavily on a single medium it tends to get clogged with inappropriate information.

Pull Insights from Each Other

Most people have had the experience of sitting through long discussions that were not immediately relevant. People learn best when faced with a problem and need ideas to solve it, when they "pull" information currently relevant. Whether using person-to-person forums or CMCs, knowledge sharing should be designed to respond to "pull" rather than "push" information out to people.

If the organization values learning and sharing knowledge, it should provide a rich ground for growing CoPs. But that means people need to give the time and encouragement to reflect, share ideas with others, and think through the implications of others' ideas. Rather than creating a new "program" for sharing knowledge learning, find the networks that already exist, enable them, and link them to other communities.

Conclusions

Community of practice can enhance learning through mentoring. Several factors identified in this study serve as a model for building a CoP for education reform. First, one must to decide what kind of connections to make between learners, to understand what kind of knowledge to share; what kind of community it is inclined to be; and how tightly sharing knowledge needs to link with work. To enhance learning one does not need to create and build them from the ground up because CoPs arise spontaneously in most organizations. However, one needs to identify and nurture them with the resources, structure, and systems they need to flourish. Developing CoPs is closer to husbandry than architecture.

When building communities on natural networks, coordinators must be generated to organize and maintain the community activities, such as building important topics, initiating simple knowledge
sharing activities and arranging social activities. The coordinators also need to provide the members with the time and encouragement to reflect, share ideas with others and think through the implications of other ideas. Because communities are organized and supported differently, community development requires a different set of tools and approaches. CoPs often require time to develop. Because they are organic, CoPs need time to find the right kind of information to share, the right level of detail, the right participants and the right forums. Individuals must support the community in making these discoveries quickly; but, since information, level of detail, participants, and right forums will be different for different communities, each community will need to discover their own appropriate forum.

Abstract: The Learning Lab is an online professional development program for teachers who want to upgrade their information technology skills and learn more about integrating technology into teaching and learning. The program is based on self-directed learning. It includes prior learning assessment and development of personalized learning plans as core components of the program. A wide range of learning paths, modules, learning objects, and resources are provided to meet the needs of teachers whose skill levels range from emergent technology learners to education technology leaders. The Learning Lab provides opportunities for teachers to work at their own pace, in the curriculum area of their choice, and to apply their research and their learning into the classroom. Offered as both a non-credit and credit program, The Learning Lab provides an easily accessible, media-resource rich, mediated model for teacher professional development programs that meets international standards and strives to address key issues in ITC training.

Introduction
The emergence of network technologies and the evolution and rapid growth of the World Wide Web in the mid-1990s has had significant implications for teacher and learner access to information and learning resources. This situation has not gone unnoticed by learners, their parents and the public, all of whom are demanding greater access to learning technologies within schools. Since the mid-1980s, access to and use of computer technology in schools has grown rapidly but unevenly. In Canada, successive technology funding programs at the provincial and federal levels have provided schools with access to hardware and wiring but until recently little attention has been paid to the development of appropriate educational content, teacher training, and technology support within schools. As a result, individual teachers often struggle with the implementation of technology due to a lack of curriculum-specific software, training, and support. Of greatest concern to individual teachers and teachers' associations is the lack of training and professional development resources and approaches available that enable educators to successfully integrate computer technology into their practice.
A number of pilot and small-scale attempts have been made in various jurisdictions across Canada and the United States in recent years to address this problem. These pilots indicate that adult training models work effectively with teachers and that the most effective approaches to teacher professional development in the use of computer technology are ones that emphasize contextualized learning. This means, for example, that if one is a social studies teacher, effective integration of technology is likely to occur when the training received by the teacher is connected to the pedagogical and instructional plan that the teacher has within the classroom.

Of equal importance in teacher education is the use of educational models that provides teachers with ample opportunity to direct their own learning within a resource-rich environment. In 1999, the Council of Ministers of Education of Canada published a series of research documents that outlined educational issues and provided a framework for evaluation of teacher education programs in information technology. The issues identified in this research and elaborated in the resulting framework document clearly showed that across Canada teachers were recognizing the need to increase the scope and quality of professional development programs in information and communications technologies (ICT). Primarily, they were looking for contextualized, self-directed, and collaborative professional development models through which they could enhance their ICT skills.

**Key Findings That Guide The Learning Lab Program**

Key findings about teacher needs with respect to ICT professional development are listed below:

1. Time, within the school schedule, to learn how to use the technology, experiment with the technology, and learn how to integrate it into the curriculum.

2. Proof that technology integration makes a difference in teaching and learning and can be academically justified in terms of improved student learning.

3. Practical “how to” knowledge and first-hand, experience-based skills with respect to using and operating technologies to support teaching and learning.

4. An organized, ongoing, varied program of professional development activities to reach all teachers “where they are at”.

5. Time and opportunity for reflective thinking about the place of learning technologies as tools for learning and teaching and about how they change the teacher’s role.

6. In-depth knowledge of learning and instructional theories - constructivism, cognitivism, behaviourism, andragogy, facilitation skills, etc.

7. Teachers using learning technologies as students and developing standards, benchmarks, and accreditation processes for pre-service and in-service training with instructional technologies.

8. Access to learning technologies in sufficient quantity and quality that activity can be undertaken within classrooms and with student groups.

9. Ongoing and on-demand access to peers, mentors, or colleague networks where expertise can be obtained and discussion can take place on issues related to pedagogy and/or technology.

10. An organized support system to ensure that school-based technology and networks are serviced or can be serviced with quick response.

---

History of the Program
In 1997 the Open Learning Agency (British Columbia) and Simon Fraser University (British Columbia) collaborated on an innovative post-baccalaureate diploma program for teachers that focused on self-directed learning and the use of online resources and interactive collaborations in teaching and learning called Teaching and Learning In An Information Technology Environment (TLITE). This 2-year, 30 credit program was innovative as well in the way it utilized local expertise and experience through the development of cohort agreements with school districts, and in the flexible accreditation that was made possible through the use of field-study credits. However, the program was and is designed to work well with a great deal of face-to-face interaction and ongoing local support by school district mentors. As a face-to-face model, the program was extremely popular and was well received by teachers in British Columbia. The number of teachers who were able to participate in the TLITE program was small (fewer than 400), while the number of teachers who needed to upgrade their information technology skills and their professional practice with information technology in their classrooms was large (more than 40,000).

British Columbia is a large, geographically diverse province with the majority of the population concentrated in the southwest corner and the rest distributed throughout the vast interior and mountainous northern regions or along the rugged shoreline with its many small islands. Training teachers in BC is a daunting task. However, we believe that all teachers and students have an equal right to high quality education, with equitable access to resources and technologies. The Province of British Columbia has spent many millions of dollars over the past 15 years in research and development through such programs as the Community Learning Network, and in networking all the schools, universities, colleges, and libraries of the province through the Provincial Learning Network.

Similar problems are evident across Canada, and the federal and provincial governments are trying to meet the challenges that face Canada’s education system. To that end, the federal government through Industry Canada (a federal ministry) has established Canada’s SchoolNet, Canada’s Campus Connection, and Canada’s Learnware programs. The Learning Lab is partially funded through Canada’s Learnware program, as the teacher education component of an experimental educational portal, The Learning Window, designed by Ingenuity Works, with partners IBM and Telus.

The Learning Lab takes the lessons learned in the TLITE post-baccalaureate diploma program and applies them to asynchronous, online, mediated, mentored, resource-rich learning for teachers. The teacher may be in pre-service programs or can be practicing teachers who need to upgrade their technology skills or enhance their use of technology in their professional practice. The program focuses on self-directed learning as the learner (teacher) strives to increase competencies in particular areas of either skill or application.

The Learning Lab is built upon the notion that adults prefer to learn in their own way, at their own pace, to meet their own individual needs. It assumes that the prior learning that people bring to the educational experience is valid and provides opportunities for every participant to complete a Technology Self-Assessment Inventory and revisit that self-assessment as often as needed throughout the program. It provides tools and opportunities for participants to design their own learning path, based on their individual curriculum areas, grade levels, and interests. It is designed to meet the needs of a wide variety of learners - from beginning technology users to educational technology leaders. And, it makes used of sophisticated, web-based competency management system to guide learners through their self-designed program of study.
Figure 1.0: The Learning Lab - Self-directed Learning Model
The Learning Lab provides opportunities for participants to address standards and competencies developed by their school districts, states, provinces, or themselves. It provides interactive online tools to assist educators to design their individual learning plans as well as to participate in pre-defined learning plans. It provides ways for participants to demonstrate that they have met learning outcomes for credit through those individual learning plans.

It is based on competencies originally described in the collaborative venture by OLA and Simon Fraser University’s Faculty of Education called the TLITE program, as well as on standards defined by the International Society for Technology in Education (ISTE) and accepted by the National Committee for the Accreditation of Teacher Education (United States). It uses those competencies and standards to provide opportunities for educators to increase competence in the use of technology, as a teacher, and as a learner. However, teachers participating in the program will be able to set their own standards, and define their own goals.

An advisory board is being assembled and currently includes two participants from U.S. universities, Mississippi State and University of Georgia. Dr. Lynne Schrum (Schrum, http://www.uga.edu/) and Dr. Larry Anderson (Anderson, http://www2.missou te.edu/~isa1/) are advising the development and delivery team on educational models, content development, and evaluation of the program.

The Learning Lab content is developed in SGML and XML. The delivery environment is designed using very innovative technologies – a Zope object database on a Linux server. This development provides the Open Learning Agency with a prototype XML object repository using open source tools. The SGML/XML development environment allows us to provide content in the form of granular learning objects, aggregate them to form pre-designed learning paths, or provide them to the users to design their own learning paths.

![The Learning Lab](image)

**Figure 2.0:** A Learning Path in The Learning Lab is made up of granular learning objects aggregated into modules.

It will be possible for each program participant to get accreditation for the same program using entirely self-designed and unique "course-like" content. The binding factor is the assessment and accreditation tools based on demonstrations of competence that meeting learning outcomes and established competency benchmarks.

**The Learning Lab** is available online at http://lll.ola.bc.ca.

Learning to Learn in Online Courses

Joan L. Whipp and Heidi Schweizer
Department of Educational Leadership and Policy Studies
Marquette University
United States of America
joan.whipp@marquette.edu
heidi.schweizer@marquette.edu

Abstract: What strategies do students use to cope with challenges in the online learning environment? Written surveys and verbatim interview transcripts of 94 online learners in five online graduate courses were analyzed. Students describe a variety of metacognitive, motivational and social strategies tailored to the online environment. These strategies include goal-setting, pacing, planning, notetaking, summarizing, self-monitoring, early navigation practice, self-talk, humor, networking, help-seeking, writing, and listening.

When learners are first oriented to online learning, often much attention focuses on the technical issues which can be major barriers to learning in this environment (Mory, Gambill & Browning, 1998). Surprisingly, little attention is paid to critical psychological factors that can be equally important. Current views of learning and motivation suggest that one of these psychological factors is self-regulation of the learning process (Olgren, 1996; Zimmerman, 1986; 1990). Zimmerman (1986) describes self-regulated learners as those who are "metacognitively, motivationally and behaviorally active participants in their own learning processes." Metacognitively, they "plan, organize, self-instruct, self-monitor and self-evaluate at various stages of the learning process." Motivationally, these students believe themselves "competent, self-efficacious and autonomous." Behaviorally, they "reflect, structure and create environments that optimize learning." While there have been many studies of self-regulation in traditional K-12 learning environments (e.g. Zimmerman, 1990), there has been little exploration of this construct in the online learning environment in higher education. Furthermore, although there is a growing literature about various managerial, pedagogical and social strategies that instructors need to use in the online environment (Berge, 1996; Everett, 1998; McKenzie, Kirby, Newbill & Davidson, 1998; Mory, Gambill & Browning, 1999), there has been little discussion of how students can maximize the environment for learning.

The online environment can offer particular challenges to a learner (Eastmond, 1995; Hiltz, 1994). In addition to technical access, problems most often mentioned in the literature are the absence of traditional communication cues, asynchronicity, multiple conversations happening at the same time, information overload, isolation of the learner, and a predominantly text-based environment. In a rare close-up study of a small group of learners in a computer conferencing environment, Eastmond (1995) found that although some learning strategies were suggested by their instructor, more "typically these students borrowed from their 'bag of learning tricks' the approaches, strategies, and tactics that had worked for them in other situations" (p. 124). Clearly, more study of how self-regulation works in an online environment might encourage online instructors to offer students more support for this critical factor in learning.

For the past three years we have been offering online courses in a masters program for practicing teachers at a large private midwestern university. The study reported here took place during the fall of 1999. It was designed to extend Eastmond's (1995) case studies of online learners by using Zimmerman's (1986; 1989; 1990; 1994) framework for self-regulation of learning to study a wider pool of students taking online courses. The study posed these questions: What is most challenging to students in the online learning environment? What specific strategies do students use to cope with these challenges? Primary data sources included: anonymously written surveys of 94 students who have successfully completed at least one of five online courses offered over a two year period and verbatim transcripts of face to face interviews with 14 of those students. Surveys and interview transcripts were read several times to identify challenges and strategies identified by these students. The strategies were then grouped under Zimmerman's categories for self-regulated learning (metacognitive, motivational, and behavioral).
Besides technical issues, the greatest challenges cited by these students in order of frequency were: time management, slow pace of discussions, isolation, work overload, and writing anxiety. Students identified metacognitive and motivational strategies similar to those discussed in literature on self-regulation (Zimmerman, 1986; 1990) but tailored for use in an online environment. They described strategies for goal-setting, pacing, planning, notetaking, summarizing, and self-monitoring that include anticipation of technical problems, server delays and the need to work both online and offline. The motivational strategies they described focused largely on beliefs about their technical competence. Many students acknowledged their initial anxiety about taking an online course but explained how early, even before the course officially began, they entered the course frequently to practice navigating and working in the new environment. Some developed special self-talk strategies to promote a positive mindset about learning online; others used humor both online as they interacted with other students and the instructor and offline as they worked on assignments. They also spoke of how they developed what they viewed as critical attitudes for online learning: patience, flexibility, and persistence.

Student discussion of behavioral strategies needed in the online learning environment focused primarily on social and communication strategies. The social strategies that students described included a variety of networking and help-seeking strategies that they used to reduce the isolation of online learning and access needed emotional and technical support early and often. Students reported networking with other students in the course, colleagues and friends. Frequent communication with the instructor and technical support people as well as consultation with printed and online "help" materials were also often mentioned. Some students also spoke of the need for specialized writing and "listening" strategies in the online environment. These included use of humor, graphics, informal speech, emoticons, and cut/paste methods to personalize communication in the online environment.

Abstract

Recently, the Turkish government has started a new project for Basic Education Schools (partially financed by the World Bank) in order to take a major step for Turkey to leap to an information society. The purpose of this study is to investigate 592 basic education schools teachers' competency on computers and training needs. Analysis of data indicated that teachers do not feel competent on and ready for computer. Finally, this study offers recommendations for effective inservice training programs and technology integration strategies for the teachers.

Introduction:

Swiftly developing technology offers new opportunities for educational practice in schools. Increasing needs and expectations of the societies from information technology require according changes in the school curricula. Studies have shown that effectively used technology has the potential to improve the educational system (Jonassen & Reeves, 1996; Means, 1994). In recent years the agenda for educational development of many countries include the integration of computer technology into education (Plomp, Anderson & Kontogiannopoulou-Polydorides, 1996). Policy makers of those countries are forming decisions with respect to the introduction of computers in education to prepare children for a life in a technological society. But, for most of those countries the current situation of computer use in education can be considered as only a beginning stage of a process that could last many years (Plomp, Anderson & Kontogiannopoulou-Polydorides, 1996). For example, at USA, for years, schools have purchased large amounts of technology in hopes that students and teachers could use these tools for improving their teaching-learning process. Public schools are increasing access to these tools by putting more software and hardware in schools; connecting schools to Internet and providing cable and satellite capabilities (Zehr, 1997; Zehr, 1998). Despite this huge investment, few of the teachers actually use technology in their teaching (OTA, 1995). The main reason for the failure of integrating technology in USA educational system is defined as, although technology access has improved, teachers have been given little support in their efforts to use and integrate technology in their classrooms (OTA, 1995; Sheingold & Hadley, 1990).

The decisions of bringing computers to the schools deal with more than questioning what type of hardware and software should be used in schools. They also address curricular concerns such as technology's desired effects on education, needs for inservice training of teachers, and sometimes even the necessity of rearranging or adapting the physical facilities of the schools to accommodate computer use (Collins, 1990). Different visions about the place of information technology in education may lead to different emphases in policy goals and consequently, in actual policies.
IT Integration Efforts of Turkey:

Parallel to the international practices in reforming preservice teacher education for the new millennium, the Turkish Council of Higher Education has developed a new teacher training curricula for schools of education in 1998. According to the new curricula, a computer literacy course became a must course for all preservice teachers to fulfill the requirements for teaching credential. This new course is designed to improve and enhance teachers' IT skills.

In the same year, the Turkish government has started a new information technology project (partially financed by the World Bank) in order to take a major step for Turkey to leap to an information society. The main goals of the project are:
1. to bring the Internet connection and computers to the basic education schools,
2. to prepare the teachers about the use of technology, and
3. to start the integration of information technologies to the educational system.

In terms of its budget (1.1 billion USD) and its scope (15,000 basic education schools of Turkey) this is a very important and large-scale project for Turkey.

The success of such a project depends mostly on the teachers who will be the key people in enacting the curriculum. Teachers shape “the eventual success or lack of success of any computers-in-education initiative” (Collins 1996, pp.22; Yildirim & Kiraz 1999). Thus, type and quality of training teachers receive shapes the future of computers in education. In the related literature, effective IT training for teachers has the following features:
(a) educational technology training needs to be integrated into the entire teacher education program so that effective technology integration is modeled for pre-service teachers;
(b) the training should link technology with curriculum;
(c) the training should provide hands-on practice so that teachers become comfortable with them; and
(d) the training needs to be in-depth (Dell & Disdier, 1994).

Teachers are naturally involved in the educational use of computers and any educational innovation is filtered through them. Therefore, their decisions directly affect computer usage in schools. Teachers are the key players for a successful integration of computers to educational system (MacArthur and Malouf 1991; Yaghi 1996). As each teacher has her/his own way of using blackboard or any other tool in their teaching, how to use technology in education and how to integrate technology with education also changes from teacher to teacher. So, the success or failure of integrating technology in education depends largely on experience and attitudes of the teachers (Yildirim, 2000; Andris, 1995; Marcinkiewicz, 1993; Moursund, 1979; Stevens, 1980). Integrating technology in their educational system is very difficult task for the teachers, because not only they have to learn the new technologies but also, change the way they teach. Still helping teachers to learn technology may be the most important part of the technology integration reforms (OTA, 1995).

The Purpose of the Study

Unfortunately, not enough research on the factors that influencing the teachers use of technology in their teaching is done in Turkey. Being aware of teachers' problems and concerns for integrating technology to their teaching will help in the decision making towards a successful integration of technology into the curriculum and will guide the teacher preparation and in-service training programs for preparing the 21st century's teachers. With these issues in mind, the purpose of this study is to investigate basic education schools teachers’ current attitudes towards computers in the school, their computer competency and training needs.

Research Questions:

For this study, we collected and examined relevant data to address the following issues:
1. What is the teachers' level of competency in using computers?
2. What are the teachers' inservice training needs?

Methods and Data Sources

Subjects:
A survey was distributed The study included 592 basic education school teachers in 7 provinces representing the 7 geographic regions of Turkey to determine their demographic information, level of computer use for instruction and administration, and their feelings toward computers in education.
Instruments:

Initial Survey:
The initial quantitative survey attempted to explore such issues as how teachers use computers for teaching and administration, what variables are correlated with computer use in the classroom, and whether a relationship exists between certain demographic information (age, gender, highest degree, and number of years teaching) and computer use.

Number of Computer Use:
Teachers were asked to report on the number of ways they use computers. Teachers were asked to rate their computer use in the following areas: preparing tests/handouts, homework assignments, administrative tasks, grading, testing and evaluation, demonstrations and simulations, drill and practice, and tutorials.

Computer Competency Scale:
A Computer Competency Scale (CCS) with nine categories of computer applications commonly used by teachers was developed. The CCS was found to be a reliable measure of competency (Cronbach $\alpha = 0.87$). Teachers were asked to rate their competency in the following areas: word processing such as Microsoft Word or Word Perfect, database management such as Access, spreadsheets such as Excel, presentation software such as PowerPoint, telecommunications (e-mail, CU-See Me), web browsing (Netscape, Explorer), education (discipline specific software), desktop publishing (PhotoShop), and Operating Systems (Windows). Competency in each area was rated from 0 (not familiar) to 3 (proficient).

Findings:

Descriptive Profile:
Data were collected from 592 (274 female, 318 male) basic education school teachers in 7 provinces of Turkey. The participants in this study were predominantly male (53.7%, n=318), and their age ranged from 22 (minimum) to 62 (maximum), and their year of teaching experienced varied from less than one year to 40 years. Their computer access is presented in Table 1.

Discussion and Recommendations:

The purpose of this study was to investigate basic education schools teachers' computer competency and training needs. Data were collected from 592 basic education school teachers in 7 provinces of Turkey. Analysis of data indicated that teachers did not consider themselves as competent users of computers even though almost 66% of them had previous computer training and experience. Another important finding of this study is that teachers did not have adequate access to computers either at home or at schools. This finding explains the reason why teachers felt incompetent users even more than half of them had previous training. It should be noted that computers should be ready for teachers after they receive inservice training on using them. Otherwise, teachers would not be able to apply and advance their computer skills that they acquired during the inservice training. Such a problem would also prevent teachers from moving one step further and integrating their IT skills into their teaching.

Basic education program (BEP), which the Ministry of National Education (MONE) of Turkey launched in 1998, aims to furnish all basic education schools at least with one computer lab. This effort, of course, will increase teachers’ access to computers. However, integration of computers into curricula requires more than presence of one computer lab in each school site. Therefore, BEP should also provide new infrastructure and strategies for bringing computers into each class, school library, and teachers' launch. For example, the analysis of data revealed that teachers use computers mostly for administrative purposes. This finding clearly indicates that teachers do not consider computers as an inevitable part of their classroom or their teaching profession. Therefore, inservice training programs that the MONE will provide should not only put emphasis on computer skills but, most importantly, on technology integration skills as well.

Results also indicated that teachers are least competent on using the Internet. Beyond and doubts, this is a challenging problem for the BEP. It should be noticed that the Internet has not only changed the way people access information, but also reformed the way that people teach and learn. Therefore, the MONE should give the highest priority to Internet skills in their inservice training programs. Additionally, teachers should have access to Internet both at home and at schools. Considering the annual income level of teachers in Turkey (approximately 3,000 USD), teachers will not be able to use or integrate their Internet skills in their profession unless the government provides them with free or low-cost Internet access.

Another important finding of this study indicated that teachers had different backgrounds (more 40 different majors) and subject matter expertise even all of them held a teaching certificate. This remains as a challenging problem for the MONE to provide appropriate training for all teachers due to their varying backgrounds.
Therefore, the MONE should inservice provide training that is designed for each teacher’s current skills, needs, and background. Finally, the MONE should realize that IT in education is more than buying computers. In order for this program to be successful, the ministry should provide effective inservice training and continue support for teachers that will suit their background and satisfy their needs in the class. Additionally, the ministry should prepare a technology plan that prescribes educational benefits of computers and a roadmap for teachers to bring these benefits into their classroom. Otherwise, either the ministry or the teachers will realize the role of computers for providing better education for the children.

References:

"As we stand at the edge of this new millennium, gazing out into its uncharted expanse, some of us feel as if we are stepping out onto a launching pad; others feel at the brink of an abyss. Some see the challenges and the marvels to come and are exhilarated; some see only the certainty of change and its uncertain outcomes and are apprehensive. How amazing it is that the influence of technology is a primary force shaping both perspectives. All of us recognize the vital role computers and other electronic tools have played in bringing us to the place where we stand now" (p. v, Roblyer & Edwards, 2000).

As the field of technology continues to develop at an accelerated rate, it brings new opportunities for teacher educators to share skills and information. The importance of instructional design during this growth has not been overlooked as shown by the quality and quantity of papers included in this year's section. There are three main categories of papers represented: (1) the discussion of theoretical constructs supporting different instructional design models, (2) the application of instructional design models in various learning situations, and (3) the assessment of how these models work.

In the past, instructional design has largely been based on behavioristic premises; however, it is adjusting to new methods and computer design tools which allow for greater flexibility in the creation of learning environments (Wilson, Jonassen, & Cole, 1993). In this section, some authors explore traditional behavioristic designs, while others investigate constructivist and cognitive possibilities as well. Many theoretical foundations of instructional design are represented here.

The application of design ranges from web-based instruction to traditional classroom settings. How should teachers be taught? Which methods of design are appropriate for the content being taught and the delivery system being utilized? Are old methods being used in new situations with a new kind of student? It is questions like these that are addressed in the following papers.

To complete the design process, several papers discuss evaluation techniques used to assess the application of instructional design models employed. Both qualitative and quantitative methods of assessment are represented.

Abstract
The Italian Ministry of Education in collaboration of the Italian National Research Council are engaged in joint activities concerning the modeling, design and prototype implementation of an adaptive e-framework supporting the interactions of various actors of the national teacher training system. The framework includes patterns of static and adaptive versions for resources-services allocation and management.

Introduction
In the knowledge society, knowledge is a primary resource at various levels including: the know what, the know how and the know why. The processes acting on knowledge: creation, acquisition, processing, evaluation, storing and transmission, and their interrelationships contribute to determine a new social dynamics. The education systems are complex organizations in the knowledge society: they offer services based on the exchange of knowledge between “knowledge providers” (research centers, universities, laboratories, museums, etc…) and “knowledge clients” (school students, enterprise employees, ) by means of “knowledge intermediaries” (teachers, pedagogical resources, etc…). Teacher training can be considered as the interaction between providers and intermediaries in education systems.

The information and communication technologies are enabling factors for the development of the knowledge society and hence of the education systems. In particular teacher training is becoming a strategic issue that requires new advanced web based solutions.

The Italian Ministry of Education and the Italian National Research Council are engaged in joint activities concerning the modeling, design and prototype implementation of an adaptive e-framework supporting the interactions of various actors of the national teacher training system.

The e-framework includes patterns of static and adaptive versions for resources-services allocation and management: a teacher training system can be modeled by composing patterns, according to its complexity:

- the static resources-services allocation: services are provided by teaching agencies to the teachers;
- the adaptive resources-services allocation: the system takes care of the teachers and training agencies profiles for matching their respective needs and supply;
- the static management of the system behavior according to the cycle: planning, monitoring, evaluation, change management and planning
- the adaptive management of the system dynamically coordinates the planning, monitoring, evaluation and change management subsystems.

Up to now a prototype of information dissemination of teacher training services, called SIF and based on the static resources-services allocation pattern, has been realized with a high degree of scalability scalability: (around 25.000 teachers and 250 training agencies). Design and implementations of advanced teacher training systems, based on more complex patterns, are in progress.
1. Resources-Services Patterns

1.1 Static Resources-Services Pattern

Training agencies and teachers interact through the matching between training resources offering and training services request. The matching is realized according to a matching schema associated to a kernel component which is specified once for all w.r.t the evolution of the overall system (i.e. "statically").

![Static Resources-Services Pattern Diagram](image)

**Figure 1: Static Resources-Services Pattern**

1.2 Adaptive Resources-Services Pattern

Training agencies and teachers interact through the matching between training resources offering and training services request. The matching is realized according to matching schemas chosen by the connectors among those available from the kernel component (i.e. "dynamically"), as specified in the following figure.

![Adaptive Resources-Services Pattern Diagram](image)

**Figure 2: Adaptive Resource-Services Pattern**
2. Management Patterns

2.1 Static Management Pattern

The global management of a teacher training system is obtained by composing local interactions of four organisms (planning, monitoring, evaluation and change management) with the kernel component. The interactions rules are specified once for all w.r.t the evolution of the overall system (i.e. "statically").

Figure 3: Static Management Pattern
2.2 Adaptive management Pattern

The global management of a teacher training system is obtained by composing local interactions of four organisms (planning, monitoring, evaluation and change management) with the kernel component. The interactions follow rules chosen by the connectors according to the availability for interaction from the kernel (i.e. "dynamically").

Figure 4: Adaptive Management Pattern
3. Patterns-based Teacher Education Systems

Teacher education systems can be modeled by composing the previous patterns: the more complex model is obtained by composing the adaptive resources-services pattern with the adaptive management pattern, as illustrated in the following diagram.

![Diagram representing Adaptive Resources-Services and Management System](image)

Figure 5: Adaptive Resources-Services and Management System

The design of such kind of complex system requires a rigorous modeling methodology. A long way in front of us!

Assessing the Integration of Technology Into the Curriculum

Mac Adkins, Ed.D.
Office of Instructional Design and Technology
Troy State University
United States
maca@trojan.troyst.edu

Abstract: An online, self-assessment is being used to measure the amount and type of technology integration by the faculty of the Troy State University College of Education. Usage of this instrument has created baseline data to track individual and group levels of technology integration. Measures of presentation, administration, collaboration and research are gathered for both faculty and students. Technologies such as Internet, e-mail, discussion boards, chat, PowerPoint, word processing, spreadsheet, database, digital camera, video camera, and video tapes are measured. Analysis of the first academic year’s data is presented in this article. This project was funded in part by a PT3 grant and is designed to gather data congruent with NCATE and ISTE standards for technology integration.

As I look into my crystal ball I can see that your school has invested thousands of dollars and hours into the purchasing of technology for your campus. I can also see that you have also well invested in the training of your faculty and staff to use the equipment and software. Something else is also coming into view ... You have also assessed your faculty’s technical competencies and designed training to meet their needs. But is the technology actually being integrated into your curriculum? To what degree are your faculty members really using it in their teaching? Oh, I wish I could tell you, but that information is very gray and fuzzy. All that I can see is that most faculty members are saying that “sometimes” they are using it. I’m sorry I wish I could give you a more specific answer.

Do you feel like the assessment of the integration of technology into your curriculum is gray and fuzzy? Do you wish that you could gaze into a crystal ball and get specific answers?

As Director of Instructional Design and Technology for the College of Education at Troy State University I felt the same way. We have invested well in the infrastructure, implementation, and training of our faculty to use technology. But when asked if it was really being used in the classroom, the best I could say was, “I think so.” But as you know, budget requests based on “I think so” do not continue to be funded. I needed authentic, quantifiable data to document our usage of technology.

So I developed the Technology Integration Assessment. This online, self-assessment allows faculty members to quickly and conveniently report the integration of various technologies into each of their courses. The instrument not only measures what technology items are being used, but also how they are being used. The real data resulting from this authentic assessment has guided our data-driven decision process for future technology purchases and training.

Several similar assessments currently exist which measure an individual’s current technology competency levels. Assessments also exist which measure faculty and student perceptions of the impact which technology is making. But instruments designed to measure precisely which pieces of technology are being and how they are being used were lacking. This void led to the development of the Technology Integration Assessment.

The online instrument is located at http://spectrum.troyst.edu/~coe/departments/technology/integration.htm. Each faculty member is asked to complete the instrument for each course they are teaching. The instrument is administered near the beginning of each semester. Through the use of checkboxes arranged in a grid, the faculty members can quickly identify which technologies are being used in what ways. This format allows the instrument to be quickly completed thus resulting in higher response rates. The average time to complete the assessment is less than five minutes per course.
The information submitted by faculty members is automatically sent to a database. After the submissions have been received, the Technology Integration Report is prepared for that semester. A sample of the data can be seen above. The complete report is available at http://spectrum.troy.edu/~coe/departments/technology/TIR_5-11-00.doc. This report allows information in the following categories to be reported: Usage By Technology Item, Usage By Integration Category, Technology Integration Index By Faculty By Term, Technology Integration Index By Faculty, and Technology Integration Index By Faculty.

We identified the following twelve technology items for which we wanted to track integration: Internet, e-mail, discussion boards, chat, PowerPoint, word processing, spread sheet, database, digital camera, video camera, and video tape. We also identified the following nine integration categories: instructor presentation, instructor administration, instructor research, instructor-instructor collaboration, instructor-student collaboration, student-student collaboration, student presentation, student administration, student research. Figure 1: Usage by integration category.

![Usage By Integration Category](image)

The assessment also allows us to establish baseline data in the form of a faculty integration index. This quantifiable information allows us measure increases in integration for each faculty member over a period of time. This serves as an authentic assessment of the results of our faculty technology training program. Some of the conclusions drawn from the data include:

- Internet usage has almost equaled word processing usage for course preparation.
- Technology usage categories of presentation, administration, research and collaboration are roughly equivalent for faculty and students.
- The technology integration index for faculty members ranged from 5 to 38.33. The average was 19.58.
- Email usage surpassed Internet usage. This indicates that faculty members are using their network connections largely for communication and collaboration.

This instrument was developed specifically for the Troy State University College of Education but it can be tailored to measure specific technologies being used by any school. In the presentation I will provide the history of the development of the assessment, demonstrate the use of the assessment, show the resulting report from the assessment, and report how this data has been used in the decision making process of the College.
PROMOTING INSTRUCTIONAL PLANNING: AN EXPERIMENT

Abstract: This study investigated the impact of the Instructional Planning Self-Reflective Tool (IPSRT), on students’ attitudes toward instructional planning with 114 pre-service teachers from seven sections of an introductory educational technology course. All participants in the experimental and control groups were taught how to develop an instructional plan as part of the course. For the intervention, the experimental group was provided with instruction how to use the IPSRT while instructional planning, whereas the control group received a review of instructional planning. It was hypothesized that the IPSRT would positively affect students’ performance, attitudes, and self-efficacy beliefs towards instructional planning. It was found that the experimental group showed greater skill acquisition, more positive attitudes and higher perceived importance of instructional planning. In terms of self-efficacy, participants who were initially high in self-efficacy reported significantly lower self-efficacy following the tool intervention. In contrast, participants initially low in self-efficacy showed significantly higher self-efficacy following the tool intervention. Findings are discussed from a social-cognitive perspective.

Many teachers learn to systematically design instruction through methods of instructional planning. A number of instructional planning models have been developed (e.g., Dick & Reiser, 1989; Dick & Carey, 1996; Seels and Glasgow, 1990) with the goal of improving teacher instruction. Reiser & Dick (1996) state that instructional planning consists of the six following phases: goals, objectives, instructional activities, assessment, revision, and implementation. Four key principles underlie these six instructional planning phases: 1) identifying goals and objectives that students will be expected to attain; 2) planning instructional activities that correspond with the objectives; 3) developing assessment instrument to measure attainment of objectives; and, 4) revising instruction based on student performance and attitudes.

While it is widely believed that instructional-planning skills are critical for instructional effectiveness in the classroom, there is no strong evidence that teachers (or even superior teachers) actually use these processes (Martin, 1990; Young, Reiser, & Dick, 1998). Research evidence suggests that teachers typically do not follow procedures acquired in pre-service teacher education programs (Kagan, 1992; Reynolds, 1993). However, Neale, Pace & Case, (1983) indicate that experienced teachers believe in the value of instructional planning and that it should be taught to novice teachers. Along this line, Reiser (1994) indicates that pre-service teachers taught to use systematic instructional planning express more enthusiasm in using these skills in the future.

Based on this research evidence, how can we better prepare pre-service teachers to both incorporate and increase their awareness of critical instructional planning components? One possibility is by providing them with tools that promote self-regulation. Self-regulation refers to self-generated thoughts, feelings, and actions that are systematically designed to achieve a goal (Zimmerman, 2000). Two core components of self-regulation are self-monitoring and self-evaluation. Self-monitoring refers to comparing one's performance whereas self-evaluation refers to tracking one's performance to a standard.
The purpose of this study was to test the effectiveness of the IPSRT (see Baylor, Kitsantas, & Chung, in press), a self-regulatory tool designed to promote monitoring and self-evaluation in instructional planning on skill acquisition, attitudes and self-efficacy beliefs of pre-service teachers regarding instructional planning. It was hypothesized that the pre-service teachers presented with the IPSRT would report a) greater skill acquisition, b) more positive attitudes, c) higher self-efficacy beliefs, and d) greater perceived instrumentality regarding instructional planning than the control group participants.

Methods

Sample

The total sample consisted of 92 pre-service teachers, in seven sections of an "Introduction to Educational Technology" course. The mean age of the sample was 20.43 years (SD=2.68). Of those reporting ethnicity, 81% were Caucasian, 8% were Hispanic, 7% were African American, and 4% were of other groups. Of those reporting gender, 22% of the sample were male and 78% were female.

Measures

Post-test achievement

All participants developed an instructional plan as a post-test measure of achievement that was implemented as a graded quiz as part of the class. Each instructional plan was scored according to three sub-components on a scale of 1-5: goals/objectives, procedure, and assessment. The overall quiz score was the compilation of these three sub-scores. After satisfactory inter-rater reliability for scoring the quizzes was established, one researcher scored the remainder of the instructional plans. The scorer was blind as to the conditions of the participants.

Attitudes

To assess pre-service teacher attitudes toward instructional planning, all participants were asked to list two adjectives to "describe what you think about instructional planning." These adjectives were coded as -1 if both were negative, as 0 if 1 was negative and the other positive, and as +1 if both were positive. The items were coded by two raters independently. There were disagreements about two sets of adjectives which were resolved through discussion. Two adjective pairs were discarded because they could not be classified.

Self-Efficacy

This scale measured the students' self-efficacy beliefs about instructional planning. It was developed based on Bandura & Schunk's (1981) guidelines. All participants were asked, "how sure are you that you can write a lesson plan" on a scale from 10 being not sure to 100 being very sure. The inter-item reliability of this scale was alpha=.96.

Perceived instrumentality

To assess the participants' perceived importance of instructional planning, the participants were asked to rate "how important is writing a lesson plan to you as a future professional" on a scale of 1 to 5, 1= not important, 2=fairly important, 3=important, 4=very important, and 5=extremely important.

Procedure

All participants answered a demographics questionnaire including questions regarding gender, ethnicity, age, and grade point average. Following this questionnaire, the participants' attitudes were assessed. Self-efficacy beliefs regarding instructional planning were assessed at two different times for both groups. For
both the experimental and control groups, self-efficacy was assessed initially to establish a baseline. In addition, for the experimental group it was assessed again after the quiz and for the control group it was assessed following the introduction of the tool. Next the instructor demonstrated writing an instructional plan; additionally, for the experimental group, s/he modeled the use of the IPSRT while writing the instructional plan. Following this demonstration, all participants were instructed to write a lesson plan. All participants were given a case study for which to write a lesson plan for homework, and were notified of a quiz the next week. The next week, before the quiz, participants were queried about their self-efficacy. For the quiz, the experimental group had the IPSRT attached to their quiz while the control group did not. Following the quiz, all participants were asked about self-efficacy beliefs, perceived instrumentality, and attitudes regarding lesson planning. The control group’s lesson plans from the quiz were xeroxed and returned to them. Next, a demonstration regarding use of the IPSRT was conducted for the control group students and they were allowed to modify their xeroxed lesson plans using a red pen. Following their modifications to the quizzes, they were queried about their self-efficacy perceptions regarding writing future lesson plans.

Results

Independent sample t-tests were conducted to determine differences between the two groups (experimental, control) and paired-sample t-tests were conducted to determine differences within each group over time.

Achievement

In terms of the effect of the IPSRT intervention on achievement, it was found that the experimental group (M=11.27) outperformed the control group (M=9.32), t(53)=-3.53, p<.001. Achievement was based on the overall quiz scores of participants in both groups.

Attitude

A t-test was performed to determine initial differences between the control and experimental group regarding attitudes toward instructional planning. There were no statistically significant differences between the two groups regarding their attitudes about instructional planning initially, t(74)= -.999, p>.3. However, following the intervention, there were significant differences between the two groups t(69)= -2.64, p<.01. Specifically, participants in the control group (M=-.094) were slightly negative towards instructional planning whereas the experimental group participants were positive (M=.41), where the possible range of scores was from -1 (negative) to 0 (neutral) and 1 (positive). See Table 3 for examples of positive and negative attitudes.

Self-efficacy

The mean score for self-efficacy regarding instructional planning for all participants following the intervention was M=80.35, with a standard deviation of 15.37. Given this distribution, low self-efficacy was defined as 70% or below (N=28) and high self-efficacy beliefs as above 80% (N=31), so participants who scored 80% were not included.

In the experimental group, those who had low self-efficacy (N=17) regarding instructional planning prior to the intervention (M=60.67) reported significantly higher self-efficacy beliefs regarding instructional planning (M=72.00) immediately following the quiz, t(14) =-3.52, p<.01. In contrast, those who had high self-efficacy beliefs (N=15) regarding instructional planning prior to the intervention (M=94.62) reported significantly lower self-efficacy beliefs regarding instructional planning following the quiz (M=83.85), t (12) =-3.48, p<.01.
Similar results were found with the control participants when the instructor demonstrated the IPSRT tool and they used it to modify their already-submitted quizzes, see Table 2. Of the control participants with low self-efficacy regarding instructional planning ($N=11$), it was found that their self-efficacy beliefs significantly improved from the initial self-efficacy assessment ($M=62.73$) to the final self-efficacy assessment following their presentation with the IPSRT tool ($M=71.82$), $t(10)=-3.62$, $p<.01$. Of the control participants with high self-efficacy ($N=16$), it was found that their self-efficacy beliefs significantly decreased from the initial self-efficacy measure ($M=95.00$) to following their presentation with the tool ($M=90.63$), $t(15)=2.78$, $p<.01$.

A paired $t$-test was conducted to determine whether there were practice effects over time for the control participants' initial reports of self-efficacy beliefs with their self-efficacy beliefs following the third instructional plan (the quiz). It was shown that there were no significant differences in self-efficacy beliefs about instructional planning over time by the control group ($M=82.5$ vs $M=83.13$), $t(31)=-.403$, $p=.69$.

An additional $t$-test was performed to examine differences in quiz performance between the low and high self-efficacy groups. It was shown that those with higher self-efficacy scored significantly higher on the quiz ($M=13.18$) than those lower in self-efficacy ($M=7.53$), $t(32)=-16.83$, $p<.000$.

**Perceived instrumentality**

For perceived instrumentality, a measure of utility value, the experimental group reported higher perceived instrumentality ($M=4.06$) than the control group ($M=3.64$) following the quiz $t(84)=-1.706$, $p<.10$. While it was only marginally significant, the difference in the means indicated that the experimental group participants viewed instructional planning as more important to them as future teachers than did the control group participants.

**Discussion**

The results confirmed that the IPSRT improved pre-service teachers' performance and attitudes, and perceived instrumentality regarding instructional planning. However, the results regarding instructional planning self-efficacy were different from what was hypothesized. Participants that were initially high in self-efficacy beliefs reported significantly lower self-efficacy beliefs while those initially low in self-efficacy reported significantly higher self-efficacy beliefs following IPSRT intervention.

Findings showed that pre-service teachers who were instructed to use the IPSRT scored higher on the quiz than the control group participants. Baylor & Kitsantas & Chung (in press) and Baylor & Kitsantas (2000) found that the IPSRT is perceived as valuable by pre-service teachers because it encourages them to self-monitor and subsequently to self-evaluate their performance. Consequently, given that both groups were instructed in a similar manner, we attribute the students' better performance on instructional planning to the self-monitoring and subsequent reflection of the IPSRT. Similarly, Schunk (1983) suggests performance feedback (such as the IPSRT) provides individuals with information on how well they are performing. Studies conducted in other areas (e.g., writing, math achievement) have found that self-monitoring enhanced students' achievement (e.g., Zimmerman & Kitsantas, 1999; Schunk, 1996).

It was also found that the IPSRT positively affected pre-service teachers' attitudes regarding instructional planning. Specifically, following the intervention, the pre-service teachers using the IPSRT tended to use more positive adjectives (e.g., "important," "helpful") to describe instructional planning than their counterparts in the control group. In fact, the control group was slightly negative about instructional planning (e.g., using adjectives such as "time-consuming," "pointless"). Perhaps the IPSRT, by facilitating reflection and illuminating the underlying systematic process of instructional planning, elicited more positive attitudes. Similarly, Driscoll & Klein & Sherman (1994) found that pre-service teachers taught to employ a systematic planning process expressed more enthusiasm about using these skills in the future.
Concerning self-efficacy, of interest was that those who were initially high in self-efficacy reported significantly lower self-efficacy regarding instructional planning following the quiz. In contrast, those who were initially low in self-efficacy reported significantly higher self-efficacy regarding instructional planning following the quiz. In confirmation of these findings, similar results were found for the control group, who received the tool at a later time.

These results suggest that for the high self-efficacious group the IPSRT highlighted the complexity and comprehensiveness of instructional planning; thus, leading them to re-evaluate their self-efficacy beliefs regarding instructional planning more negatively, or perhaps more realistically, following use of the IPSRT. On the other hand, the use of the IPSRT may be detrimental for high self-efficacious participants because it leads them to be less optimistic about their instructional planning capability.

On the contrary, the low self-efficacious group participants reported significantly higher self-efficacy perceptions following the quiz. This suggests that those initially low in self-efficacy became more confident in their ability to write an instructional plan given the IPSRT. By enhancing pre-service teachers' self-efficacy perceptions it is expected that they would be more likely to engage in systematic instructional planning in the future. In support of this interpretation, Bandura (1986) proposes that self-efficacy beliefs influence the choices that individuals make, the effort that they expend, the perseverance they apply, and the emotional reactions they experience. Further, consistent with Bandura's (1997) theory of self-efficacy, high self-efficacious participants performed better on the quiz than the low self-efficacious participants.

In terms of perceived instrumentality, or utility value, of instructional planning, results showed that instructional planning was more important to the experimental group than the control group although it was only marginally significant. The tool enabled them to view instructional planning as a more substantive and significant part of instruction, and engendered more respect for the instructional planning process. Consequently, use of the IPSRT may increase the likelihood to change pre-service teachers' attitudes regarding the importance of instructional planning.

Conclusion

This study indicated that self-regulatory processes such as self-monitoring and self-evaluation, promoted through the IPSRT, guided students' learning, enhanced their performance, and improved their attitudes regarding instructional planning. In terms of self-efficacy, the IPSRT facilitated the high self-efficacious pre-service teachers to realize the depth and complexity of instructional planning whereas it facilitated the low self-efficacious pre-service teachers to feel more competent.

Additionally, the IPSRT promotes a reflective dialogue for the pre-service teacher instructional planner, fulfilling the role of Moaellmen's (1998) description of teacher reflection-in-action. Given that instructional design is a highly complex and spontaneous task and cannot be reduced to a set of procedures, this reflective dialogue is critical. These findings are important for instructors who must prepare their students to practice writing instructional plans effectively on their own.

Future research should examine the value of the IPSRT for more experienced teachers, and/or pre-service teachers later in their academic careers. Follow-up structured interviews would be useful to determine the specific reasons for the changes in pre-service teachers' existing self-efficacy beliefs. In addition, longitudinal studies could examine whether the pre-service teachers' instructional planning-related attitudes and beliefs change once they enter the classroom.

Learning and Using Web Page Construction as a Vehicle to Teach Preservice Teachers How to Develop and Design Integrative Middle School Curricula Appropriate for Early Adolescents

Dr. Candy Beal, Department of Curriculum and Instruction, North Carolina State University, USA
candy_beal@ncsu.edu

Abstract: This research paper examines a unique curriculum design project that was introduced to teach web page construction in the context of an undergraduate middle grades teacher education course. College students, some novice and some experts, developed learning components for a theme-based technology driven unit whose lessons met the developmental needs of early adolescents. The process used by the preservice teachers to develop and construct the website proved that when technology is used in a risk free, supportive environment to build a high interest unit it empowers students and guarantees their further use of technology.

In a sense, we are all preservice teachers. At some point in our lives we will teach another how to do something. Research supports the view that to do this teaching we will fall back on the model used to teach us. For this reason, my Foundations of Middle Level Education course examines preservice teachers’ memories of their middle school classes and teachers. They study best and worst practices in teaching and learning, as well as early adolescent development characteristics, in the context of their own experience. Their findings suggest everyone has a different style and stage of learning and teaching, thus validating Gardner’s multiple intelligences (Gardner, 83), Piaget’s concrete and abstract learning (Piaget, 72) and Vygotsky’s cognitive socialization (Vygotsky, 78). Another finding, the importance of service learning to build character and establish a sense of place, echoes Arnold & Beal (Arnold & Beal, 95), Garbarino (Garbarino, 83), Erikson (Erikson, 68) and Kohlberg (Kohlberg, 72). Once students have become familiar with teaching and learning styles, developmental characteristics and the nuts and bolts of writing a lesson plan, they tackle the issue of integrating technology into their classroom. So they don’t see technology as an add on or gimmick to capture the students’ attention, they work in teams to prepare a totally integrative theme based unit that blends all core subjects and delivers the unit via technology. At this point, I should own up to the fact that curriculum design is my passion and technology is not. However, like my students, I fully appreciate the power of technology and am learning, as my students learn, to incorporate it into my lessons.

Because of our earlier study, students already have a firm foundation in middle level teaching and learning before we begin our project. Teams discuss the theme, study grade specific curriculum and brainstorm ways to weave the unit together. Besides the technical aspects of webpage construction, both the students and I must consider the following:
1. Audience: The material must be developmentally appropriate, of high interest and deal with big questions and issues that would interest and inform early adolescents, be colorful, and be in an easy to read format.
2. Mechanics: The page must be easy to navigate, have clear instructions, an easy to read font, a reasonable text size and a print color that shows up well on a colored background.
3. Community outreach: The unit must incorporate service learning.
4. Team work: In addition to college students experiencing team work, the unit must provide opportunities for the middle school students to work together.
5. Learning outcomes: The unit must provide alternative forms of assessment.
6. Finally, the overall experience both in development and use of the unit must be positive and empower students to continue to learn and use instructional technology.

For this particular class, the teacher education students investigated a global environmental issue, the world’s use of water resources, on a trip to the Exploris Children’s Museum of the World. Ostensibly, they were at the museum to study how to put together a meaningful field trip, but were intrigued at how a teacher, whose class was visiting the museum, could make a world issue relevant to the lives of children in North Carolina. Because of the hurricanes, floods, local water shortages, runoff of hog waste and the

1239
appearance of dangerous organisms in rivers in North Carolina, the students decided to address the issue of use and abuse of water resources in North Carolina.

The class attended a research retreat at the Trinity Conference Center in Salter Path, NC. This was sponsored by NCSU’s Humanities Extension Publications, a department of the University that supports education in southern coastal issues. At the workshop, students spoke with experts in the field of water resources. NCSU graduate students and professors helped the students research their topics and learn about the technology that would enable them to construct their web pages. Students learned how to use digital cameras and make a panoramic display. Laptops enabled teams to begin their web page construction. Time together away from the university enabled greater team bonding. Upon returning to the university, the students spent the rest of the semester researching their topic and learning about how to construct a website.

Teams, following the six points already noted, made their components stand-alone lessons. After numerous critiques and corrections, they combined them into one large website called SwimDog. SwimDog was the character that appeared on the homepage and helped students navigate through the entire website. Website components include: household tips on how to conserve water, study of specific local waterways, hurricanes and their effect on the coastal plain and beyond, the impact of the hog industry on the economy and the environment, the use of water by coastal NC Native Americans, young adult literature dealing with the coast and how to help your parents landscape the yard to retain moisture and conserve water. Students did much of their own research about their topic on the web, incorporated maps, photos and graphs into their activities, used digital pictures and built a variety of assessment forms into the lessons. They posed reflective questions that addressed moral considerations and the seriousness of the use of water resources issue.

This exercise demonstrated that a unique and meaningful topic can be a hook that makes learning basic technology exciting. It also illustrated that teachers do not have to be driven to incorporate technology for technology’s sake, but that technology can be used as a vehicle to enable students to expand their approaches to teaching. Data collection by this researcher showed that by the end of the semester students had greater comfort and skill level in using technology. Those who were initially lacking in technology confidence felt better able to use it and incorporate it in their own teaching. Finally, the complete product, tailored for early adolescents, enabled students to see theory become application in dealing with adolescent development, integrative unit construction, team building and technology integration.

Abstract: This paper reports on an innovative approach adopted in the training of tertiary education teachers in instructional technology. An integrated approach was adopted to increase the motivation of teachers to use Information and Communication Technologies (ICTs) in their teaching-learning practices. The researchers describe their 'action research' efforts to design a course where participants learn and apply new ICT skills in a context of becoming 'designers' themselves of online learning resources. The notion of 'course design as action research' provided a focus for a flexibly structured course relevant to students needs and responsive to ongoing feedback in terms of a more proactive reflective practice. The paper argues that in the fast changing Internet age all teachers need to go beyond traditional approaches if they are to use ICTs well in their educational practices.

Introduction

The ability to use ICTs has become-is becoming as fundamental to a person's ability to navigate through both school and society as traditional skills like reading, writing, and arithmetic. In Moore’s (1991) words, teachers awaken one day with computers in their rooms without having requested them. Most colleges and universities have Internet connections that provide students and faculty access to a world of information resources. The challenge for teachers and the administrators is integrating these resources into the curriculum.

According to 21st Century Teachers Network (21CT) Director Wade D. Sayer, persuading teachers to use new technologies has been tough. Unlike the GenX or NetGen of younger students, most teachers did not grow up around computers and the Internet. So using technology does not come naturally to them. Indeed, the thought of presenting a lesson in PowerPoint or of creating an interactive Web-based lesson is alien to many (Kurkowski, 2000).

McKenzie (1999) designates teachers in particular as late adopters and reluctant technology users. He outlines the following strategies for reaching late adopters and reluctant users: clarify the bottom line, focus on student performance, deliver a complete package eliminate, risk and surprise, speak their language, emphasise teams, find out what turns students on, provide rewards and incentives, and don’t rely on pioneers alone to plan for reluctants. Similarly, we have discussed elsewhere our strategies for converting reluctant or intimidated students (especially teachers) into keen users of Internet in education (Richards & Bhattacharya, 2001a).

Effective integration of ‘instructional technology’ (IT) in teaching and learning demands the teachers to flexible, innovative, and effective reflective practitioners ready to trial and apply ICTs within their own educational setting. In other words, rule-based and transmission approaches to teaching are no longer sufficient in the “internet age” to productively address changing educational needs and requirements.
Background Information

All the participants in this course were teachers of English as a second language in China. These in-service teachers were invited to come to National Institute of Education, Singapore to pursue a Postgraduate Diploma Course in English Language Teaching. They were also required to undertake a unit on instructional technology. Many of these teachers were reluctant to learn about ICTs.

The strategic approach we adopted for this unit represented a refinement of our previous 'action research' experience and projects in and outside the classroom in India, Japan, and Australia teacher education Program. Both of us were newly arrived when asked to work together to take this particular course almost immediately. Little background information was available to us about the course-content for the course on "Instructional Technology". Some prior information about the participants was collected through casual conversation with the faculty members who had taught this course before and from the computer laboratory technicians. The gathered data was not very encouraging. As one source put it: "Some of these participants never handled a keyboard. It would be enough if they learn to do word processing".

All these bits and pieces of information served as a challenge for us to come up with an innovative course where the planned activities would act as motivator as well as help the participants to understand the relevance and application of ICT in education today. Also the course design aimed to have participants develop a core range of generic 'learning technology' skills relevant to the internet age especially, and applicable in various educational contexts. For instance, culminating activities in the course had participants upload and publish their animated presentations on web pages.

Design Procedure vis-à-vis Action Research

Traditionally, 'instructional design' refers to the process of instructional program development from start to finish. Many models exist for use by different levels of instructional designers and for different instructional purposes. However, the process can be summarized into five general phases as summarized by Braxton (1995): Analyze, Design, Develop, Implement and Evaluate (Fig. 1). Sometimes phases overlap and can be interrelated. The evaluation phase measures the effectiveness and efficiency of the instruction. Evaluation should actually occur throughout the entire instructional design process - within phases, between phases, and after implementation.

According to Norman (1999) the focus of action research should be a specific problem in a specific setting. The emphasis is on precise knowledge for a particular situation and purpose. A proactive model of action research is concerned with innovation, change, and the ways in which new approaches; methods or even ICT programs may be implemented in on going systems. Such a framework of reflective practice is appropriate to any context where a specific problem needs solving.

Figure 1: General Instructional Design Phases

Figure 2: Action Research Design
Therefore, an action research approach was most appropriate to the situation described above where there was no prior preparation time was available for the design and development of the course.

The cycle of an action research project involves the identification of a problem, the collection and analysis of information, plan the action or intervention for implementation, followed by implementation and finally, monitoring the outcomes (Hitchcock & Hughes, 1995). A representation of an AR protocol by Kemmis (cited in Hopkins, 1985) is given in Fig. 2. The protocol is iterative or cyclical in nature and is intended to foster deeper understanding of a given situation, starting with conceptualizing and particularizing the problem and moving through several interventions and evaluations.

In the present study we have used the action-reflection cycle as a means of in-service teachers' training, and thus a context for equipping teachers with new skills and methods. We came up with an innovative design procedure, which is a hybrid form of traditional instructional design and the action research design (Fig. 3).

### Innovative Course Design

In accordance with the traditional instructional design, phases the we started with a pre-course survey questionnaire in order to establish the participants' previous experiences in computer and Internet usage in their day-to-day teaching situation. This established that the participants of the course consisted of mixed ability (mostly low ability) group of people in terms of computer skills and knowledge. We concentrated on the following conditions for effective adult learning (Engel, 1991) in the framing of an 'innovative course design model':

- Active learning through posing own questions and seeking the respective answers.
- Integrated learning, learning in a variety of subject concurrently through learning in the context in which the learning is to be applied in real-life situation.
- Cumulative learning to achieve growing familiarity through a sequence of learning experiences that are relevant to the learner's goals, experiences that become progressively straightforward but more complex, as well as less non-threatening but progressively more challenging.
- Learning for understanding, rather than for recall of isolated facts, through appropriate opportunities to reflect on their educational experiences, and through frequent feedback, linked with opportunities to practice the application of what has been learned.

We faced a number of problems in the process of designing the activities and assignments in accordance with the conditions for effective adult learning. For example, the participants were not well known to each other, and did not seem enthusiastic about the idea of working together on a project or even helping each other. Therefore, group activities were organized in such a way as to allow the participants to become familiar with each other and work collaboratively towards a common goal. It took us some time to establish a rapport with participants, and for the participants to develop their confidence with ICTs.

Motivational strategies used for designing a model of instant course delivery were based on ARCS Model of Motivation developed by John Keller. According to Keller, 1983 there are four categories of motivation – namely; attention, relevance, confidence, and satisfaction. These categories represented a useful model for increasing the motivation of our course participants.

An action research methodology became the basis for strategically developing the course to the stage where it was increasingly being seen by participants as relevant and useful. An action-observation-reflection cycle was followed in the process of course design, development, implementation and evaluation.

### Course Design

Main Objective:
Participants will be able to demonstrate competencies in the use of IT on successful completion of the course.

![Figure 3: Innovative Course Design](image-url)
The course design was an ongoing process of refining approaches to, and connections between, some of the core skills and knowledge in terms of ICTs. This process also involved motivational strategies for emphasizing realistic practical relevance, and promoting confidence and a sense of achievement in learners.

Our own enthusiasm and belief in the materials we were using was crucial in convincing the participants that instructional technology is a useful, important and relevant component of their teaching. A list of about twenty activities was made including the following: composing text in Microsoft word, demonstrating of skills such as cutting and pasting, opening email account and sending emails to the members of the group by forming mailing list, searching the internet for information on certain topics and listing the search strategies used, booking marking internet site for resource development and converting the same as a web page, evaluating web pages and learn about web page design, preparing slide show on MS power point, developing own homepages, uploading files in the web pages, etc.

Every week a hand out containing a short description of activities was given to the participants. The link between the different activities was crucial. Different activities listed according to Tab. 1 were skillfully interwoven to reinforce each other. The role of the 'teacher' in this course involved being part of a learning community as well as a general facilitator of learning.

<td>➢ Completion of reflection survey, teaching and course evaluation forms.</td>
</tr>
</tbody>
</table>

Table 1: The Implementation Process of the Course

Typical examples of some of these activities are described in another publication (Richards & Bhattacharya, 2001b). While the activities are presented in an order, the sequence in which they are undertaken in practice is likely to be far less ordered. Recursion to previous stages in the process was possible because of the flexible nature of the framework, which avoided imposing arbitrary constraints. This was important to cater for the different skill levels, and the different stages of temporary frustrations encountered by learners.
Assessment and Feedback

The achievement of various ICT skills and general knowledge was assessed in terms of different activities and assignments to be completed or demonstrated by the participants within a stipulated time frame. This was necessary to bring all the participants up to a certain desired level of ICT competency at a particular period of time. Help sessions were provided whenever required for establishment of the given task. Formative evaluation was carried out throughout the course. Finally, the demonstration of learning outcomes, i.e., the integration of ICTs in various educational activities, was done through both online and classroom presentations by the participants.

In addition to responding to all the problems faced by the participants throughout the process of teaching-learning, we also carried out a 'course and teaching evaluation' at the end by collecting feedback from the participants about the design and delivery of the course. An evaluation of 'innovative course design' was done by analyzing and interpreting the results of ongoing action research as well as student artifacts and feedback. The data was collected through various means such as questionnaires, email communications, classroom observations, task performance, and semi-structured interviews. This provided a basis for the research focus on the three key domains of learning: cognitive, psychomotor and affective including attitudinal changes and development of interpersonal skills.

Discussion

Even though educational institutions are busily filling classrooms with computers, a large percentage of teachers remain reluctant and skeptical. Unfortunately, much of the technology professional development of the past two decades was designed by technology enthusiasts with little empathy for reluctant learners - who have failed to convert reluctance into enthusiasm, and to address the very real concerns of many reluctant learners (McKenzie, 1999).

In this study we undertook the challenge of developing a course, which more effectively catered for reluctant ICT learners (the teachers). As a result, we came to appreciate more fully that these teachers have special needs, interests, and learning styles, which must be addressed with respect and ingenuity if we expect to see such teachers embrace the new technologies being placed in their classrooms.

In the training of teachers the main concern should be to make them more confident and enthusiastic about learning technologies so that they in turn apply the skills and knowledge in their own classrooms and outside the classrooms. In the "information age" our instructional methodologies must change from that of the "industrial age". Tab. 2 shows, what and how we, teachers, need to shift our educational paradigm from "old" to "new" according to the demand of the society.

</tbody>
</table>

Table 2: Shift from an industrial age to an information age (Reigeluth, 1996)

We must replace the piecemeal assembly of educational knowledge and develop larger chunks of expected knowledge and skills to be mastered in an integrated fashion (Andrews, 2000). We recommend instead a focus on demonstration of applied knowledge and skills.

It is unrealistic to seek "universal solutions" to implement ICTs into courses across different disciplines and subjects. Therefore a flexible 'action research' design complements the requirements to
increasingly customise ICT courses for particular audiences and contexts. In sum teachers need to be designers of new courses integrating ICTs as well as effective reflective practitioners.

**Conclusions**

Integrating technology can be very rewarding for both teachers and students. It need not be daunting as it might appear at first sight. The crucial component of effective ICT integration is a framework, which adequately recognises and caters for learner motivation. The introduction of ICTs into education generally requires more innovative approaches to the teaching and learning situation as well as course materials and learning activities. This paper has argued that an innovative course design is required which is structured, developed and applied as 'action research' in the sense of proactive reflective practice.

Abtracts In this paper, the design of Web-based inquiry simulations used in science classrooms for students to explore coastal science issues is discussed. In response to the demand of reform efforts and the lack of an appropriate design model approach, the Carolina Coastal Science project commenced with an idea to develop a Web site that was an organized, non-linear information resource in the context of an inquiry-based constructivist learning environment. Several modes of learning and teaching strategies were developed to be available to the users, including a role-playing simulation-debate, open-ended inquiries, guided inquiries, independent research, and cooperative group learning. The paper concludes with the claim that creating an instructional system in an online environment promotes the use constructivist theories in student learning due to the nature of their engagement within a hypermedia environment.

Introduction

An instructional system may be defined as an arrangement of resources and procedures used to promote learning (Gagne, R., Briggs, L., and Wager, W., 1992). The Dick and Carey (1990) systems approach model for designing instruction is the most well-known systematic instructional design model (Table 1). Traditional systems approach to instructional design by itself is not compatible with the concept of inquiry-based learning required in an online learning environment. The traditional systems approach is most directly applicable to the development of print instruction used in linear environments. The systems approach is being challenged by constructivist theories and models which recognize that social context, roles, and relationships are central to learning (Jones, Kirkup, & Kirkwood, 1993). Non-linear development models also recognize that learning is dynamic and unpredictable and that learners can and do make their own decisions about learning tasks (Thorpe, 1995). The systems model approach can be modified with the application of constructivist tenets to fit the conditions of non-linear, Web-based instruction. Constructivism is based on the premise that knowledge is not something that can be transferred from one person to another, but instead must be built by an individual. In a constructivist Web-based instructional system, students learn by doing. Knowledge is constructed through experience and learning is an active process.

In a constructivist Web-based instructional system, learning is based on students' active participation in problem-solving and critical thinking regarding a learning activity that they find relevant and engaging. The student's role is active, not passive in this setting. The Web-based medium becomes a learning environment that offers more than just text to read followed by a multiple-choice question to answer. This article describes how we used the systems approach model to provide a base for the design and development of an instructional system for an online learning environment for science education.

Reform movements in science education

New reform efforts taking place in science education today are framed by the tenets of constructivism. Constructivist theorists regard learning as an active process in which a learner constructs knowledge and understanding in an active manner through personal experience or experiential activities. Constructivism has its roots in twentieth century psychology and philosophy and the developmental perspectives of Piaget (1954), Kant (1959), Bruner (1966), and Vygotsky (1978).

Another focus of the current reform movement in science education is to develop students' ability of inquiry as well as understandings of inquiry (NRC, 1996). The national standard on scientific inquiry defines
scientific inquiry as "diverse ways in which scientists study the natural world and propose explanations based on the evidence derived from their work" (NRC, 1996). Inquiry also refers to the activities of students in which they develop knowledge and understanding of scientific ideas, as well as an understanding of how scientists study the natural world. The process of scientific inquiry can be embedded in a Web-based instructional system. In such a system, the learning process is facilitated by an environment that emphasizes active student involvement. The Web-based medium becomes a learning space where students can make observations, classify objects, communicate observations and data, make measurements, formulate inferences, and make predictions. Furthermore, online scientific inquiry can be facilitated by resources students explore from distant geographical locations, including remote environments, laboratories, museums, and reference libraries.

Initial ideas for developing the Web-based instructional system

In response to the demand of reform efforts and the lack of an appropriate design model approach, the Carolina Coastal Science project commenced with an idea to develop a Web site that was an organized, non-linear information resource in the context of an inquiry-based constructivist learning environment. Most of the content would be original, created specifically for the site, while other material would be available via links to other sites.

One of the main goals of this project was to create an online environment for primary, middle school, and upper secondary students of varying abilities to engage in authentic scientific inquiry including: identifying questions that guide scientific investigation, using technology to improve investigations and communications, formulating scientific explanations using logic and evidence, recognizing and analyzing alternative explanations and models, and communicating and defending a scientific argument. This instructional system was created on the World Wide Web due to the fact that the nature of hypertext mark-up language (HTML) supports a user-centered learning environment through a non-linear information landscape. Also, a Web site is not a static entity. It can be a dynamic, changing entity in ways that are simply not possible with traditional printed material. Designing effective materials for science educators that provide instructional strategies based on constructivist approaches and various uses of technology was a challenge of this project.

Another important goal of the design and development process was to create a user-friendly interface that would make it easy for novice teachers and students to navigate within the Web site. Several modes of learning and teaching strategies were chosen to be available to the users, including a role-playing simulation-debate, open-ended inquiries, guided inquiries, independent research, and cooperative group learning.

The Carolina Coastal Science Web site

The resulting Web site, Carolina Coastal Science (available online at http://www.ncsu.edu/coast), contains 6 separate areas to engage students in different types of inquiry including:
1. An inquiry simulation in which students investigate the issues concerning the fate of the Shell Island Resort and then debate the future of this and other oceanfront structures threatened by coastal erosion;
2. An interactive photojournal that students can use to construct their own set of inquiry questions to explore;
3. An inquiry exploration in which learners investigate the issues concerning the relocation of the Cape Hatteras Lighthouse.
4. A section of "Inquiry Images" which can be used as whole class guided inquiry activities;
5. A "Coastal Research Technology" section that students can use to identify the scientific instruments used by oceanographers and coastal geologists to collect data;
6. An educator's guide with a variety of teaching suggestions to assist teachers with incorporating the Web site into primary, middle, and upper secondary school classrooms. The educator's guide also shows the correlations of the activities in the Web site with the goals stated in the National Science Education Standards and the North Carolina Science Curriculum Standards.

The Shell Island Dilemma simulation

The Shell Island Dilemma is a simulation, in which students investigate the issues concerning the fate
of the Shell Island Resort and then debate the future of this and other oceanfront structures threatened by coastal erosion. As students engage in the investigation, they identify the social, political and scientific issues with which different stakeholders must deal. Students place themselves into the role of one of the stakeholders. Questions are used throughout the instructional system to focus student's thoughts during their exploration: "As you explore the resources, remember that you are in the role of a stakeholder. Think about the current North Carolina policies regarding the placement of hard structures in public trust areas such as the beach. How does the current coastal policy affect your vested interests as a stakeholder?"

Students are first presented with a video clip that introduces the dilemma. After being introduced to the problem, students are to select their stakeholder role. The roles for this simulation include: the Shell Island Resort homeowners, the Wrightsville Beach town manager, North Carolina Coastal Resources Commission members, coastal engineers, coastal scientists, and members of the environmental advocacy organization, the North Carolina Coastal Federation.

Each stakeholder role Web page includes a brief description of the role and a recommended list of important resources to review. The resources include authentic documents and photographs, including aerial photographs illustrating the recent history of the migration of Mason's Inlet, photographs of the Shell Island Resort, a QuickTime Virtual Reality panorama of the inlet hazard zone, newspaper articles, statements from coastal engineers, permit applications to construct a hard structure, and meeting proceedings from the North Carolina Coastal Resources Commission. After students review the resources, they are to prepare a statement to decide what should be the next course of action regarding the Shell Island Resort. Students present their statement in a debate to decide the future of the Shell Island Resort. Each student also completes a "Position Statement Handout". After students have had enough time to review the resources and prepare their position statements, a class debate is held to decide the next course of action. When the debate is complete, students take a vote on the proposed solutions and conclude the debate when a consensus of 2/3 of the class agrees on a proposed solution. A "Student Record Sheet Assessment" is completed by each individual student at the conclusion of the debate. Both the "Position Statement Handout" and the "Student Record Sheet Assessment" can be easily adapted to be used with other controversial environmental topics such as solid waste disposal, water pollution, and air pollution issues.

Modifying a linear instructional systems model to the Shell Island simulation

Although this instructional system was designed to be delivered in a nonlinear environment, each stage of the Dick and Carey model was applied to the design. The Dick and Carey model was then augmented with constructivist components. The following explains how each component of the Dick and Carey model was implemented with regard to the instructional design and development of the Shell Island Dilemma simulation:

1. Determine Instructional Goal
The instructional goal arose out of a need for good environmental science teaching curricular resources that align with North Carolina Department of Public Instruction instructional objectives within the framework of the National Science Education Standards. There is currently a lack of inquiry-based simulations that North Carolina secondary school teachers can use in their classrooms that pertain to real-life problems in the state of North Carolina. The instructional goal of the system is for learners to identify the social, political and moral issues that different stakeholders must deal with in a current environmental science issue - the fate of the Shell Island Resort.

2. Analyze the Instructional Goal
When students are performing the goal, they investigate the issues concerning the fate of the Shell Island Resort. Students take a position for or against building a hard structure to protect the Shell Island Resort. Students develop a personal view of the issue. Students also identify environmental and economic concerns of various stakeholders regarding the issue.

3. Analyze Learners and Contexts
Learners use technology skills to explore an online Internet resource of information and use data to construct a reasonable explanation for an unresolved issue. Students must use critical thinking skills to explore an issue that is currently unresolved. Learners take a position in their role-playing that they may not necessarily agree with.
Students understand and act on personal and social interests that facilitate development of decision-making skills while experiencing science in a form that engages them in active construction of ideas and explanations. They also communicate investigations and explanations.

4. Write Performance Objectives
   • Students will identify environmental and economic concerns that may result from building a hard structure to protect the Shell Island Resort.
   • Students will list the 3 strongest arguments in favor of building a hard structure to protect the Shell Island Resort.
   • Students will list the 3 strongest arguments against building a hard structure to protect the Shell Island Resort.
   • Students will identify all individuals, interest groups, or organizations that are in favor of building a hard structure to protect the Shell Island Resort.
   • Students will identify all individuals, interest groups, or organizations that are opposed to building a hard structure to protect the Shell Island Resort.
   • Students will prepare a statement to decide what should be the next course of action regarding the Shell Island Resort.

5. Develop Assessment Instruments
   Two different assessment instruments were designed to parallel and measure the learner's ability to perform the listed objectives.
   1. After students review the resources, they prepare a statement to decide what should be the next course of action regarding the Shell Island Resort. Students present their statement in a class debate to decide the future of the Shell Island Resort. Each student completes a "Position Statement Handout" which is designed to assess the stated objectives before the class debate occurs.
   2. A "Student Record Sheet Assessment" is to be completed by each individual student at the conclusion of the debate.

6. Develop Instructional Strategy
   The strategy used in the instruction to achieve the terminal objectives was to design a role-playing activity. A current unresolved issue is selected - the fate of the Shell Island Resort, which is in danger of being destroyed by the migrating Mason's Inlet. Background information is collected. A real-life scenario is then developed. Stakeholder roles of real people are identified. Student roles are developed. An online research resource is created. A debate format is selected with set time limits. A time limit of two days (assuming 90-minute block periods) is given for student research and a period of 1-2 days is required for the actual debate.

7. Develop and Select Instruction
   The instructional materials are developed in the context of a Web site called "The Shell Island Dilemma" which is a section of the Carolina Coastal Science Web site. An Educator's Guide is provided which recommends teaching strategies and assessments for implementing the instructional unit. A web site was chosen as the delivery mechanism of instruction because many resources students can explore such as newspaper articles are readily accessible in an online environment.

8. Design and Conduct Formative Evaluation of Instruction/Revise Instruction
   The Shell Island Dilemma's formative evaluation was conducted in a small group setting with a group (n=13) of primary, middle, and upper secondary school educators enrolled in a graduate course on instructional design and evaluation of educational materials at North Carolina State University. According to Reiser and Kegelmann's (1994) review of current methods of evaluating instructional software, teachers are recommended as the individuals who should be responsible for rating software designed for delivery in classroom settings. Our evaluation group was presented with an overview of the activity and was then instructed to review the activity as a teacher and then as a student. Each reviewer completed an evaluation sheet of the Shell Island Dilemma activity. The evaluators were asked to rate the individual program features of the activity using a Likert-type scale, indicating the degree to which the feature is present. The features evaluated included instructional design, content, learning considerations, documentation, and the goals and objectives of the activity. The evaluators were also asked to look at the activity holistically and reach an overall conclusion based on their impressions. After the evaluators completed the evaluation form, a focus group discussion was
conducted to discuss the strengths and weaknesses of the activity. The focus group made recommendations to modify the instructional program, including creating a specific description of each stakeholder within the instructional system and developing a "Student Record Sheet Assessment."

The Shell Island Dilemma debate simulation was field tested with a 10th grade environmental science class. The teacher of this class served as the evaluator. The students (n=30) spent two days in the computer lab gathering information on their stakeholder role and one day debating in the classroom. The evaluator stated that "the Student Record Sheet Assessment made sure that they (the students) were well-prepared for the debate." The evaluator also stated that the students' attitudes towards the activity were positive. Additional recommendations after the field test resulted in the creation of a "Position Statement Handout" to be utilized by students during their investigation.

9. Conduct Summative Evaluation

Summative evaluation was conducted by a marine education specialist, a coastal geologist, a university professor with expertise in curriculum and instruction, and two secondary school environmental science teachers. The evaluators were asked to examine the instructional effectiveness of the Web-based activity and provide their overall impressions. Each reviewer was requested to pay attention to science content issues, Web site navigation, Web site design, performance, and multimedia issues. The marine education specialist and the coastal geologist were asked to pay particular attention to the accuracy of the scientific facts and issues presented in the activity. The evaluators were requested to use the North Carolina State University's SERVIT Group's (Science Education Research in Visual Instructional Technologies) "Evaluating Science WWW Resources" paper as a guideline during their review of the Shell Island Dilemma. Reviews were returned to the instructional designer via e-mail. Each review was positive and no further recommended changes to the activity were stated. One reviewer even commented that this activity would be an effective tool for a social studies teacher to discuss the handling of social issues.

Constructivist Elements

The following elements were incorporated into the Dick and Carey model to create a constructivist environment within the instructional system:

• Learning occurs with the context of an authentic learning environment in which students use real information and make decisions in a learning environment.
• Learning occurs within the context of a social experience.
• Learners are provided an experience from multiple perspectives.
• Learners are provided with experience in a knowledge construction process.
• Learners are aware of their knowledge construction process.

Conclusion

The Carolina Coastal Science Web site is an instructional system defined as an arrangement of resources and procedures used to promote learning. Although the Dick and Carey systems approach model for designing instruction was designed for linear instruction, this approach can still be used as part of the instructional design and developmental process in an inquiry-based online learning environment. Creating an instructional system in an online environment promotes the use constructivist theories in student learning due to the nature of their engagement within a hypermedia environment. Although the systems approach is currently being challenged by constructivist theories and models which recognize that social context, roles and relationships are central to learning, the Shell Island Dilemma on the Carolina Coastal Science Web site illustrates that the traditional systems model continues to provide a base for the design and development of instructional systems in an online constructivist environment for science education.

Principles for Designing Online Instruction

Harriett Bohannon, Ph. D.
Course & Faculty Development
Florida Gulf Coast University
United States
hbohanno@fgcu.edu

Abstract: Integration of technology in teaching and learning is part of the unique mission of Florida Gulf Coast University (FGCU) to increase access to higher education, not only in Southwest Florida, but beyond. To gain a better understanding of the web in education, the University organized a study group to review learning theories, and to reflect on the courses designed and taught at FGCU. The group identified guiding principles and best practices for teaching, managing, and supporting web-based instruction at the university. This presentation will address issues in web course design and development, web course management and institutional support. The issues will be examined from the perspective of faculty, administrators, and support staff. The goal of this work is to bring a better understanding of the use of the web in higher education, its impact on teaching and learning, and implications for support staff, faculty, and administrators in the university.

Introduction

Florida Gulf Coast University, America's newest, is part of the Florida State University System and has been chartered as a center for innovation. The state-of-the-art campus, opened in 1997 in a pine and palmetto forest in southwest Florida, weaves technological sophistication with a fragile coastal ecosystem. As part of the founding faculty and staff we participated in the development of over 200 courses using the Internet as a major or supplementary part of the course designs.

After two years of operation, a study team of experienced on-line faculty and instructional designers from the colleges and the Department of Instructional Technology reviewed the literature and reflected on their own experiences. This helped to identify a set of principles for online instruction to guide continuing design, development and delivery of online courses at FGCU. This brief article gives a summary of four major topics - instructional design, course management, visual design, and support. The full text of the Principles for Online Instruction has been posted at www.fgcu.edu/onedesign

Instructional Design

Instructional design is one area in which guidelines are recommended for web-based online instruction at FGCU. After reflecting on our own practices and reviewing related literature, we identified a set of guiding principles for online instructional design. It is recommended that instructors conduct instructional, content, and audience analyses for online courses. The analyses can provide baseline data for online course design and lead to the formation of instructional goals and objectives.

To implement the principles in web-based online instruction design, we ensure that every online course at FGCU is created with clearly defined instructional goals, well thought-out learning activities, and appropriate assessment methods. We suggested using Bloom’s (1956) taxonomy to define instructional objectives and determine areas of knowledge and skills for a course. In one online course, for example, we clearly related each instructional goal to 3 levels of learning hierarchy: information, application, and evaluation. This clarified the instructor's expectations and provided a student-centered learning environment in which they can appropriately allocate their time and energy to the course and take responsibility for their own learning.
Clearly defined instructional goals, on the other hand, enable the instructor to design specific instructional activities that are directed toward reinforcing and practicing skills and knowledge. While recommending that instructors engage students in active learning and provide students with meaningful learning experiences, we suggest a list of possible learning activities such as test/quiz, case study, journal, portfolio, simulation/games, and authentic projects for online instruction. Each activity facilitates students' achieving a specific learning goal in a course. For example, a self-assessing quiz in the Health Assessment course in College of Health Professions helps students to recall information such as concepts, principles and rules of health assessment. It draws students' attention to key concepts of the course and directs students to further readings and reinforcement activities if they fail to understand. The case study method is used in the Client Education in Health Care course where critical thinking and problem-solving skills are main course goals. Students were plunged into an authentic learning environment provided by case studies. They were not only asked to recall information, but analyze cases, identify problems, and find possible solutions.

In addition to the learning objective and hierarchy analysis, instructional analysis also involves content analysis, which usually determines the selection and sequence of a course content. Course content analysis for online instruction examines a course's suitability for online delivery. For example, an anatomy course in Arts and Sciences has both lecture and lab sections. Without a sophisticated online lab for students to engage in hands-on manipulation of each anatomic part of a human and assemble/disassemble parts, students will lose the opportunity to reinforce and integrate information learned in lecture sections. Student learning will suffer as a result. Such a course is not the most appropriate candidate for online instruction with present technology. As online labs become reality rather than dreams, the situation may well change. For the courses that are deemed not suitable for online instruction at present, a number of methods can be taken to meet the needs of distance students. Some of these courses are delivered in a flexible mode with both online and campus lab sections. In most cases, the course instructor is the most qualified person who can recommend the suitability of a course for online instruction.

Audience analysis for online instruction goes beyond traditional learner's personal characteristics, intellectual skills, and subject knowledge level. In audience analysis, we try to find students' technology skills and previous experiences with online instruction. For instance, a large number of online courses at FGCU are designed with a technology skill assessment and preparation module. Students are usually required to go through the module during the first week or prior to the first week of a course. Knowing students' technology skills, the instructor can direct students to technical support services for workshops, one-to-one training sessions, or online tutorials according to an individual's skill level. The instructor can even advise those whose technology skills are below the required level to take the course next semester. Since students are coming with different level of technology skills, it is suggested that the instructor should plan for naive users of technology and provide basic instruction throughout the course so that all students have the same chance of succeeding.

While course design, which consists of instructional, content, and audience analyses, lays the foundation for an online course, appropriate interaction and course management ensure that students follow the course plan and achieve the instructional goals specified in a course.

Course Management

Planning for course management during the development and design stages may alleviate some problems encountered during the delivery of the course. We considered the following factors in the delivery of a successful on-line course: time commitment; tracking and evaluating student progress; providing adequate feedback; and communication.

An increased time commitment exists for both students and instructors. Instructors interact with every student on a regular basis, while students become independent, self-directed learners. Since a sizable amount of our instructors' time is spent on course management once the semester begins, we encourage the completion of total course design and development prior to Internet delivery.

Tracking and evaluating student progress starts at the beginning of the course by ensuring our students are capable of utilizing technology and by presenting consistent, organized lessons and assignments. Most of our students are required to attend face-to-face technology orientation sessions or participate in an on-line technology orientation. The on-line technology orientation is incorporated as the first lesson or part of the first lesson of the Internet course. Student progress is tracked through the course
students are evaluated by various methods: projects, homework, examinations (online testing or proctored), and online discussion.

When providing feedback to students, we use any available method such as e-mail, online discussion, telephone, or face-to-face meetings. We establish a clear pattern of response time that students can recognize as being efficient. Some of our online instructors tell students how long they can expect to wait for responses to e-mails. For example, some instructors tell students they can expect an e-mail response within 24-48 hours. We also notify students when assignments are received with a simple response of 'got it.' We have found students look for the 'got it' message. If they do not receive it within a reasonable time frame, the students will resubmit the assignment or check with the instructor as to whether or not it was received.

Communication is necessary to create and promote an atmosphere of caring and sharing. By setting clear expectations for students' online activity and allowing opportunities for social contact through chat cafes, face-to-face orientations, personal welcome letters, personal photographs, and student web pages with direct links to e-mail, a vibrant and orderly learning community can emerge.

Visual Design

Internet design is neither art nor science, but there is a 200-year history of design theory that informs online design. This theory suggests that form should not be separated from content and design should serve learning (Bull 1998).

Our experiences confirmed some suggestions from the literature. For example, information on a course web page should be organized to enhance learning and artistic design should not be the prime purpose. Navigation devices should also be carefully designed to orient the user and provide a sense of direction. Graphics should be used to support learning by presenting additional information without unnecessarily extending download time.

In the fast changing world of multimedia our designers not only had to determine the optimum use of text and pictures, but also consider various methods of incorporating audio and video. Numerous questions resulted. Should media be linked or streamed? Should web pages incorporate linear media such as PowerPoint presentations? Should web sites or pages be narrated and/or streamed? When are animations effective or irritating? The limitations of both student and equipment are critical when multimedia elements are incorporated. Do students have the right "plug-in" to display the multimedia? If not, can they install or download the plug-in? Are student modems fast enough to transfer information? An error in judgment here can create an absolute barrier to learning (Pavio, 1971).

Support

At FGCU we learned very quickly that the integrity of our online instruction, directly related to the support services we provide to the faculty and students who were involved in these courses. We divide our support services into three categories: Technical Services and Support, Academic Services and Support, and Library Support Services. Each one of these categories offers faculty and students help in facing the challenges of learning and succeeding in our web-based education programs. You will find specific examples of this support system at the following URL: http://www.fgcu.edu/onlinedesign/techsup.html

We provide technical support services to our faculty through: 1) workshops on using the technology to develop and deliver courses via the Internet; 2) individual training sessions (house calls) providing one-on-one instruction, and 3) instructional design assistance to faculty requesting their collaboration. Some examples of our technical support services for students are: 1) on-line tutorials, 2) class mentors who assist new students in navigating through the technology, 3) computer labs that provide instruction to students through workshops and lab assistance, and 4) demo courses for students to review prior to taking a web course.

Academic support services provide our online users with admission forms, registration, and financial aid through the Internet. In addition, on-line tutoring, proctoring services, and on-line book ordering forms support those students who cannot come to campus. Students attending the University through distance receive a Guidebook for Distance Learning. This document assists them in their journey from admission to course completion. To assist DL students as they progress through their course of study,
academic advisors in each of the colleges provide on-line orientation and advising through email and phone. Library support services at Florida Gulf Coast University provide reference services and information-literate instruction appropriate to meet the needs of distance learners. Providing course material on electronic reserve is a primary function provided by the library. In addition students have easy access to the library catalog, WebLuis. The FGCU library provides students with remote access to some full text journal articles directly through the Library web site. Students may use the form on the web site to request information or contact the reference staff for further assistance.

Implications

There are now over 200 web-based or web-enhanced courses being taught at FGCU and the whirlwind of activity that characterized our inaugural years has settled into more predictable routines allowing us to reflect on our experience and identify the implications of our work. First, the Design Principles provide a benchmark for quality assurance to guide the continuous improvement of web-based course materials. In addition the Principles provide a theoretical framework for designing faculty development activities that can people develop a working mental model of web-based instruction. For example, how can you incorporate an impassioned classroom debate into cyberspace? What will it look like, how will it work, and can it be as powerful a learning experience as its classroom equivalent?

The Design Principles also inform the decision-making and policy development tasks. What kind of technical support is adequate? How can we build a development team that provides the complementary skills for online course development while the faculty learn to work as online instructors and students become online learners? Online learning is fast becoming a fact of life in higher education and it requires that some time-honored practices be reconceptualized. It is our hope that the Principles for Online Instruction will inform the work of faculty, staff and administrators as they answer the question, "How might I use the Internet to enhance teaching and learning?"

Effective Presentation Design

Terence Cavanaugh, Curriculum and Instruction, College of Education and Human Resources, University of North Florida, Jacksonville, FL USA. tcavanaugh@unf.edu

Cathy Cavanaugh, Curriculum and Instruction, College of Education and Human Resources, University of North Florida, Jacksonville, FL USA. ccavanaugh@unf.edu

Abstract: Presentation software tools are powerful and adaptable products for creating custom lessons and presentations. Electronic presentations are used for education in three delivery formats: Teacher to Audience; Teacher to Individual; and Student to Audience. Effective presentations follow established design principles and include interactivity such as brainstorming, organizing, and reviewing. Benefits of interactive presentations include sensory engagement through multimedia and easy reuse and updating of saved files. Tutorials, interactive lessons with feedback, review, and even testing, can be created as presentations. Using this approach, people can work at their own pace, and can experience individual remediation or enrichment. As a powerful learning activity, students can share their learning with their class, their parents, their community, and the world. By developing a presentation or electronic portfolio, learners gain extensive experience with organizing information, and they experience the real-world task of communicating knowledge to others.

Desktop presentation creation software applications have become more than linear presentation tools. Software such as web page editors, Inspiration and PowerPoint now support branching navigation, custom buttons, interactive menus, program control, and web interactions. These features can make a presentation software tool a powerful and adaptable product for creating custom lessons and presentations. Realism is enhanced with multimedia elements such as sound, graphics, animation, photos, and movies into a presentation. In addition, a presentation can include Web links, and files such as databases, spreadsheets, and charts.

Presentation software can be used for education in three general formats: Teacher to Audience; Teacher to Individual; and Student to Audience. Teacher to Audience presentations involve the teacher or presenter sharing information with a group in the room or lecture hall or even across the web. A presentation can be used to do more than just to share information; it can also become interactive with brainstorming, organizing, and reviewing. Benefits of interactive presentations include sensory engagement through multimedia and easy reuse and updating of saved files. Teacher to Individual presentations are often delivered by way of a hands-on computer station. Here learners or small groups can work on tutorials, interactive lessons with feedback, review, and even testing. Using this approach, people can work at their own pace, and can experience individual remediation or enrichment. This type of program can be run in a computer lab, through a school's network, or on the World Wide Web. Student to Audience presentations allow a student or group of students to share their learning with their class, their parents, their community, and the world. By developing a presentation or electronic portfolio, learners gain extensive experience with organizing information, and they experience the real-world task of communicating knowledge to others.

When creating a presentation, some design considerations are important. The effective application of these considerations makes presentations easier to follow and understand and make the presenter appear more professional. A rule of thumb for designing a presentation slide or screen is known as the rule of threes: a slide should contain three base elements. The elements are generally a title or topic, text, and illustration such as diagram or chart. Slides are best understood when they are limited to a maximum of six text items as phrases or bullet points. Any more causes the text to become too small or presents too many points for the audience to keep in mind. More than five or six points should be grouped or "chunked" into subtopics, and then further information can be presented on its own side. Slides should include plenty of white space to avoid clutter. Material should not extend from edge to edge. People read faster and comprehend better when there are margins around material. Using a few high-contrast colors works best for a presentation: too many colors can become confusing, and a lack of contrast between text and background can render a presentation unreadable. While people prefer to read dark text on a light background, light text and dark backgrounds are also acceptable. The contrast must be sufficient.
One of the most basic elements to consider is the structure of text. Text should flow from left to right and down from the top. When adding moving text to a slide, place text so that it moves from the right to the left, because viewers are accustomed to reading from left to right. Younger readers prefer a simple font such as Arial, a sans serif font. Experienced readers change their preference to a serif font such as Roman or Times New Roman. It is best to use clean fonts and large font sizes. Decorative fonts should be avoided; classic Arial or Roman font types are preferable. A 20-36 point font size is effective for distance reading. A small increase in font size may make written material much easier for viewers to understand. While the larger words will occupy more space, the slide will look less crowded, therefore making viewers feel more comfortable. It is recommended to use both upper and lower case letters. The shape of the written word produces an image to a reader that helps in decoding, by providing clues to words. Avoid using multiple fonts within a document or presentation. A change in font or use of bold should be used to make important information stand out. Common word processor functions of bold, italicize and underline text can help viewers recognize important words and phrases. Research has found that the contrast that exists between yellow and black is greater than the contrast between black and white, making items highlighted in yellow much easier for most people spot and recognize. Since web use has become very common, it is advisable to be sparing in the use of the underline and limit it to URLs and references only, so that underlined words will not be interpreted as hyperlinks. Fonts should be clear and simple to read.

Multimedia is the combination of more than one form of media together to create a more powerful message. The media that are combined include: text, sound, graphics, and video. Multimedia is an excellent way to enhance a presentation. Graphics, sound, video, animation, and charts can all add to the message. Multimedia files should be kept small, since they will have to load into the presentation computer's RAM before being displayed and therefore may cause delays or pauses in the presentation. Additional media should be added to a presentation when they improve the quality, increase the impact of the message, or present information better than text alone. No image or sound should be included in a presentation just because it exists or it is possible to do so. An image or sound that has no bearing on the presentation can be more distracting than helpful.

Images included in a presentation should relate to the topic. Images may inform about the topic, to entertain, or to create an emotional response. The developer of the presentation must decide upon the goal of the presentation and which type of image or mixture of images is appropriate. Otherwise, the image may cause confusion, or it may distract from the message. The use of pictures will motivate viewers to read the text by breaking up the slide and creating more white space. Pictures should not be added to the content material in such a way that they interfere with the reading flow. It is not effective to place pictures in the middle of text; instead they should be located near the edges and some white space should be left around a picture to separate it from the text.

Moving pictures can be very disruptive because when we look at a slide our brains and eyes are automatically attracted to the moving object. As a viewer is reading across the screen, attention will be constantly drawn to the moving object. Motion can be added to a presentation in order to demonstrate action. Motion files include digital video, animations, morphs, and virtual reality. Any motion clip should be set to play once or a limited number of times. This approach provides the presenter with more control, and allows viewers to focus attention on other items on the slide after the motion segments stops. It is recommended not to set video clips to automatically start in a slide, but instead to allow the presenter to choose when to start the video segment. It may be better to have a small still image to click on that will start the video in a new window.

Sound adds realism and should be limited to uses that enhance the presentation. Avoid repetitive sound because they usually distract from the purpose of the presentation. A short tone is usually acceptable, but something longer that repeats is often disruptive and distracting.

It is best to test the presentation on other computer platforms and settings from the computer with which it was created. Different computer platforms and settings can cause changes in the display, and can cause disruption of the presentation by having a different contrast level or changing how the images appear. A presentation should also be tested on how it displays on with a projector or television. Computer monitors usually have a much better picture quality and show colors and contrasts much better than television screens or video projectors. A developer should be careful about including new features with a software program without knowing for sure that the presentation computer will have the same features. Also, if possible, test microphones, speakers and any other peripheral multimedia equipment needed before a presentation starts.
Letting teachers to interact with the idea of “Interactivity”:
What is “Interactive?”

Abstract: This report is the findings of the research on Interactivity, to find the possible characteristics, contexts, limitations, and ideals, of Interactive Learning Environments for future mathematics and science education areas respectively. A web-based survey was used to gather data on diverse views of the academicians, researchers, and teachers. With the help of their answers and our own questioning, we were able to come up with a four-leave model for Interactivity, with social, intellectual, technical, and physical dimensions constituting the four leaves. We hope that this research would give an idea to teachers for what they should expect from “Interactivity” or not.

Introduction

The main question of this study is “How could we characterize an interactive learning environment?”. Recently, interactivity sounds like a magical machine as if when you put something into it, it changes the entire nature of that thing to a something wonderful. We may choose to be puzzled by this “big” idea or we may choose to decide how to use this big idea for the benefit of effective instruction and learning of students through any kind of medium. With extensive research, we were able to come up with a huge range of divergent uses of the same term, in classroom, a textbook, a instructional program, a design issue, feedback-corrective loop, or even metacognitive act (Kirsh, 1997; Rose, 1999; Cezikturk, Kahveci, & Cirik, 2000).

One could be able to find an array of theories underlying the idea and its use in the educational practices. Vygotskian social constructivism stresses the importance of interaction between learners, their peers and teacher for an effective learning environment. One of the first tenets of cognitivism is “metacognition” and it stands for interaction within each person’s mind for their own thinking. Informational processing theory points to the both interaction between components of thinking process (short-term memory, long-term memory and senses), and interaction between several media to have a general understanding of something. Behaviorism favors feedback, which can be thought as interaction, either (Duffy & Jonassen, 1992; Pressley & McCormick, 1995).

Procedure

What is Interactivity or what should it be? The answers to this question is thought to be achieved both through the data collection via a web-based survey over Internet (one of the mediums that is generally thought to be "Interactive") and also with some direct questioning and discussions with researchers and teachers. Last year, we have asked to two distinct samples of researchers (one group was our listeners on MSET, 2000, and the other group was ACRIDAT* members in University at Albany, SUNY) on their ideal “Interactive Learning Environment” for students, and faced with a pile of innovative responses ranging from an environment for communication in a variety of learners in which the learners have the capability of observing, experimenting, debating, playing, navigating with and within a huge information system to a learning environment, which looks
like star trek module; a holographic n-dimensional shared environment, very powerful palm sized computers, with a lot of opportunities for hands-on experiences or manipulatives.

The survey has included two main web pages, first being the title page, second being the main survey. In the second part there have been two main parts; one for detecting demographics of our sample, and one for main items related to Interactivity. Part two included 19 items, 7 open-ended and 12 closed-ended items respectively. We have thought that close-ended, highly rank order or checklist items would give the respondent a chance to see our stance, and open-ended items would enable them to state their own views directly to researchers. Main items functioned to identify the contexts (social interaction research, technology integration, programmed instruction) in general as well as the specific contexts as discussions, lecture, debates, simulations, narratives, problem solving, etc, the place of occurrence (student to medium, student to teacher, student to content, computer to computer, a novice and an expert, etc.), and the context which would stimulate most (real time and time-delayed, as well as WWW and IRC, MUDs, MOOs, as much as Virtual Reality. Items also designed to identify the examples for both instructional methods, and activities for most Interactivity. We have decided our respondents to be academicians, researchers as well as teachers of subject domains as mathematics and science. Although our study is situated in the context of mathematics and science education, the results of the study may perfectly serve for the purposes of other subject domains as well.

![Figure 1. A four leave model for interactivity](image)

### Results

Survey data indicated that there are mainly 4 dimensions to Interactivity. Social dimension is thought to be including one to one (student to teacher, novice to expert) as well as a group activity (discussions, debates). Intellectual refers to interaction with content, or with text. Technical is meant to be between computers, human-computer, and between soft wares. Finally, physical refers to stimulus-response in especially experiments, student-centered learning, action, movement, etc. These are not distinct categories. They should have in common, as well as different aspects than the others. Figure 1 shows that those 4 leaves can be thought as 4 intersecting sets. Their utmost intersection indicates where Virtual reality lies. It is energetic, it is supposed to be a copy of the reality, hence social (think about role playing, MUDs, & MOOs). It is technical since it requires a highly developed interface of human-computer interaction. And it is intellectual, since it is partly not real. It needs to be interpreted by the brain for common elements to the reality, and differences. It is physical, since it requires movement, and active student engagement as well. We are certainly aware the cost of time, and material of VR technique in the classroom. Even with narratives in a classroom, teacher can make students to learn by doing, with the help of at least a poster, a relevant schema, or a computer with Internet for achieving technical interactivity, with discussion groups and making students to reflect on the narrative, a lot more can be achieved. However, VR can be used for modeling real classroom experiences, and for impossible experiences. The remaining part is to find a way to model VR in a classroom.

Qualitative Data Analysis to Ascertain the Benefits of a Web-Based, Teacher Oriented Project

April A. Cleveland, Department of Mathematics, Science and Technology Education, North Carolina State University, United States, ajclevel@unity.ncsu.edu

Dr. John Park, Department of Mathematics, Science and Technology Education, North Carolina State University, United States, park@unity.ncsu.edu

Abstract: Qualitative data is often overlooked when judging the success or failure of a web-based project, but can be a valuable resource in evaluating the potential needs and experiences of the participants. Research has determined that the use of both qualitative and quantitative data as an analysis tool to determine the success or failure of a venture provides a holistic look that provides insights that may not have been obvious in a quantitative only type evaluation. This paper will analyze the use of qualitative data to determine the benefit of a teacher oriented web-based project. The participants, who were upper level elementary, middle and high school teachers, participated in the web project in one of two ways. One, by attending a three-hour workshop in which they were introduced to the online project and instructed in its use. Secondly, they could participate online, by completing a registration form and receiving a password that allowed them to access a web tutorial as an introduction to the project. The purpose of this analysis is to determine if and to what extent peer-to-peer interaction and face-to-face interaction with a workshop leader affects the involvement and participation in a teacher oriented web-based project.

Introduction

Qualitative data is often overlooked when judging the success or failure of a web-based project, but can be a valuable resource in evaluating the potential needs and experiences of the participants. Patton (1980) feels that qualitative data "permits one to understand the world as seen by the respondents." By using a form of open-ended questioning, the respondents are free to express their opinions and needs without the predetermination that often is associated with questionnaires and surveys. An example of open-ended questioning associated with this project is a question that gave the participants an opportunity to explain how they planned to use the project in their classroom once they completed the workshop or the web tutorial. This type of question contains none of the predetermination that would be associated with a question that provides a list of options from which the participant can choose. This type of questioning also provided the researcher with the opportunity to evaluate the respondents' comments and place the responses in a category designated by the researcher, if necessary. This is not to say that quantitative data is not useful in evaluative situations, but a combination of both quantitative and qualitative data provides a holistic view of the respondents' use and involvement in the project (Levin, 1990).

Data Collection

The data, which was analyzed, included field notes compiled by the researcher who acted as a participant observer in the role of workshop leader, videotapes of workshop participants, listerv interactions, and individual emails. Videotape data was compiled with the field notes as a means to determine the types of interactions between participants. For example, the formation of work groups as opposed to working individually during the course of the workshop (Winschitl, 1998). The participants took part in the project in one of two ways: by attending a workshop or by participating online with the use
of a web tutorial. In the latter case, the data was submitted on a form via email or regular mail depending on the type of data being collected.

The researcher acted as a participant observer, which increased the opportunities for interaction and also allowed a view of the project as seen through the eyes of the participants. As a participant-observer, Patton (1980) feels that the direct personal contact and experience in the project provides the researcher with valuable insights that would otherwise be lost in a quantitative only type evaluation. Patton (1980) feels that the role of a participant observer may change over a period of time. The researcher may begin as an onlooker, almost an outsider, and gradually become involved to the point that he or she may begin to fully experience the program in a similar manner to the participants. This allows the researcher the opportunity to develop an insider's view so that they can see as well as feel what is occurring throughout the duration of the project. In observing and participating in any type of project, it is of the utmost importance to avoid equating the success of the project with only the formal activities of the program.

Patton (1980) also states that a qualitative approach provides a researcher with the opportunity to look at informal patterns and "unanticipated consequences." An example of such an "unanticipated consequence" may be the creation of a teacher support system in which teachers have the opportunity to interact and share resources. Since teaching is traditionally known as an isolating profession, this type of interaction is often not available to teachers during their daily routines. But this type of interaction is necessary for the continual growth and development, which should be an integral part of the teaching profession.

These types of interactions were noted frequently among the workshop participants. For example, as the teachers interacted throughout the course of the workshop they began talking about resources they use or contact people for specific items, oftentimes exchanging email addresses and phone numbers before the workshop concluded. In addition, participants who often seemed to prefer to work alone at the beginning of the workshop were interacting and discussing their findings and results by the end of the workshop.

The participants, both workshop and online, were also subscribed to a listserv as a way to interact with their peers and also the researcher. The researcher sent out messages approximately twice a month to encourage participation by the collection of water quality data and its submission to the water quality database. Participants were encouraged to use this venue as a means to exchange information or ask questions of the other participants. The following is an example of a request from a web participant:

"Hi—we are testing local stream water in Wilmington DE using the materials from the water what ifs workshop. When we are done we will post the results on the web site. A very capable 6th grade student is helping run the water quality tests. He posed an interesting question: Is there a maximum safe level of dissolved oxygen in a given body of water? Feel free to respond. Thank you!"

This particular request for help received three responses about dissolved oxygen levels. This type of interaction helps to reduce the isolation of the teaching profession and opens doors for teachers to interact not only with other teachers, but also students who may be involved in independent type projects where help is needed after school hours. In addition to the listserv, individual email was also used as a means of contact and enabled the researcher to request information from the participants who were not responding in a timely manner.

Conclusion

For workshop participants to have increased interaction and to form working groups, the number of participants needs to be increased. An increased number of participants tend to facilitate the need to work together due to the size of the facility or the available lab materials. One three participant workshop group worked individually for the majority of the workshop and interacted more often with the workshop leader than the other participants, whereas a workshop group of ten interacted primarily with each other rather than the researcher. As the number of workshop participants increased, so did the number of interactions among the participants. A larger number of participants allowed the workshop leader to maintain the role of a coach or a guide as the participants’ questions were normally addressed by their peers.
A major part of the impact of the program may be occurring in the informal, unstructured portion of the project, on the periphery of the structured activities, outside the formal workshop setting. The listserv was one of the activities that occurred on the periphery of the structured activities, but provided a way for the teachers and the researcher to stay connected after the initial interaction. This gave the teachers the availability of a support system on which they can rely for additional help if the need arose. Both the use of the listserv and the availability of the researcher via email, were a support system that was utilized primarily by the web participants in this project. In addition, the majority of the water quality data collected and posted to the database came from the web participants. Interaction between the researcher and the workshop participants was minimal after the initial interaction in the actual workshop. By collecting and evaluating qualitative data, these types of activities and interactions can be evaluated and added to the researcher’s report as an additional component in conjunction with the quantitative data analysis. In conclusion, by looking at the informal activities associated with this project, the researcher was able to see that it did provide benefit to a number of the participants in the form of a peer support system. These benefits would not have been established in a quantitative only type study.

Yekioyd Statistics and Their Interpretation

Steven Dickey and Kevin Zachary
Eastern Kentucky University
United States
ecodicke@acs.eku.edu

Abstract: This paper introduces a family of statistics for item analysis. Their construction is based on a model of perfect internal consistency between each item and the test as a whole. Weighted versions of the statistics mirror the concerns of an educator in evaluating test items. In addition to identifying flawed test items, these statistics also indicate something of the nature of the flaw. Another advantage of the statistics is that their interpretation can be derived directly.

In these two pages, we will introduce three item analysis statistics. We refer to an exam item with difficulty statistics p and q that is answered by n students. In a case of perfect item consistency, the np top scoring students will answer correctly and the nq lowest scoring students will answer incorrectly. Such a situation describes what we will call the Yekioyd model. The cliché that you either knew it or you didn’t is the source of the acronym Yekioyd.

Deviations from the model occur when either a student in the nq lower scoring group answers correctly or a student in the np higher scoring group answers incorrectly. The statistic described below, YB, has a value of zero in a situation of no deviation from the model. Its design leads to a value of one in the situation of maximum possible deviation from the model. The students are ranked in descending order by their overall percentage scores on the test and divided into two ranges. These ranges are the upper np students and the lower nq students for the p and q of the question. The maximum possible number of deviations is the smaller of 2np and 2nq. Half of the deviations must necessarily occur in each range. For each range, the deviation variable D is constructed. Its value is one for all upper range students who answered incorrectly and all lower range students that answered correctly. Otherwise, its value is zero. Since the Yekioyd model is a model of perfect internal consistency, the YB statistic is an internal consistency measure. The basic Yekioyd statistic YB is given by:

1. \[ YB = \sum_{i=1}^{n} D_i + \text{[the smaller of } 2np \text{ or } 2nq \] 

Imagine a rank ordering of the scores of the higher scoring np students followed by a rank ordering of the scores of the lower scoring nq students. Deviations are of severe concern if they distant from the dividing boundary and of nearly no concern if they are near that boundary. The shortcoming of the YB statistic is that it treats a deviation as equally important no matter where it occurs. The desired construction is a weighted statistic that reflects the greater undesirability of deviations that occur far above or far below the line of division between the upper and lower ranges. Such weights should reflect the distance from the line of division to the number line location at which the deviation occurred. This division point will be calculated by the average of the scores of the two students on the boundary of the np/nq division. This average serves as the boundary value, B.

Once it matters where in the rank order a deviation occurs, deviations in two ranges take place in incomparable environments for any value of p other than .5. For this reason it is necessary to treat the two ranges separately. Two Yekioyd statistics, an upper range YU and a lower range YL, are the result of this separation. This division brings additional benefits. The measures indicate two different types of question flaws and directions for improving questions (See the discussion of interpretation below.).

For each student, a value of the weighting variable W is constructed from the student's score and B. In the upper range, B is subtracted from the student's score. In the lower range, the student's score is subtracted from B. W is not a weight in its own right. The actual weight given to a deviation occurring with a particular student is the W value associated with that student divided by the base for the weighting. In each range, the
base for weighting will be the summation of W values in that range.

Both statistics will be scaled by a factor reflecting the number of locations for deviations divided by the number of possible deviations. Multiplication by the scaling factor provides for a maximum possible value of one for YU for all possible p values. The result of this treatment is that the statistic treats questions with different p values comparably. The scaling factor has a value of one for YU if $p > .5$ or for YL if $p < .5$. In these situations, the number of possible deviations is equal to the number of rank order locations. It was noted earlier that the maximum number of possible deviations in each of both ranges was the smaller of np and nq. We will represent this smaller one of the two values with $[np:nq]$.

Let $i$ be the index of the rank order of student scores, with 1 assigned to the highest student score and n assigned to the lowest student score. The value of the upper range Yekioyd, YU, is given by:

$$YU = (\sum_{i=1}^{np} Wi(Di) + \sum_{i=1}^{np} Wi) (np + [np:nq])$$

The value of the lower range Yekioyd, YL is given by:

$$YL = (\sum_{i=np+1}^{n} Wi(Di) + \sum_{i=np+1}^{n} Wi) (nq + [np:nq])$$

The contribution of a question to the consistency of a test can be measured in terms of deviations. Deviations occurring are a negative contribution. Deviations not occurring are a positive contribution. A YB value of one means that the question contribution to the test is entirely negative. A value of .5 means that a question is adding to and taking away from the consistency of the test in equal measures resulting in a zero net contribution. At .25, the contribution of the question to the consistency of the test is half of its potential. These statements apply equally in interpreting YU and YL. The table below further summarizes interpretation of the Yekioyd statistics.

<table>
<thead>
<tr>
<th>Y Value</th>
<th>Deviations Not Occurring</th>
<th>Deviations Occurring</th>
<th>Net Contribution</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.0</td>
<td>0</td>
<td>2nq</td>
<td>-2nq</td>
</tr>
<tr>
<td>.75</td>
<td>.5nq</td>
<td>1.5nq</td>
<td>-nq</td>
</tr>
<tr>
<td>.50</td>
<td>nq</td>
<td>nq</td>
<td>0</td>
</tr>
<tr>
<td>.25</td>
<td>1.5nq</td>
<td>.5nq</td>
<td>nq</td>
</tr>
<tr>
<td>0.0</td>
<td>2nq</td>
<td>0</td>
<td>2nq</td>
</tr>
</tbody>
</table>

(* The table applies the assumption that nq < np. Otherwise, np would appear instead of nq, with no change in implications.)

YU, the upper Yekioyd, primarily responds to 'trap' characteristics or vagueness in a test question that are throwing well prepared students off the correct answer. YL, the lower Yekioyd, primarily responds to weak distractor answers and question structure that points out the correct answer. Questions that are easily guessed are identified by the YL statistic.

In this paper, we have introduced three item analysis statistics. Software for calculating these statistics has been developed by Kevin Zachary. Longer versions of this paper are available. Contact Steven Dickey at ecodicke@acs.eku.edu for further information.
gLearning: The New e-Learning Frontier

By Steven Donahue
sdonahue@broward.cc.fl.us

Emerging technologies have always had an innovative impact upon the language: horse-less carriage became car; steamship became ship; wireless cell phone is becoming just phone. Eventually the "distance" portion of distance learning will also fall away and become just "learning". But, will e-learning be the same mode of learning? Or will it necessarily take on a new meaning; hence, a new linguistic form?

There are three problems associated with translating a face-to-face classroom into a Web-based one. First, there is the CONTENT problem of rendering traditional content suitable for Web delivery. Second, there is the DELIVERY challenge of distributing the learning material anywhere, anytime. Lastly, there is the PARTICIPATION aspect of ensuring that everyone is optimally involved in the learning process.

By learning it is typically meant the process of Recognition, Re-organization, and Regurgitation or sharing of some knowledge object. For example, an ESL learner might learn to recognize the distinction between /f/ and /v/; re-organize his or her native phonology system so as to adapt /f/ or /v/ into the new English system; regurgitate that new knowledge in a reflective test or through peer interaction. The context or the physical setting of this learning experience has since antiquity a room, seats, a writing board, and written or oral tests of some sort or another.

Imagine that day when you had the perfect teaching experience as a teacher. Or that day when you had the peak learning experience as a student. When all the students are a buzz of activity, the teacher’s teaching plan unfolds like an orchestrated piece, and all the pedagogical elements are in harmony. When there are no tardy students, no absences, and no daydreaming. Imagine a day when students smoothly break into groups and help each other learn. A day when the students madly scribble notes as the teacher speaks and fill in those blanks in knowledge so that that magical “learning moment” crystallizes and sends the students out of the classroom with an exhilarating warm glow that has positively transformed lives.

Dream on. The perfect days are rare. The difficulties inherent in having twenty-five students rendezvous at a definite point at the same time and in the same ready-to-learn frame of mind pose daunting barriers. Cars, jobs, babysitters all intervene to thwart the perfect learning moment. On the other hand, the efforts thus far to harness the power of technology to affect the perfect learning moment have been wanting. A simple transfer of the architecture of the face-to-face classroom to a Web-based environment has not been a cure-all for the deficiencies of the on-ground classroom it was intended to replace. Indeed, the early attempts at distance education have been marked in common by a lack of imaginative re-engineering.

In fact, the "distance" has yet to fall away from "learning". A plethora of terms have been proposed for this new form of e-learning: "Learnativity", "e-Learning", "CALL", "CBT" and so forth. In a linguistic turn, we propose the term “gLearning” for a re-engineered learning experience befitting the full, unleashed power of the Internet. The new coinage is composed of “glean”—picking up nuggets of sustenance after a rich harvest and “learn”—the personal ownership of knowledge. The “g” also harkens to “global” or invokes the phonetic intensive words “gleam”, “glint”, “glisten” and has connotations of shimmering light; hence, enlightenment through learning.

The definition of “gLearning” [pronounced either “gee-learning” or “glurning”] revolves around three principles: gLearning is Adaptable; gLearning is Ubiquitious; gLearning is Uniform. In short, “gLearning” is not Learning—it is not place-bound, role-bound, or time-bound. In fact, it is a new form of Learning and Teaching where both learner and teacher assume new, exciting roles.

Adaptable. In the earth-bound, role-bound classroom, whether it be grammar, pronunciation, or math, the teacher delivers a lesson that is new material for some and known material for others. It is the “shotgun “ approach. In the gLearning classroom each student receives only the particular lesson or incremental learning step as required. Customized learning objects are filtered to the learner in a hierarchy that maximizes acquisition of new material. Moreover, the student owns this customized material and can interact with it individually until the lesson has been
mastered. Each student owns and controls their personal “Bell Curve” for learning and mastery of a subject area. (Figure 1).

Figure 1

Ubiquitous. The traditional classroom is necessarily place-bound and time-bound. The catchword is that they are “synchronous” or in real time. The online classroom can operate outside of the constraints and be “asynchronous.” However, the true power of the Internet has not been realized because the architecture of most course management systems looks suspiciously like the place-bound classroom, and the roles of the teachers and learners eerily echo the role-bound onground class. (Figure 2)

Figure 2.

Uniform. The unevenness of the conventional classroom is a multivariate problem that defies solution. Teachers, students, text, assignments, grading rubrics, exigencies, and policies all conspire to make each class a unique “pot luck” experience. In the gLearning environment the roles of the student and teacher are radically altered. Moreover, their rights are clearly stated and delineated in an Online Glearner’s Bill of Rights. [see note]. With the gLearner, the students exchange purposeful, standardized, pre-formed “Participation Units” or “e-Learning Currency” that must be spent and which ensure that all students cooperate in teams, circles, communities and so forth. (See Figure 3)

Figure 3.
gLearning sounds great, but how does it work?

Computer-Based Training and Testing (CBT) and has been around almost since computers have been invented. CBT has been used to teach and test everything from accounting to zoology, from how to perform surgery to how to talk to customers on the phone. CBT got a big push in 1974, when the National Science Foundation awarded grants to two universities to further the use of computers in learning. This grant eventually spawned several CBT-based authoring systems (the hardware and software used to create CBT) and through those several thousand courses.

With the advent of the Web in the early 90s, CBT began to move to the Internet, transforming into Web-Based Training (WBT). Whereas CBT was usually delivered over closed networks in an organization or distributed on CD-ROM, WBT allowed a course to be created and placed on one computer (a “server”) to which anyone in the world with the proper authorization could connect and learn.

This new approach has provided several distinct advantages, not the least of which is easy maintenance of a course. If a problem is found and fixed, no new CD-ROMs need be sent. A change is made on the server, and that’s that.

Normally, learners who are taking a web-based course stay connected to the Internet for the duration of a session, during which time the lesson materials are “streamed” to the user. Streaming refers to the downloading of course materials to the user a little at a time, so that it appears that the course is running smoothly.

Unfortunately, this is easier to envision than to make a reality, especially for those who live in areas where connections to the Web are slow or sporadic. A constant connection may not be possible or the connection may be slow. Other methods must then be employed.

One method is to download an entire lesson at a time. This, however, can be time consuming and the user is not able to study the lesson until it has completed downloading, an obvious disadvantage. In addition, if the connection to the Internet is interrupted during the download, the partially downloaded file would normally have to be scrapped and the download restarted the next time the user connects.

I-CALMS: Adaptable

A more viable approach includes that employed by the gLearner system— I-CALMS : Intelligent Content Adaptive Learning Management System. Here, the user downloads a small diagnostic test first, after which the Internet connection can be broken. After answering the questions, gLearner will determine which items the user needs to study. After checking to see if any of those items are already resident on the user’s system, it will proceed to reconnect to the Internet and download in the background any items the user still needs. When it has finished downloading those items, it can then disconnect from the Internet again and the user is able to continue studying. If the Internet connection is accidentally broken (for whatever reason), items already downloaded will not need to be retrieved again.

I-CEGS: Ubiquitous

This basic approach is encompassed in I-CEGS : Intelligent Content Engine Generator System, an “intelligent content engine” which can work with any collection of lesson content files. Following some basic rules, it takes content pertaining to the current lesson and arranges it correctly for the user to study. It also collects data regarding student progress and question item analysis. The “intelligent” part of the content engine is the new role for the teacher or content expert who consult on a page-by-page basis to rapidly “glearn” a course and adapt it to the Web. The role of the teacher has been radically changed. In the recent past, the terms facilitator and coach have been used to describe this new, emerging online role for the teacher. In gLearning, the teacher helps define what is the “learning moment” for a particular knowledge domain. The gLearning teacher becomes a “Participation Expert” who pre-defines the “e-Learning Currency” that must be spent during the course of a particular online course.

Through an Intelligent Content Engine, the teacher helps create “twinned” software that enables them to follow a student’s learning progress on a page-by-page basis. It is as if the student and teacher collaborate and create a living and breathing text that contains knowledge mutually constructed. A living text co-constructed out of a vast sea of Internet information, which has been discovered, gleaned, and "glearned". Thus, the locus of where learning takes
place has been radically altered. Teaching shifts from just delivering packet of information to mutually exploring the best way to use that knowledge.

**I-PALMS: Uniform**

But learning is sharing what a student has acquired. Through I-PALMS: Intelligent Participation Adaptive Learning Management System students are matched with other students in units ranging from Buddies, to Teams, to Circles, to Communities to work on collaborative, competitive, and cooperative tasks that re-enforce learning. The participation involves a variety of tasks: Competitive, Cooperative, and Collaborative in ascending higher order thinking skills. Course content for the most part is standardized with interchangeable learning objects. So the English pronunciation course is more or less the same in Boston or San Francisco.

![Fig. 4](image)

Why are CBT and WBT so popular? It should be made clear that they can never completely take the place of a live instructor. However, CBT/WBT can be effectively used to teach many of the more elementary lessons, reserving instructors for the higher order thinking tasks.

The best CBT/WBT courses capture the best minds in a discipline of study and present a consistent and rich experience to learners. Learners are able to take lessons anywhere and at any time, even on a small pocket PC. In addition, a well-made CBT/WBT course will customize itself to each learner’s need, something that is very difficult for an instructor to do in a classroom setting. Each learner can move at his or her own pace because the computer has infinite patience.

Do we have to wait for fast lines?

Because users will be connecting to the Internet at varying speeds, an elegant WBT will accommodate the different speeds by presenting materials in different ways. For instance, a high-bandwidth (fast) connection will allow the use of digitized video files. The same course when confronted with a narrow-bandwidth (slow) connection may opt to use still pictures and limited audio instead. While the effectiveness of the learning materials may not be as rich, the instruction may be almost as effective. Certainly, at narrow bandwidth connections, a course without video and audio is better than no course at all.

In the gLearning environment, a student and teacher enter into a life-time learning environment. The learning environment is ambient and can be accessed through learning instruments such as PCs, Cell phones, PPCs, and Pagers. In the gLearning environment the learner can begin a lesson in the morning on their home PC, continue the lesson on a mobile phone in a traffic jam, do more on the lesson on the work PC, and finally finish the lesson at night back at home. The course follows the student; not the other way around. Knowledge objects are acquired in packets at the learner’s convenience. A learner’s lifetime learning accomplishments are instantly available on an individual URL which can be accessed publicly, as a student wills.
Conclusion

Technology has taught us that there is a critical mass that is necessary for an invention to work. All the ingredients must be in place for a new form to work. When the steam engine was invented, wooden sailboats burned up. The invention would not work until steel hulls were utilized. The analogy is similar to the online classroom. The makers of horse carriages built the same horse-designed vehicle only equipped with an engine. However, not a single horse-less carriage manufacturer went onto become a car maker.

Preliminary results from using the gLearner at Broward Community College this semester show that improvement in mastering English pronunciation is improved on the order of two standard deviations. Raising achievement by two standard deviations in equivalent to raising the performance of 50th percentile students to that of 98th percentile students. In other words, virtually every student is getting an “A”. Perhaps, with the help of technology we can say “adios” to the Bell Curve! (Figure 5)

While the future form of online learning is still unclear, it is not going to fail or go away. It will probably look something like the gLearner—Adaptive, Ubiquitous, and Uniform. And teaching and learning will never be the same.
Orchestrating Virtual Learning

Abstract: One case study of instruction in a virtual learning environment (VLE) was presented. The instruction was aimed at adult learning as part of a professional development initiative for practicing K-12 teachers. Further, this research concerns the use of the Internet as a text medium for supporting synchronous communication and the coordination of learning activities between teacher and students. The aim is to provide some conclusions useful for the future, as the Internet becomes a knowledge and learning resource. This paper focuses on the challenges that instructional designers must consider and teachers must manage in order to make sure that the students get the benefits of learning in virtual environments.

Teaching in a distance learning environment places many challenges on the instructor and student. In a synchronous virtual learning environment (VLE), many things happen simultaneously. Teaching in this environment may be compared to conducting, playing, and listening to an orchestra at the same time. The role of the instructor is like the role of a music conductor. The conductor must attend to the details of each orchestra section and individual musician, while providing the entire orchestra with a direction for tempo and harmony, based on the outline of the musical score, tempered with the conductor's own interpretation of the music selection. The music conductor uses many tools, extensive planning, leadership skills, instrumental technical knowledge, and an interpretation of the musical score to accomplish a successful performance. What do teachers need for orchestrating a virtual synchronous learning environment?

The Environment

The virtual learning environment used in this study was built on a Multi-User Domain (MUD)-client, called TappedIn (http://www.tapnedin.org). This environment enables people to write to one another simultaneously as in a so-called "chat-channel." It offers much more however, such as objects, which participants can use to communicate, interact and share information. It also offers a spatial layout that can be used for moving around to different rooms, libraries, and individual office space.
Hurdles

From this case study, the researchers examined the implications of four (4) hurdles, which were identified as part of the case analysis. Through an examination of these hurdles we begin to see the vision of what is involved with learning today and in the future. This study demonstrated ways in which VLE facilitators can design online coursework so online learners can overcome these hurdles.

Technical Knowledge

Most K-12 teachers in the United States know about computers, yet they are not well versed in the use of the Internet as a knowledge and learning resource. In using the Internet, teachers encounter technical problems and may see these as insurmountable. This frustration leads to increased computer anxiety and anti-technology behaviors.

A key to minimizing this anticipated fear is to carefully select software and Internet sites which require a low learning curve. Since the instructor will not always be logged on when students use a VLE, a strong support network is essential for novice computer users. Online assistance, accompanied by a useful guide (print version) means students can get assistance in navigating the virtual environment and performing object-oriented tasks. A face-to-face start up meeting is recommended if possible.

Online Learning is No Different

Teachers and students engage in computer-mediated learning undergo a paradigm shift in their understanding of the virtual learning environment. It is the students who will be leading themselves through the online course, built on the framework for learning, which the instructional designer and course instructor have mapped out. Online is different and students must acknowledge this.

There are a number of general guidelines to follow. The assignments for each module of an online course need to be grouped into categories, which are used as advanced organizers for each module of the course. Instructors should scaffold the course with a broad selection of resources to support each module topic or learning unit. It is advisable to diversify the instructional strategies used in the online course to meet the learning needs and technology competencies of each student.

Online Communication

In a text-based, synchronous environment, multiple speakers may submit messages in a short time. Students learn to dissect multiple, interwoven threads of conversation as a class discussion evolves. The role of the teacher becomes one of facilitation. Specific leader strategies may be incorporated to guide the discussion or "conduct the orchestra" in a synchronous environment. As a participant in synchronous discussions, students must learn to listen to the chorus of simultaneous and seemingly chaotic voices.

In a VLE, the communications skills must be learned first. Equip students with distinct tools for the varied types of communications in which they will engage. For each virtual class meeting, it is useful to have a set plan for how you plan to use that time. Safeguards should be in place for the students who arrive late, have schedule conflicts, or encounter technology problems when you have a scheduled virtual meeting.

Use of Objects

Objects are an essential part of many virtual learning environments. Some of the objects have practical applications in that they are used to facilitate communication, instruction, and learning. Other objects are designed to more for entertainment, which may help to relieve some anxiety about the technology intensive atmosphere.

Students should receive object-use introduction and practice in a face-to-face technology orientation session. Print guides and access to online helpdesk professionals is critical to a successful VLE as well. The teacher should work with the instructional designer to develop a progressive object skill acquisition plan for the objects you plan to use in the course.

Conclusions

Various online teaching methodologies can help instructional designers and online teachers to meet the demands of the virtual learning environment. Through careful course design, instructional planning, and training, these methodologies can break down the barriers to creating a successful virtual learning environment. There is no single best method of coping with the hurdles listed in this paper instead, a complement of strategies must be used.
Constructing an Enhanced Instructional Presentation

Leslee Francis Pelton
lfrancis@uvic.ca  University of Victoria

Timothy Ward Pelton
tpelton@uvic.ca  Brigham Young University

Abstract: In this document we describe the development of an Enhanced Instructional Presentation (EIP). “If a good educational presentation is like a fine string of pearls, then an Enhanced Instructional Presentation puts that fine string of pearls, along with access to any supplementary information needed, into the hands of the learner in order to ensure full appreciation.” (Pelton & Francis Pelton, 2000)

Enhanced Instructional Presentations

Although the traditional linear presentation (exposition, demonstration, activity sequence, etc.) is often a useful instructional method, and may be effective for a large portion of the target audience, improvements are possible. We have identified five different issues leading to the loss of learning opportunities or a reduction in learning efficiency in the context of a traditional fixed linear presentation:

1. Presentation rate is either too fast or too slow for individual learners causing selective attention or inattention to presentation content.
2. Short term memory overload or processing delays cause concepts, context, questions and even answers to be dropped before they can be committed to memory (Miller, 1956).
3. Verbal ability in the domain is insufficient to allow the learners to articulate the questions they have.
4. Social constraints (pride, consideration of others) prevent the learners from expressing the questions they have formulated in a classroom setting.
5. Answers to learners' questions are not available in real time.

To overcome these difficulties, and improve learning efficiency from linear presentations, we suggest the construction of an Enhanced Instructional Presentation (EIP). Our EIP model is a hybrid extension of the linear presentation that addresses the learners' needs for organized and synthesized content while providing for individual differences in background experience, learning orientation, and cognitive abilities.

In this paper we present an outline of the plan for constructing a specific EIP to teach the concepts and skills associated with “Constructions with a Straightedge and Compass”. We add two caveats: First, the process of constructing an EIP is a process, and multiple iterations are intended. We present only the first iteration. Second, only a few of the potential media types and interactive features that might be used in an EIP are included in this example. Ultimately, the EIP model is a hypermedia instantiation of van Merrienboer's 4C/ID model (van Merrienboer, 1997), and is moldable to meet many different educational needs.

The Traditional Linear Presentation of: “Constructions with a Straightedge and a Compass”

0. Introduction to Constructions with a straightedge and a compass
1. Duplicate a line segment
2. Duplicate an angle
3. Duplicate a given triangle
4. Bisect a line segment
5. Bisect an angle
6. Construct a perpendicular line through a point on a line
7. Construct a perpendicular given a line and an external point
8. Construct a line parallel to a given line and through a given point
9. Construct square, rt. triangle, equilateral triangle, parallelogram etc.
10. Construct various angles (90, 60, 30, 45, etc degrees)

Now although we would agree that the ideal presentation of this topic might be more hands-on, we will for the sake of example imagine it being presented as an instructional video. In this format, only a few really quick learners and those with significant background in the topic area would be able to capture all of the concepts and procedures mentioned and demonstrated. For many of the students, the pace of the video would be too fast and their background knowledge too limited to allow them to capture much at all.
The Development of an EIP for: “Constructions with a Straightedge and a Compass”

The conversion of the linear presentation into an EIP involves identifying start/stop points in an existing presentation, generating a supplementary content network and designing a feedback and interaction mechanism. These elements are combined with the EIP shell (under development) to generate the working EIP.

Identifying start/stop points in an existing presentation

We break the video presentation into content segments and describe each with a short statement. A good starting point would be the outline given above, but to enhance the accessibility and playback control further, we would find the start/stop points for each sub-activity. For example:

4. Bisect a line segment
   i. Set compass width > 1/2 of line length
   ii. Place compass point on end of line segment
   iii. Draw an arc above and below the estimated midpoint
   iv. Repeat ii and iii from other endpoint of line segment
   v. Draw a line between the intersections of each arc pair

A control matrix (spreadsheet) is constructed with a row for each content segment. With each row containing: item number, item type, file name or URL, start/stop points, description, outline level, confusion rank, and an array of links to other segments. The potential for learner confusion rank will be used by the prompting mechanism to stop the regular playback at key points and prompt the learner with the supplementary content linked to that segment. Segments may be individual files or portions of larger video files (or other internally addressable media files).

Generating a supplementary content network

Our preference is to build an EIP with only a few hyperlinks for anticipated questions, challenges, assessments, etc, and then in a trial of the EIP, collect and respond to authentic questions from learners in order to augment the EIP further. Some anticipated questions and challenges for the segments described are:

A. Why does the compass width have to be >1/2 of the line segment?
B. What do I do if my compass can't stretch that far?
C. Is there another way?
D. Why does this work?
E. Now you try it!

Presentations are generated for each of these supplementary segments (videos, powerpoint presentations, simulations, text, narrated stills, web pages, etc.). These segments are also entered as individual rows into the control matrix with the same parameters as above. Finally, links between segments (original and supplementary) are added to the control matrix to define the supplementary content network.

Design a feedback and interaction mechanism

The feedback and interaction mechanism is accomplished by building a web page containing forms, assessments, surveys, links to other web sites and discussion forums etc. An additional line is added to the control matrix to identify the location and type of the feedback page. Two types of feedback pages can be specified. The first will only be loaded when the learner requests it, and the second will be loaded after each content segment (to facilitate the collection of learner questions or participation in some related activity).

In the current example, we might begin by building a form to collect questions from the learners and send them to the instructor via email. As the supplementary network grows and the demand for additional resources wanes, the feedback page might be replaced with a page offering formative evaluations and links to related geometry sites.

The content segments are then placed in a directory (on a local hard drive, CDROM, or on a server) along with the control matrix. The resulting EIP can be updated as frequently as needed, and adapted to the needs of individual learners by setting the prompting level (confusion parameter). For additional information on the EIP shell please contact the authors.

Abstract: The design and development of preservice and inservice teacher education distributed learning environments, specifically World Wide Web-based (Web-based) courses, emphasize the need to think through numerous issues that may not be apparent within traditional face-to-face environments. A metaphorical representation that emphasizes the conceptual framework through out the Web-based course environment offers the preservice and inservice teacher educators a consistent with the knowledge being presented and based upon the prior knowledge of the learner.

Introduction

The design and development of preservice and inservice teacher education distributed learning environments, specifically World Wide Web-based (Web-based) courses, emphasize the need to think through numerous issues that may not be apparent within traditional face-to-face environments. Since Vannevar Bush "invented the foundation for the World Wide Web in 1945 and founded much of the early thinking about human-centered computing" (Nielsen, 1999, paragraph 2) and Ted Nelson as a "pioneering and vocal advocate of users' right to simple computers that everybody can figure out and use as a communications medium rather than a glorified calculator" (Nielsen, 1999, paragraph 2), the design and development of a nurturing, creative learning environment has been at the forefront of enlightened thought. The creation of a Web-based communal learning environment is one that has gained momentum over the previous five year period, and shows no sign of slowing.

One issue within the online learning environment is the emphasis placed upon developing a conceptual framework through which the learners will begin to develop an understanding of the knowledge presented. A metaphorical representation that emphasizes the conceptual framework through out the Web-based course environment offers the preservice and inservice teacher educators a consistent with the knowledge being presented and based upon the prior knowledge of the learner. Therefore, the three areas of emphasis pertaining to the design and development of preservice and inservice teacher education distributed learning environments shall be Web-based learner support within a preservice candidate's curriculum of study, the building of a learner's conceptual framework, and the developmental importance of a metaphorical representation.

Web-Based Learner Support Within a Preservice Candidate's Curriculum of Study

The design and development of Web-based preservice teacher candidate's professional development curriculum lends a supportive environment through which the preservice teacher can further develop her knowledge within key areas of the curriculum of study. This is also true of the inservice teacher educator's
professional development opportunities that may be available online. The creative and nurturing aspects of the
learning environment not only model the desired learning environment for the PreK-12 learners, but also
create an environment in which the preservice and inservice educators develop a level of comfort and freedom
through which to learn. The design of such an environment is of utmost importance to the success of the
learner. Design is an imperative aspect associated with an online learning environment, wherein “the key
issues in interaction design and the main determinant of usability is: what to say” (Nielsen, 2000, paragraph
5). Usability and appropriate interactive activities are the main concern within an online environment, second
only to the content provided to the learner. As has become a distinct feature of discussions surrounding the use
of the Web, “People often talk about how the Web changes on ‘Internet time’, but usability issues seem to
change much more slowly since they stem from human capabilities and interests” (Nielsen, 1994, paragraph
2).

Conceptual Framework

The learner’s conceptual framework of understanding is imperative towards the creation of a firm
knowledge base through which the learner develops a view of the world. The conceptual framework is created
through not only the knowledge that is “input”, but also deals primarily with the creation of a mental model, a
framework, of understanding that is associated with the knowledge acquisition and the melding of the
knowledge into the already created and constantly changing conceptual framework. Such a framework through
which the learner develops an understanding of the knowledge being attained, and forming this knowledge
into useful information within a conceptual understanding of the world and where this knowledge lies within
the “larger picture”, can be aided through the use of a metaphorical representation. This metaphorical
representation can be integrated within the learning environment to aid the learner in constructing appropriate
frameworks of understanding. Conceptualizing the knowledge being obtained with in an appropriate
framework.

Metaphorical Representation

The emphasis placed upon the metaphorical representation of the information within the Web-based
course environment at the beginning of the course design and development will lead to a tightly bound,
cooperative, understandable course framework at the conclusion of the course design, development and
implementation processes. The preservice and inservice teacher educators must rely upon prior knowledge
within any course environment, independent of the subject matter presented; however, the uncomfortable
levels of stress and strain felt by many preservice and inservice teacher educators when faced with a Web-
based course can impact the learning environment as well as the course objectives. For this reason, the
inclusion of a metaphorical representation within a Web-based course emphasizes a heightened level of
comfort on the part of the preservice and inservice teachers, which re-focuses the attention towards the
information presented and away from the Web-based course environment. Therefore, a discussion surrounding
the inclusion of a metaphorical representation within a distributed learning environment, specifically a Web-
based course for preservice and inservice teachers, is essential to accentuate the importance of such a necessary
technique.

Conclusions

The design and development of preservice and inservice teacher education distributed learning
environments, specifically World Wide Web-based (Web-based) courses, emphasize the need to think through
numerous issues that may not be apparent within traditional face-to-face environments. A metaphorical
representation that emphasizes the conceptual framework through out the Web-based course environment
offers the preservice and inservice teacher educators a consistent with the knowledge being presented and
based upon the prior knowledge of the learner.

Abstract: What do teachers need to know and be able to do with technology in a middle-grades classroom? This research project by four middle-grades students set out to accomplish two objectives: 1. Survey the staff of a middle school to develop a table of main themes taught during a school year, and 2. Find and organize outstanding resources from a student's point of view that would support learning across the curriculum. Secondary objectives of the research included 1. Providing students with a chance to apply what they had recently learned in an online course “Introduction to html” and 2. Demonstrating that both students and teachers can learn something new about teaching with technology. Parents, working with online resources, have been the impetus and primary supports for the project. The school administration also assisted by making time and space for the activity to be included during the school day.

Introduction

How can teachers better incorporate technology into the school curriculum? This is a paper prepared by 8th grade students at Stowe Middle School in Stowe, Vermont, who have analyze the problem and helped to incorporate technology into their school. The paper discusses what they wish all teachers knew and could teach to other students and compares their thinking to national technology standards for teachers. It also offers some creative and helpful ways to bring technology into the school curriculum to improve learning experiences for students and teachers.

Why Do We Need Better Use of Technology in School?

Technology has become a prevalent driving force that affects every person in the world directly and indirectly, economically, socially and culturally. Students need to understand the impact of technology on the world, and know how to critically evaluate social changes resulting from technology. Therefore, schools today have the responsibility of preparing students for an emerging information-based global society.

According to the Information Technology World Congress, 209 technology jobs are created every hour in the U.S. Additionally, many more jobs use or incorporate computer technology. Students need to be ready to take advantage of these technology opportunities. Technology thus needs to be incorporated into as much school curriculum as possible.

The International Society for Technology in Education (ISTE 2000) has developed a set of standards that can help point the way for teachers to develop the skills we wish they had. In what follows, we first brainstormed what we wish our teachers knew or would teach more thoroughly. Then, our project advisor looked at our work and compared it to the ISTE standards, giving a preference wherever there seemed to be a good fit. We decided to leave the organization in terms of how we thought about things, allowing the standards references to weave throughout our text. Our text is followed by a closing piece by our project adviser, talking about what standards in ISTE we did not mention in our narrative.

Searching and Search Engines
In some of our academic classes, we are expected to do research outside of the classroom using the Internet. For example, we might have to look up an important historical figure for social studies. The students who don't have Internet access at home have to sacrifice other school time to do their research project. ISTE 6. e. If teachers brought the students to the computer lab or the library, it would be helpful if he or she could help them get the necessary research completed. ISTE 3. d. One way that they could help would be to teach us how to use search engines effectively. ISTE 3. a. Many times, students will type in the subject, then randomly choose one site out of a few hundred sites on the topic. Most students don't really know what the best site is. We know how to do "dumb" searches, but we don't know how to do "smart" searches, or advanced logic searches. A dumb search is like flipping through a big resource book trying to find a single subject. A smart search is like using the index.

For example, when of our classmates was recently researching Puerto Rican art. She went to a search engine and typed in "Puerto Rico Art." She found no good sites but, she did find a site about a person named Art from Puerto Rico. If she had done a "smart" search, she probably would have found more useful web sites.

When using computer encyclopedias and references, teachers need to teach students how to get quotes effectively and use them in their work, as well as find and use primary and secondary sources, a thesaurus, dictionaries, and translators. ISTE 3. a.

How to Use Technology to Become More Productive in the Classroom

Instead of handwriting that may make documents or instructions harder for the students to understand, teachers should post clear computer-generated documents. ISTE 2. a. For example, a teacher might hand write a math sheet assignment, but a typed one would be easier to read. ISTE 5. c. Also, teachers could type papers when discussing an important topic. If there were an area that students didn't understand, computer-generated documents would be much easier to comprehend. Students can generally learn more by seeing a complex idea has opposed to hearing it in a lecture. ISTE 3. c.

Teachers also need to know how to correctly use the technology that is provided for them or available for their use. ISTE 1. a. Our classrooms need better incorporation of technology in everyday studies. Some examples might be satellite images and video microscopes. Satellite images can be used in geography to document forestation, light pollution, or cloud cover. Video microscopes can be used in biology to display cells. These are just two small examples of how technology can be used. One thing that might help would be contacting students from other places to share and work with ideas. ISTE 2. b.

Teachers Need to Ask Students to Use Technology in Classroom Assignments

One teacher who uses technology often asked us to create a Powerpoint presentation or a computer-generated brochure. It was fun and interesting to learn how to use the programs. However, that has been our only technological opportunity. ISTE 3. b. Other technological opportunities could easily be provided. For example, Photoshop could be utilized for science or social studies graphics. iMovie and multimedia productions could be incorporated into our studies.

Middle school education has not moved very far from the traditional way of learning. For example, language arts assignments typically include essays and work sheets. Language arts might not seem like a subject to use technology, but students could be asked to write newsletters, create play scripts, produce page layouts, use e-mail to communicate and get feedback from other students, write in on-line journals, and publish electronically. ISTE 2. d. Graphics, movies and multimedia productions will motivate students who don’t like reading or writing.

Computer Use Should be Taught Throughout All Grades ISTE 2.

Kindergarten, first grade, second grade and third grade children should start using technology. They could use drawing programs, Jump Start programs, CD-ROM games, Thinking Things, and interactive CD books. Typing should start in second grade.

4th and 5th grades should be typing fluently, using word processing and more complex programs. These could include simulations such as Sim City; applied math like Operation Neptune, Operation Express, Oregon Trail, Spellbound, African Trail, Widget Workshop, Adventure series, Carmen San Diego, and other logic games. They
should be using spreadsheets in science, be able to make and sort lists, and create number spreadsheets that do simple math.

6th through 8th grades should have already mastered the basics of technology. They should have mastered word-processing, fluent typing, creating indexes, formatting, integrating pictures and graphs, spreadsheets, simple databases, and telecommunications, (Internet, email, Instant Messenger). They should be able to do image processing including scanning photos, importing and exporting photos, and image manipulation. Movies should be used and students should be familiar with animation and editing. Scientific images could be used, such as satellite photos and medical images (body scans X-rays).

Teachers Need to Address the Ethical Issues of Internet Use ISTE 6. a.

Teachers need to help students understand the difference between “good” information and “bad” information from the Internet. ISTE 6. Students should always compare information from the Internet to multiple sources to be sure of its accuracy. ISTE 2. c. These could include books, different web sites, primary sources, or person-to-person interaction. Students need to be able to tell when someone is promoting his or her personal views. Using the knowledge students have learned from writing persuasive essays, they should be able to tell if a piece sounds one-sided. Persuasive writing often only brings up one idea that actually works and shoots down all other ideas that might be mentioned; therefore, you don’t know if you are getting all of the truth or just what someone picked to sound supportive of their view. When searching for information on a web site, students should consider who owns the site: a university, business, or a private or nonprofit organization. ISTE 6. b. & d.

For example, if a breast cancer cure sponsors a web site, and the content is women’s health, the web site will concentrate upon how good the company’s treatment is and not present side effects of that company’s treatments. It might not display other useful treatments by other companies.

Teachers Need to Use Technology to Let Students Learn Outside of the Classroom

If teachers cannot provide information in some subject area, then technology could help them offer additional resources or classes in that subject. These could include on-line classes or courses. ISTE 2. c. Teachers should know how to use technology so they can help students learn independently. Student projects could include extra credit, visits to other schools to see how they use technology, and use of CDs and multimedia programs. ISTE 3. d.

What the Students Didn’t Say...

What the 8th graders didn’t say is revealing too. Not a word was mentioned about “assessment and evaluation.” ISTE 4. It is perhaps not surprising that students might not think of this area, since “grades” and “doing homework” belong to “school work” and so much learning with technology does not, as yet. I wonder if that might not be a good thing. However, there is one thing I regret. I feel badly that students do not work every day in an environment where high quality feedback gives them more ideas, helps them improve their work to very high levels, and teaches them concepts and techniques “just in time” to use them effectively in a real context. If they did work in such a setting, I bet that they would ask for more feedback. Assessment and evaluation would not go unmentioned if it were helping them to learn, achieve and maintain a high level of interest and motivation.

The 8th graders also didn’t mention several aspects of “productivity and professional practice.” ISTE 5. They expect a basic level of productivity, but do not expect or perhaps know about the teacher as a lifelong learner. This too, I feel, is a shame. What would their perceptions be if they had many teachers who were actively learning and growing in front of them, so they could see what an adult learner looks like? I’m afraid that more often, what they see is an adult who is controlling the flow of events, saying what can and can’t happen, talking most of the time except when asking a direct question, then responding to the student who answers before any other student can.

There are notable exceptions. When I interviewed the students during a long car ride on our way to a statewide conference on technology, all of their examples kept coming back to essentially two teachers in the school. I pointed this out, saying, “Has anyone else during your three years at the middle school used technology to teach? Let’s see. You’ve had about six to eight teachers each year, about 24 teachers. Are there just 2 who are teaching with
technology? They replied, “That’s about it.” The two notable exceptions used outstanding approaches and gave multiple opportunities for students to learn with and use technology in expression and exploration. Most important, these were "core academic" teachers of history, science and language arts in their small school where teachers often do double and triple duty. But clearly, we need to find a way to raise the expectations that all teaching must follow their example, or else our students will not be as prepared as they need and want to be.

Conclusion

What do we wish our teachers knew? That technology is vitally important to our future and our world. That working with technology is fun and helps us learn. We wish they knew that we students are highly motivated to learn with technology. We wish they understood that we like to be stretched to our highest skills and that by letting us show what we can do, we feel good about our academic achievements.

Abstract: This paper analyses and describes the implementation of a tutorship system based on a telecommunication network that pays attention to the different interests and requirements of students and teachers of the School of Business Administration (University of Valladolid – Spain). The system has been designed to modify and improve the traditional tutorship system by the use of Internet. In this way, the system supports the “learning process” without the necessity of physical presence of the different agents implied. Using the electronic tutorship support system it is possible to solve problems and queries related to academic subjects of the Business Administration Degree. Actually, we are evaluating and analyzing the impact and acceptance of the system for both, students and teachers. Besides, we are attempting to involve as professors as possible in the test and evaluation phase, as well as in the redesign and implementation of other telematic services applied to education in a collaborative form.

Introduction

At the end of 1998, the Spanish Government offered the possibility to provide economic support to those investigation projects related to the design of educational systems as support and improvement of teaching skills.

Many professors of the School of Business Administration (University of Valladolid – Spain) were aware that two of the main problems of their students were the overcrowding in classrooms and the high number of students that could not attend class (they are usually full-time workers). A good solution could be the implementation of a tutorship support system using a telecommunication network as well as the design of complementary didactical hypermedia material, which could facilitate not only the learning process of different disciplines, but the potential use of Internet as well (Bouras, 1998, Davies, 1997).

Besides, students could use the system in order to get access to all general and academic information that is normally displayed on a notice-board.
Identifying the Problem

The School of Business Administration of the University of Valladolid has just ended an auto-evaluation process made by some university specialists, professors and Business Administration students (assisted by an extern-committee of evaluation).

One of the conclusions obtained by all agents implied was the conviction that the traditional tutorship system was inefficient, hardly used and almost exclusive for the query of doubts or concrete questions just before the exams. Two important drawbacks were found.

On the one hand, the fact that an elevated number of enrolled students for this degree (in comparison with other degrees of our University) are full-time workers, makes that they have a lot of difficulties attending lessons and asking for help in the resolution of questions related to their studies.

On the other hand, the possibility to maintain a close interaction between professor and students without dependence on time and physical presence could facilitate a more flexible communication and, therefore, improve the promotion of equal opportunities (Verdú, 1998a).

Fortunately, an element which could help to introduce, innovate and, by the way, stimulate the professor's work, is the introduction of computers in the teaching process and, of course, the possibility of access to Internet in the sense not only of information transmission and retrieval but also as a communication channel (Penfield, 1996, Verdú, 1998b).

So, the School of Business Administration has made a great effort in order to implement the electronic tutorship support system described in this paper as part of the teaching process.

We hope that students use the system (Fig. 1) and improve the situations or processes they consider not sufficiently developed in the classroom. We believe that this system can become a great help in the sense of getting new habits in the teaching skills. Moreover, students can obtain a better quality of learning than the one that professors can offer right now with only traditional teaching methods (Flur, 1996, González, 1998).

The complete analysis of the system will be carried out on May 2001.

Objectives and Contents

The developed project can decrease some of the deficiencies found in the report about the quality of the Business Administration degree. In this sense, we could enumerate the following general objectives:

- **Create a new professor role**, not only as source and transmitter of knowledge to the students but also as a collaborator and guide.
  Students, with the guidance of professors and the interactions with the rest of the group, can develop a new "active role", which additionally provides a better adaptation to the professional world (very important in future) (Dix, 1997).

- **Integrate several activities of the current classes**, where the traditional explanations, the resolution of problems on the blackboard and the exercises based on the use of the computer in the laboratory are clearly separate issues.

As last objective, we could consider an electronic classroom where it were possible to integrate different issues such as information search, queries, collaboration ways, theoretical and practical contents, design of study alternatives, etc., (using the telematic infrastructure of the open system) (Khasnabish, 1997).

- **Extract the common characteristics of several subjects** in order to design a generic system applicable not only to subjects imparted by the participants in this project, but also to the whole Business Administration degree.

So, we are attempting to involve as professors as possible in the research, design and implementation of telematic systems applied to education in a collaborative form (Boutaba, 1997).
Using the general objectives described before we can conclude the following concrete objectives of the project:

- **Elaborate didactic hypermedia material** that includes practical examples and theoretical help to the classroom knowledge. This material must be designed in two ways:
  - first, as a complement to the traditional lessons (it will allow students to apply classroom knowledge to real-world situations) and,
  - second, as a support that facilitates a close interaction with faculty and classmates.

- **Implement a mechanism of electronic tutorship**, looking for:
  - support, guide and evaluation of the learning process;
  - a flexible way to suggest new academic activities, and;
  - feedback to the learning process regarding the starting level of knowledge, the results of the evaluation and the acquired information by the tutorship action (Abdulla, 1997, 1998).

- **Maintain and create an efficient Web environment** where students can access to sources of information referring to the different courses: programs, examination dates, qualifications, activities to develop at the School, didactic material, etc.

If we are able to complete these objectives, we will motivate students, implying them in the development and resolution of the proposed tasks. Besides, it will permit a better assimilation of the theoretical concepts explained in the classrooms.

![Figure 1: Homepage (in Spanish) of the tutorship system (http://www.emp.uva.es/herner/)](http://www.emp.uva.es/herner/)

**Methodology**

During the implementation phase the next six points were considered in an integrated way:

- **The technology** used for the development of the system.
- **The selection of appropriate contents of the main courses** that were included in the proposed material.

For doing this, it was considered the experience of both, professors and specialists in distance learning.
- **Task postings.** The experimental character of some subjects included in the project forced to design new exercises that could be included in the system in an easy way.
- **Supervision of the academic tasks** through the network. Professors should respond at most 48 hours later the student request.
- **Encourage of the use of Internet**
- **Resolution of the proposed exercises.** Students must be able to reach the solutions and/or get support in order to resolve the proposal activities. The interaction mechanism should be easy and, if possible, just in time.

**Implementation Phases**

It is very important to describe the different phases followed in the implementation of our system. In fact, this sequence could be used for the elaboration of other similar electronic tutorship systems.

**Analysis of the professor’s requirements**

In a first phase, it must be analysed the learning requirements to be covered by the system. The perspectives and necessities can be studied through the academic programs.

In this sense, it is necessary to carry out meetings with professors and specialists in distance learning in order to study problems and solutions. The study would be the base to future enlargements (other courses or other University degrees).

**Design of the electronic tutorship support**

With the conclusions of the previous phase, next step would be the translation of the learning requirements to the telematic system. This is a design phase of functional characteristics and learning contents.

It is very important to specify the concrete subjects, the kind of questions to request and the type of tasks to include. It must be specially considered the use of the metaphor that we call "*the integrated classroom*", which permits the integration of the different modules of the system.

**Design and development of the hypermedia didactic material support**

In this kind of systems it is very important to develop didactic material as support to the learning process. It should consist of a set of theoretical aspects and/or practical habits but focused in order to be used easily through the system.

One of the most important objectives is that students can feel more motivated by the high interaction grade, guide and supervision implemented. This would solve one of the typical problems of the traditional tutorship system because it offers an easy way to communicate alumni with faculty and classmates.

**Development and implementation of the proposed system**

The system must be able to give access to all students’ requests. Also, the interaction with the professor should take place in an efficient and easy way, avoiding a complex interface. In our case study, a good solution was the use of the Windows environment because students are familiarised with this interaction mode.

**Evaluation of the system**

In a last phase, the system should be evaluated based on the observations and conclusions derived of its use. Profiting this accumulated experience in the design, development and application of the system, it could proceed in two directions: correcting the errors detected and studying its applicability in the total subjects involved in the University degree.

In this sense, we have designed a survey to be done at the end of the academic calendar by more than 1000 students. This survey has been designed by specialists, and the objective is to detect the problems with the use of the system and the validation of the contents provided as complement to the classroom knowledge.
Conclusions

This paper discusses the design, development and implementation of a new electronic tutorship support system, based on the use of Internet as help to the traditional learning process in the University of Valladolid. The system is being used at the School of Business Administration to solve the problem of overcrowding.

Based on our experience, it has been presented the characteristics of this kind of systems, the most important objectives, the proposed methodology and the different phases involved in the implementation.

Acknowledgements

The work presented in this paper would have been impossible without the close collaboration of Ana Bedate, Justina Casado, Beatriz Fernández, Jesús González, Fco. Javier Galán, Manuel de Prada, Mª Arantzazu Rivas, Chantaly S.Phambixay, Angel Sanz, and Felicidad Viejo, professors and researchers of the University of Valladolid, Spain.

Activities for Integrating the Internet in Teacher Education Classes

Marie Hegwer-DiVita
College of Education
Education Specialist Program Area
California State University, Long Beach
United States
mhegwer@csulb.edu

Abstract: A taxonomy of Internet activities may be useful for teacher educators who are new to using the Internet in instruction. In this paper, three categories of Internet activities are outlined: Direct, Web Quests, and Complex. Tasks, examples, and resources representing each of the categories are presented; examples from special education teacher education courses are emphasized. Instructors may begin with simpler activities and add more complex assignments as skills develop. Using different types of tasks increases student motivation and demonstrates variety in instructional planning. This taxonomy and the examples are being developed for use by a faculty "tech buddy" to aide in supporting colleagues participating in a PT3 Implementation Grant.

Activities for K-12 students utilizing the Internet are featured in many journal articles and teacher resources, websites, and books. These activities range from very simple to very complex and with descriptive titles from "Internet Fieldtrip" to "Web Quest." Teacher education classes also increasingly use the Internet and can benefit from utilizing the same sort of activities. A list and description of a range of Internet activities may be useful for teacher educators who are new to using the Internet as an instructional tool. Instructors may begin with simpler activities and add more complex assignments as their skills and students' skills develop. Using a variety of types of tasks both increases motivation through variety and demonstrates variety in instructional planning for teachers.

Three categories of Internet activities are outlined here: direct, Web Quests, and complex. Tasks representing each category will be discussed, including examples and resources. Examples from special education teacher education courses are emphasized. Unless otherwise stated, "student" refers to university students in pre-service or inservice teacher education classes. This taxonomy and the examples are being developed for use by a faculty "tech buddy" to aide in supporting colleagues participating in a Preparing Tomorrow's Teachers to Use Technology (PT3) Implementation Grant.

Direct Internet Activities

These activities are generally relatively simple and direct tasks: multi-media or integrative project products are not involved. They seldom require skills beyond knowledge or comprehension and seldom more than one skill at a time. Sample activities in ten subcategories include:

Site evaluation

Students are given a specific URL and complete a description and evaluation worksheet, which may include downloading a part of the site. An introductory example that could be investigated in less than 30 minutes is http://www.pcnafriend.com/, the site for Pen-A-Friend which facilitates penpals between people with and without developmental disabilities. (However, one hopes that reviewers might use it and establish a penpal relationship!) This type of evaluation task becomes more complex when websites with multiple components, menus, and links are the target. An involved example is the award winning mega-site www.ldonline.org, a service of The Learning Project at WETA (Washington Educational Television Association) in Washington,
D.C., in association with The Coordinated Campaign for Learning Disabilities. It would require weeks to fully investigate and read all the documents and resources materials available. It would probably be a more realistic, yet still involved task, to require students to review specific parts of LDonline, such as “ABCs of LD and ADD” at http://www.ldonline.org/abcs_info/articles-info.html.

Required reading

Many valid and accurate sites exist which can be used as required reading. Such material is often very timely and less costly than textbooks. For example, in a class on classroom management with a component on legal aspects of suspension and expulsion, http://www.cde.ca.gov/spbranch/sed/sussex.pdf has “Suspension/Expulsion Handbook,” an excellent 60-page document describing best practices in California with narrative, education code, and suggested forms for the process.

Find a site and summarize it

Search skills are involved when students are given a specific topic or theorist related to course content and asked to find one or more pertinent websites. Brief summaries verifying pertinence may be required by the instructor.

Site worksheet

The instructor makes a worksheet of questions (multiple choice, T/F, fill-in, or short answer) pertaining to a specific website related to the course. There are several K-12 teacher resource books of such activities (Burgstahler & Utterback, 2000; Sherwood, 1998). For example, one blackline master by Burgstahler & Utterback, entitled “NetWork: The Ghost Train Letter,” lists a website URL, directs students to a specific part of the site, and then has room with lines for primary students to write two words from a specific sentence having a silent letter “h.” Such books are useful for K-12 teachers and can be used as a source of activities in teacher education classes to teach Internet skills while modeling K-12 activities and resources (Hegwer-DiVita, 2000).

Scavenger hunts

This activity is very similar to a site worksheet. Usually a list of related sites is specified by the instructor. The student is given a number of short answer or fill-in questions to complete using information from the site list (Rekrut, 1999). Questions tend to be factual in nature. Milwaukee High School has developed an excellent example of a well-developed scavenger hunt at http://www.teleport.com/~billf/Internet_Lesson_Plans/Navigating.the.Internet/Internet.in.the.Library.html for basic Internet skills. In a slightly different format, Tammy Worchester has developed a number of Internet activities, including a structured scavenger hunt useful in self concept and community building: http://www.essdack.org/tips/allaboutme.htm.

Online quizzes

While there are software products for creating paper- or disk-based test banks, there are also some sites with templates for online tests and quizzes. Quiz Center, originally developed by the University of Hawaii, is now housed at http://school.discovery.com/quizcenter/. Instructors and teacher education students can use this site to easily build online quizzes. The Hawaii site still lists other links to quiz programs at http://motted.hawaii.edu/et_tools/quizcenter/otherquiz.html. Instructors can make quizzes covering course material or ask students to make and share quizzes for each other or for K-12 students. Sites, such as http://www.myschoolonline.com/golocal/, will host online quizzes (and school web pages) in a commercial
venue. Peirce (2000) has a brief overview of online tests in relation to critical thinking. The conclusions are appropriate for K-12 and teacher education classes.

**WebBytes**

Brief, specific tasks supporting course content may be assigned to document students’ visits to a given site or pair of sites ([http://www.learningspace.org/webbyte/](http://www.learningspace.org/webbyte/)). The assignments should be short and specific and cover only one or two closely related sites. An example from an assistive technology course is:

b. Read “A Call to Action” by Dave Edyburn at [http://www.pappunikou.uconn.edu/edymbn2.html](http://www.pappunikou.uconn.edu/edymbn2.html)
c. Select 3 of their research purposes &/or priorities and explain how they might guide the development of your course contract for this class.

**Topic packets**

Each student poses a question or topic pertaining to the teacher education course content. Then, each student finds 3-5 websites which, taken as a whole, respond to the question/topic. The student writes an integrated (not website by website) response/discussion, referencing the sites. To document the extent of their searching, students may also be required to list at least 5 sites which they encountered in their search and the reason they rejected each site. Students may be required to electronically share their packet with classmates and the instructor. For example, in a class on positive behavior support, an Adaptive PE student chose to investigate her rights as a teacher in a school with regard to violent and “acting out” behaviors. She used the following sites in writing and sharing an excellent paper: [http://www.rppi.org/ps234.html](http://www.rppi.org/ps234.html), [http://www.colorado.edu/espv](http://www.colorado.edu/espv), [http://eric-web.te.columbia.edu/monographs/ads107/preventing_contents.html](http://eric-web.te.columbia.edu/monographs/ads107/preventing_contents.html), and [http://www.idea.practices.org/lawandregs.htm](http://www.idea.practices.org/lawandregs.htm). She also briefly described why she had discarded 5 other sites, principally for being off topic and non-specific.

**Internet fieldtrips**

As discussed at [http://teacher.scholastic.com/fieldtrp/guide.htm](http://teacher.scholastic.com/fieldtrp/guide.htm), these assignments require K-12 students only to read brief descriptions or related sites and to use the links to visit the sites. Field trips at Scholastic’s Field Trip site are in categories such as Children’s Literature, Language Arts, K-2, Math, Science, and Social Studies. These field trips could be used as written in introductory teacher education courses or perhaps easily modified by adding requirements for student output.

**Group bookmark set**

Students could contribute website bookmarks and comment on such listings by using [http://www.backflip.com](http://www.backflip.com), a free but commercial site that lets users setup a bookmark file that can be accessed or amended from different computers. A university instructor could easily setup a file, for example, on the topic of depression and suicide in children and adolescents. Students, from home, work, or lab, could access the bookmark file of sites listed by peers, add to the listing, and comment on the relative merits of sites, how they compare to course texts, or other summarizing or evaluative tasks. This site also has benefit to anyone trying to coordinate bookmark files between home and work!
WebQuests

The term “WebQuest” was coined in 1995 by Bernie Dodge. Since then, what appears to be an entire subculture has developed. (See the appendix for a list of select WebQuest Internet resources.) WebQuests may be characterized in their own 12 subcategories (Dodge, 1999): retelling, compilation, mystery, journalistic, design, creative products, consensus building, persuasion, self-knowledge, analytical, judgment, and scientific. WebQuests involve a practical task and, often, a complex product. Inquiry, application and synthesis skills are always involved. The instructor describes a task or gives a problem scenario along with a number of select Internet sites that will be useful in completing the project. Students are not limited to the sites given and non-Internet tools may also be used. Sharing the results, often through technology, is required. While WebQuests for K-12 students may take anywhere from a class period to a month to complete, teacher education student products qualifying as true WebQuests are more likely to be culminating course assignments or even sole course assignments because of the concept and resource integration required for completion. The apparent complexity of WebQuests does not prevent their use in special education (Kelly, 2000). A good place to begin understanding WebQuests is http://edweb.sdsu.edu/webquest/overview.htm.

Overall, WebQuests are better seen than described. An example of a short WebQuest on Positive Discipline is at http://www.guilford.k12.nc.us/webquests/pd/pd.htm. This activity is appropriate for any teacher education course related to classroom management and was developed by staff at Guilford County Schools in North Carolina. The Kentucky Department of Education and SERC at the University of Kentucky sponsor a much more complex example investigating interventions for an elementary student with behavior problems at http://ebdcoe.uky.edu/webquest/webquest.html.

Complex Internet Activities

This category is evolving as more creative ideas and integrations are fashioned. For instance, Teachers College, Columbia University, at http://www.ilt.columbia.edu/k12/livetext/curricula/general/webcurr.html, has many links and discussion of complex web design from a constructionist view. It is likely that any of the previous categories and examples could be made into complex tasks. Complex tasks are closely integrated with multimedia technology in presentation by the instructor or in the student’s product. Synthesis, analysis, and evaluation skills will be evident in every complex activity.

HyperTasks

These project assignments make use of HyperStudio or other such commercial products for teachers or students to use as a vehicle for their presentation or for ultimate use by their own K-12 students. Plano Independent School district in Texas provides a site with tutorial information, resources, and links highlighting HyperStudio tasks: http://k-12.pisd.edu/HyperStudio/HyperInternet.html.

Web activity templates

Perhaps the best known of the easy-to-use website templates is TrackStar from the South Central Regional Technology in Education Consortium at http://trackstar.hprcc.org/. This site, in addition to having a step-by-step template for developing online lessons integrating websites, also has a library of such lessons developed by other teachers. Filamentality, at http://www.kn.pacbell.com/wired/fil/, is another excellent template for web-based activities and also includes tutorials and libraries of lessons.

Website publishing

Without getting into HTML programming, software products such as “HyperStudio” and “SiteCentral,” make producing web pages fairly easy even for novice and intermediate users.
Interactive PowerPoint presentations

A brief article (Tomei & Balmert, 2000) outlines the use of PowerPoint for branching, interactive lesson development reminiscent of old Apple // software such as “Story Tree” by Scholastic. Basically, students are given information and a related question or choice. The choice they make takes them to the response slide and so on, branching depending on student responses. Such techniques may also be used by IHE instructors and K-12 teachers. The main advantage of this technique is that PowerPoint is commonly available in universities and schools and is increasingly being used for presentations in both environments. Consequently, many users already have familiarity with the software. Tomei and Balmert refer to an example from biology available at http://www.duq.edu/~tomei/skeleton. Such a technique could be an especially effective use of SmartBoard technology.

Conclusion

It is easy to say that these activities are nothing new and the computer is just being used as a fancy tool to complete good, old library research projects. While these activities all have their origins in such tasks as paper& pencil worksheets, library research, and drama, they do have some unique advantages. They utilize computer technology that is still new to some learners and rapidly developing or changing for all of us: novelty and motivation are valuable instructional variables! Internet material needs to be carefully evaluated, but can be more current than that in a textbook. Also, as more preservice and inservice teachers have computers and Internet access at home, they are able to use and develop such activities at home at a time that best fits their personal schedules. For many of our students, the best time for their personal study, research, or production time is late at night after traditional libraries have closed or are too far away. This list of Internet activities is a work in progress. There are certainly variations and combinations of each of these activities and no doubt many other such activities. Perhaps by viewing simple Internet activities as part of a continuum of options, faculty who are just developing their own skills at incorporating technology in course requirements will be more encouraged to begin some activities to their courses.

Results of a learning software design competition
Brad Hokanson, Simon Hooper, and Paul Bernhardt
College of Education and Human Development, University of Minnesota
bhokanson@che.umn.edu

Abstract: This paper presents the results of the first Learning Software Design Competition sponsored by the University of Minnesota. Results and observations from the process of the competition are included.

We established the University of Minnesota Learning Software Awards as a mechanism to identify and promote exemplary and innovative educational software. Our long-term goal is to establish an electronic forum featuring best practices in the field. We want to influence educational design by providing access to samples of work judged to be exceptional, and to create a form of eJournal that publishes active samples of exemplary practice-in-action, not simply written articles.

One criticism of our field is that we have not identified what we consider to be exemplary projects. Although many design professions have well established and easily accessible archives of their best work (e.g. art galleries, buildings, and books), the field of Instructional Technology has done little to establish resources where students or practicing designers can examine the best and most inspirational works.

During the fall of 1999 and spring of 2000, we solicited and received approximately 65 entries from across the United States. Judging involved a two-phase process. First, a pool of 35 judges screened entries. Twenty entries were forwarded for further consideration. Three expert judges conducted final judging: Tom Duffy (UNext), Lloyd Rieber (University of Georgia), and Stan Trollip (Capella University). The judges selected the following award winners and honorable mentions.

First place awards
The Writing Trek by Sunburst Communications
Math Problem Solving by Plato Education
Psychology Experiments by Kenneth McGraw, University of Mississippi
Off the Wall by Michael Gardner, University of Georgia

Runners-up
Research Assistant by Dan Schuch, Florida State University
Tuberculosis Case Management by University Research Co.

Honorable mentions
Claymation by Mary Beth Kiser, Edina Public Schools, MN
Probability Explorer by Hollylyne Stohl Drier, University of Virginia
Bohr’s Atomic Model by Jeff Wilden, Weber State University

Although it was beyond the scope of the competition to provide full-access to the projects, all the winners provided resources that can be accessed and examined. Samples representing their projects are available at the competition website: http://design.umn.edu/learningcompetition In addition, each of the winners has submitted an article for a special issue of Tech Trends outlining the problems they addressed in their projects and commenting on how they designed their solutions.

Innovation:
Our primary goal was to support the development of innovative uses of technology. We focused on three dimensions of innovation for this competition. The first dimension involves using new capabilities of technology for educational advantage. For example, the very scale and accessibility of the Internet is used to the advantage of researchers and
students alike through Psychology Experiments by Kenneth McGraw. There, the power of the Internet connects researchers and research subjects, and provides educational examples for study. Off the Wall by Michael Gardner uses the interactive capabilities of multimedia to investigate the artist Chuck Close. Users explore the work of the artist, interacting with elements of scale, brush stroke and subject. Jeff Wilden describes an interactive multimedia program titled Bohr's Atomic Model. This web-based interactive simulation allows students to build an atom using an atomic construction set.

The second dimension involves solving existing problems in a new or unusual way. Plato's Math Problem Solver and Sunburst's Writing Trek use unique capabilities of the computer and the Internet to assist learners while providing diverse and challenging learning environments. Plato's Math Problem Solving software uses real-world math problems and employs three levels of scaffolded support to guide the user through the solution process. Writing Trek includes a great variety of writing activities and provides the opportunity to publish student work on an Internet site. In contrast to these commercially developed products, Dan Schuch created Research Assistant, a database, to support the complex cognitive demands of graduate education. Not all winners were fully computer-based. Mary Beth Kiser's fifth grade class completed a learning activity involving clay, video, and the World Wide Web.

The third dimension includes new, under-addressed, or under-served problems. Tuberculosis Case Management by Elisa Knebel and Probability Explorer by Hollylynne Drier use the capabilities of the computer in this manner. Tuberculosis Case Management helps medical workers in the Third World, far from Silicon Valley, diagnose and treat a deadly disease. Probability Explorer is oriented to younger students. It engages children through probability experiments and exploration, and allows them to construct a more accurate understanding of the nature of chance.

**Observations:**
Our observations from the competition provide insight into the development of educational software. First, it is clear from the descriptions presented by the award winners that the design processes employed varied greatly across the projects. Some groups followed formal methodologies, and in some cases, the strategies employed are the result of a formal design process. In other cases, however, the innovation appears centered on the overlap between expertise in the subject matter and a use or interest in a technology. Often, creative inspiration appears to occur as sudden insight.

Second, access to development funds did not limit creativity. As noted above, three winners were graduate students. Apparently, innovation does not require large teams or budgets. Third, comments from the competition judges about the value of the judging process were overwhelmingly positive. Many people commented that the process of reviewing competition entries was enlightening and worthwhile.

The competition was funded by the Design Institute at the University of Minnesota. The second round of the competition is currently being planned. Information about the competition, including a video and samples of this year’s winning entries, can be accessed at the competition website.
Interactivity: The Key to Successful Web-Based Learning Environments

Mary Ann Kolloff
Curriculum and Instruction
Eastern Kentucky University
United States
marvann.kolloff@eku.edu

Abstract: The creation of online courses demand more attention to the paradigm of learner-focused instruction with high levels of interactivity. As a result, it is becoming increasingly important to suggest more precise methods of design and analysis of web-based instructional activities. This paper suggests criteria for designing interactive web-based student activities and gives examples used with pre-service and in-service teachers.

There is no question as to the value of interaction in the classroom. Students interact for understanding and faculty depend upon the interaction for feedback from students to determine success in achieving objectives. Interactivity in the online course becomes more critical as it is often the "life line" or connection between the distant student and instructor and the student and classmates. Currently, many faculty members have to transform their courses from the traditional on-site model to the web or web-enhanced model. In order to accomplish the transformation, faculty must often participate in a variety of professional development sessions. The immediate challenge for faculty is to become familiar with the mechanics of the computer delivery tools being used. However, in doing so, all too often the focus is on the technology itself rather than its effective use.

After the faculty has mastered the delivery tool, a critical problem becomes the effective use of online interactivity, especially in the area of high-level critical thinking. In order to have successful interactions in any course, requirements include physical and cognitive processing. And, successful interactions are often mediated by quantity and quality of effort (Hannafin, Hannafin, Hooper, Rieber, & Kini, 1996). What techniques can instructors use to be confident that interaction is required for the discussion of concepts, principles, and assignments? How can the instructor design the course so effective interaction occurs in web-based learning environments? Ensuring active, attending behavior in web-based learning environments is challenging for many instructors. Interactivity should engage the learner with the material, the ideas of fellow students, and the ideas of the instructor. The end result is to build a community of learners based on learning requirements that include the exploration and development of ideas, application of principles, refinement of interpersonal skills, and modification of attitudes.

It is the intent of the presentation to share techniques for designing web-based or web-enhanced learning environments that include a high level of interactivity that lead to successful learning communities. Examples of practical applications with undergraduate, pre-service teachers and graduate library science students in activities such as preliminary interest inventories, role playing, author visits, and debates will be presented and discussed. Examples will be categorized according to the learning requirement.

Interactivity as a Concept

The classic instructional theory definition of interactivity has its bases in behavioral theory. Basically, the meaning of interaction is that it provides a way for learners to receive feedback. One means of providing feedback, in the classical sense, is error correction. Identifying errors engages the learner in recognizing inadequacies in their mental models and motivates the learner for a deeper understanding of the concept, skill, or attitude. Errors that remain undetected are repeated and reinforced since there isn't any feedback. (Hannafin, Hannafin, Hooper, Rieber, & Kini, 1996). Giving the corrective feedback concerning the adequacy of the
statement is often not enough information for the learner. Additional information or elaboration is needed for effectiveness and for the changing of mental models of concepts.

In Michael Moores’ concept of “transactional distance”, he discusses three types of interaction essential for any distance learning environment. These are learner-instructor, learner-content, and learner-learner interaction. Learner-instructor interaction is defined as the components of motivation, communication, and feedback between the instructor and student. Learner-content interaction is defined as methods by which the learners obtains cognitive information from texts, and other resource materials such as web pages, videos, or journal articles. Finally, learner-learner interaction is defined as the communication and exchange among students about information, course content, assignments, and attitudes (McIssac & Gunawardena, 1996).

Muirhead defines interactivity as that which involves “participation by the learner in on-line communication between learners and their class tutors” (p. 1, 2000). Muirhead further defines interactivity as having three components: communication, participation, and feedback.

Interaction is a complex variable that includes many different aspects and issues. These elements provide a fundamental for involving interaction in the design of the course. Variables to consider include the amount of interaction, type, methods (viz., asynchronously or synchronously), spontaneity, quality, and timeliness of the interaction.

**Interactive Strategies in Online Learning communities**

In order to create well-structured and meaningful interactive activities, several criteria for designing the learning environment must be considered. In other words, what the teacher must provide and the student must do. Reigeluth & Moore’s (1999) comparison points for analyzing instructional theories are useful as a basis for the planning or analysis of an interactive class activity. Specifically, these criteria are: types of learning, control of learning, focus of learning, grouping for learning, interaction for learning, support for learning. An additional category, the online discussion technique, is added to clarify the computer conferencing tool implemented.

Several examples of interactive activities used in pre-service and in-service education online classes are analyzed below using the criteria suggested.

**Activity One: Copyright**

The goal for activity one is to gain a knowledge base of the copyright law and applications of the law for school library media centers. Students were given a list of questions about copyright. The number of questions equaled the number of students. Each student was randomly assigned one question. After a period of two weeks, each student was required to post an appropriate answer to the question and lead an online discussion on the issue. Each student was also responsible for responding to three additional postings. An analysis of this activity is outlined below:

- **Types of learning:**
  The type of learning involves building and application of knowledge

- **Control of learning:**
  The teacher controls the learning since the education goal is directed by standardized testing for the certification area. The teacher selects the content, selects the resources, decides the activity, how it will be accomplished, and in what order. In this particular case, students are to find appropriate answers, by visiting web sites and referring to their text, to copyright questions prepared by the instructor.

- **Focus of learning:**
  The focus of learning is centered on a particular topic, copyright.
- Grouping for learning:
The grouping for learning is individual with small group interaction. The assignment reads that each student is responsible for leading the discussion of one question. Three additional students are to extend and elaborate to the initial posting of the question.

- Interactions for learning:
The interactions needed for this activity is student with material and student with student. Students respond to guided questions and react to the posted response. Team membership is built since the whole class is responsible for building the database for the knowledge needed for the topic. Ownership of the information is vital since questions concerning the topic appear on the standardized test. Issues often arise in the discussions concerning fair use and the violation of copyright laws and as the law is implemented in schools. This provides students with real-life examples of application of knowledge to real life experiences.

- Support for learning:
The instructor provides cognitive support for the activity by providing appropriate textbook and web sites for the students to use in order to find appropriate responses to the guided questions. The teacher is also responsible for providing feedback to the whole group based on the accuracy of the responses. Emotional support is also provided for the standardized test since the students have access to a document that is easily reviewed prior to taking the standardized test.

- On line discussion technique:
Discussion forum is used in order for students to complete the assignment over a two-week time period.

Activity Two: Interviews with Authors

The goal for activity two was to gain an understanding of authors as individuals and the influences of their lives on their writings. An interview can occur with a live author or deceased author role-played by an expert. Either a guest or a student may be the expert and role-play a particular author.

- Types of learning:
The type of learning involves the understanding of authors and their ideas. In addition, conducting an interview strengthens interpersonal skills.

- Control of learning:
The teacher selects the content, decides the activity, and how it will be accomplished. In this example, students were to find an informational or biographical book focusing on Shakespeare. They were to develop questions they would like to ask him based on their readings of the book.

- Focus of learning:
The focus of learning is centered on a particular topic, Shakespeare.

- Grouping for learning:
The grouping for learning is individual with whole group interaction. The assignment reads that each student is responsible for reading one book and posting questions to a discussion forum in order that the whole group may review the questions. The whole group then participates in a chat session in order to conduct an interview with Shakespeare.

- Interactions for learning:
The interactions needed for this activity are student with material and student with teacher (viz., the expert). Students were to read a book and prepare questions they found important to further their
understanding of the author. Questions were shared so the students could review the types of questions prepared prior to the interview. A Shakespearean expert role-played the playwright. This provided students with a real-life experience in order to gain understanding of the author’s life and works.

- Support for learning:
The instructor provided cognitive support for the activity by stating the reasoning behind interviewing an author and choosing an appropriate book to read. Shakespeare was chosen for this activity since class discussions often focus on appropriate authors to read and study in the middle grades. Emotional, or attitudinal, support is also provided since most students recall reading Shakespeare only in high school and having little understanding of the language used in his works. The instructor also provides debriefing activities focusing on the meaningfulness of the experience and using similar activities in middle grade classrooms.

- On line discussion technique:
Discussion forums were used to post questions and a chat session for the interview.

Activity Three: Debate

The goal for activity three is to gain an understanding of controversial topics. Applying an understanding of the topic is crucial since controversial issues, such as child abuse, AIDS, school violence, or drugs, are often at the height of discussion in educational settings.

- Types of learning:
The type of learning involves the knowledge and understanding of controversial ideas and issues. Furthermore, in real-life situations, students need to be prepared to engage in a high-level of thinking as ill-structured problems arise in schools.

- Control of learning:
The teacher selects the content and decides the issue. For this activity, students were placed in either a pro or con group. Learners have control over preparing the arguments, designing the environment, and determining how their argument will be presented.

- Focus of learning:
The focus of learning is centered on a particular topic, challenging and censoring books.

- Grouping for learning:
The groups were composed of seven or eight members. Each group worked independently in order to prepare their argument.

- Interactions for learning:
The interactions needed for this activity are student with material and student with student. Working in small groups students were to prepare arguments for the debate.

- Support for learning:
Supplying a list of web sites and appropriate textual materials for both sides provided cognitive support for the activity. The instructor also furnished cognitive support if students requested additional information. Cognitive and emotional support was provided in debriefing sessions as the arguments were reviewed and the energy necessary to implement a debate was reinforced.

- On line discussion technique:
To prepare arguments, students used discussion forums and chat sessions. A chat session was used to conduct the debate.
Summary

Instructors can conduct an analysis of the activities in their courses using the criteria provided by Reigeluth & Moore (1999) to ensure confidence that interaction is embedded in the discussion of concepts, principles, and assignments. The criteria also provide a means for the instructor to reflect on the design of the learning environment in order that it may be learner-focused. In addition, the criteria enable the instructor to give appropriate support to their students in a web-based environment.

1. INTRODUCTION

One of the challenges of teaching is to ensure the learning content is not only meaningful to learners, but also has the desired educational impact on the quality of their learning. All too often, however, carefully crafted teaching/learning materials tend to be presented in such a way that they have limited impact on learners. One explanation for this, is that many teachers feel unable to convert their expert knowledge to the needs of different learners because they do not have the appropriate preparation in integrating teaching tools into their lessons.

This paper describes a method to guide the designing of learning environments, based on the work of an interdisciplinary team of researchers and teachers at the Université de Valenciennes (France). The first part of the paper discusses research conducted at the University using Kolb's Learning Style Inventory (1984) to establish the perceived learning styles of 179 adult learners (Study 1). This is followed by giving the results of a study into learners' self-observation of their dominant learning style (Style 2). The second part of the paper outlines the historical legacy of different pedagogic models via six educational paradigms, cross-referenced to nine operational aspects of teaching. To put this analysis in perspective, a study was conducted into the expressed learning modes of 575 adults learning English as a Foreign Language (EFL) (Study 3). This is followed by a comparison of two dominant educational schools of thought, drawn from the work of Piaget and Vygotsky. The third part of the paper explains step by step how to draw up a scripted lesson via a series of interconnected pedagogic fragments. To do this we define key concepts such as: lesson, document, hyperdocument, lesson script, diagese, script, scenation, scenic, and setting up the situation. This process is called the scenistic approach to lesson planning. Finally, the paper proposes different personalized learning tracks based on two broad types of lesson scripts with their respective advantages and disadvantages in the classroom.

2. FOUR BASIC LEARNING STYLES

There is consensus about the idea that a lesson based essentially on the apparent convenience or fascination for teaching tools is doomed to failure. From an educational point of view, teaching tools are not neutral, if nothing else by the fact, for example, that they depend on the teacher's perceptions of learning styles and what s/he expects of learners in terms of the tools' capabilities. In this light, David Kolb's (1984) inventory of learning styles (viz. Reflector, Theorizer, Pragmatic and Activist, see Table 1 below) can help us to help understand what may be going on in the learning process. The advantage of using Kolb's inventory is its widespread use and cross-curricula application. In practical terms, a dominant learning style represents the likely starting point of how an individual marshals his/her resources. If this initial approach should fail, the learner might then turn to other learning modes.

To put Kolb's inventory into the context of continuing education, a study of 179 learners (Study 1) of EFL (September – October 2000) filled in a close-ended questionnaire at the Université de Valenciennes to establish a four-faceted profile of learners, with each one of the four facets representing a maximum score of 100% each. In this context, of the learners questioned: 70.8% describe themselves as Reflective; 67.2% see themselves as Theorizers; 66.1 % consider themselves as Pragmatic; and 58% perceive themselves as being Activist. In short, more than two thirds of the French adult learners asked for a pedagogic structure that allows them time to carefully weigh up the different sides of the question (Reflective), followed by their need to adopt the Theoriser (questioning) and Pragmatic ("get the instructions-then-do it on your own") learning modes (see Table 1 below).
After having filled in the initial questionnaire, 42 adult EFL learners (TOEIC average score of about 405 points) were personally explained what each of the four learning styles were and then asked to identify explicitly which particular style best described their approach (Study 2). The direct self-report of perceived dominant learning style shows that: 40.5% of learners describe themselves as Reflective; 33.5% of learners see themselves as Pragmatic; 19% of learners see themselves as Theorizes; and 7% of learners see themselves as Activist. This study contrasts sharply to the results of the more indirect survey of perceived learning styles of their co-learners (Study 1). The impact of a directive (jacobine) and "rationalist" French culture on adult learners' perceived learning style could be an important factor in explaining the apparent gap between indirect (Study 1) and the more direct self-reports (Study 2).

Given that self-observation reflects learners' image of themselves and that of the social process (e.g. the educational/cultural system), several implications can be drawn from the studies into learner self-reports. First, teachers in (French) adult education need to take into account the needs of Reflective learners who tend to focus on, for example, gathering (consuming) information, rather than creating (producing) information (contrary to the Pragmatist and Activist modes). Second, how can the planning of lessons cater for other types of learning styles, notably that of Theorizers and Pragmatists. Finally, when compared to the results of the 179 learners polled (Study 1) a significant amount of learners seem not to be aware of their own probable "learning style" when directly questioned about the subject (Study 2). Failing to understand one's learning style, may explain, in part, some of learners’ difficulties in attaining their learning objectives due to not being able to assimilate the data in an "appropriate" way in terms of their cognitive processes. How can they be made aware of their likely learning style?

3. SIX EDUCATIONAL PARADIGMS

For teaching to be effective as an act of mediation between what learners know and what they want to know, it is useful to have an overview of the achievements of previous generations of pedagogic style that inevitably influence current teaching practice. From the adult learner’s point of view, this approach could explain, in part, their expectations and needs when (unconsciously) referring back to the educational experiences of their youth. For teachers, highlighting this legacy may bring out ideological self-interest, rarely made explicit, forming part of what Thomas Khun (1962) calls a “paradigm” or unquestioned theory or set of beliefs within a given scientific community.

Based on the initial work of Puren (2000), it is possible to expand his initial analysis into a broader nine-faceted table (Table 2 below) to present a mosaic (a series of non-related elements linked more for historical reasons rather than for any intrinsic causes) of various features of the teaching and learning approaches of the last few decades.
To put this analysis of educational paradigms into the classroom context, a one-year study (September 1999 – October 2000) of the sensorial modes of 575 adult EFL learners, at the University (Study 3), reveals that of those who filled in the questionnaire: 67.3% feel they are teacher-dependant; 60.2% see themselves as needing to be physically active (Kinaesthetic); and 60.3% say they are able to learn by listening (Aural). It seems then that more than two thirds of adult learners expect explicit guidance from the teacher and 60 % of the learners want to be given an opportunity to be physically active and to learn by listening. In other words, even if being physically active and listening to what the expert says are important to learners, they expect even more to have the guiding hand of the teacher present. Given this need for pedagogic guidance, the work of Grangeat (1998:183) allows us

Table 2. Mosaic of educational paradigms

*Definition: Learners favouring the *aural mode* are specially sensitive to human values, like human warmth and a convivial environment. They tend to focus on communication, teamwork and respect for others in the group (Labour 1998:107). Aural learners represent around 30% of the population cf. [http://www.demon.co.uk/mindtool/mindmaply.html](http://www.demon.co.uk/mindtool/mindmaply.html) (consulted 27.10.2000), this reference is also used concerning visual and kinaesthetic oriented learners (see below).*

*Definition: In learning by observing, a *visually oriented person* focuses on the details, and the applications of what is being observed. Visual learners make up about 65% of the population (see above). For McLuhan (1964:291) the visually-dominant mode tends to see all things as continuous and connected. This is done by nurturing a fixed point of view, an attitude of detachment & non-involvement, and in separating functions/stages/tasks in time and space (McLuhan 1964:217, 247, 291).*

*Definition: Kinaesthetic oriented learners prefer learning according to how they perceive physical performance (e.g. paralinguistic communication involving body language, eye contact, hands and gestures in a given language-culture) in terms of effort, self-image, efficacy, etc. Kinaesthetic learners make up around 5% of the population (see above). This mode is not situated in any one particular part of the body, as those of seeing and hearing, and involves a nonlinear perceptual process.*

*Definition: The *verbal mode* implies a system of communication that consists of statements with a syntax.*

*Definition: Sequentiality implies a process that has a pre-set beginning, middle, and end.*

*Definition: The *non-verbal mode* consists of statements with no obvious syntax (e.g. images, gestures, tones of voice, use of space, clothing cues, colours, taste) and assumes a high level of literacy. Studies show that nonverbal cues are 50% effective, while words are only 7% effective cf. [http://www.trnwy.edu/depts/education/teach/communication/nonverbal.htm](http://www.trnwy.edu/depts/education/teach/communication/nonverbal.htm) ; [http://nhbe.com/socscience/speech/commcenter/mgnonverbal.html](http://nhbe.com/socscience/speech/commcenter/mgnonverbal.html) (consulted 27.10.2000)

*Definition: Non-sequentiality has no pre-set order, the person chooses how to organise the available segments of data.*
to look at how two dominant educational approaches, inspired by the works of Jean Piaget and Lev Vygotsky respectively, tackle the issues of how people acquire knowledge in terms of external teaching agents.

4. THE CONCEPT OF SCRIPT CREATION APPLIED TO THE DESIGN OF A LESSON

It is not sufficient, however, just to know what information content is suited for learners. It is equally necessary to know how to present this information in an “appropriate” way. To do this the preparation of information content involves selecting and organizing data, in other words defining a planned structure consisting of sub-sections, itself able to be broken down to its most basic level. The term “document” designates this organized structure.

**Definition:** A document is an organized structure of lower level elements of information. A document is thus information content that can be applied to a given medium/tool. Hence, a computer screen, a cassette audio, a book, a piece of canvas, etc. is not in itself a document but only the material base/tool of the document.

**Definition:** “A hyperdocument is a content of information made up of a nebulousity of fragments, whose sense is constructed by each of the given reading routes” (Balpe 1990). This definition does not make any reference to a corresponding physical medium. It is linked to the concept of “document” mentioned above, but adds the dimension of the multiplicity of (reading) routes, presupposing the possibility for users to intervene in the distribution of the contents, in particular in the means of selection or in the numerous choices (interactivity).

**Definition:** A lesson is a hyperdocument with pedagogic or cultural aims. A lesson consists of having access to objects of knowledge available via the various teaching media as well as their technical variants (hyperdocuments, hypermedia, and more traditional tools like chalkboards, books, etc.). In short, the term “lesson” refers to the structure that controls the organization of the constituent pedagogic sub-elements while being totally independent of the physical object ultimately constructed.

When designing a lesson, it is often useful for the teacher to have a way to make explicit the intended structure of the lesson. This can be done by creating a mental/conceptual model of the lesson. Traditionally, teachers design a lesson plan based on a “document” structured into different interconnecting parts. The lesson plan can then be given to the learner by way of a “summary”. With the summary, learners can then look up any section of the document wherever it be on the chosen medium/teaching tool. In this way, a distinction is established between the actual physical putting into practice of the (teaching) content, and the various aids used to look up the different parts of the lesson. Though a sequential style of reading is still the most common, with this technique different types of reading routes now become possible even in the case of a linear approach. For example, widely diffused written culture, i.e. the press, has diversified the ways of having access to knowledge in introducing parallel procedures of looking for data. Newspaper and magazine pages present with the body of the main article, clearly visible footnotes, cross-references, sub-titles, condensed margin texts, illustrations, boxes of information, etc. In this vein, when one wants to really use the possibilities of sound documents and moving pictures one may need to go even further than the written medium.

In the audiovisual world, the “script” is the working model of creation. The concept of script is complex, and yet has not been the object of much in-depth, critical reflection. The numerous specialized guides that do exist on how authors can improve their script writing techniques (e.g. Seger 1998) give the illusion that the notion of
script is self-evident and thus does not need any further discussion. Yet, this is far from being the case today when the script can no longer remain at the level of lock-step linearity, inherited from the centuries-old written culture aided and abetted by a traditional audiovisual approach in education which has remained the dominant model in the minds of many.

In the case of the cinematographic document, the script is a tool that aids the creation process from the initial idea to the continuity of dialogues. The extended script is able to integrate the different functions of interactivity and allows a break with linearity. In this context, the “lesson script” is not a physical model of data to be put on a given medium nor is it a model of interaction with the learner. The script is a way of accompanying the creation of the lesson from the initial idea to its finished state. It serves as a concrete translation of a teacher’s mental representation of a given lesson. This type of script can thus evolve dynamically during the creation process. Between defining the lesson content and creating a complete lesson there is, however, a series of intermediary phases. Previous studies (Leleu-Merviel 1996) have introduced concepts that take into account the evolutive dimension of the script in the progression of the dynamics of the lesson creation process. The first phase, linked to the definition of the lesson content, corresponds to the concept of diagese.

Definition: The diagese includes everything that belongs to the imagined/proposed setting of the document as expressed through the lesson content.

Definition: The script refers to a structured content that progresses through a series of events. While the script develops the logic of the different pedagogic events, the scenation organizes these events together as interacting elements. It can be equated as the “route” (or path) that the learner takes within the structure defined by the script. The scenation is associated with the surface structure as opposed to the deep structure of the script. In particular, the impact of the interactivity modes is transformed by a scenation that, though predetermined, develops itself during the interactive session. It is in this sense that a teacher can interrupt the linearity of a prepared lesson to “spontaneously” present a part of the lesson, which should have been dealt with at a later time, in order to instantly and directly respond to a question.

Definition: The scenation (Colin 1992) implies the organized structure of events and/or states with which the learner actually interacts. It is made up of a body of fragments taken from the script to determine how the physical data is linked to the actual production of the script. When the creation of the script and the scenation’s outline has been done, the lesson exists in an “abstract” way. It is, for example, the text of a play, or the musical partition. It is neither the play itself (the theatrical performance), nor the concert (the musical performance). The performance transposes the abstract document into a reality perceivable to the physical senses.

Definition: The scenic, or the concrete presentation, refers to the process that allows the transposition of the text into a concrete reality. It is the result of aesthetic choices, practical or financial constraints, conditions of usage, etc. The scenic deals with the choice of the medium for a given fragment taken from the scenation’s structure: text, sound, or both together, etc. Similarly for the data of the document, the scenic affects the precise translation of fragments extracted from the script, given that one should carefully consider how the learner’s interaction with the environment of the document will be translated in concrete, hands-on terms.

Definition: Setting up the situation defines the modes of the concrete facilitative links between the user and the data of the document. In the multimedia world, it is on the level of setting up the situation, and only on this level, that the creation of user functions will be linked to a button, an icon, a joystick, a click, a capitor, a data glove, a virtual reality immersion headset, etc. In this way, we see how setting up the situation deals with the way that concrete means of action allows the user to navigate in an environment presented by the scenic in order to facilitate the acquisition of knowledge in a given context.

In short, our approach to facilitate the creation of a lesson implies: constructing the diagese linked to the description of the content; constructing the script (architecture) in which the acquisition of knowledge progresses sequence by sequence though a series of organized events; creating the scenation, as a constituted structure of fragments from a script with which a user is potentially placed in a real context of interaction; choosing the scenic, which translates the text into a body of physical data, that the user’s senses can perceive; defining the degree of setting up the situation to establish concrete modes of relations between the user and the data of the document. The term “scenistic approach” of lesson planning thus designates using this approach in presenting teaching content. Its novelty rests in distinguishing five levels of script writing (described above) which, in practice, are far too often misunderstood at the expense of the efficiency of the outcome for the learner.

5. DEVELOPING PERSONALIZED LEARNING TRACKS

Guided by the various educational paradigms (Table 2) and the insights of Piaget and Vygotsky (Table 3), two broad types of lesson scripts can be proposed. First, there is a lesson script based on optional tasks to ensure that learners who have had access to the same core data can, at various moments, supplement or refresh the input of
data according to their personal preferences. This approach is particularly useful when dealing with areas of teaching/learning which are likely to cause difficulties (learning black spots). A practical example, of such a lesson script is that of proposing various pedagogic activities to be done in a pluri-media resource center. Using books, video tapes, audio-tapes, computer programs and network connections, a custom-made “database” can guide learners to appropriate sections of encyclopaedias, pre-recorded demonstrations, lesson summaries, exercises, etc. The danger with this type of script, however, is that it may ghettoize learners, or reinforce preferences and tastes which may not always facilitate a broadening of the learner’s mind.

The second type of lesson script is that based on a “tunnel” of multimodal activities to get students to explore different ways of appropriating data. To do this, activities are proposed for learners to enter a pedagogic “tunnel” to try out, for example, different learning styles through a series of activities in order to complete the lesson. This approach implies that learners need to explore different ways of tackling a given subject. In this way learners are likely to do better in some activities, while in others they may need help. Such an approach can prove particularly useful in guided project work (e.g. case studies, simulations, co-operative activities), evaluation activities (e.g. France’s innovative Diplôme de Compétence en Langue based on a standardized script to validate language abilities) and with innovative subjects that demand a significant change in the habits of learners.

A well-laid out lesson scripts can thus: help those with apparent learning difficulties based on their cognitive and perceptual preferences (accessibility); encourage learners to make choices and/or to explore alternative ways of learning to surpass themselves (self-discovery); orchestrate different teaching/learning resources e.g. email, newspaper articles, videos, sound recordings (co-ordination); be adopted based on feedback from learners and acquisition of new resources (updating); demonstrate how financial investments are being used (accountability).

6. CONCLUSION

The underlying idea of our script-based tutoring system is that there is no ready-made recipe for successful learning. Any attempt at increasing the efficiency of a teaching/learning system ultimately depends on matching learner needs and expectations to the cognitive demands of the learning task and to the constraints of the teaching/learning context. But, before tackling the inevitable questions of logistics and costs in setting up such a tutoring system, it is vital to have in place a system of objective measures to evaluate the efficiency of the different types of tutoring schemes in terms of what learners do, what they feel they have learnt, and how feedback facilitates planning and decision-making. This preoccupation in establishing reliable measures linked to a quality assurance approach is the driving force of our ongoing research in this domain.

ABSTRACT

The audiovisual approach in pedagogics, so closely associated with a lock-step view of teaching in the seventies, has undergone a revolution in recent years. By way of examining how teachers can script a body of pedagogic sequences, or lesson, we look at the different phases of the lesson planning process and how a more innovative audiovisual approach can facilitate this process. First, we outline different learning styles as perceived by learners themselves. Second, we propose an overview of the different pedagogic approaches available to teachers. Third, the different phases of creating ‘a lesson script are described based on a scenistic approach. Finally, we suggest two broad types of lesson scripts for the development of personalized learning tracks to demonstrate some of the advantages of having a common platform for apparently contradictory teaching methods, namely linking a narrowly sequential to a broader non-sequential style of teaching.

Distance education, as once described by a colleague, is sitting in the back row of a three hundred-seat auditorium. It has traditionally been thought that to successfully teach a large class, you needed to herd students into an auditorium, and proceed to lecture them for several hours. This provides the students with very little opportunity to interact with fellow students or the instructor.

Over the past few years we have discovered that, with the advent of the Internet, large classes (one hundred to one hundred and sixty students) can be successfully taught at a distance. Over the past several semesters we have collected data regarding student perceptions of these courses and the instructor, as well as demographic information. Our results show that not only do the students enjoy taking these courses, but that they are as, if not more, successful in them then in traditional large classes.

At the University of Central Florida, distance education was embraced in 1996 almost as a necessity. With 33,000 students in the fall of 2000, and 52,000 expected by 2010, UCF is growing faster than brick and mortar buildings can be constructed. Until recently, class space was rented during the day at a movie theater nearby.

Distance education provides some relief to this problem. UCF had divided its courses that have a web presence into three categories, enhanced (E), media enhanced (M), and web-based (W). The E courses provide the instructor with the ability to use the web without reduced seat time. The M courses use the web as an integral part of the course and reduce the seat time by 1/3, 1/2, or 2/3. The W courses have no regular class meetings. Some do however have an optional orientation and/or proctored examinations. These course designations are designed, in part, to inform students of the modality of the course. The designations and explanations are listed with the course, as well as instructor contact information, in the course schedule.

Survey Results

Our survey (UCF, 1999) looked at student demographics and perceptions of entirely web-based courses. Three courses were examined over two semesters. Two undergraduate courses, with between 110 and 125 students, and one graduate course with 35 students.

The demographics determined from the survey responses indicated a higher percentage of female students then males compared to university norms. 77.6 percent female compared to overall University norms of 54.9 percent female. 49.3 percent of the respondents were employed full time and 37.3 were employed part-time.

The students were asked of their overall satisfaction with the course, from very satisfied to very unsatisfied. 87.8 were satisfied with the course and only 12.2 percent were neutral or un-satisfied with the course. When asked of their likelihood of taking another on-line course, 65.9 percent indicated that they definitely would, 26.5 percent said they probably would, and only 7.6 percent were unsure, or did not wish to take another web-based courses.
Students were also asked to assess the amount and quality of their interaction with other students compared to similar face-to-face courses. 64.7 of the respondents found no difference, or an increase in the amount of interaction. 71.8 of the students found no difference or an increase in the quality of interaction with other students.

Similarly, students were asked to assess the quantity and quality of interaction with the instructor. 67.9 percent of the respondents found no difference, or an increase in the amount of interaction. 77.2 percent of the respondents found no difference or an increase in the quality of the interaction with the instructor.

Methodology

Teaching a large web based course takes quite a different approach then teaching the traditional class. It becomes very much a team effort. The support of all levels of administration, colleagues and teaching assistances is intrinsic to the success of the course. The University of Central Florida has put their full weight behind this endeavor. Several new non-academic departments have been developed to support faculty in the creation and development of their courses. Course Development and Web Services provide training and resources for faculty in the form of classes, instructional designers, graphic artists and web programmers. The Center for Distributed Learning oversees the administration and planning of on-line courses as well as other modalities, such as video and interactive television. The Research Institute for Teaching Effectiveness (RITE) was created to lend support to faculty who wish to do research regarding distance education. (Sorg, et. al., 1999).

In addition to support, a better understanding of the learner is needed. Where does learning occur? Does it occur during the lecture, the reading of course text, or in the research of a term paper? How about the library, in study groups or even last minute cramming for an exam? Learning occurs with all of those activities, and more. Learning does not necessarily occur in any one of those activities more then another. Technology’s role in the learning process is to enhance the instructor’s ability to convey the subject matter to the learner. Distance learning can be used to supplement the traditional course or, in many instances, replace it completely. (Lytle, et. al., 1999)

Learning Tools

The software we use to deliver course content, WebCT, allows the instructor to choose from a list of available learning tools. We have found that the use of five to seven of these or other tools is ideal for teaching a totally web based course. The ones we have chosen are all asynchronous, never requiring students to meet or work at the same time as one another. Some of the most successful of these are E-mail, forums (discussions), electronic grade book, calendar, quizzes, drop-box, On-line glossaries and a simulated hospital.

While the Asynchronous Learning Network we have developed allows the learner the freedom to work at his or her own pace, the course is still highly structured. Course materials are divided into "themes". Each theme has reading materials, an activity, homework assignment and quiz. Each theme activity, homework assignment and quiz has a due date during the semester. The student is given between one and two weeks to complete the assignments and take the required quiz. The student also communicates via e-mail and the forums with other students and the instructor. The created illusion of autonomy gives the students confidence. The instructor trusts them enough to work at their "own pace" yet they have other students and the instructor available to support them.

This structure is not only important on the student side, but necessary on the instructor side as well: We have developed a set of standard operating procedure (SOP) for dealing with each of these courses. We know what we need to do and when, to stay on schedule. The students also know from this, what to expect from us.

Ralph Waldo Emerson once said "the years teach much which the days never knew." Time has taught us, through trial and error and trial again, what works for the courses we teach, and what doesn’t. What may work for one discipline, may not work for another. What works for us today, may not work tomorrow. It is only through trial and error, and an understanding of the learning process that education may grow with students.

Perceived Difference Between Classroom and Distance Instruction

Doo Hun Lim
Human Resource Development
University of Tennessee
United States
dhlim@utk.edu

Abstract: In an effort to compare the perceived degree of learning and application between different groups of students in terms of gender, instructional delivery formats, length of study time, and learner motivation level, an HRD course of a university was studied. Data analysis was conducted to compare the learning and application difference and the reasons for high or low learning and application were identified and categorized. From the findings, issues in distance learner, instructor, and instructional design to enhance learning and application were discussed.

Introduction

In comparing the learning difference between classroom instruction and distance education method, several studies have revealed that there is no significant difference between the two (Relan, A. & Gillani, 1997; Russell, 1999; Wentling & Johnson, 1999). Even though comparing the learning difference between different delivery formats has been a major research focus in distance education, seldom has been conducted to identify the difference in learning application between classroom and distance instruction (Ravitz, 1997; Wentling & Johnson, 1999). One problematic situation in higher education is that most classroom and distance instructions have focused not on the application of learned subject content but on the conceptual understanding of the subject content. From several research studies, it was identified that a high degree of learning does not always result in a high degree of application because there are many factors inhibiting application of the learning during and after the instruction (Foxon, 1997; Lim, 1999).

Along with this learning application issue, promoting a high degree of learning and learning application in virtual environment has become another important issue in higher education as more universities and colleges try to develop and deliver quality distance instruction. While we can apply many of the learning application strategies for classroom instruction to designing an applicable distance instruction, it is still a fact that distance instruction requires unique strategies to meet the needs of distance learners' learning and application of their learning in virtual environment. Different delivery formats such as satellite-based and web-based instruction within distance education even may have to adopt different instructional strategies to satisfy unique learning needs of each delivery format.

Methodology

To address the issues of learning and application in classroom and distance instruction, finding the reasons why certain delivery formats (i.e. web-based, satellite-based system) incur a high or low learning and learning application and deploying appropriate instructional strategies to enhance students' learning and application seem critical to assure high quality distance learning. In order to identify these instructional needs, the purpose of this study is to compare the perceived degree of learning and application of learning made by different groups of students in terms of gender, delivery format, study time, and motivation level and identify instructional strategies and design factors promoting higher learning and application.

The subjects for the study included nineteen undergraduate HRD (Human Resource Development) major students who took an instructional systems design course through the three different delivery formats (web-based instruction, classroom, satellite-based instruction) respectively at a mid-western university. Among
the students, eight students had taken the course through web-based instruction, six students through satellite-based instruction, and five students through classroom instruction respectively. All students were given an option to select one of the three delivery formats voluntarily during the course registration period.

The instructional systems design course was designed for the three delivery formats and delivered by an instructor. The classroom instruction was delivered in a multimedia classroom equipped with satellite-based delivery capability where the classroom and the satellite-based instructions were implemented simultaneously. The satellite-based system utilized one-way video and two-way audio communication system for instruction.

An online questionnaire was developed to obtain the students' perceived degree of learning and application for the thirty-four learning objectives extracted from the instructor's lesson plans that were used during the semester. The questionnaire also asked reasons for high or low learning and learning application made by the students during the class. The question items used a five point Likert-type scale to measure the perceived degree of learning and application. Students were asked to complete this online survey at the end of the semester. The study times spent by the students who took the web-based instruction were assessed by asking each student's study time for one learning module in a logout form at the end of each learning module.

The data analysis of the study utilized both quantitative and qualitative analysis. The differences in the degree of learning and application were analyzed using Kruskal-Wallis Test for the three student groups of different delivery formats. Mann-Whitney Test was used for other comparison groups such as gender, motivation, study time since the mean scores of the perceived degree of learning and application for the comparison groups did not show normal distribution. The reasons for high or low learning and application were identified and classified into categories.

Findings

Learning and Application

In order to identify what was learned or not learned from the course, the students were asked to rate their perceived degree of learning for each of the 34 learning objectives of the course. As a group, the nineteen students indicated a fairly high perceived degree of learning. The population mean score for the perceived degree of learning was 4.04 on a 5 point scale (scale range was 1 to 5), which indicates "mostly understood" in the rating scale of the questionnaire. Further analysis was conducted to examine the differences in the degree of perceived learning between the different student groups in terms of gender, delivery format, study time, and learner motivation. In general, it was found that there were no significant differences in the perceived learning between the groups as shown in Table 1. As a whole group (8 students in the web-based instruction), the average time to study a learning module (one learning module was equivalent to one week's study load) was 83.2 minutes.

The mean scores of all students' perceived degree of learning application was 3.89, which can be interpreted as "frequently applied". Regarding the perceived learning application differences between the groups, it was found that there was no significant difference. In comparing the perceived degree of learning and learning application made by the students, there was a high relationship between the two. The Pearson’s correlation between the mean scores of learning and learning application showed a high degree of relationship (r=0.896) at the 0.01 level (2-tailed).

From the qualitative analysis, several reasons have been identified as the factors to promote high learning. Among them, instructional effectiveness, instructor effectiveness, and learner motivation were found as the major categories for the reasons to enhance students’ learning (accounted for 70% of the reasons for high learning). Some example reasons of the instructional effectiveness are: instructional design, interactive interface, and learning activities. According to the different delivery formats, certain reasons were more frequently replied from a certain group. For example, reasons in instructional effectiveness were mostly replied from the web-base instruction group while reasons in instructor effectiveness were mostly replied from the satellite-based instruction group. Several reasons were found to inhibit the student learning. Some instructional design factors (unclear content, not applicable content, too much information for a class), personal reasons (miss the classes, lack of interest, short of time to study, short attention span), and lack of opportunity use the learning are those reason categories that negatively influence the student learning.

The reasons for high application of the learned content varied. First, the most frequently replied reason was that the learning content was constructed in such a way that it could be applied to students’ studies and current job tasks. Opportunity to use the learning on the jobs and during the instruction was another major category of reasons for high application. High understanding and interest toward the learning content were also found as another category of reasons promoting high application of the learning. Regarding the reasons to negatively affect the application of student learning found, those were low degree of learning, not applicable to the students’ jobs and tasks, lack of opportunity to use, and lack of interest.

**Instructional Design Issues**

When the students were asked to provide their specific learning experience from the instruction, diverse opinions and feelings could be collected and categorized. The first category was the interaction and interface design of the instruction. Some representative comments made by the students were:
- need to reflect students’ dominant learning style to designing the instruction,
- appropriate grouping of student work groups,
- more time to practice the learning during instruction,
- alternate way to complete group project in case a group work didn’t work well,
- more instructor/student and student/student interaction, and
- weekly chat session to promote more interaction between students.

The second category of the students’ responses was issues in delivery and student support. Some expressed concerns were:
- fast feedback of the assignment and questions raised during self study,
- fast technical assistance,
- timely announcements of class activity on the web page, and
- providing basic computer skills class before the class starts.

For asking the general quality of web and content design of the instruction, most students replied that the web design was good and constructed in a user friendly manner so they could move around the learning module web pages easily. Regarding the content design, several students indicated that the text was designed clearly so they can find the main points at a glance. The layout of the text content was said to provide clear...
instructional cues for student's learning process. Other comments were also added that the text layout was structured to display plenty of information into meaningful chunks and units. The graphics used in the instruction were said to be very attractive and represent appropriate information for the instruction. Multimedia components of the instruction were indicated to be effective since they were used only when the multimedia content was needed for students' learning.

Discussion

Learning and Application

From the data analysis, it was identified that there was not a significant difference in the perceived degree of learning between the groups. This finding supports Russell's (1999) research study claiming there is "no significant difference" in learning between the classroom and distance instruction in general. One valuable finding from this study is the fact that the "no significance" symptom occurs even in the application of learning for the comparison groups. From this finding, it can be argued that attaining certain level of learning and application of learning from a course may not be severely influenced by the different types of delivery formats. Rather, it may be influenced more frequently by instructional design factors and strategies that decide the quality of the instruction.

One major benefit of using web-based instruction in higher education was found to exist from this study. The finding of no significant learning and application difference between the shorter and longer study time groups may be interpreted as an evidence that each student could study the lessons by their own pace and competency level, which resulted in different study times between the students while attaining the same level of learning and application. This finding provides a rationale to use self-paced and individualized learning method for web-based instruction. The no significant difference between the higher and lower motivation groups, however, seemed contrary to the general notion that higher motivators learn and apply better. One possible reason for this finding might be because the small sample size does not have enough power to detect the difference between the higher and lower motivation groups.

Instructor Effectiveness in Satellite-based Instructional System

Instructor effectiveness was identified as one of the major factors affecting student learning and learning application for the satellite-based instruction group. Nine out of the eleven responses regarding the reasons for high learning were replied from the students in satellite-based instruction group. This finding seems natural since the instructor of any satellite-based system, as a subject matter expert and facilitator of the learning, becomes the major conduit to deliver learning content to the students. Among the several factors in instructor effectiveness, clear presentation is the most frequently replied response. This finding leads to a recommendation to provide appropriate training of presentation skills for the instructors using satellite-based system. Other competencies required for the instructors might include instructor's command of the subject matter, use of class time, way of summarizing or emphasizing important ideas in class, use of examples and illustrations, use of challenging questions, and listening skills.

Instructional Design Issues

The study findings also raise several issues and problems related to web-based instruction. When delivering instructional content through web-based delivery method, the quality of instructional design factors seems to be critical for student learning and application. Among the reasons for high or low learning, reasons in instructional design factors were ranked as the top reason category for making student learning successful or unsuccessful in web-based instruction group. A recommended instructional strategy to promote high learning and application for web-based instruction is adopting diverse learning activities such as case studies, scenario analysis, simulations, individual and group project, and frequent short quizzes checking students' learning progress to retain student motivation throughout the course.

Applicability of learning content is another instructional design issue found from the study.
Applicability of learning content was indicated as one major reason category for both high and low application of learning. To make a learning experience meaningful for students in higher education, the learning content needs to be “applicable.” Several recommendations are advised to enhance learning application. First, instructional content need to be constructed plain and simple enough to be applied to students’ studies and current tasks involved. In many cases, heavy use of text presentation to explain theories, principles, and concepts in web-based instruction is not effective for student’s application of learned content. The learning activities to solve this problem are case studies, short fill-in question items asking application examples of the learning content, scenario analysis, peer evaluation of class assignments, web searches for application examples, and group and individual projects. Second, as Baldwin and Ford (1988) recommend, the learning content needs to be identical or at least similar to the actual application settings. Developing class assignments that have similar construct and procedure with the learning content is one effective way. Providing individual practice followed by a step-by-step guided practice after a segment of instruction is another strategy to promote application of the learned content not only to similar but even to different context.

Conclusion

This study has identified several facts about college students’ learning and application experience occurred in an HRD course from a mid-western university. Even though the size of the population limits the generalization of the study results, several issues in instructional design were stemming from the study findings and possible solutions and recommendations were seek to enhance student learning and learning application. One major contribution of this study to the related study fields is that the symptom of no significant difference between face to face and distance instruction is found only from the learning but also from the learning application. The generalization of this finding, however, may need another set of studies using a broader population in national level.

One distinct benefit acquired from this study is that the findings provide basis to choose various instructional strategies to improve the technology-based instructional delivery methods. As instructors or instructional designers, our major concern is then to test and wisely apply these instructional strategies to design an effective instruction. The effectiveness of the instruction, however, will be dominantly affected by the level of our experience and insight toward these instructional strategies and concerns for more meaningful application of these strategies in our instruction.

On-Line Delivery of Multimedia Courseware

Leping Liu, Ph.D.
Assistant Professor of Instructional Technology
Towson University, U.S.A.
Email: iliu@towson.edu

Abstract: This paper introduced some methods of using the Web as a template to deliver multimedia courseware, including CBI (computer-based-instruction) applications created with multimedia authoring tools and tutorials accompanied with the applications. The author converted CBI applications created with ToolBook, HyperStudio, and Director into the Web version and then delivered them on the Web as an on-line courseware package. From the perspective of instruction, this project extended the concept of computer-based-instruction to a Web environment. From the perspective of technology integration, this project increased the uses of technology in school classrooms and, meanwhile, it reduced the equipment requirements to schools. From the perspective of information delivery, it used the Web as the template or organizer to deliver the courseware, instead of using certain particular software environment.

Introduction

Multimedia learning environment has been found effective to stimulate students’ thinking and memorizing process, and to enhance learning (Wadsworth, 1992; & Alessi, & Trollop, 2001). In the field of education, the term “multimedia” indicates computer-controlled interactions of information from different media—text, sounds, images, graphics, video, and recently, Web resources; and computers control the multimedia via authoring tools (Simkins, 1999; & Grabe & Grabe, 2000). Computer-based-instruction (CBI) refers to the use of multimedia authoring tools such as ToolBook, HyperStudio, or Director to develop a lesson, drill, or test for the purposes of presenting information, reinforcing or assessing instruction and learning, which are implemented in that particular authoring environment (Criswell, 1989; & Gibbons & Fairweather, 1998). When we talk about multimedia courseware, it refers to a package consisted of CBI components, the use of other media, or paper-print of course documentations/materials (Ivers & Barron, 1998; Elin, 2001; & Lockard & Abrams, 2001). Originally, courseware—that appeared as educational software—was designed and implemented by computer software experts. Teachers could only use the existing products. One common issue was that teachers had difficulty in finding appropriate existing software that could fit the particular learning/teaching purposes, no matter how well developed the software was (Tiene & Albert, 2001). Therefore, a practical idea was that teachers develop their CBI programs themselves to achieve specific goals/objectives of learning/teaching. This became possible while more and more multimedia authoring tools were available (Zahn, Azhn, Rajkuma, & Duricy, 1999; & Alessi, & Trollop, 2001).

Using self-developed CBI programs brought out many critical issues to teachers and students, among which courseware delivery was a major one that we need to deal with. After the CBI program was completed, how can our students access them (Tiene, & Albert, 2001)?

The author taught three graduate level multimedia design courses offered by the Instructional Technology Master program. In these courses, students learned three authoring tools (ToolBook, HyperStudio, and Director) and developed courseware packages. Most students in these classes were school teachers. They hoped they could use their courseware for their classroom teaching. However, their schools did not have the software for their classrooms, and most public schools were lack of budget to purchase these expensive multimedia authoring-tools for students’ use. Therefore, the author started the current project trying to convert the courseware packages into Web version, and put them on the Web. The purposes of this project were to (1)
explore the effective and convenient methods to do so, and (2) develop instruction modules for students/school teachers to learn the methods.

Products from Three Instructional Technology Courses

The first course was titled "Computer Assisted Instruction." The purpose of this course was to apply the principles of instructional systems development to the design of instruction and training to be delivered via a computer-based model. The computer laboratory tasks focused on the construction of a lesson using an authoring tool—ToolBook. In Figure 1, "The Types of Graphs" is one "page" from a lesson unit "Construct Graphics" developed by student.

"Theory and Design of Computer Based Instruction" was an advanced course that investigated several theoretical strategies appropriate to development of computer-based instruction (CBI). Principles and methodologies of information systems development were applied in the context of instructional systems design process. Computer laboratory tasks enabled students to use the more complex functions of authoring tools and Web based applications in constructing a CBI lesson. Director was the major tool for the CBI project. In Figure 1, "Charting a Filling" is one "stage" of a training unit (Director program) "Dental Charting" developed as a team project.

The third course was "Technologies in Reading" -- A course designed to help teachers develop technology-based reading instruction. Emphasis was on integrating current computer technologies and software applications into reading curriculum design. Course content included designing reading segments on phonemic awareness, vocabulary development, comprehension, and writing, using presentation, graphics, and multimedia authoring software HyperStudio. In Figure 1, “Can You Identify a Setting?” is one “card” of a lesson unit (HyperStudio program) “Read a Good Book and Write a Good Story” developed to assist children’s reading and writing.

In the three courses, at the phase of project planning, students had the options, and were encouraged, to choose the topics that they could use in their real life teaching or work. At the point they completed this course, some of them implemented a complete short program; some of them well developed a structure of a huge program and completed one or two sections as the lesson units. They were anxious to test the programs in a real life setting, rather than the final project presentation, and to examine students' learning effect. Then, came the problem to deliver the program to the classrooms.

Issues of Courseware Delivery

Traditionally, these CBI programs only can run in the same environment in which they were developed. That is, for example, as in the above sample projects, the "Construct Graphics" only can run in the ToolBook environment, the "Dental Charting" only in Director, and the "Read a Good Book and Write a Good Story" only in HyperStudio. In order for students to use the CBI programs or the courseware packages in classrooms, they must have the particular authoring software installed in their computers. Therefore, the issue is whether or not our schools can afford to purchase enough copies to support each classroom. The educational site license price of ToolBook is around $300 per copy, around $240 per copy for Director, and around $90 per
copy for HyperStudio. There is no statistics that shows the distribution of software in schools. But, the interesting situation was: there were around 48 students in the three classes; none of them had the authoring software available in classroom or at work.

Some other issues, such as hardware capacities and Mac-PC compatibilities, are also need to be considered. Are the hardware capacities powerful enough to support the software? Can we use the programs across different platform?

So, what is the point if our students worked through the courses and learned to develop course packages but there is no environment for them to use their knowledge, skills or products? The search for a technique solution led us to the Web; with the rapid development of World Wide Web, Web applications have been available in almost all the areas (Khan, 1997; Niederst, 1999; & McCormack & Jones, 1998). Online courseware delivery may provide a new or different conceptual framework for “computer-based instruction.”

**Online Courseware Delivery**

There are four major steps to deliver the courseware on the Web:

1. Converting CBI program into HTML files
2. Editing HTML files
3. Uploading the courseware HTML files on the Web
4. Downloading, installing, and setting the properties of multimedia Plug-Ins

In each step, some technique problems need to be considered and dealt with carefully. The procedures were written into several lab modules that can help our further students, or school teachers, learn the techniques of online courseware delivery. From the experience of converting project files created with the three authoring program, the author found that the following tips were very useful and sometimes were very easy to be ignored.

**Converting HTML Files**

First step is to convert the CBI programs into Web version—HTML files. Programs developed with the three authoring tools require different conversion procedures. To convert HyperStudio stack to HTML, from Extras menu, choose Export Webpage, and in the Save Web page dialogue box, save the file as HTML file.

Converting Director programs (movies) is called “making movies for the Web.” Before you convert the movie, make a back copy of it. Because after you convert it, there is no way to decompress it and recover the original file. Next, set up the movie playback properties (See Figure 2). Then save the file as ShockWave file, as well as generate it into HTML. You should have one ShockWave file and one HTML file.

To convert ToolBook files (books), the complex procedure is to set up the HTML Export properties. Different from Director movie conversion, each page in the “book” is saved as one HTML file. That is, if we have 30 pages in the program, we will have 30 HTML files—similar as the conversion of PowerPoint presentation slides.

![Figure 2. Set Movie Playback Properties to Convert Director Movies into HTML](1317)
Editing HTML Files

After the program is converted into HTML file, some editing work is necessary before uploading them on the Web. For example, the title appears on the first page of the converted Director movie is automatically converted using the original file name. As in Figure 3, the title is “web-standardtest.dcr” that is the original file name of the CBI program. We need to edit this HTML file changing it an appropriate title. Also, we need to develop a Web page as the organizer to navigate the HyperStudio, ToolBook and Director CBI applications and necessary course materials.

Figure 3. Director CBI Web Version

Uploading HTML Files onto the Web

We can use FTP to upload the HTML files on the Web. One thing different form uploading common Web pages is that both the HTML files and original files (HyperStudio, ToolBook and Director CBI files) should be uploaded onto the Web and in the same folder. For Director, all HTML file, ShockWave file, and the original movie file should be uploaded.

Working with Multimedia Players—PlugIns

The last step is to download and install PlugIns. To obtain the multimedia interactive effects, we need multimedia players in the computers that the users/students worked on. Even though all the necessary files are on the Web, the online programs won’t work without the required PlugIns installed in the computer. In Table 1, listed are the URLs for free downloading all the PlugIns for running HyperStudio, ToolBook and Director CBI courseware on the Web.

<table>
<thead>
<tr>
<th>Plug-Ins</th>
<th>Download Site URLs</th>
</tr>
</thead>
<tbody>
<tr>
<td>For HyperStudio</td>
<td><a href="http://www.hyperstudio.com/resource/hsplugin/plugin.html">http://www.hyperstudio.com/resource/hsplugin/plugin.html</a></td>
</tr>
<tr>
<td>Shockwave and Flash 5 Player</td>
<td><a href="http://sdc.shockwave.com/shockwave/download/triggerpages_macromedia/default.html">http://sdc.shockwave.com/shockwave/download/triggerpages_macromedia/default.html</a></td>
</tr>
<tr>
<td>For Director</td>
<td></td>
</tr>
<tr>
<td>Quicktime 4.1.2</td>
<td><a href="http://www.apple.com/quicktime/download/">http://www.apple.com/quicktime/download/</a></td>
</tr>
</tbody>
</table>
It seemed, to the author, that the most complex portion of this project was to deal with plug-ins. Each program required different plug-ins to run it. The latest versions of browsers have the built-in plug-ins for most multimedia programs. But, the users/learners’ computers may run different versions of the browser. Therefore, downloading the multimedia players from the web sites of each software company was the important step before the courseware could run on the Web.

Figure 4 shows some examples of the online CBI projects developed by students from the three classes:

![Figure 4. Examples of Online CBI Projects](image)

**Outcomes**

Because contents and schedules of the three courses did not allow enough time to add one more project like this, the author provided students the modules to the classes as an optional project. Some students tried it and students tried their online programs: one did with her third grade class; the other one shared with her colleagues. Some feedbacks indicated that students showed more interests in learning with the on-line courseware, they were motivated to spend more time on the learning topic/concepts through the courseware than they did in traditional learning, and their interaction with the program provided them more opportunities to rehearsal what they learned. Also, some other schoolteachers felt that this was convenient, and especially those non-technology teachers felt that using technology in classroom was not something in the air.

This project also resulted in the revision of the three instructional technology courses and advanced the technology levels of the three courses to keep up with the contemporary technologies. The author revised the course syllabus adding the online delivery contents into course work.

**Summary**

Overall, this project was implemented in two dimensions: (1) technically, the author explored the necessary techniques of designing a multimedia courseware package in the Web environment, develop a technical model of implementing such courseware, and design a sample interactive on-line lesson including CBI designs (using authoring tools) and course materials, and (2) instructionally, the author developed instructional modules for students to learn the techniques to create such on-line courseware.

This project went beyond the normal scope of courseware design in three ways. First, from the perspective of instruction, it extended the concept of computer-based-instruction into a Web environment.

Second, from the perspective of technology integration, it increased the uses of technology in school classrooms for more students and in a wider range and, meanwhile, it reduced the equipment requirements to schools.

Third, from the perspective of information delivery, it used the Web as the template or organizer to deliver the courseware, instead of using certain particular software environment.

Further experimental study would be conducted to examine the learning effect of on-line courseware. Also, we are expected to explore or deal with more technique issues that might occur because of the continuous development of new technologies.

Teaching with Geographic Information Technology

Amy K. Lobben
Department of Geography
Central Michigan University
USA
Amy.Lobben@cmich.edu

Abstract: This paper highlights curriculum designed to train pre-service and in-service teachers to teach with geography technology. Because geography, like many disciplines, has evolved into a field that implements technology into many areas of research, teacher educators must incorporate the teaching of geographic technology into their education curriculum. One particular area of geography, which has developed over the past decade is known as Geographic Information Science (GISci) and involves the gathering, manipulation, analysis, and display of spatial information. The burgeoning of this new science presents geography educators with several challenges: how do we teach pre- and in-service teachers to implement the new technologies in their classrooms, can in-service teachers use the new technologies to help create educational materials for the changing geography curriculum, can new geography technologies help present and future educators better understand the field of geography, and can we help educators to use the technologies to build geographic resources for their classrooms.

Introduction

All disciplines are part of the information age; the extent to which information technology is adopted varies from field to field. Geography is the study of the surface of the earth and includes the study of people, the environment and their interaction; it "combines a description of places with the formulation of principles and concepts [and] it promotes an understanding of patterns, processes, and the resultant landscapes on the planet (Hardwick and Holtgrieve, 1996 p.6). As a result, the focus of the discipline is volatile; we witness in the evening news everyday the massive changes occurring around the earth, from natural events, such as hurricanes, floods, volcanoes, or earthquakes to cultural events, such as political coups, massive immigration, or medical disasters. Because of the volatility of what geographers study, the field itself has seen major theoretical and philosophical shifts throughout its academic history. The most recent shift is occurring today, as society moves even further into the information age. Geography is at the forefront of technological development and implementation and has developed the new sub-field of GISci. The development affects the way geographers view geography and, therefore, the way geographers are teaching geography.

GISci Defined

GISci is the study of spatial information, utilizing various technologies. In its most simplistic definition, this area of study includes three components: remote sensing (the data gathering component), Geographic Information Systems (GIS) (the data manipulation and analysis component), and cartography (the data display component); each is defined below.

Remote Sensing

Remote sensing may be defined as reconnaissance from a distance; what makes the data collection intrinsically remote sensing is that the instrument used to gather the data is not in contact with the object of study. Several instruments may be used in the process of remote sensing, but the two most
common platforms are aerial photography and satellite sensors. The sensors compile images in two primary ways, by either actively sending signals or by passively receiving light (Lillesand and Kiefer 1994). First, some sensors transmit radar signals, which hit an object on the earth and return to the instrument, providing a visual image of the objects on the surface. Second, sensors can detect the length as well as amount of electromagnetic radiation emitted or reflected from objects on the earth. The EMR received by the sensor forms a photograph of sort of the objects on the surface. Scientists identify various features based on the varying amounts of EMR they emit or reflect. All of these images allow for geographic studies including analyzing the changes in areas of ecological concern such as the Brazilian rainforest or the polar ice caps. Time series images captured in these areas allow scientists to ascertain the land use or land cover changes in the rainforest or the change in area of the ice caps.

Data gathering is also accomplished with Global Positioning Systems (GPS) and remote sensors to aid in data gathering. GPS allows geographers to record with accuracy within centimeters the absolute and relative position as well as attribute data of spatial objects. GPS units, which may be small hand-held units up to large field-grade units receive time signals transmitted by a constellation of about 24 satellites maintaining separate orbits, each approximately 11,000 nautical miles above the surface of the earth (Campbell 2001). Each satellite signals at the speed of light in all directions; the signals include the time the signal was sent (measured on highly accurate atomic clocks) as well as the exact location of the satellite in its orbit. The GPS unit receives signals from multiple satellites (ideally from at least 4) and determines the unit position based on the linear distance calculated between the unit and each satellite from which signals were received.

GIS

Through computer software specifically designed for GIS, scientists use spatial data to solve geographic problems. A spatial database includes objects’ x,y locations and attributes (qualitative and quantitative). A GIS program provides an organizational framework in which links between the attributes and locations allow the GIS user to conduct spatial analyses. Organizational structures include attribute tables that store data for points, lines and polygons, a map area that allows the user to see a graphic depiction of the data, identifier tables that reveal the results of a query, and layered data that may be analyzed independently (per layer) or wholly (per project). Environmental data such as soil type, ground cover, and water table data entered into a GIS program could help scientists determine the best location for a landfill, an animal refuge, or a commercial development.

Cartography

Cartography is the art and science of mapping and provides a data display method that allows all geographers to represent their spatial information using continually advancing mapping technologies. As a separate discipline, cartography has a rich and long history (over 2000 years) and many researchers conduct cartographic research completely outside the domain of GIS and remote sensing. However, most applied cartographic work is now conducted with GIS software and in conjunction with GIS or remote sensing research or projects.

Educational Applications of GISci

While GISci is a burgeoning sub-field within geography, much of the focus of GISci instruction and research reveals the building blocks of the entire discipline of geography, in general. Pre- and in-service teachers, in particular, would benefit from additional instruction in GISci. Traditionally, the geographic education or teachers was conducted in a classroom over the course of a term. However, because of the nature of GISci, the discipline is well-suited for teaching and learning in the format of a workshop or seminar series. Presented below are four ways in which pre- and in-service teachers may be trained in the area of spatial information technology.

1. Teach pre-service and in-service teachers how to incorporate geographic information technology into their curriculum.
Global Positioning Systems (GPS) may be used to help teachers enforce basic geographic concepts. World coordinate systems, such as latitude and longitude, as well as mapping are part of the geography curriculum as early as the third grade. Teachers can use GPS units with students on the school grounds to illustrate coordinate systems. With units set to a navigate position, students can walk north, east, south, and west routes and observe how the direction, distance, and latitude/longitude coordinates change as they walk. Also, GPS units can record coordinates for points (fire hydrant, mailbox, or lamppost), lines (sidewalk, slide, or path), and areas (pond, sandbox, or parking lot). The recorded points, which are stored in the unit, may be downloaded easily into any geographic information systems program. With the GIS program, the teacher and students can color-code each attribute to create a GIS database of the school. Students can also enter spatial attribute information on the school community available from sources such as local governments or the US census bureau (the bureau provides community level socio-economic data throughout the US in digital format called TIGER files) to create a database for the entire school district. These data can be used to solve hypothetical geographic problems, such as where to locate new schools, fire stations, or soccer fields. In addition, the data in the student-created community GIS database may be used to design thematic printable maps of the community.

Remotely sensed satellite images are publicly available from a variety of sources. Agencies such as NASA or SPOT (a private French company) provide images for purchase or free. The quality and resolution vary by price, but high-resolution images of many areas are available for nominal charge or free through the US government. In fact, NASA maintains a link on their web-site designed to provide materials specifically for educators and includes a table of contents of images, instructions for downloading, and suggestions for classroom use (see Figure 1).

Teachers can use these images in many areas of the geography curriculum. For example, remotely sensed images taken throughout the year show the browning and greening process of deciduous vegetation. They can also show the land use patterns of local communities and land cover changes, such as deforestation or desertification. Figure 2 contains images gathered in 1984 and 1990 by the NOAA satellite. These images illustrate the reduction the Sahara Desert experienced after four years of steady and significant expansion. Also, thematic maps created from the geographic information systems technology can be overlaid on remotely sensed images of the same area to create orthophotographs, which help students understand the concept of spatial distribution and mapping (Figure 3).

2. Teach present and future teachers to use spatial information technology to create educational materials for their classrooms.

GIS software, such as ESRI's ArcView can be used quickly and easily to create many types of maps for use as supporting educational materials. These GIS programs make available a plethora of empty basemaps (counties, states, countries...) that can be printed and used for geography projects such as map development or place-name exercises where students can draw their own map symbols and include missing data (drawing in missing rivers, streams, or lakes for example).

In addition, GIS programs allow for easy incorporation of thematic data, which may be used to create thematic maps showing specific socioeconomic or physical data distribution. These maps provide an invaluable resource for teaching human, cultural, or physical geography. A linguistic map can accompany a lesson on cultures; a population distribution map can provide graphic display for a lesson on US migration; or, a map representing the flow of goods can help students better understand the topic of world trade.
The thematic data are widely available from national sites such as the USGS (www.usgs.gov), the census (www.census.gov) as well a local or state sites such as state DNRs. Also, the data are often accessible in a format that can be opened directly in a GIS program. Acquiring ready-made data sets significantly streamlines the task of creating maps. With a reasonable working knowledge of ArcView, the thematic map in Figure 4 is very quickly created, from beginning (locating the data) through the creation (opening in ArcView and highlighting the desired theme) to printing the final map.

3. Use GISci technology to help teachers better understand geography.

Geographers in all areas amass and analyze a great deal of information. Throughout the discipline, scientists are turning to GISci as a method of data collection, analysis, and display. The basic principles of GISci are geographically universal and an understanding of these principles provides the foundation for basic geographic theory. Geography is necessarily the study of all things spatial and GISci provides the theories and methods behind the gathering, analysis, and display of spatial information. An understanding of the application of spatial information technology provides a basic understanding of geography, itself. As a result, introductory level courses in GISci are required in most teacher preparatory programs. These courses introduce teachers to basic concepts such as data gathering methods, data measurement, data manipulation, data visualization, analyses, mapping, and distinguishing between the concepts of location and attribute. Geographic technology is employed in the teaching of these concepts in a variety of ways. For example, while discussing data gathering methods, teachers gather data using GPS units, which require distinguishing between location (UTM or latitude/longitude coordinates, for example) and attributes (point, line, or area features, such as trees, roads, or lakes, respectively). The data gathered are down-loaded into a computer and a GIS program allows the teacher to explore the data and apply geographic theory from nearly any area of the discipline (landuse planning, cultural, economic, medical or physical geography) while conducting geographic analysis. In addition, the program allows the teacher to map the data.

![Figure 4: ArcView Map of Michigan’s Lakes and Wetlands](image)

4. Build geographic resources for classrooms using information technology.

GIS programs such as ArcView provide a platform for easy storage and retrieval of geographic information gathered by the teacher for instruction or gathered by the students in learning activities. A classroom database can be created, maintained, and queried by students and teachers. By maintaining a robust set of geographic data, including maps, location, and attribute data, the classroom may be a stage of geographic exploration.
Also, because many geographic data are available from government web-sites, the classroom computers provide an ideal storage device for such information. The World Wide Web is arguably the largest and most accessible source of information, today. Hundreds of quality geography sites are available. Many of these sites not only provide geographic information, but also provide activities that may be completed at home or in the classroom. Information provided at the sites includes quality maps, aerial photographs, and environmental and cultural data. Teachers and students can create a valuable classroom resource simply by creating a class web page containing categorized links to useful geography web-sites. In effect, they can compile an interactive annotated bibliography of geographic references.

Conclusions

While the benefits of the new spatial information technology provided by GISci have been enjoyed by geographers over the past several years, geographers instilled with the responsibility of educating tomorrows teachers should begin to incorporate the new technology into the teacher education curriculum. This incorporation has been slow, as GISci is itself, struggling to define its position in the field. In addition, and probably the most important factor of the slow merger of GISci into teacher education is the lack of academic geographers trained in the new area. Finally, those academics who are trained devote much of their time and research to furthering the new area through theoretical and applied research.

But, the spatial information technology utilized in the study of geographic information science can be a valuable resource for the in-service geography teacher. Not only does the understanding of the new field in geography improve the teacher’s understanding of the entire discipline, but the technology may also be used to help teachers improve and expand their existing curriculum by applying it to develop student projects, to provide classroom resources, and to create educational materials for classroom use.

The suggestions outlined in this paper provide a starting point for GISci teacher education instruction. But, teacher educators need to design a geography curriculum that incorporates geographic information technology and, unfortunately, often the most useful courses are not within the list of “required” courses in a teacher education program. Due to the changing nature of this as well as other information technology based disciplines, the curriculum should advance and morph to mirror changes in the field, itself.

Abstract: This paper presents some issues in the use of web pages as supplements to traditional, on-campus courses. It also presents some technical and design problems currently found in such pages, as well as some suggested solutions. Some of these problems can be rectified by better use of hypertext markup language (HTML), while others are more pedagogical in nature. Attention is given to ensuring that pages are accessible to individuals with disabilities.

Introduction

The World Wide Web is in the process of revolutionizing almost every element of worldwide culture, and, because of the incredible speed of its growth in size and popularity, it began to do so before most of us had an inkling of its true importance. An index of the unprecedented growth of the web is the fact that there were fewer than 50 web pages in existence when President Clinton took office. Today, in the last few weeks of the Clinton presidency, there are over 1 billion web pages, and, according to a joint study published by Inktomi and NEC Research, at least 67,000 new sites are added each day (Sullivan, 2000).

Growth in access and popularity have also been phenomenal as measured by the number of people who use the Internet and the Web. The Computer Industry Almanac (Juliussen & Petska-Juliussen, 2000) estimates that in 1999, there were nearly 260 million users, 110 million of them in the United States. The Almanac goes on to note that by 1999, there were 25 countries where over 10 percent of the population were Internet users. The Almanac predicts that there will be 490 million worldwide users by the year 2002 (79.4 per 1,000 people) and 765 million users by year-end 2005 (118 per 1,000 people worldwide). In such a rapidly changing environment, up-to-date figures are impossible to obtain. NUA Limited (2000), in a slightly more recent study, estimates that by September of 2000, there were at least 377.65 million Internet users in the world, with over 161 million located in the U.S. and Canada. By the year 2000, 50% of U.S. homes had a computer (UCLA Center for Communication Policy, 2000), nearly 50% used the Internet, and 700 new households were being connected to the Internet each hour (Office of the White House Press Secretary, 2000).

With so many people using the Internet and the Web, and with such incredible growth in size and popularity, it was inevitable that the influence of the web would begin to expand exponentially. In fact, the growth and popularization of the Internet and the Web has been, and will continue to be so important, that this phenomenon may be remembered as the single most influential development of the second half of the Twentieth Century (Maddux, Johnson, and Willis, in press).

Because changes in education typically take place only after changes in the culture at large, education in general was slow to respond, and computers began appearing in K-12 schools only after they were firmly entrenched in businesses, in homes, and in most other walks of life. Access to the Internet and the Web was even slower to reach public schools, and remains spotty to this day. Nevertheless, schools continue to acquire
technology at a rapid pace. In 1999, the most recent year for which reliable statistics are available, over 870,000 additional instructional computers were installed in U.S. schools and the ratio of students to school computers improved to 5.7 to 1. Furthermore, 90% of schools gained Internet access, and of those, 71% had access within instructional classrooms (Market Data Retrieval, 1999).

Higher education has been even slower than K-12 education to make use of the Internet and the Web in teaching and learning. Although most professors now have computers and Internet access in their offices, higher education classroom use of technology in general and the Internet and the Web in particular is not common. However, within the last few years, educational administrators at all levels, particularly those in higher education, have begun to show greatly increased interest in the Internet and the Web for use in distance education. This interest has been motivated by greatly increasing competition for students by private entrepreneurs, especially those known in academic circles as "diploma mills." These organizations are mounting massive commercial distance education programs in diverse fields of study that are beginning to erode the dominance of traditional colleges and universities in attracting students, especially non-traditional students who continue to make up increasing proportions of the U.S. higher education student body. This widespread entry of the private sector into higher education has taken place because the business world has suddenly become aware of the potential educational power of the Internet and the Web, the increasing cost-effectiveness of related technology to carry out distance education, and the potential student demand.

(Business leaders) are licking their entrepreneurial chops in ravenous expectation of the profit-taking gorge to come. Everywhere one turns, they are waxing eloquent about the new opportunities, and making estimates of the profit potential in terms of not millions, but billions of dollars per year. (Maddux, in press)

Given the huge profits now being realized, and the even greater ones being predicted, it is not surprising that the private sector wants into the act. Last year, private, online learning companies took in about $500 million dollars. More importantly, Merrill Lynch estimates that by 2003, online higher education will gross 7 billion dollars a year and will then grow at the rate of 55 percent a year (McGinn, 2000). Other estimates are even more extravagant, with some running as high as 9 or 10 billion dollars a year by 2003. In any case, the U.S. is now spending a total of 810 billion dollars a year on education, and the business community is gambling that the portion devoted to distance education, both public and private, will continue to increase rapidly. That seems a safe bet, as students are signing up in record numbers for courses delivered completely online, and even for completely online degree programs offered by a variety of public and private institutions and organizations.

I cannot help but believe that the current rush to completely online distance education will, in the long run, harm higher education. Quality control problems are obvious, and the temptation to sell courses and degrees with little if any rigor or respectability has already proved irresistible to many providers. Ironically, some of these providers are colleges and universities themselves, many of which are now maintaining completely online courses and programs in direct competition with their own on-campus offerings.

Part of the problem, it seems to me, is a failure on the part of many students, professors, businessmen, and administrators to distinguish between information and education. The web is a fantastic resource for information location and retrieval, but education, although it includes information, requires much more than hardware, software, and a medium. Nevertheless, as web-based, multimedia technologies evolve, improve, and become even more cost effective, distance education is sure to expand its involvement with completely web-based courses and programs.

Although it appears that the marriage of the web and distance education may be largely unfortunate and ill-conceived in its completely online incarnation, I believe the web has considerable potential to improve on-campus offerings. Since the web is a highly efficient and incredibly vast repository of information, its potential is considerable as a supplement to, rather than a replacement for, traditional on-campus courses.

Unfortunately, many colleges and universities are not building an infrastructure or support system to encourage web sites as supplements to on-campus offerings. Instead, web consultants and other campus technical support personnel are often assigned to help develop completely online courses while professors who want to provide supplementary websites for their courses are left to teach themselves how to design and maintain web pages. Many have done so, but most do not have the time, the motivation, or the ability to become proficient webmasters. Partly because of this, and partly because the web is so new that widely accepted style and design standards have not evolved, many supplementary pages are not as effective as they could be, and some are so poor that they are worthless.
The purpose of the present paper is to present a variety of aids and cautions for developers of web pages that are intended to be supplementary to traditional courses.

HTML and HTML Editors

Web pages are written in a simple markup language that evolved from the editorial marks placed on pages before they were sent to the printer for typesetting. The language is called HTML (hypertext markup language). Although HTML is easy to learn, there are a variety of editors and translators on the market, and these are widely used. HTML editors and translators are intended to make it possible to produce web pages without the need for learning HTML. Instead, the user enters text in more or less traditional format, and the software converts it to HTML.

There are many problems with HTML editors. One of the most serious is that there is no such thing as a WHAT YOU SEE IS WHAT YOU GET (WYSIWYG) editor, and consequently, it is almost always necessary to make modifications to the code produced by editors. However, those who have not learned any HTML are unable to do this. Consequently, they often end up with a page that is not really what they wanted, or a page with many technical problems. Another problem is that the code produced by editors is typically highly compressed, lacking in sensible line spacing and white space, and without comment code to clarify difficult sections. Therefore, it is difficult for anyone, even experts in HTML, to edit code produced by such software, thus making even simple and minor modifications almost impossible to accomplish quickly and easily, if at all. A third problem is that the complexity of many editors is such that it is as difficult and time-consuming to learn to use it as it would be to learn HTML in the first place. Finally, those who rely on editors can work only if the computer they are using has the editor installed, while those who learn HTML itself can work on any computer that has a word processor.

Web Accessibility

Another common problem with many web pages is lack of accessibility for individuals with disabilities. The scope of the problem can be appreciated in light of the fact that there are 35 million people with disabilities in the U.S. and around 740 million people worldwide (Lazarro, 1998). Accessibility is an issue, because many people with disabilities must use adaptive aids in order to use the Internet and the Web. The World Wide Web Consortium has recently published a document entitled Web Content Accessibility Guidelines 1.0 (1999). The document presents an excellent explanation of the need for special consideration of web access for individuals with disabilities:

For those unfamiliar with accessibility issues pertaining to Web page design, consider that many users may be operating in contexts very different from your own:

- They may not be able to see, hear, move, or may not be able to process some types of information easily or at all.
- They may have difficulty reading or comprehending text.
- They may not have or be able to use a keyboard or mouse.
- They may have a text-only screen, a small screen, or a slow Internet connection.
- They may not speak or understand fluently the language in which the document is written.
- They may be in a situation where their eyes, ears, or hands are busy or interfered with (e.g., driving to work, working in a loud environment, etc.).
- They may have an early version of a browser, a different browser entirely, a voice browser, or a different operating system.

Content developers must consider these different situations during page design. While there are several situations to consider, each accessible design choice generally benefits several disability groups at once and the Web community as a whole. The document goes on to describe specific methods for web page design that will maximize access for individuals with disabilities.

There is an excellent web site that should be used by all web page developers. The site, entitled Bobby (http://www.cast.org/bobby/), will check web pages for disability access and provide a comprehensive report of any problems found as well as suggestions for solutions to these problems.
Problems and Solutions

HTML codes are called "tags" and are located between "greater than" and "less than" brackets. Many HTML codes are "containers," requiring one tag to activate a function and one to terminate it.

The TITLE tag is such a tag, and many web pages written by novices lack a good, descriptive title. The web page title should be placed between <TITLE> and </TITLE> tags. Omitting an HTML title causes search engines and directories to list these pages as "UNTITLED" or with titles that are incorrect or misleading.

Another problem is that beginners often omit META tags (tags containing a brief narrative description and list of keywords for use by search engines and directories). This may cause search engines and directories to list such pages in the wrong categories, or to provide descriptions that are not accurate. Two excellent web pages that will write the HTML for good META tags is (a) The Meta Tag Generator (http://www.web-source.net/meta.html) and (b) The META Tag Builder (http://vancouver-webpages.com/META/mk-metas.html). These sites present a form for users to fill out in which they specify keywords, descriptions, and other information about their page. The site then writes the HTML for good META tags and presents the code so that it can be copied and pasted into the user's HTML.

Many pages do not optimize their use of graphics. One the most common problems is the tendency to use too many graphics. Graphics take time to load, and the more graphics in a page, the longer it will take to load fully. Web users are notoriously impatient, and pages that take more than half a minute or so to load will often be abandoned before they are even viewed. There are a number of HTML verifier pages on the web. These sites will prompt for a URL, then examine the underlying HTML and provide a report of any problems found. Some of these sites will provide an estimate of the number of seconds a page will require to load given a connection of a specific speed. An excellent example of such a page is Dr. HTML (http://www2.imageware.com/RxHTML/).

Whenever possible, web designers should re-use graphics rather than making use of many different graphics. Such a technique is practical for graphics such as line dividers, and is good practice because once a graphic has been loaded into a user's browser, it can be used again on that page without reloading time.

Other good practices with regard to graphics include the following:
1. Always include a text description for any information communicated with a graphic (for users with adaptive aids and for users with browsers that cannot display graphics).
2. Always specify height and width of all graphics (in order to permit a browser to display text while the graphics are loading),
3. Always use the ALT= attribute to specify a description of the graphic. (Any elementary HTML manual will explain exactly how to do these things, or interested individuals may consult the author's website at http://unr.edu/homepage/maddux/proglsylcp411.html.)

A sample of the HTML code for displaying a graphic of an elephant in a file called "elephant.gif" that is 75 pixels in width and 100 pixels in height is:

```
<IMG SRC="elephant.gif" WIDTH=75 HEIGHT=100 ALT="Picture of an elephant">
```

4. For large images, provide small, "thumbnail" images that are links to the full-size image. Since large images require longer to load, the long wait will result only for those users who wish to view the large version of the graphic.

5. Developers should never make use of an image that is stored only on another server. Instead, developers should copy the image into their own accounts and display it from there. Displaying images on someone else's server slows down loading and places a load on the other server. (Of course, no image should be used in any fashion unless it is in the public domain, or the owner has granted written permission for its use on another's site.)

6. The use of "image maps" should be avoided. These are graphics with special areas that function as links) Many web users may not realize that areas of graphics can be made to function as links, and, at the present time, adaptive aids cannot cope with image maps.

7. Refrain from using "frames." (an HTML strategy for dividing the browser window into separate displays or windows.) Bookmarking a page with frames is problematic, adaptive aids have difficulty with them, and some individuals dislike them so much that they will not visit pages that employ them.
8. Every page should contain a link to the e-mail address of the developer. The link should display the full e-mail address.

9. All pages should contain a link at the bottom of the page to permit a quick return to the top of the page.

10. All pages should contain a link back to the home page. This is essential because most users find pages through a search engine. If there is no link back to the home page, such users may be unable to find that home page, since they cannot simply click on the browser "back" button, as they could if they had found the page by "surfing" to the home page and then choosing a relevant link.

11. Content of the page should be current, and there should be a line at the top or bottom of the page giving the date the page was last modified. It is especially important that links presented on the page be tested often to be sure they still function. Users who discover that many links on a page no longer work will leave the page and never return.

12. Limit the length of pages to two or three screens at the most. Long sections should be broken into "chunks" and placed in separate files that can be reached through links.

13. Develop a color scheme for each course for which there are supplementary sites. That way, students will always be aware of which supplementary page they are viewing.

14. For lecture courses, lecture notes should be included, and should be posted as quickly as possible after each class. My experience and the result of several informal surveys shows that students view lecture notes as the single most useful part of a web page.

15. Do not promise to post specific information and then neglect to do so.

16. Include a page of links to other pages on the web that deal with course-related topics. However, be sure to carefully preview all such sites to be sure the content is accurate and otherwise appropriate. Links that lead to irrelevant or improperly described pages will soon be ignored by students.

17. Include links for downloading all class handouts. This is viewed by students as next in importance only to lecture notes. Then too, such links will relieve the instructor of the tedious chore of locating handouts and arranging copies to be made for students who were not in class or who have lost important handouts. Handouts can be placed on one's server in word processing format, and students can choose a link to the file, save it on their own computers, or print it out.

18. Include a full syllabus that includes all grading policies and criteria.

19. Ensure that all pages employ correct mechanics of writing including spelling, punctuation, grammar, etc.

20. Ensure that all information is correct and presented in understandable ways.

21. Do not expect that supplementary web pages will result in instructor time savings. Web pages are time consuming to construct and maintain properly. Although some time will be saved by avoiding the need to search paper files for handouts that students have lost, giving "private lectures" to students who were ill, etc., the time required for web maintenance will more than make up for time saved. The purpose of a supplementary page should be to improve teaching and learning, not to save time.

22. Be prepared for students to quickly come to expect and to depend upon supplementary web pages. It is amazing how quickly many students progress from gratitude about access to a supplementary page to an attitude of entitlement.

Conclusions

Web pages that are supplementary to traditional, on-campus courses can be highly beneficial to students and professors. However, there are many common problems that can limit the usefulness of such pages. This paper has presented a few of these problems as well as some simple solutions. For a complete discussion of these and other recommendations, readers are referred to Maddux (2000), Maddux and Cummings (2000), and Maddux and Johnson (1997). Interested readers are also encouraged to visit the first authors' supplementary web site for his course on web site design and maintenance. Abstract
The Italian Ministry of Education in collaboration of the Italian National Research Council are engaged in joint activities concerning the modeling, design and prototype implementation of an adaptive e-framework supporting the interactions of various actors of the national teacher training system. The framework includes patterns of static and adaptive versions for resources-services allocation and management.

Introduction
In the knowledge society, knowledge is a primary resource at various levels including: the know what, the know how and the know why. The processes acting on knowledge: creation, acquisition, processing, evaluation, storing and transmission, and their interrelationships contribute to determine a new social dynamics. The education systems are complex organizations in the knowledge society: they offer services based on the exchange of knowledge between “knowledge providers” (research centers, universities, laboratories, museums, etc...) and “knowledge clients” (school students, enterprise employees, ) by means of “knowledge intermediaries” (teachers, pedagogical resources, etc...). Teacher training can be considered as the interaction between providers and intermediaries in education systems.

The information and communication technologies are enabling factors for the development of the knowledge society and hence of the education systems. In particular teacher training is becoming a strategic issue that requires new advanced web based solutions.

The Italian Ministry of Education and the Italian National Research Council are engaged in joint activities concerning the modeling, design and prototype implementation of an adaptive e-framework supporting the interactions of various actors of the national teacher training system.

The e-framework includes patterns of static and adaptive versions for resources-services allocation and management: a teacher training system can be modeled by composing patterns, according to its complexity: In particular:

- the static resources-services allocation: services are provided by teaching agencies to the teachers;
- the adaptive resources-services allocation: the system takes care of the teachers and training agencies profiles for matching their respective needs and supply;
- the static management of the system behavior according to the cycle: planning, monitoring, evaluation, change management and planning
- the adaptive management of the system dynamically coordinates the planning, monitoring, evaluation and change management subsystems.

Up to now a prototype of information dissemination of teacher training services, called SIF and based on the static resources-services allocation pattern, has been realized with a high degree of scalability: (around 25,000 teachers and 250 training agencies). Design and implementations of advanced teacher training systems, based on more complex patterns, are in progress.
1. Resources-Services Patterns

1.1 Static Resources-Services Pattern
Training agencies and teachers interact through the matching between training resources offering and training services request. The matching is realized according to a matching schema associated to a kernel component which is specified once for all w.r.t the evolution of the overall system (i.e. "statically").

![Figure 1: Static Resources-Services Pattern](image1)

1.2 Adaptive Resources-Services Pattern
Training agencies and teachers interact through the matching between training resources offering and training services request. The matching is realized according to matching schemas chosen by the connectors among those available from the kernel component (i.e. "dynamically"), as specified in the following figure.

2. Management Patterns

2.1 Static Management Pattern

The global management of a teacher training system is obtained by composing local interactions of four organisms (planning, monitoring, evaluation and change management) with the kernel component. The interactions rules are specified once for all w.r.t the evolution of the overall system (i.e. "statically").

Figure 4: Adaptive Management Pattern
3. Patterns-based Teacher Education Systems

Teacher education systems can be modeled by composing the previous patterns: the more complex model is obtained by composing the adaptive resources-services pattern with the adaptive management pattern, as illustrated in the following diagram.

Figure 5: Adaptive Resources-Services and Management System

The design of such kind of complex system requires a rigorous modeling methodology. A long way in front of us!

Abstract: The purposes of this study were to incorporate computer technology into parts of an undergraduate exercise physiology course, to motivate students, to get them actively involved in the learning process and to enhance learning. Two classes of third year students were studied; the first was taught using problem-based learning (PBL) activities with on-line discussions on a course web page while the second was taught using traditional lectures. Student perceptions about the use of technology and PBL were collected. Data related to student knowledge, comprehension, and application of course material were collected. The teaching methods resulted in similar grades on exam questions and final course marks with only one significant difference, that being a higher score (15%) in the PBL and technology group's answer to a question of “application of knowledge” (p=0.02). Lastly, this project verified the viability of these teaching methods and demonstrated their acceptance by undergraduate students.

Introduction

Many believe that the use of computer technology to support teaching activities in university settings contributes significantly to student learning (Blumberg and Sparks, 1999; Levine et al., 1999; Carroll, 1998; Todd, 1998; Wiemer, 1998; Davis et al., 1997; Dwyer et al., 1997; Richardson, 1997). Acadia University provides unique opportunities for faculty to incorporate computer technology into their teaching. Since the implementation of the Acadia Advantage program in 1996, all Acadia University students have received an IBM laptop computer with rental cost included in tuition fees. Faculty members are encouraged to use the computer and associated features to provide learning opportunities, which integrate the technology into their courses. The Acadia Institute for Teaching and Technology (AITT) is a new unit, which has as its purpose to provide technical support to Faculty at Acadia University. The AITT has developed a web-based Automated Courseware Management Environment (ACME) program, which is heavily used by faculty. Each course has a web-site with numerous features including course information, class email, access control, notes, discussions and tests. Students have unlimited access to their course pages.

Attempts have been made to integrate problem-based learning (PBL) into traditional lecture-based undergraduate courses (Béliveau and Martel, 1995; Edwards et al., 1999; Finch, 1999; Lim and Chen, 1999; Niederman and Badovinac, 1999; Purdy et al., 1999; Sullivan et al., 1999; Barrows, 1998;
McInerney, 1998; Huang and Carroll, 1997; Stern, 1997; Cliff and Wright, 1996). It has been suggested that regular use of PBL is a valuable addition to traditional methods of lectures, textbook readings, and laboratory exercises for the teaching and learning of physiology (Des Marchais, 1999; Galey, 1998; Stern, 1997; Cliff and Wright, 1996). Problem-based learning in undergraduate courses is student-centred rather than faculty-centred (Saarinen-Rahiika and Binkley, 1998), thus supporting the cognitive learning theory (Svinicki, 1998). Furthermore, problem-based learning is believed to develop problem solving skills in undergraduate courses (Dalton, 1999; Lim and Chen, 1999).

Purpose

The goals of this study were to incorporate the technology available to parts of an undergraduate exercise physiology course, to motivate students, to get them actively involved in the learning process and to enhance learning. The aims of this initial research project were to compare students' knowledge and retention of course material taught using traditional methods and taught using problem-based learning (PBL) activities utilizing computer technology, to evaluate students perceptions of the two teaching methods and learning activities and to identify teacher actions and/or learning activities that help or motivate kinesiology students to learn exercise physiology. Finally, this project could provide pilot data on the usefulness of these strategies in teaching a variety of similar undergraduate courses.

Methods

All procedures were approved by the institution's research ethics review process. Two classes of third year students were studied; course material was taught using lectures and laboratory exercises, however one section of the course was taught using supplemental problem-based learning (PBL) activities with on-line discussions on a course web page while the other section was taught using only traditional lectures. Both groups received identical laboratory experiences. Students randomly selected one of the course sections and lab sections during the registration period and were not aware of the instruction methods to be used.

At the beginning of the semester, the study was outlined to all prospective participants. All students agreed to participate (ie. allow use of GPA, course/ exam marks in reporting group data, course evaluations, etc). To ensure that groups were similar, grades in the prerequisite courses, as well as overall GPA, were compared and no significant differences were found between the group taught with technology and PBL and the group taught with lectures (see Table 1).

A subgroup of students from each class also volunteered to participate in other parts of the study. Student perceptions about the use of technology and PBL were collected using the Nominal Group Technique (Delbeck et al., 1975) and the Evaluation by Group Animation Technique (Talbot and Bordage, 1985). These students were subsequently compensated financially for their participation. Data related to student knowledge, comprehension, and application of course material, were collected using identical exam questions in both course sections at the end of the semester. Retention over time will be assessed using the same exam questions administered one year after the end of the courses. The questions used to evaluate knowledge and comprehension of key concepts as well as ability to apply course material to specific situations were “Name and describe the different methods by which body heat is lost during exercise in a hot environment. Identify the major heat loss mechanism and the physiological problems that the prolonged use of this mechanism imposes.” and “Your grandparents are leaving for the hot and humid climate of the Caribbean islands for the Christmas break. They would like to exercise during their trip and ask you, an expert in exercise physiology, what they should do before, during and after the exercise sessions in warm environment. Explain why you recommend these procedures.” respectively.

A one-way analysis of variance was used to compare group means. Significant differences were accepted at the 0.05 level of probability. All data are expressed as group means and standard deviations.

Results

Random selection of course and lab sections by students during the registration period prevented bias from the researchers. However, to ensure that the groups were similar, grades in prerequisite courses (2nd year Anatomy and Physiology) were compared for each group. Group average GPAs at the end of
second year also were compared. There were no significant differences between the two groups on any of the variables (Table 1).

Table 1. Groups

The two teaching methods resulted in similar grades on exam questions and final course marks with only one significant difference, that being a higher score (15%) in the technology and PBL group's answer to a question of "application" of knowledge (p=0.02, PBL vs lectures). This was not surprising as the problems were developed to encourage students to apply the basic exercise physiology concepts to real life situations. The PBL and technology group also performed slightly better in the exercise physiology course (Table 2) although this did not reach significance. These preliminary findings suggest that students may benefit from the use of technology and PBL in exercise physiology.

The result of this first experience, using a web-based program to teach exercise physiology employing PBL and technology, was overwhelmingly positive. Student comments included: "Not only does the incorporation [of technology and PBL] help to add to my learning, I feel like without it I am being cheated". Students also indicated that this teaching method "allowed the use of the computer" and "online discussions are more effective". The majority of students who participated in the PBL problems suggested that it made the material "more relevant and meaningful". It appears that the majority of students enjoyed and appreciated this teaching style and were positive about its use in undergraduate curriculum.

The most important findings of the present study are that students who were involved in the PBL and technology course responded very positively to the method and that this teaching style was similar to the traditional style (ie. lectures and laboratory exercises) in teaching effectiveness as assessed by exam answers and grades. Technology education has been designed to reduce the number of formal lecture hours, to enhance student enthusiasm and to assist learning (Abdulla et al., 1983; Levine et al., 1999; Carroll, 1998; Davis et al., 1997; Dwyer et al., 1997; Richardson, 1997). In fact, computer-assisted education is now considered a useful resource to teach physiology to undergraduate and medical students (Blumberg and Sparks, 1999; Levine et al., 1999; Carroll, 1998; Todd, 1998; Wiemer, 1998; Davis et al., 1997; Dwyer et al., 1997; Richardson, 1997) and to teach health education to physical education students (Béliveau and Martel, 1995). The present study provides support for the use of these teaching strategies in undergraduate exercise physiology.

Currently available research supporting technology education suggests that in general, the incorporation of technology into higher education has not proven detrimental. On the contrary, some studies have reported that the introduction of technology is beneficial to undergraduates' learning (Blumberg and Sparks, 1999; Devitt and Palmer, 1998; Levine et al., 1999; Davis et al., 1997; Richardson, 1997). One might assume that kinesiology students also could benefit from the contact with this technology in the classroom. Moreover, according to a recent report prepared for the American Federation of Teacher and the National Education Association (Phipps and Merisotis, 1999), most studies supporting the use of technology done to date, have been descriptive and few had control groups to compare teaching methods. This study is the first to control for teaching method and suggests that technology and PBL can contribute to learning in an undergraduate exercise physiology course. Also, there is little information available on the long-term impact of technology in teaching of exercise physiology. The students involved
in this study will be recruited and tested again to determine the degree to which information was retained in both teaching styles. Furthermore, few studies have addressed undergraduates’ perceptions of technology education in the instruction and learning of exercise physiology (Davis et al., 1997; Richardson, 1997). In the present study, student perceptions were sought. Overall, students indicated that this teaching method was interesting, effective and appreciated. Students commented that the use of technology with PBL was more effective because some of the learning could take place without the need to get together as a group.

Bloom’s (1956) taxonomy of educational objectives domain identifies six aspects of learning, the first three being knowledge, comprehension and application. Because application requires the use of general principles to solve a problem, technology and problem-based learning exercises can help students to apply their understanding (comprehension) to new situations (Carroll, 1998). The students who participated in the PBL and technology class were, overall, better at answering an exam question which was designed to evaluate their ability to apply their new knowledge to a specific situation. There is evidence that knowledge acquisition and reasoning skills are greater for students taught using PBL than students taught using conventional methods (Finch, 1999; White et al., 1999; Doucet et al., 1998; Kaufman and Mann, 1998). Students commented that PBL problems made the information more pertinent. This may be a reason why students believed this approach to teaching was more relevant to their needs.

Anecdotally, the use of computer technology and problem-based learning exercises was adopted by another faculty member teaching in the same Kinesiology program. In another undergraduate course (growth and motor development), second year students also commented positively on course evaluations about the use of PBL and technology, suggesting that this method could be used more extensively in undergraduate kinesiology curriculum delivery. Also, recent studies have indicated that students find problem-based learning beneficial (Béliveau and Martel, 1995; Kuhnigk and Schauenburg, 1999; White et al., 1999; Birgegard and Lindquist, 1998; Doucet et al., 1998; Lancaster et al., 1997; Stern, 1997; Cliff and Wright, 1996). Specifically, students explain that such an experience enhances reasoning, integration of content and professional behaviours (Stern, 1997). Students did feel however, that problem-based learning was not effective if they did not feel confident that they were learning the content their instructor had intended them to learn (Huang and Carroll, 1997). The use of the web-site discussion provided the instructor/tutors opportunities to give feedback and minimize the likelihood of this being a major problem in the present study. Feedback could be provided promptly, individually or to the group and ensured that the students were studying the correct material.

One problem that remains to be resolved is the choice of appropriate outcome assessment measures to evaluate the effectiveness of technology and PBL as a mode of learning in undergraduate courses (Linn and Chen, 1999). In the present study, exam questions were developed and grades on selected questions as well as final course grades were used. Long-term retention of course material will also be assessed using the same exam questions. Although present assessment methods may not be the best, in the present situation, they were deemed the most appropriate.

Conclusions and Perspectives

To our knowledge, experimental learning such as problem-based learning has not been performed previously using the computer as a learning tool in exercise physiology. This pilot project verified the viability of these teaching methods and demonstrated their acceptance by undergraduate students in kinesiology. In summary, we suggest that regular use of problem-based learning activities and technology education can be useful assets in teaching undergraduate exercise physiology or other kinesiology courses. The integration of technology education into an alternative approach such as problem-based learning to teach exercise physiology could very well motivate students to learn as well as improve student performance particularly with regard to information application. There is little research on the effectiveness of the use of computer technology to help teach using a problem-based learning approach although there is a vast potential for education using these methods. For example, these methods could be very useful for continuing and distance education. Finally, this first project demonstrates the short-term benefits of using technology in problem-based instruction in exercise physiology.

Abstract

Teachers must be prepared to teach higher-level thinking skills and to incorporate technology so that students will have the proficiencies and skills needed to enter this new and creative era. The purpose of this paper is to present several critical thinking models that have been researched and used successfully across the curriculum for all grade levels and are now being adapted to incorporate technology such as: Concept Attainment, Suchman Inquiry, Conflict Resolution, and the Memorymodel.

Introduction

The introduction of critical thinking skills into teaching repertoires is crucial to helping all students reach for excellence in the 21st century. However, if teachers are unprepared to teach those higher-level thinking models that invite active learning (beginning with the early grades and onward) students will not have the proficiencies and skills needed to enter a new and creative era. Furthermore, most assessment procedures for teachers require that higher-level thinking be included in their lessons. Teachers may fail to achieve excellence on their evaluations if critical thinking skills are absent in their classroom observations. In addition, testing for many state certification examinations also require preservice teachers to have a clear understanding of critical thinking and those methods needed to increase critical thought for their students. Teachers who understand and implement teaching models that provide students with the necessary opportunities to improve critical thinking skills will better prepare their students and better prepare themselves professionally as well.

The purpose of this paper is to present critical thinking models that have been researched and successfully used (Eggen et al, 2000; Gunter et al, 1998; & Weil et al, 1998) and are now being adapted to incorporate technology to encompass a wider variety of resources and presentation tools. Teachers currently integrate technology into their lessons in many ways: student research projects, web page design, online projects, Internet lessons, and reports and presentations via slideshows such as PowerPoint, KidPix, and so forth. For teachers willing to do a bit of online research, multitudes of resources are available for Internet lesson plans and projects. Such lessons undoubtedly enhance thinking skills for the students. It is important, however, that teachers consciously plan and utilize teaching models specifically intended to further develop these skills. We have adapted several critical thinking models by incorporating technology (another often-required and highly desired element in current lesson planning). The results are that many critical thinking activities and ideas in the classroom can be improved and enhanced through the addition of multimedia sources, computer software, and Internet resources.

Concept Attainment
The first model adapted is the Concept Attainment model (Gunter et al., 1990). This model is extremely constructivist in nature and requires inductive thinking. Students must formulate their own definitions from positive and negative examples rather than gain the concept through a direct teaching manner. For a simple example, let us say that the concept to be taught is "transportation." Instead of a stated or written definition, students are first given the words "airplane" and "train" as examples, while they are given "book" as a non-example. The game continues, adding words such as "kayak" and "bicycle" in the examples column and "table" and "dress" in the non-examples column. Students and teacher add to the list of examples/non-examples until the students "get it" or the concept is "attained." Continuing, students define the concept and list all other examples they know. This example game is one for young children, but it is easy to see that by increasing the difficulty of the concept and adapting it to any subject area, this process can be used across all grade levels.

Preparing children from an early age to do this type of thinking is a skill that is most desired. Bruner (1977) explains that when students are allowed to "discover" the attributes of a category that is already formed in their minds (as opposed to simply being given a definition), they are engaging in higher level thinking. Eggen and Kauchak (1996) note that this "game" capitalizes on a "sense of the unknown." This triggers motivation through student arousal, defined as a "physical or psychological reaction to the environment" (p. 118).

Our preservice teachers and teachers in post-baccalaureate programs have described their success in teaching this model. Preservice teachers were given the format and rules for the model, and after practicing with each other in small groups, they were required to use the model in several lessons "out in the field." They reported excellent attention and results with their students at every age level and across all subjects.

The traditional use of this model is to list examples and non-examples of a concept orally or by writing them on the board. While this is an effective way to introduce the Concept Attainment model, we took it a step further and introduced pictorial representations of the concept. Most often this would involve cutting images out of magazines or copying them from books. This naturally led us to the addition of images found in various graphic art collections on the computer as well as searches on the Internet for specific pictures to use in the "game." When teaching our students this model at the university level, we then decided to move from the customary presentation of "holding up the pictures and walking around the room" to a more updated technological presentation using PowerPoint. This allowed a more interactive approach in a class of over 50 preservice teachers. As the images appeared on-screen everyone could easily see them and could make decisions as to whether the picture belonged in the example or non-example category. Using the Internet and graphics programs to gather images saved time, and presenting them on the large-screen monitor allowed everyone to see them at once. Finally, a larger range of examples can be quickly accessed on the Internet, allowing learners to see a greater variety. For instance, in social studies, if the concept is "mountains," a number of pictures of various types of mountains can be found, such as those with jagged peaks, those that have been weathered to smoothness, those formed from volcanoes, those covered with snow or jungle, and so forth. This is certainly a more optimal approach than simply writing a definition on the board or referencing a single picture in a book. This model is also very motivating for teachers, as they must also be constantly thinking and engaged with students during the "play." Imagine how much more thinking students do in this model than if they are simply given the definition of the concept followed by one or two examples.

The format we used for designing this was simple. A PowerPoint slide show was created with approximately 20 slides per concept. First a new picture is introduced and the class is told whether it is an example or a nonexample. The next slide shows the first picture placed in the correct category, example or nonexample. The third slide introduces a new picture by itself and students are told to consider in which category it might fit. The fourth slide shows the picture in the appropriate category. From this point on, a new picture is introduced on every other slide, followed by its correct placement among all of the previous pictures. The teacher uses his or her discretion to stop and ask students for other possible examples and when students are ready the teacher directs them to name the concept. The concept is written on the last slide of the show. Education students were then encouraged to select concepts for their own classrooms.

Suchman Inquiry

After successfully adapting the Concept Attainment model to include technology, we then examined several other higher-level thinking models usually presented in education classes. The Suchman
Inquiry model (Gunter et al, 1998) seemed to be another easily adaptable model to technology. This model requires that students actively use questioning that can be answered with only "yes" or "no" responses to find the answer to a situation or idea. It is very much like the game of "Twenty Questions." The teacher keeps an answer to him/herself ("an eggplant" for example), and students in a whole class situation ask questions ("Is it green? Is it round?) to narrow their thinking until they reach the correct answer. Of course, in upper level classrooms, the item/situation is more complicated. One difficulty in bringing children into a productive pattern of questioning is that they tend to "pot shot" their questions with no logic or organized system of thought. However, we sought to help students develop logical questioning patterns by utilizing a variation of this model adapted to technology.

While the whole-class version of this Inquiry model has its advantages, we felt that students could also improve their understanding of successful questioning patterns by playing a version of this "game" individually at the computer. We developed a flow-chart approach using HTML documents that provided options for narrowing the inquiry process. Students correctly navigated through a questioning pattern that logically led to the correct answer. In this way, they were forced to develop the questioning patterns we sought to build. For example, instead of young students guessing, "Is it a cabbage? Is it a carrot? Is it a potato?" we directed them to make choices, beginning with "Is it a large vegetable or a small vegetable?" followed by "Do we eat it cooked or not?" and "Is it red or not?" In the first step students make a guess among several broad choices, such as "Animal" "Mineral" "Vegetable." If they choose the wrong one a message flashes saying "Try again!" When they choose the correct picture, the next page offers several more choices such as "Has wings" "Has fur" "Has fins." Some choices are purposely written to distract students, for example after choosing "Has fur" another choice might be "Has gills." Clicking on this choice would reveal a silly picture of an imaginary creature and information about mammals explaining how they breathe. Students continue to navigate through the options until they reach the correct answer. With the use of technology, pictures and clip art can be used with or without text so that even nonreaders can engage in this activity. By navigating through the available pictures and options, students naturally begin to develop a sense of logic for the hierarchical arrangement of information. They are informally utilizing patterns of classification and organization to find the correct answer. It is believed that such learning enhances students' critical thinking processes.

Conflict Resolution

Another teaching model that requires critical thinking is that of Conflict Resolution (Weil et al, 1998). In this model students are divided into groups, given a topic to debate, and then guided through the process of gathering information. They list important issues or points to support their position and present their arguments to the other side. Naturally, this process requires students to use higher-level thinking skills (analysis, synthesis, and evaluation). For this model, we assigned a topic and divided students into groups. They gathered information to support their views by searching the Internet. Here they collected up-to-date information; they assessed the importance or popularity of the issue based on how many web pages or URLs were associated with it; and they collected data and made comparative judgements about their side of the debate after reviewing contrasting and supporting information. Current researchers encourage both cooperative groupings for upper level decision-making as well as the use of active technology in the classroom. The combination of the Conflict Resolution model with technology works best to provide these elements.

Memory Model

Another teaching model that is often recommended for higher levels of thinking is the Memory model (Weil et al, 1998). Students are asked to create a method to help them remember pieces of information. Quite often ridiculous association pictures are encouraged. For example, one might remember the hard minerals (quartz, beryl corundum, pyrite) by picturing a man in a car (for corundum) pulled up to a stand made of barrels (beryl) where he is purchasing a pie (pyrite) for a quarter (quartz).

Once more, we wished to involve a higher-level thinking activity (creating) through technology by having students use technology tools to design these ridiculous images. After students are given information, they are assigned to a computer as a small group and given the task of developing images that aid in memorization of the materials. For example, in a fourth grade science class studying groups of
animals, students constructed a picture of military men marching along in rows ...but they had changed the heads to those of chimpanzees. This funny image illustrated that many chimpanzees are a "troop." Because the students generated the image themselves, the information is more meaningful and the memory association is likely to be much stronger than one shown to them by the teacher or some other source. The resources available to students on the computer offer many options for creating these "silly associations." Various graphics software can be used to create such images, and students who may not consider themselves artists are quite capable of producing unique and creative Memory models using technological resources.

Models of teaching "engage" students in higher-level thinking skills. In combining these various models with technology, both areas reach for excellence in the classroom. The value of these models of teaching is in their versatility. Teachers and students are able to employ these models in their own classrooms across subject areas to gain a much greater depth of understanding. Using technology as a tool, there are few limitations.

How Can We Share Teaching Experiences in Different Countries through ICT?  
- Concepts, Models and Propositions for Instructional Design and Analysis -

NISHINOSONO Haruo  
Bukkyo University  
Kyoto, Japan  
E-mail: nisinohr@bukkyo-u.ac.jp

Abstract: Information and Communication Technology (ICT) enables pre-service and in-service teachers to share their experiences with one another while in different places. In other professions such as architecture, medicine, engineering, etc, specific symbols and models are used to express ideas and inventions. In the educational profession, there are no common symbols or models for teachers to express their ideas or to share experiences. This paper proposes a procedure of instructional synthesis and analysis, concepts for teaching, graphic representation of models and logical expression of instructional propositions to enable teachers to share their experiences through ICT.

Introduction

The new Information and Communication Technology (ICT) comes to teachers' desks and into classrooms enabling teachers and children to communicate each other from different places. The Internet, Cyberspace, Computer-Mediated Communication (Ryan 1992) and other concepts emerging from ICT are opening a new era in education on a worldwide scale, connecting people from different culture and countries. Computational communication technologies can play a vital role in the formation and successful operation of work-based learning communities, (Gordin, et al, 1996). Direct communication between children in foreign countries is spreading widely on the Internet despite their insufficient fluency in foreign languages. On the contrary, teachers cannot share their teaching experiences fully with others in a different culture or even within the same county due to the different frameworks used to express ideas and professional experiences. In professional areas such as engineering, medicine, music and other disciplines, members can express ideas, inventions and efforts in common international languages or symbols which are different from daily spoken languages. The teaching profession also needs an internationally understandable language to facilitate communication among teachers from different areas. This paper examines the possibility of sharing experiences among teachers in different workplaces through ICT.

A Framework for Generating Lesson Plans

In the case of conventional lesson plans, we start by describing educational aims and goals, specify instructional objectives and predict teaching and learning events which may occur in the classroom. In this procedure, we start from our educational intention and aims and move to instructional contents, teachers' actions, teaching materials, students' activities and other remarks. However, when we start to develop our ideas from educational norms, educational values differ from teacher to teacher, from school to school and from society to society. It is not difficult to express ideas as expectations and philosophical views in written statements, but it is hard to reach common agreement on educational goals and subsequent teaching, or to describe instructional events which will occur in the teaching process in advance. The same description of teachers' intentions and instructional objectives does not necessarily result in a similar learning or common visible student outcome due to differences in teachers' experiences. Teachers' intentions in written form are easy to read, but it is difficult to reach a common understanding and agreement, to modify the statements or replace them with other statements. On the other hand, when we start from students' activities, learning environment and a visible outcome, it is possible to describe them, to reach same agreement after critical
discussion on visible events, to collaborate each other and work together to assess and support students' learning. In this context, we try to describe the physical and psychological environment needed for an effective learning by means of concepts, models and propositions.

There are two directions to follow regarding instructional design. One is to start from our specific intentions and aims for instruction, proceed to images, models and a rational sequence of teaching, develop a concrete lesson plan and conduct it in the actual classroom. Another direction is to start with a flexible instructional strategy, conduct the lesson, observe the teaching-learning process, analyze the behavior of teacher and students in the classroom and predict teaching-learning events for the next lesson. In the real teaching situation, both directions are taken into consideration to generate a lesson plan. The designing procedure proposed here consists of several components; images, codes/categories, synthetic and analytic concepts, empirical models and propositions, which form sequential steps shown in the following figure in English and Japanese.

Figure 1. Procedure for instructional synthesis and analysis in English and Japanese.

In other professions such as construction, architecture and chemistry, internationally understandable symbols, concepts and models are available to express ideas and facilitate communication. When we start to develop a lesson plan from a prescription of teaching-learning events, it is easy to select common symbols, concepts, models and propositions from a database of instructional materials and to describe the lesson plan with such elemental components. If a theoretical model applicable to the lesson is available, it is suitable to adopt it for effective teaching. Whole configuration of symbols, concepts, models and propositions constitutes a structured lesson plan and represents specific educational aims. Graphic representations of symbols and concepts for instructional design enable teachers to develop their ideas and revise them ceaselessly. These components stored in a database are applicable to other instructional situations to be utilized by other teachers. In this context, the components of symbols, concepts, models and propositions are free from any specific educational values.

The proposal described here aims to give in-service as well as pre-service teachers a new framework for preparing instructional plans in daily teaching. They construct a lesson plan by selecting images/models and propositions stored in computers. They can add and store new images, models and propositions at will. They start writing lesson plans in a very primitive way using pictorial images, proceed to the stage of keywords or concepts, represent ideas in graphic models and describe judgment and explanations in propositions. The revising procedure is vital for improving an initial lesson plan before experiencing the actual situation to be observed in the classroom and reaching a refined plan to enable realizing and assessing the intended instructional goals. New models and propositions will be created endlessly just like new car models emerge one after another. Components for the synthesis and analysis will emerge always and will be far too many to memorize.
In spite of such a multiplying of components, we can store these components and utilize them to express our experiences through ICT.

Appendix I shows a tree structure of variables and Appendix II PowerPoint slides representing a few examples of images and models. Appendix III represents examples of propositions. The method for instructional design is named a MACETO model representing meaning/values, activities/actions, concepts/contents, environment, tools/techniques and outcome. The following table shows pairs of components in both English and Japanese. If a teacher describes a lesson plan in English, it will be simultaneously translated into Japanese, and vice versa.

If there is a correspondence between English technical words and the foreign equivalents, teachers in different countries can exchange their experiences through English as an international language.

Implementation of the Procedure in Pre-service Education

The procedure of synthesis and analysis for instructional design was introduced during the course 'Instructional Technology' to confirm its applicability in pre-service education. Students in this course were requested to follow these instructions.

1. Describe an imaginary lesson to be developed in workgroups with images and models and elaborate it further according to their own ideas. Explain the rationale used to design such lesson referring to documents of instructional standards (issued by the Ministry of Education and/or Local Boards of Education in Japan) and literature on education.

2. Develop a lesson plan using images and models referring to the MACETO model to select synthetic and analytic concepts. The plan should be relevant to children’s activities, learning situations and the educational environment.

3. Report their learning experiences during the course and evaluate them referring to the learning plan prepared at the beginning of the lessons.

At the beginning of every session, 'Topics for this week' and 'Learning plan of this week' were distributed. The class was conducted by showing the lesson plan of this course through PowerPoint presentation and handouts of 'Learning plan of this week' to be filled and submitted at the end of each session. Students worked hard collaboratively in groups as well as individually to accomplish their tasks.

Pre-service students have a long history of attending classes in elementary and secondary schools. They hold rigid and sustaining images on teaching from these experiences. At the initial stage of instructional
designing, they tend to refer to such images and follow the experienced framework to generate lesson plan. It is hard for them to change the framework and accept new types of instruction not written in the form of conventional lesson plans. New types of software such as PowerPoint enable us to express ideas in a flexible way and to revise them with ease. Repetitive revisions enable us to refine these ideas and making them relevant to instructional events observed in the real teaching situation. In this context, components used to describe a lesson plan should be flexible enough to change its structure at a very early stage of designing.

The following figure shows the image of a whole course representing students' ambiguous states at the beginning, gradual clarification, creative contribution, panel presentations and submission of final report. This image has an entirely similar structure and representation in English as in Japanese without any modification.

Figure 1. Instructional procedure of ‘Instructional Technology’ representing graphic images

Conclusion

The course can be described in the form of images, concepts, models and propositions that are exportable to professional teachers through the Internet or other communication technology, enabling them to share professional experiences on teaching. There is no clear cut distinctions between image and model, but the image represents teachers' ideas and expectations, while the model represents teaching and learning events observed in actual classes in the form of conceptual figures and concepts. Synthetic concepts are derived from images and are intention-oriented; analytic concepts come from an analysis of teaching/learning process and are behavior-oriented. There is no continuous or reliable procedure for converting a lesson plan from concept to empirical model. This requires intuitive ideas and back and forth repetition to refine the lesson plan. If we succeed in standardizing symbols and concepts internationally, it is possible to share our teaching experiences in other countries.

Teachers try to predict learners' activities in a class, develop instructional materials, provide an interesting learning environment, select tools for effective learning, support students' learning and then expect to achieve their instructional goals. There may be various procedures to develop instructional plans, teaching in classroom and evaluation after teaching. This developing procedure should be described in internationally understandable symbols and languages to enable teachers to share their experiences with people from different cultural backgrounds.

Researchers propose models to apply scientific knowledge to solve problems in teaching/learning, and
Many models have been proposed to make this procedure rational and effective so as to achieve predetermined educational goals and instructional objectives. However, the unilateral application from theory to practice is not always effective in the complicated real situation. Teachers have to develop their own framework to confirm applicability of their knowledge accumulated from previous experiences. In this circumstance, they have to equip themselves with the competency to originate practical knowledge suitable to solve problems tackled in their work place. Experienced teachers nominated by the Local Board of Education in each school district supervise novice teachers and give them advice on teaching during the first year of their professional careers. Nevertheless, novice teachers heavily rely on their individual experiences but share them with colleagues only occasionally. This procedure reproduces empirical consistency and professional continuity in successive generations among teachers. It is hard to change the framework of writing lesson plans in the conventional style or to introduce a new concept of instruction. However, it is indispensable to develop a new style of lesson plan that enables teachers to express ideas in very primitive state and revise them repeatedly in order to create a refined lesson plan.

Appendix II : Images and models for instructional designing using PowerPoint
Appendix III: List of instructional propositions (about 60 propositions are stored)

It is possible to develop students' competency for instructional designing through a sequence of training sessions to form pictorial images, key concepts, graphic representations, models and propositions.

Alternative strategies regarding degree of freedom in learning

1. When we increase the degree of freedom in learning and give more initiative to students, learning results in a wide range from excellent to poor outcomes in quality and quantity.
2. When we decrease the degree of freedom in learning and give less initiative to students, learning results in more reliable but a mediocre outcome of less quality.

When we feel confident by a gradual formation of an outcome in ourselves, we realize the meaning of learning.

There are two possible ways to proceed to forming empirical models.

1. Students observe recorded teaching, take notes and analyze them. After this analysis, they try to describe the process in keywords and put them in a graphic representation.
2. Students repeat describing their own experiences in keywords and show activities in a graphic representation, and succeed to express relationship and procedure in a model.

To recover autonomous learning, it is effective to concentrate on developing a lesson plan dominated by activities, rather than one dominated by contents of the subject matter.

To manage a large group of students to learn autonomously, it is effective to form groups or clusters of groups, to encourage active participation and let them recognize their responsibility for autonomous learning.
Abstract: The amount of text that we are required to read in the present days is amazing. One of the reasons for a poor performance of electronic text systems may result from the fact of users to avoid reading the whole text and make decisions mostly based on their headings (Fox, 1992). Aiming to minimize this problem, we have developed a computer-based tool for continuous zoom interfaces (graphic interface that allows a text to be continuously magnified or decreased). Prior to displaying the text, this tool performs a previous analysis of the text, taking into account its grammatical classification. Then, the text is displayed in its most condensed format and lowest zoom level, where only the most important words are shown. For that, the tool uses the artificial intelligence technique (pattern matching). The text is then displayed in its most condensed format and lowest zoom level. As zoom increases, more elements of the text become visible. It should be highlighted that the tool deals with language “traps” and whenever the pattern recognizer fails to classify a certain word, it makes that word visible in its most reduced zoom format.

Introduction

One of the most important aspects of an electronic document reading is the user interface (Knight 1999). Zoomable User Interfaces are a kind of information visualization (Benderson 2000). Ken Perlin of New York University defined the concept of Zoomable surface (Perlin 1993). Ben Benderson designed and implemented PAD++ tool, which in Maryland University gave rise to Jazz (Benderson 2000), which in turn provided a Java API to develop the Zoomable User Interfaces (ZUI). When working with version 1.0 of Jazz, we had to make several extensions to its original format.

The objective of this work is to contribute to reduce the effort to read general electronic documents; to produce and test new ways to analyze texts and identify patterns of sentence constructions, as well as to classify grammatically each of their components. One of the most important questions about electronic documents lies in the research of their usability, which advantages will be provided and how they will be (Maes 1992).

Pattern Recognition

One critical natural language processing task is that of determining the syntactic structure of a sentence, also known as parsing. Correct parsing of unrestricted text is an exceedingly difficult task, due to the ambiguities in part of speech (noun, verb and so on) and structure (Goldstein 1999). Natural languages constitute a number of traps for any pattern recognition tool; for instance, a Word may have several meanings under diverse contexts. Such meanings could lead to a different grammatical class. In English, the word Kiss analyzed separately can be either a verb or a noun. The final definition will depend on the
context it is employed. In other words, almost always it is necessary to analyze a whole sentence to be able to define the grammatical class of each of its components. Sometimes, the definition of a particular element of the text can influence that of another text. This problem may lead the inference algorithm to an endless loop condition. In this case, after a certain number of attempts, our program ends by classifying the word as "indefinite classification". This special class is given a differentiated treatment. Should a second element, in order to obtain its classification, need the classification of another element in the same sentence and the latter is defined as "indefinite classification", the former also assumes this condition. Therefore, as shown below, at constructing our patterns, we should be more economic in generic expressions, that is, we should use to the extent possible rules that should not depend on others. The more indefinite classification we have, the poorer the results obtained. There is also the problem of verb conjugations. Here, the existence of a rule to deal with them is indispensable. Otherwise, we would fall into the "indefinite classification" condition. Word classifications may be constant, such as adjective, adverb, definite article, verb, etc., or indefinite.

**Continuous Zoom Interface**

Of all extensions, that dealing with the management of the zoom stands out. Since we are working with text, each element will be assigned its particular zoom control. This is due to the fact that we will control the exact time when the element (text) will be visible to the final user. That time basically depends on both its classification defined as above and the text style. Style, as briefly mentioned in the introduction, may vary greatly according to the purposes for which the text was produced. Documents can differ along several dimensions, such as length, writing style and lexical usage. Thus, specific classifications and expressions assume diverse importance in different styles.

To address this issue, the program will be provided with a zoom dictionary specific for each style. Note that while the pattern dictionary defined in the previous section is generic for a given natural language, our Zoom dictionary is more specific. This way, the program can work with any combination of both the dictionaries predefined by the final user.

**Conclusions**

Initial tests have proved promising. It was clearly confirmed that the law for formation of rules for the natural language dictionary are sufficiently consistent to express any set of <Exception1>, <Exception2>, <ExceptionN>, ... <Rule> for word classification in Portuguese language. We have also succeeded in introducing Continuous Zoom resources to the list of computer resources that help online reading.

Abstract: One of the fundamental problems in distance delivery of educational content is to determine the amount of learning that is taking place. Merely delivering content is not enough - some form of assessment (at a distance) is necessary. Traditional methods for assessing students' understanding of course content (e.g. multiple choice problems short answer problems) can be enhanced and supplemented through the use of computers and information technology. Timing and tracking information collected in real time, coupled with information from interactive, specially designed Java applets and scripts, can be used to supplement traditional assessment methods by capturing information about students' decision-making processes. This paper describes how to develop databases and assessment methods based on cognitive models of information processing, to better interpret performance data and more effectively deliver instruction at a distance.

Cognitive Foundations

To address issues related to the diversity of educational problems and lack of consistency in instructional approaches, the field of education is moving to models of cognition based on logical-mathematical principles (Anderson et al. 1998). Using models that can be implemented and tested on modern computer systems, performance can be analyzed rigorously and compared to experimental observations. This offers some defense against recent criticisms of poor scientific practice (Labaree, 1998). We feel that theories of information processing (Anderson 1996), cognition (Anderson et al. 1998), knowledge representation (Sowa 2000) and database design have progressed far enough to enable one to design, analyze and test the effectiveness of instructional delivery systems. The particular systems we have in mind are web-based, and designed for use both in-class and at a distance.

Borrowing from classical Philosophy, "ontology" is defined as an explicit formal specification of how to represent objects, concepts and other entities that are assumed to exist in some area of interest and the relationships that hold among them (Gruber 1995, Guarino 1998, Guarino et al. 2000, Stutt 1997). "Knowledge Engineering" is a relatively new discipline that has arisen to transfer human knowledge and expertise into computer systems (Sowa 2000). The goal is to build Knowledge Based Systems (KBS), systems that store and use very large amounts of information about an application (or knowledge domain) and serve as an intelligent assistant rather than an expert system. An example of this has been the work done in the area of Intelligent Tutoring Systems (ITS). There is an enormous body of literature regarding the construction and design of KBS to which we refer the interested reader (Boose et al. 1988, Gauthier et al. 2000, Ringland et al. 1988).
Rather than pursue an abstract theoretical approach, we will focus on a concrete example. Suppose we wish to teach methods of integration to students in Mathematics. The identified knowledge domain within mathematics would be integration methods. From the standpoint of student comprehension, however, integration methods is too broad a topic to teach, thus, the knowledge domain would be broken down into sub-domains or components that restrict both the teaching and learning focus. In this example, our target sub-domain might be integration of functions of a single variable. Subsequently, we may recognize that the sub-domain itself is too broad, so instructional focus may shift to a single objective, for example, integration by parts. Although integration by parts might also be considered a sub-domain, we refer to it as an objective, and view the sub-domain of single variable function integration as being covered by multiple objectives as depicted in Figure 1.

![Figure 1: Decomposition of a knowledge sub-domain into overlapping objectives](image-url)

Once we have identified a specific objective, we must come up with a suitable knowledge representation. We follow the general information processing approach (Anderson et al. 1998) by identifying three types of knowledge: declarative, procedural and strategic. Roughly speaking:

- **Declarative knowledge** consists of basic factual knowledge; for example, formulae or rules of a restricted form (such as derivatives of polynomials, trigonometric and exponential functions).
- **Procedural knowledge** consists of algorithms; for example, changes of variable or trigonometric substitution.
- **Strategic knowledge** consists of information about alternate ways to perform sequences of actions, usually in the course of problem solving; for example, identifying groupings of terms or reducing terms to standard forms.

The knowledge needed to accomplish the objective (in this case, integration by parts methods for functions of a single variable) is then partitioned into declarative, procedural and strategic knowledge. This process is analogous to the Cognitive Task Analysis done when building an ITS (see Figure 2).

![Figure 2: Decomposing an objective into declarative, procedural, and strategic knowledge components.](image-url)

This decomposition is usually performed by a Subject Matter Expert (SME), someone who is knowledgeable about the sub-domain and the relationships among the knowledge components. The decomposition is not necessarily complete, and should be extensible to allow for improving the model.
One of the problems encountered in knowledge engineering is designing systems that are independent of the knowledge domain ("re-usability"). We need to design a structure that is flexible enough to capture relationships but allows for variable content. We accomplish this through a particular database "schema."

**Database Design**

The knowledge representation within the database includes both the content and meta-data about the content. The data are all listed within a single table that includes the name and description of the datum, the data type (e.g. declaration or procedure or strategy) a list of dependent data, and a list of questions that test a student's knowledge of the content area. These data content and the relationships between the data are dependent on the particular knowledge domain (sub-domain or objective), but the structure of the database is independent of any specific content area.

Figure 3 illustrates the inter-relationships between the declarative, procedural, and strategic knowledge associated with a specific objective.

![Figure 3: Linkages between declarative, procedural and strategic knowledge.](image)

In this example, strategy 1 depends on strategy 3 and procedures 2 and 3. Strategy 3 depends on declaration 10 and procedure 1. Procedure 2 depends on declaration 1 and declaration 2. Declaration 2 depends on declaration 10, etc. An important constraint to these relationships is that no circular references should occur. A second constraint is that no lower order meta-datum should depend upon a higher order meta-datum. That is, a declaration cannot depend upon a procedure and a procedure cannot depend upon a strategy. All other inter-relationships would be legitimate.

The final piece of the knowledge representation is the questions. The database stores the questions and their properties within a single table. The primary fields are:

- question id
- question type
- question text
- variable definitions
- stems
- solution
- explanation
- keywords
- estimated time for completion
- estimated difficulty
- comments
- evaluation method
- hints

It is important to note that because the structure of the database and tables are not dependent on the particular knowledge domain (or sub-domain or objective) under consideration, it is possible to design software tools and interfaces which help build a knowledge representation as part of an iterative process.

**Assessment**

Up to this point, this type of conceptual modeling or knowledge representation can be done without any instructional goals in mind. In order to test whether learning is taking place, a set of questions is created which address the particular objective. These questions act as "probes" which help build a model of the student's understanding. The simplest questions merely test the basic factual knowledge (declarative knowledge) through true-false or multiple-choice questions. Single-step procedural knowledge can be tested through multiple-choice or short answer questions. More complicated multi-step procedural knowledge can be tested through short-answer, multiple-choice or workout problems. Strategic knowledge can be probed through workout problems that are skill based.

One of the benefits of the question database is that during the process of adding questions to the database (e.g. by an instructor, through an authoring tool) it may become apparent that some type of knowledge has not been included (e.g. a basic differentiation rule has been omitted). This provides an...
opportunity for the knowledgebases to be updated or edited. The author benefits from greater awareness of
the underlying knowledge representation.

Although this seems like a complicated structure, it is invisible to the student. When a question is
presented to the student, it is in the form of standard HTML (which may include graphics, multimedia,
forms, scripts or applets!) The student's response is then recorded and compared to the solution, using the
appropriate evaluation method. This includes the following:

- Strict numerical equality or equivalence ("5/2" or "2.5" compared to "2.50")
- Numerical equality within a prescribed tolerance (e.g. "3.14" compared to "3.14159")
- Strict string equality, ignoring case (e.g. "Parabola" compared to "parabola")
- Symbolic equivalence (e.g. \( \sin^2(ax)+\cos^2(ax) \) compared to "1")

The evaluation method then returns a measure of student performance (which can then be
weighted by difficulty, elapsed time, number of hints received, etc.)

Pre-tests can be given to provide information on the students understanding of declarative and
procedural knowledge, prior to instruction. Post-tests can be given to test strategic understanding after
instruction. Tests for "retention" are also useful to see how much knowledge has been "proceduralized"
and how much is in long-term memory versus short-term memory.

Based on the performance metrics returned for each question, and because of the underlying
database structure of the questions, an analysis can be performed for each student. For example, suppose
10 questions on integration by parts were given, of these 5 questions were missed. Suppose further that
each question that was missed involved differentiation of trigonometric functions (one element of the
declarative knowledgebase). If none of the questions that were answered correctly involved differentiation
of trigonometric functions (only polynomials or exponentials), a recommendation would be given to the
student to work on a module involving differentiation of trigonometric functions. This recommendation
could be in the form of a diagnostic report to the student or possibly by forcing the student to complete
(successfully) a module on trigonometric differentiation prior to resuming instruction. In either case, we
are following the general paradigm of "assessment inform instruction."

Assessment takes place continually, in conjunction with content delivery. Assessment may be
formal (pre-test or post-test), it may be graded or non-graded (for use in tutorials or practice tests). Usually
it will occur informally as part of the feedback provided by the student back to the instructional delivery
system.

Implementation

The assessment components described in this paper have been used for several semesters in two
Educational Psychology Statistics courses and an analysis of the effectiveness of this system can be found
in (Hall et al. 1999, Pilant et al. 2000). In the Hall, et al. (1999) study, 41 graduate and undergraduate
students enrolled an applied statistics course self-selected into one of three groups. Group 1 took chapter
pretests online and printed out results. Subjects in group 2 printed copies of the pretests but did not take
tests online. Group 3 did not access the pretests. Pretests for exams 1 and 3 were made available through a
class. Groups could not be distinguished, a priori, based on demographic data, self-reported motivation,
time spent studying, class goals, or math skill scores. There were, however, statistically significant
differences among groups on exam performance, favoring students in the online-pretest group.

Currently, the authors have developed and are testing a limited version of the assessment tool
outlined in this paper. A series of linked components make up the online testing instrument. The first is an
"administration" or "authoring" component that is web-based and password protected. In this environment,
an instructor can build or modify questions and exams and create classroom databases. A second
component provides students access to the actual interactive testing. Finally, the third part is the database
itself, currently Microsoft ® Access, which is completely hidden behind a web front-end (for portability).

One of the unusual features programmed into the online testing tool is the ability to capture
information related to motivation through use of sliders that measure student's "familiarity" with content
objectives prior to testing, and "confidence" about response accuracy as the test proceeds. This provides
students and instructors with information regarding depth of preparation, level of skill, and degree of
uncertainty. Each question is timed transparently to the student. The format of the questions is
unstructured - any valid HTML code can be included. Question types currently supported are true/false,
multiple choice, short workout, and detailed workout. Questions can be interactive (through embedded
JAVA applets), and can contain graphics and multi-media. Responses are recorded and a printable
summary of the students' work - including computer-graded questions (true/false and multiple choice),
explanations, time spent answering individual questions, reported confidence and help, and reported
familiarity with learning objectives - can be returned to students when all questions have been answered.
In the pretest mode, students review one question at a time and once questions are submitted, they cannot
be revisited. If there is not enough time to complete a pretest, a bookmark feature allows a student to return
to the test at the point where he/she stopped.

Using this tool, instructors can maintain question, exam, student, and class databases, and link
questions to categories and/or objectives to individual questions. The authoring tool is completely
accessible through the Web (although it is password protected for security reasons). In not providing
immediate feedback to students regarding the correctness of their responses, students experience exam
level questions in a context that mimics in-class exams. When the pretest is completed, students are
provided with their test results and with explanations for each of the questions. These reports are intended
to be used as study guides and include detailed explanations for each question with embedded links to
tutorial material, detailed workouts, and interactive graphics.

A more recent version of the online testing program is being used in actual classroom testing.
This version features a random question function so that students sitting next to one another are not
working on the same question at the same time and allows students to review their exams (all or targeted
questions) at the end of the test before submission, to skip questions that they want to return to later, and to
justify responses to multiple-choice or true-false questions. All question types are supported and graphics
and applets can be integrated into the questions.

Conclusions

In this paper, we have outlined a methodology that a significant portion of the system is independent of
the knowledge domain - specifically, the database structure (schema), authoring tools and HTML delivery
system. The main features of this process are:

1) Identify a set of objectives that cover the knowledge (sub) domain
2) For each objective, identify an initial set of:
   a) Declarative Knowledge
   b) Procedural Knowledge
   c) Strategic Knowledge
3) Create a question database

The main driving mechanism is the creation of a question database that dynamically updates the
declarative, procedural and strategic knowledgebases. This is accomplished through an interactive HTML
based authoring tool. One of the side benefits is the explicit awareness of the underlying knowledge
structure (ontology) on the part of the instructor.

Questions may be formulated using any valid HTML code, which allows the inclusion of
JavaScript and Java applets. Java Applets allow much more interactivity, and provide the opportunity for
skills-based testing. Recording time-on-task, either through the applets or through JavaScript, provides
additional insight into the learning patterns of individual users.

Finally, it should be emphasized that this type of knowledge engineering approach works in the
field, having been tested in two different Educational Psychology courses during the last two years.

Acknowledgements

This research was supported in part by a grant from Brooks/Cole Publishing, Inc. We are grateful
for the support of our respective departments, as well as all the instructors and students who have
participated in the development of the assessment tools described in this paper.

Abstract: Taking on this challenge, a professor and graduate student at a major urban university with over 40,000 students and 600 preservice teachers restructured a traditional instructional technology course and piloted a constructivist model without changing the content. The mission was to train teachers to utilize current technologies in the classroom effectively through a two-credit course. During this project, the researchers tracked the progress of both the course and the success of the students. Multiple variables merged to create a meaningful experience for preservice teachers about to embark on their teaching career. Approximately twenty-one technology skills were assessed using a pre-post self-assessment tool. All 26 teachers in the sample reported a significant increase in their technology skills by the end of a 10-week restructured instructional technology course for elementary teachers (ISTE, 1999).

Introduction

The overriding purpose of the course was not have students become “technology proficient” in every application, but that preservice teachers (students) in the class develop a “fearless approach” to learning new technology. Objectives focused on the development of skills necessary to model lifelong independent learning. To achieve this, the class setting modeled both constructivist and behaviorist perspectives. Demonstration of technology integration into traditional transmission and constructivist-compatible instruction was presented. Students observed the differences in learning with technology within both types of pedagogy.

Approach

Topics covered in the course were flexible and evolving, centering on the needs of the learners (students). Relevant learning theories discussed included a diverse segment of scholars: Piaget, Vygotsky, Skinner, Papert, Gagne, H. Gardner, Bloom, Bruner, and Dale (Cone of Experience.) Students engaged in on-line discussions as well as essay writings in studying the learning experience.

Instructors placed special emphasis on lesson planning analysis, particularly in the areas of objectives and assessment. Students utilized the learning plan model called “ASSURE” to examine effective planning for integration of technology. Class members created rubrics and utilized them to evaluate various assignments to include the final presentation.

Instructional Design

In designing the course content, both students’ interest and newly implemented standards became important. The preservice teachers in this course will soon be subject to technology standards being implemented by the state of Ohio and based on the nationally developed standards by ISTE (International Society for Technology in Education). This course attempted to instill the confidence these future teachers will need to meet the new standards.
Participants

The convenience sample for this exploratory analysis of an isolated instructional technology class for elementary preservice teachers included 26 preservice teachers. The teachers were classified as interns or teaching assistants who were in their 4th and 5th year of teaching preparation. Class members completed projects and presented their authentic learning in using technology to enhance the instructional process and student understanding over a 10-week period. Thus, sharing of multiple examples that demonstrated “appropriate use of technology” occurred. Students engaged in software evaluation, multimedia production, and portfolio presentation. A particular assignment involving action research by the students challenged them to observe and interview a classroom teacher on the topic of technology integration. Results of this particular learning experienced varied as much as the use of technology in today’s classroom. It became a very telling event for all. Figure 1 provides a description of the course structure, instructional approach, activities, assessments, and outcomes.

Course Description: Instructional Technology for Elementary Teachers:

This is a two-credit course offered on foundation technology skills, pedagogy, and instructional designs, which support learning and teaching with technology in elementary learning communities. The course structure and content are intended to address educational reform and basic technology foundation skills. (National Commission for the Accreditation of Teacher Education and the International Society for Technology Education (NCATE/ISTE; Available: iste.org)

Prerequisites: Recommended for 4th and 5th Year Preservice Teachers and a Basic Computer Literacy

Readings:

All textbook reading should be completed before class. After reading, complete a summary KWL reflection for class discussion and your portfolio. Summaries must be "word processed".

Other required reading and Internet Web-sites

Websites to visit:
Software Review Projects, Supportive Online Lessons, and Ohio Technology Standards for Students http://www.ohioschoolnet.k12.oh.us/home/contents.asp
Kathy Shrock’s Guide for Educators (http://www.capecod.net/schrockguide/)

Overview:
The course will incorporate activities connected to the Ohio SchoolNet Learner Technology Profiles sites and other Internet resources that were created to guide teachers as they integrate technology into the curriculum. The course is organized around the six categories:

(1) Basic operations and concepts
(2) Social, ethical, and human issues
(3) Technology productivity tools
(4) Technology communication tools
(5) Technology research tools
(6) Technology problem-solving and decision-making tools.

Instructional Design:
The course structure is based on learner-centered theoretical perspectives. This approach is supported by multiple instructional strategies to encourage a constructivist learning environment. Technology skills learn technology skills by engaging in integrated and collaborative activities. The activities are intended to demonstrate ways in which technology tools can be effectively integrated into the instructional environment to encourage collaboration, exploration, and/or the development of problem solving skills.

Coursework:
The modular units incorporate discussion, project-based, and exploratory approaches throughout the learning and instructional process. A few specific technologies include: PowerPoint, HyperStudio*, Netscape Communicator, Excel, Internet/WWW, basic Windows computing skills, and reviews of educational software. See SchoolNet Software Review Project at: http://www.ohioschoolnet.k12.oh.us/home/contents.asp

Weekly Assignments

Grading Criteria
Assessment and Evaluation: Student performance is based on individual and team projects. The final grade will be based on all completed papers, projects, comprehensive portfolio, and an oral presentation. The final grade will be based on a 200 point system (100 points for class assignments and 100 points for a final project/portfolio). See grading scale following assignments.

All assignments will be graded based on an appropriate rubric for each project--- guided by the following principles:

1. Clarity of assignment—covers the relevant details required for the specific project.
2. Integration—ideas for classroom use discussed.
3. Products are clear and useful following all principles of visual presentations.
4. Choice of software is appropriate for the audience and environment.
5. The ease of presentation, quality of the assignment, and the ability to answer questions evidence knowledge of the software and technology.

Summary Class Projects 1/3 = 100 points, Portfolio 1/3, and Final Presentation 1/3 = 100 points
Total: 200 points.

Figure 1. Sample Syllabus for Instructional Technology Class

Course Objectives:
The course is designed to help students:

Basic Operation and Concepts
1. Demonstrate a sound understanding of the nature and operation of technology systems.
2. Become proficient in the use of technology.

Social, ethical, and human issues
1. Understand the ethical, cultural, and societal issues related to technology.
2. Practice responsible use of technology systems, information, and software.
3. Develop positive attitudes toward technology uses that support lifelong learning, collaboration, personal pursuits, and productivity.

Productivity tools

1. Use technology tools to enhance learning, increase productivity, and promote creativity.
2. Use productivity tools to collaborate in constructing technology-enhanced models, preparing publications, and producing other creative works.

Technology communication tools

1. Use telecommunications to collaborate, publish, and interact with peers, experts, and other audiences.
2. Use a variety of media and formats to communicate information and ideas effectively to multiple audiences.

Technology research tools

1. Use technology to locate, evaluate, and collect information from a variety of sources.
2. Use technology tools to process data and report results.
3. Evaluate and select new information resources and technological innovations based on the appropriateness to specific tasks.

Technology problem-solving and decision-making tools

1. Use technology resources for solving problems and making informed decisions when planning and assessing classroom learning activities.
2. Employ technology in the development of strategies to solving problems encountered in real classroom environments.

Attendance Policy

Student presence in class and labs is required to earn credit for assignments. Please arrange with the professor for planned absence. In case of emergency you must call (513) 556-4385 and leave a voicemail message. Sending E-mail is not a substitute, but you may do both.

Collaborative Work: There is only one group assignment. Each member of the group is equally responsible for the work.

Portfolio: Details on your portfolio will be given at a later date. However, all assignments completed in class will become a part of your portfolio. You are asked to keep a journal of your reflections on all readings and class projects/assignments.

Online Participation and Discussion

Due dates: All assignments will be given a due date during the class time and updated on E-mail each week in case of a change.

Performance-based Assessment

Pre & post assessments administered to students determined their self-perception in the acquisition of technology integration skills. The results of the assessments, along with evaluations of individual assignments, presentations and a cumulative portfolio, combined to determine students' final grades. Course analysis was used for planning and restructuring the class as indicated by student achievement and performance.
Lessons Learned

In recent years, the vision for technology in the Division of Teacher Education at the University of Cincinnati has increasingly been shaped by both state and national standards for the teaching and use of technology in the classroom. SchoolNet, an Ohio technology education agency, has established standards for identifying and strengthening skill levels for preservices' appropriate use of technology in the classroom. Nationally, the National Council for Accreditation of Teacher Education (NCATE) standards, which incorporate International Society for Technology in Education (ISTE) standards, outlines those skills that are necessary for preservices and faculty to hold. This project will result in comprehensive incorporation of these standards into the University of Cincinnati's nationally recognized preservice education program. In 1998 UC College of Education (CITE program) received the Exemplary Practice Award in Support of Teacher Education Accreditation by the American Association of Colleges for Teacher Education (AACTE, 1998). U.S. News & World Report and Modern Maturity hailed the UC College of Education as "cutting-edge" for teacher reform (Educator, 1999).

The Cincinnati Initiative for Teacher Education (CITE) at the University of Cincinnati's College of Education is a five year preparation program that is nationally recognized as a leader in systemic school reform and innovative methods of teacher education. The program is built on the Holmes Group model and has been in place for five (5) years. During the professional preparation year (Year 4), students are considered Teaching Associates. They take methods classes, content area classes, and spend 4 to 6 hours per week each quarter in schools, teaching and observing. During their internship year (Year 5), students complete their advanced methods requirements, participate in coordinated seminars, and teach half time in a school for a complete and full school year.

Interns typically receive pay from the school systems and are teachers of record in their classrooms, bearing the full responsibility of two classes of students in a secondary school and a half-day teaching in an elementary school. Students are placed in schools (Professional Development Schools) that have agreed to work closely with the College of Education to provide supportive and extended induction experiences. Currently five high schools and 11 elementary schools support teaching associates and intern teachers through the Professional Development School concept and in keeping with the College's urban mission. Many of these schools are located in the Cincinnati Public Schools district.

Identification of Specific Gaps and Weaknesses

The mission of the CITE program is to develop high quality teachers experienced in working with the special needs of inner city schools and pupils. A primary focus is the Cincinnati Public Schools (CPS). Currently, pre-service teachers in the CITE program receive inadequate training in technology. A comprehensive program analysis has determined that one critical component missing from this program and from many of the courses taught by the teaching associates and intern teachers, is technology. At the present time the average number of IT hours per CITE student is between two and three credit hours (2.5 cr. hrs.). Students get these hours of technology instruction only in the 4th or 5th year of the program (Figure).

The use of technology has been infused only sparsely into methods and curriculum areas. Of even greater concern are the inconsistent and ineffective methodologies employed during instruction. Access to professional development and technical assistance for faculty is only rudimentary. Although, during 1997-1998, the instructional technology methods for courses were revised to introduce focus on curricular integration; project based learning, inquiry-based and exploratory learning, collaborative learning, standards-based lesson planning, and technology integration, the small insulated change was inadequate to meet the need of preservice teachers with little or no experience in technology environments.

Evaluation data indicates that students participating in the enhanced courses demonstrated increased potential to perform at higher levels of achievement and an ability to use a variety of instructional technologies with their own pupils in the schools. However, a large percentage of students expressed frustration with non-traditional constructivist learning and teaching strategies and most did not include new
instructional strategies in their technology integration lesson plans. This was evident across all the teacher education programs. An analysis of the course evaluations revealed that students' skills vary widely, over half of the students wanted more direct instruction. Students also expressed that in a constructivist learning setting, the traditional textbook and syllabus are highly ineffective tools because of the emerging information and new knowledge from web-sites and practical field experiences. In addition, teachers indicated that most of their mentor teachers preferred the traditional lesson plan format, therefore they were unable to apply much of what they learned in their field experiences in the public schools.

Conclusions

After fully evaluating the data, it became apparent that to bring about a comprehensive change in teaching practices, it would be necessary to expand the implementation to include all methods, faculty, and students across programs and subject areas.

Extending the Learning Environment: Potentials and Possibilities in a Web Mediated Course

Rose M. Pringle Ph.D  
University of Florida  
rpringle@coe.ufl.edu

Abstract: Asynchronous learning tools on the World Wide Web have opened up possibilities and potential for a new environment for teaching and learning. One program, employing this learning tool was the Connecting Communities of Learners (CCL) developed by a team of science educators and programmers at Florida State University in the mid 1990's. This paper describes how it was used as one tool in a science education course for pre-service teachers. Facilitating dialogue journal, notice board, grade book and critical review, the CCL extended the physical learning environment beyond the traditional class contact periods. Learners were afforded the opportunities to work with materials and tools while operating at a pace convenient to them and appropriate for learning within the social context of the learning community being developed.

Introduction

Modern computer technology has made possible a new and rich learning environment (Lee, 1999). Today as we perch, poised for the next millennium there is evidence that the computer and the World Wide Web (WWW), have become a more viable option for teaching and learning. The Internet has quickly become a ubiquitous open WWW of interconnected, global computer networks (McIntyre, & Wolff, 1998), allowing for interaction and much collaboration among learning communities.

Developments in technology coupled with research in teaching and learning have led to substantial alterations in the way computer technology is now used in education. Today, asynchronous learning tools on the WWW have opened up possibilities and potential for a new environment for teaching and learning. The central pedagogical idea in an asynchronous learning network is collaborative learning at the time and place of the individual learner's convenience (Nulden & Hardless, 1999). Researchers contend that learners are afforded the opportunities to contribute their understandings on issues from any place and at any time that is personally convenient. At the same time, it allows for multiple discussions to occur simultaneously. Asynchronous learning network utilizes different tools for computer mediated communication. It employs the integration of these tools as a means of slowing down the dynamic face-to-face interactions, characteristic of the traditional classrooms (Nulden & Hardless, 1999). One of the hallmarks of the asynchronous learning network is that it reduces competition for airtime among participants allowing for equal voice in communications. In part, this is accomplished as the time available for reading or rereading materials is increased, allowing for critical reflection and formulation of thoughts.

Connecting Communities of Learners (CCL)

One program employing the asynchronous learning tool was the Internet application known as Connecting Communities of Learning (CCL). This was developed by Kenneth Tobin and a team of educators and programmers at Florida State University (FSU) in the mid 1990's. Embracing social constructivism, giving credence to the social context of learners and their individual needs, emphasis was placed on the active role of learners in knowledge construction and the social construction of this knowledge.

Structure of the CCL

The CCL consisted of a number of sites for posting students' work. Identified by a named button, some of these were critical reviews, dialogue journals, research papers, proposals, portfolios and notice board. A mailroom system also allowed for selective or mass dispatching of e-mails to all members enrolled in the course along with the instructor. Access was facilitated through the use of a log-in name and a private password that allowed entry into the website. In this paper I will discuss how the CCL was used as one tool to facilitate learning in a science education course for pre-service teachers.
Website Teaching and Learning Tools

Dialogue Journal

The dialogue journal, a semi-private site, offered a safe base, learning environment where participants became involved in academic discourse, shared perspectives and had access to the ideas of their peers. It also provided a platform where group members could work collaboratively on projects. One project, The Moon Model, required group members to observe the moon over a period of time and create a model to explain their observations. Group members were able to continue their discussion on their science project without having the constraints of a common meeting time. Within this environment they shared their observations, offered explanations and reflected on their model as it was being constructed.

Critical Review

Critical review was one of the teaching strategies used in the course. As a course requirement, each week the students were required to read one chapter of the assigned text: Teaching with the Brain in Mind, Jensen (1998). For each chapter the students wrote formal critical reviews that were posted in the appropriate sections on the web. To complete the assignment, each student critiqued the review of one of his or her peers who was randomly assigned. This forum provided useful feedback to the individual whose work was being critiqued and at the same time provided an avenue for further learning to the person doing and receiving the critique.

Notice board

The notice board was a site for brainstorming and speculative thinking. At the beginning of the semester the notice board served the purpose for easy accessible instructor’s general notices and public communication. However, as the semester unfolded the notice board provided the forum for participants to verbalize their positions on specific ideas generated from reading, or other experiences such as observation and reactions to micro-teaching. Topics such as assessment, the nature of science and the level of science teaching in elementary schools became the focus of discussion on the notice boards. Responses in the form of feedback then provided the opportunities for elaboration or modification of views while interacting with the ideas of their peers. This provided the opportunities for the creation of shared beliefs and enabled much critical thinking.

Grade Book

The grade book provided easy access to feedback and grades. It included distribution of ratings from each peer review as well as all the related feedbacks from peer, instructor and self. These feedbacks occurred at two levels; providing private comments addressed to the individual and public comments that served to inform the work of the general class.

Conclusion

There is no doubt that the computer and the WWW have revolutionized much of our day to day actions and interactions. Harasim, (1990) and Linn, (1998) note that computer technology has introduced unprecedented options for teaching and knowledge building while expanding the opportunities for creating communities of learners. The possibilities now exist for learners outside of traditional classroom settings to become active, reflect on interesting issues raised during the development of a course of studies and then share with their peers in a non-threatening environment. Extending the traditional learning environment and the contact times, the CCL has moved the on-line capabilities offered in university classrooms beyond e-mail only communication. The challenge therefore, is for instructors to strive for more effective teaching strategies and instructional design in this new social context afforded by web technology.

Abstract: Internet-based, distance learning solutions may prove effective in facilitating advanced study coursework for remotely located, place-bound students. However, the conditions for promoting online learning success have not been entirely defined. We present as an example the teaching challenges and benefits of an online graduate-level Instructional Design course for in-service teachers taught through Western Governors University and Washington State University. This paper addresses some of the teaching challenges for this online instructional experience, focusing specifically on how teaching styles were used to build online learning community, to effectively promote productive and satisfying learning interactions, and develop student problem-solving and critical thinking abilities. Also discussed are those instructional design strategies that were repeatedly employed in multiple course sections to increase online student engagement, critical thinking, and enhance student learning. This paper should prove of interest to anyone currently developing or delivering online instruction.

Introduction

Online Learning Environments

Computer-mediated instructional environments, or online learning environments (OLEs), are networked learning tools that are finding increased use in institutions of higher education. Online learning environments provide an interaction space that allows students to actively engage in critical dialogue and reflect on information in a way that facilitates knowledge construction and higher order thinking (Jonassen, Carr, & Yueh, 1998). Effectively designed OLEs also provide a communal workspace for group and peer-based teaching and learning (Collis, Andermack, & van Diepen, 1996). By incorporating instructional methodologies that support higher order thinking, OLEs can provide an interaction space for increasing student metacognitive awareness, critical understanding rather than simple knowledge retention, and problem solving abilities (Hannafin, Hill, & Land, 1997). Online learning environments are seeing increased use in institutions of higher education that are feeling pressures for delivering educational materials to a wider student audience. Many colleges and universities are investing considerable time and money in distance delivery methods to meet the diverse needs of learners. In spite of the effort and resources being spent, we do not have a comprehensive understanding of what factors influence successful student learning in online domains (Brahler, N.S., & Johnson, 1999).

Online learning environments are thought to provide a venue for developing higher order thinking skills in college students (Ewing, Dowling, & Coutts, 1999; Jonassen, 1995a), and are widely assumed to have a positive impact on student higher order thinking and learning. However, opinions differ greatly on how to effectively implement online technologies into learning (Ewing et al., 1999). Technology-enhanced OLEs can potentially provide higher order thinking opportunities, but technology does not of itself cause the development of these advanced cognitive abilities (Jonassen, 1995a). Rather, a major determinant of higher order thinking skills development is the quality of discourse that occurs within well designed, properly structured OLEs (Oliver, Omari, & Herrington, 1998). Ideally, OLEs possess several characteristics: a means of accessing, generating, and sharing information; support learner articulation of knowledge and reflection on what they have learned; represent and simulate authentic, real-world problems and contexts; provide structure for student thinking; support critical discourse among learners within a learning community (Jonassen, 1995b); promote student control of learning decisions; and integrate multiple learning perspectives (Jonassen, 1993).
unrealized, as many instructors use online learning environments as simple knowledge repositories (Jacobson & Spiro, 1993). When properly structured and utilized to their potential, OLEs are capable of moving education from teacher-centered, lecture-based, passive instruction to learner-centered, self-reflective, active learning (Lan, 1999). Emphasizing this concept, Diaz and Cartnal (2000) state, “Because more online courses will invariably be offered in the future, some assurance must be provided to the college, the faculty, and the students that distance education will meet expectations for a good education. Not only will students expect an education that is equal in quality to that provided by traditional offerings, they will expect a student-centered learning environment, designed to meet their individual needs (Diaz & Cartnal, 2000). While considerable research has touted the purported benefits of OLEs (Collis & Smith, 1997; Goldberg & McKhann, 2000; Hiltz & Turoff, 1994; Jones, 1996; Koschmann, 1994; Scott et al., 1997); little work has been done specifically dealing with how instructional design and styles of teaching influence student higher order thinking in these environments.

Teaching Styles, Instructional Design, and Online Learning

Teaching styles, hypothetical constructs used to characterize the teacher-student interaction (Fischer & Fischer, 1979), are based on several criteria. An instructor's beliefs regarding teaching and learning, how these beliefs are translated into teaching practice within a learning environment (Fereshteh, 1996; Grasha, 1994), how instructors present information, interact with students, manage and supervise learning tasks, and mentor students (Fereshteh, 1996; Grasha, 1994) are all components of teaching style. Instructors' teaching styles vary considerably; unfortunately, not all variations effectively promote student learning. The question remains: which styles of teaching most effectively develop student higher order thinking skills in OLEs? Many instructors are under the impression that the same teaching styles and approaches used in their traditional classes will also work in an online classroom (Diaz & Cartnal, 2000). While it is unclear whether traditional classroom teaching styles can translate to online domains, instructors utilizing facilitative, guidance-based, interactive teaching styles more effectively create critical thinking opportunities for the majority of students (Kember & Gow, 1994). Students report greater learning satisfaction with facilitative styles of teaching as compared to traditional authoritative instruction (Friday, 1990). Concurrently, facilitative teaching approaches that promote problem solving and critical thinking can be uncomfortable for students, and may be in contrast to students' superficial approaches to learning (Andrews, 1996).

Collectively, these findings indicate that teachers that use facilitative, problem solving-based instructional approaches provide thinking challenges despite student discomfort with critical thinking.

Instructional design also plays a significant role in online learning success (Winfield, Mealy, & Scheibel, 1998). While technology can enable learning opportunities, it is teachers' careful planning and incorporation of instructional strategies that contribute to student interaction, growth, and learning (Kirby, 1999). In particular, instructional designs that incorporate student-centered learning approaches in online learning environments support student reasoning, problem solving, and higher order thinking (Land & Hannafin, 1997). Furthermore, the instructor's questioning skills significantly affect student critical thinking outcomes in college courses (Bonnstetter, 1988; Elder & Paul, 1997). By using systematic questioning techniques (Hannel & Hannel, 1998) and/or research-based questioning methods (Adams, 1993) in their teaching style and instructional design, teachers can enhance critical thinking skills in student learners (Adams, 1993; Hannel & Hannel, 1998).

Instructional strategies used to enhance student mental engagement and critical thinking include: not asking questions with known answers; waiting an appropriate length of time for students to think; increasing instructors' non-evaluative responses to students; and avoiding questions requiring a "yes" or "no" response (Bonnstetter, 1988). In addition to questioning techniques, the quality of the college student learning experience (i.e. critical thinking) is partially determined through other, less tangible, instructional design components like planned social interactions, alternative, non-lecture teaching formats, student learning choices that exploit personal interests and strengths, teaching approaches that provide real-world contexts for learning, and course material demonstrating the value of diverse cultures and perspectives (Stage, Muller, Kinzie, & Simmons, 1998).

The Study

The present work focused on the quality of student learning as a function of teaching style in an online learning environment hosted by Western Governor's University and Washington State University. Student participants, a collection of technology professionals for their respective K-12 school districts, were enrolled in a graduate level "Instructional Design and Performance Improvement" course as part of the Masters in Technology and Learning degree at Western Governor's University. For this content area, class size was strictly limited to 20 or
fewer students, based on recent suggested benchmarks for Internet-based distance education (Quality on the Line: Benchmarks for Success in Internet-based Distance Education, 2000).

The Instructional Design and Performance Improvement course was comprised of an informational website (http://education.wsu.edu/TL/522/) and the primary communicative tool for the course, an email listserv. The course website contained an outline of course requirements, student evaluation criteria and grading procedures, required and recommended texts, and instructions for completing the primary assignments for the course, three problem-based Instructional Design projects. In addition, several descriptive hints for project development were included. The three projects comprised the majority of the course grade (90%) with the remaining 10% for student participation in weekly online discussions. Also included on the course website were email hyperlinks for direct student access to the course instructors and coordinator, as well as instructions for subscribing to the email listserv. Students were assigned readings from the required textbooks, and the instructor posed weekly questions to the listserv so that all class members could potentially participate in any aspect of any posted discussion. Questions were structured and goal-oriented but open ended, and were designed to develop student research and evaluation skills that were necessary to successfully complete each of the three projects. An email listserv format was chosen as the discussion tool as it was anticipated that all students had ready access to email technology. Hardware and software requirements for full email functionality were minimal; using more sophisticated communication systems could have limited student access potentially. Students were required to post at least one well-developed, thoughtful answer to each weekly question as a criterion for student course performance.

The course design specifically emphasized problem-based learning by requiring students to develop three in-depth research projects that were distinct but built upon one another. The first project invited each student to evaluate and assess their specific, unique instructional environment by constructing a well-developed instructional technology assessment rubric, and to preliminarily identify a pressing instructional problem particular to their environment. The second project requested that each student describe in further detail his or her specific instructional problem, and provide supporting rationale with relevant literature. The primary goal of the second project was to research and develop a proof-of-concept model for pilot testing a potential solution to the identified instructional need, and to determine the instructional effectiveness of the proposed solution via educational testing. Finally, the third project bid each student to critically reflect how their instructional practice has changed, what aspects or models of the instructional design process were most useful to them, and how they planned to implement their solution in future instruction.

Methods

Research Question and Variables

In an attempt to identify and comprehend some of the important criteria for learning online success, our research question was: Does teaching style and instructional design affect the quality of student learning and satisfaction in online courses? For this study, our first independent variable was the instructor's teaching styles, which represented 1) instructional design content expertise, 2) provided learning structure and guidance, 3) provided a personal example for learning and instructional leadership, 4) guided, questioned, and facilitated student interaction, active learning, and critical thinking, and 5) cultivated student learning abilities so as to empower student learners to become independent, functional Instructional Designers. Our second independent variable was the course instructional design, which reflected the structure and purpose of inherent course activities. Our dependent variable was the overall quality of student learning in the online domain. Indicators of student learning quality included the frequency of interaction, the quality of weekly teacher-student and student-student discourse, the level of student writing confidence and development of content expertise, and the degree of reflection and revision indicated in student responses.

Learning Quality Assessment

The categories of the teaching styles independent variable were determined using a validated Teaching Styles Inventory (Grasha, 1996), whereas the student learning quality dependent variable was evaluated qualitatively (Guba & Lincoln, 1982) via weekly and semester observation. In addition, students evaluated various aspects of the course, the instructor, and their learning experience with a 140-item, validated survey questionnaire (Silhouette Flashlight). Specifically, the Flashlight survey asked students: 1) the degree to which course assignments were stimulating, challenging, and encouraged student creativity; how quickly students received feedback, and how effective the reflection and revision process was; 2) the instructor's teaching effectiveness with regards to the
teacher’s ability to build students’ confidence and promote student learning success; 3) how authentic the context and relevance to working environment was; 4) whether the instructor provided an informative, thorough evaluation of student thinking process and course performance specifically highlighting strong points and points for improvement; 5) the degree to which the instructor provided yes or no answers; 6) how well the instructor bolstered student learning confidence and stimulated excitement about course material and productive student interaction; and 7) whether students would recommend this general type of distance course, this particular course, and the course instructor to others. The survey also assessed student comfort with the course, specifically focusing on 1) student satisfaction with assignments; aspects of community building; 2) the level of thought put into responses; 3) whether students were likely to spend time on issues not related to course; 4) whether students were more likely to try and search for their own answers before approaching the instructor; 5) if they were better able to visualize course concepts; and 6) the effectiveness of the course structure and design.

Results

Below are the results of the Teaching Styles Inventory (Table 1), which was used to characterize the course instructor’s instructional approach, and a profile of interaction within the Instructional Design and Performance Improvement course.

Table 2: Instructor Interaction with Online Students over the Course Term

A collection of student quotes regarding the effectiveness of online instruction and utility of the online learning experience are as follows:

“Given the fact that the facilitation was on-line and we never talked face to face, I feel it covered all the needed areas and provided the feedback and information needed as well. Answers to questions were prompt and to the point. You gave useful feedback and insight into the instructional design field.”

“Overall this course has been a very good experience. I have learned a great deal. Thank-you for letting me make this course relevant to my day job. Being able to do that has been invaluable.”

“This was my first experience with a listproc, and it was very helpful to be able to read all the comments and submitted assignments. The weekly assignments did a great job guiding us into the different projects. I now feel I have a very good understanding of the instructional design process. The personal and professional growth attained through participating in this class has made me a better professional educator.”

BEST COPY AVAILABLE
"I did appreciate your comments, and took them to heart whether it was on a weekly question, or as part of evaluating my projects. Your sense of humor kept things in proportion, but still deadlines were deadlines, etc. I always want to know where the line is and with your reminders, there was never a doubt."

"[I] wanted to say that although I didn't think that operating through a listserv was the best way to take this class, I've changed my mind over the last month and a half... this class has been straight forward and I think that the listserv has actually drawn us into the class more effectively than using web boards."

Discussion and Conclusions

Online learning, for better or worse, appears to be an educational trend that will continue for some time as educational institutions look for innovative ways to provide a quality learning experience for their students (Brahler et al., 1999). This qualitative study provides some insight into the distance learning process, and identifies some factors that may partially determine learning success for students in online domains.

The results of this study suggest that specific teaching styles can be used to promote effective student learning in online learning environments. In this distance learning experience, Facilitator and Delegator teaching styles were used most by the instructor, and were characterized by such activities as problem-based project development, guided student exploration, online group discussion, self-discovery exercises, learning debates, case studies and independent, student-designed research, and using the instructor as an independent resource (Grasha, 1994). To a slightly lesser extent, the Personal Model style was used by the instructor to illustrate alternatives, demonstrate ways of thinking, outline the thought processes involved in research-based project development, and to share personal viewpoints (Grasha, 1994). Finally, both Expert and Formal Authority teaching styles were used to provide a modicum of content expertise; however, the primary instructional goal for this online course was to begin with graduate students with little or no research or instructional design experience, and guide them on a path of self-discovery to a point of autonomy and independence within the Instructional Design field. Accomplishing this goal meant that students needed to develop their own content to a large extent. Collectively this meant that the instructor had to nurture student confidence and guide student development of independent research and individual critical thinking skills; thus the high scores for Facilitator and Delegator teaching styles. In this case, Expert and Formal Authority styles were utilized to provide structure within the independent learning environment, and to emphasize the high performance standards set for the students.

For the graduate Instructional Design and Performance Improvement course offered through Western Governor's University and Washington State University, we found that interplay between the teacher's and students' personalities was essential to productive learning. These findings were consistent with previous research that states teachers' personalities must be built into online courses (Winfield et al., 1998). Initially, it was essential that the WGU instructor establish a level of trust, professional credibility, and community with the students. Since the students were unable to 'see' any physical expressions of the instructor, it was vital that the teacher's initial responses were confident and competent, and that students felt part of a larger community of learners. As teacher confidence and competence was conveyed, the students expressed more trust and confidence in learning from a teacher in an online context, and shared more personal information in initial community building exercises as a result. When one has a class of 20 students, small, collaborative subgroups may spontaneously form. This phenomenon was also observed in the online classroom. Much research has shown the benefits of small group collaborative learning in online environments (Collis et al., 1996; Hiltz, 1998; Newman, Johnson, Webb, & Cochrane, 1997); however, in this context, small online groups served the purpose of community cohesion rather than collaborative learning.

Despite the high demand for this course, the course coordinator strictly limited the number of students to 20, a number that ensured a reasonable teacher/student ratio and was consistent with professional recommendations (Quality on the Line: Benchmarks for Success in Internet-based Distance Education, 2000). In addition, it was important that student learning become the focus of the course, not the teacher. In this case, the simple technologies used for this course and the design of the instruction allowed the technology to blend into the background and become more transparent; as a result, the students spent more time engaged in rigorous discourse and developing research abilities and critical thinking skills. In this scenario, the technology was a convenient, effective means to an end.

An interesting observation from the WGU teaching experience was how student perception led to increased performance expectations. In traditional face-to-face classrooms, student work is generally not publicly displayed, and the instructor is many times limited to teaching to students with the worst performance to try and increase
average class performance. In the online classroom, students were encouraged to submit works in progress to the listserve as project development proceeded. This had the unexpected effect of increasing average class performance, presumably because less motivated students were exposed to high-quality projects and were prompted to increase their efforts by class overachievers. In this case, the instructor was not limited to teaching to the lowest performing students; instead students tried to emulate the project quality of the best students. It is unclear whether this shift in student perception would have occurred in a traditional classroom.

The Instructional Design and Performance Improvement course relied on an email listserve. This asynchronous method of communication allowed students to contemplate their submitted comments prior to submitting them for perusal by their class peers and the course instructor. Face-to-face interactions, such as those that occur in a traditional classroom, tend to be more spontaneous and unstructured. As a result of the asynchronous method, student responses in the online classroom tended to be more structured and well thought out.

In conclusion, we maintain it is the quality of human interaction that determines online learning success. We conclude that online instructors can use teaching styles to achieve instructional goals and provide rich, satisfying learning experiences for online students. The results of this study are intriguing; however, this study is not without limitations, and the conclusions drawn by the authors are speculative and preliminary. Only a small sample was used for this qualitative investigation, and as such there are limitations to how far these findings can be generalized. Additional studies in this area are necessary to more definitively support these conclusions.

The process of learning has been a source of amazement and fascination for centuries. Investigators have continually attempted to describe both animal and human learning in a wide variety of interactions and contexts. More recently, larger number of actual experiments has been conducted. It is perhaps ironic, given the sheer magnitude of the learning research that has been undertaken that we still do not know precisely how human beings learn.

Learning process has its own science at the level of professionals. New research and development has always been a key issue at all levels and at all geographic regions around the world. Teaching and training staff has been the backbone of the whole learning methodology, as to how disciplined training staff would be, and how effective the training would be. To improve the quality of training and its disciplines, an interesting training video has been developed and pictured. It is been presented in the form of a VCD, which also includes user-friendly software designed and developed for Faculty and Staff Development. This VCD is a helping tool for teachers and trainers involved in professional education and deals with students or trainees of competence-based vocational areas like computing, multimedia, CAD/CAM etc.

This training video is a helping tool to acquire qualifications in Teaching and Training, especially covering the course “International Diploma in Teaching and Training” by City and Guilds International (UK awarding body).

The video-training program has been categorized into five main stages and subsequently sub-stages:

a) Identify individual learning requirements
   • Identify individual learning needs
   • Identify suitable available learning opportunities

b) Plan and prepare learning sessions and materials
   • Prepare learning session plans
   • Select and prepare resources for a learning session

c) Deliver teaching and training sessions
   • Establish a positive learning environment
   • Make presentations to groups
   • Instruct learners
   • Promote group learning
d) Assessment, evaluation and review
   - Assess learner performance
   - Review progress with learners

e) Evaluate own performance and identify self development needs
   - Evaluate own performance
   - Identify self-development needs

As this video covers the Learning Cycle with 5 stages of learning and then 12 sub-stages; for each sub-stage a detailed learning session has been shown. Stages have been captured through role-plays, role-demos, different techniques used by trainers at each level and the moods and styles of trainers and its effect on the trainees. The video also includes trainer's body language and personality improvement techniques.

The other important part of this video CD is software designed by keeping in view the requirements of training staff. At each stage or sub-stage, the software helps to design and prepare slides, material, write-ups, records, data and other training updates.

In the help-line, this software has the provision to get connected via the Internet with the producers to get more assistance, updates or any trouble shooting.

Abstract: This paper is a preliminary report on a study of the use of a 3D virtual world designed to present a sequence independent distance learning environment. Students taking a class about the integration of computer technology into instruction were presented with a world that presented no prescribed sequence for exploring topics and no time schedule for completing various activities. The world was structured into “areas” that implied common topics and the students were asked to complete products that were identified with these “areas.” Students were asked to report on their experience, participate in surveys about the world and their experience, and interviews about their experience. The instructor was interviewed about his intent for each of the readings and activities and his perceptions of student participation and completion of products.

Introduction

Teacher schedules and commitments make it difficult for them to pursue long term learning environments that help them develop the skills and understandings necessary to exploit the use of technology in their own classes. Therefore, there is a need to understand the role various technologies and formats play in distance learning environments for training and supporting teachers in the field.

Many web-based distance learning environments use web pages to transmit information and assignments and use email, chat and threaded discussions to afford students with opportunities to interact with the instructor and with each other. These courses tend to follow traditional schedules for student activity. Students may work at different locations and at different times during the day or week but the overall expectation is that they work on the same content and activities during roughly the same time frame.

The World Wide Web has the potential to provide a completely time independent exploration of content. Courses that have sought to exploit this potential have taken on the characteristic of programmed learning in which the students follows a sequence of content presentations and assessments of understanding. There is usually no opportunity afforded for interaction with other students and, often, little opportunity for interaction with an instructor. The student may move through the course at his or her own pace but must follow the sequence provided and must do so with little or no interaction with another person.

Another feature of the World Wide Web is the freedom with which an individual may explore information. A person may make many choices on what to pursue and in what depth to pursue information in a given area. While this may seem antithetical to the notion of a course, whether delivered via the web or otherwise it does pose an interesting avenue to explore when considering using a web-base environment as the basis for distance learning.
Can a learning environment be developed in which a time independent exploration of content is afforded the student and in which the students have an opportunity to interact with the instructor and other students? Further, can this learning environment provide an opportunity for students to plot their own path through the content rather than following a rigid specified sequence?

The Virtual World

Appedtec, a 3D virtual world, was built in which physical representations of the students (avatars) moved through representations of physical objects. Students in Appedtec could see other students' avatars when they were in the world together and could chat with them. The physical objects represented varied from buildings to walkways to trees and lampposts to chess pieces on a chessboard. There were signs to provide help and to indicate activities that were to be completed. The signs and many of the other objects (chess pieces, lampposts, tables) were linked to web pages that provided directions, links to readings, and links to forms to be completed or to the threaded discussions. Appedtec could be accessed by any Windows computer with access to the Internet.

There were four areas in Appedtec that were part of the class in which the students were participating. Students entered into a main plaza. The side of the plaza they faced when entering this area had signs that provided directions and links to the threaded discussion areas. The other three sides of the plaza led to each of the other areas. One of these areas was a garden. In this garden the students were linked to readings and activities designed to help them focus on the role of computer technology in the learning setting. A second area was a chessboard with chess pieces on it. Each of the chess pieces linked to readings and activities designed to help the student explore the factors that influence the ability of teachers to integrate computer technology into instruction. And a third area was a building in which the students were linked to resources and activities designed to help them analyze their skills and knowledge related to the use of computers.

Students were asked to complete three products, in no particular order. One was a plan for integrating computers into an environment of their determination. Another was a statement of their concept of the role of the computer in learning settings. And another was an actual unit plan in which computer technology is an integral part of the learning activities. Students were informed that they could send their products in (as email attachments) at any time and that the instructor would provide feedback as many times as it was desired.

There were two chat times arranged for the whole class in which the nature of the products was discussed. The instructor also met with the class (face-to-face) periodically, to make sure everybody was comfortable with the experience, and was available via email at anytime and in Appedtec at prescribed times.

One assignment asked students to arrange a chat time with another student to discuss readings and to then post a set of conclusions. Other assignments asked students to contribute to threaded discussions. And some assignments asked the students to complete forms such as a self analysis of computer skills or perceptions of factors that influence computer integration. This experiment with Appedtec was conducted during the course of a regular semester rather than as an open entry completion experience.

Initial Results

At this writing not all surveys and interviews have been completed. Initial results indicate that there was early frustration with a class that did not impose a timeline (other than the fact of the end of a semester) or a clear starting place. However, this discomfort appeared to disappear with time spent in the Appedtec as students began establishing their own schedule for participation. Students initially expressing the most satisfaction were those who had the greatest distance to travel to get to a campus-based course. The degree to which students felt comfortable interacting with each other and with the instructor through the threaded discussion, chats, and other forms is still not clear. If such an environment is to be successful in bridging the opportunities to explore information in one's own time and order with the opportunities to interact with fellow explorers who may be working on a different timeline and sequence, then understanding the degree to which these tools functioned is vital.
Learn the principles of creating and administering Web-based tests and assessments using Question Mark™ Perception™ software. Find out how to use Perception's authoring wizard to create questions in a variety of formats: multiple choice, multiple response, hot spot, text, numeric, selection, and matrix questions as well as explanation screens that can include text, graphics, and multimedia. Participants will also learn how to create multiple question banks from which to assemble tests, surveys, and questionnaires. Other topics include how to set up interactive feedback, create adaptive tests, analyze test results, and create reports. Example questions will be presented from various applications including competency testing, employee recruitment, customer satisfaction questionnaires, study aids, diagnostic tests, skills assessments, product knowledge exams, course evaluations, and certifications. The presentation will cover such issues as test security, linking with learning management systems, and the use of Perception Secure Browser for high-stakes tests.
Edu-Effectiveness and Distance Education: How to Measure Success in the Online Classroom

Judith M. Smith, Ph.D.
Vice President, Instructional Development
CertiLearn, Inc.
Herndon, Virginia, USA
Jsmith@certilearn.com

Abstract: How we determine the quality of online education in the classroom is of primary concern for all institutions and organizations providing continuing education via new technologies. Recent statistics from the National Center for Educational Statistics reveals that enrollment in distance learning courses roughly doubled in two years from 754,000 to 1.6 million. With heightened enrollments come heightened expectations from adult learners that the quality of their online instruction will be (at minimum) equivalent to that which they can obtain in traditional learning environments. Despite the lack of national standards (at present) for delivering online educational courses, there are effective (and peer-reviewed) strategies that online faculty can use to measure and ensure an effective online classroom experience for the learner. This session will explain those strategies, and provide models for other faculty to use in their online classroom experiences.

Introduction

How we determine the quality of online learning, which translates into success in the online classroom is at the heart of this research report. As more individuals turn to online education as a means of maintaining continuing education requirements for certification, as well as look for convenience without the sacrifice of quality in learning, the standard for online education providers will become a significant goal to achieve and use in online course development.

This project proposes to use previous research which measured the impact of critical incidents in the online classroom as a standard for identifying barriers to excellence and effectiveness in the online classroom, and for use in creating models of online learning excellence for institutions.

The Study

For this research, we are choosing to focus on measuring effectiveness in the facilitated online classroom of adult learners who are taking courses offered by associations and professional membership groups online. The measure of effectiveness was further defined as determined by faculty members facilitating the course and by students taking the courses, as: having completed the course from start to finish; having felt as if new knowledge was gained, which would be advantageous professionally (student perspective); having felt as if the learning was immediately applicable to current professional work or professional growth (student perspective). (Note: The learners, in this instance, do not necessarily receive "grades" as in a traditional academic course. Many individuals, depending on the industry in which they work, are required to take continuing education courses to maintain professional certification, and these courses do not necessarily return "grades," but proof of attendance or a record of completion for the learner having finished the course.)

The actual measure of effectiveness is being determined by: course participant persistence; number of completed assignments by course participants; level and intensity of interactivity between course participants; level and intensity of interactivity between adult learners and faculty members; frequency and amount of feedback among course participants; frequency and amount of feedback between faculty
members and course participants; quality and quantity of written conversation among course members and faculty members; and, success in problem solving or resolution of course difficulties (if any) by course participants and faculty members.

Findings

At present, the findings are inconclusive, because the research is ongoing. However, a overview of current data on the associations reveals the main issues at the heart of determining effectiveness in an online course that includes association member-users tends to focus on consistency, quality, and reliability of regular communication, both in the online classroom and in using alternative communication tools when necessary.

Conclusions

While any conclusion is considered early at this stage of the research, it is hoped that the specific findings from this project result in the development of guidelines and an assessment tool for associations to use in creating viable online education opportunities for their members.

Abstract: Problem-solving instruction is a growing field within education. However, for distance education and other Web-mediated courses the traditional methods of assessment, namely multiple choice and short answer, are not sufficient. Although these formats can record final answers they cannot assess detailed aspects of the problem-solving process without becoming intrusive. A better assessment strategy is to use simulations and other highly interactive systems. Such tools can discreetly track student performance data without interfering with the problem-solving process. This paper will explore the use of interactive environments as an assessment technique of the problem-solving processes within Web-mediated courses and will focus on an example developed by the authors for use in an applied statistics course.

Introduction

An essential component of effective teaching is to constantly assess the level of understanding throughout instruction. Within a classroom the teacher performs this task by observing students' actions while asking questions and assigning tasks. The teacher can then adjust the flow and method of instruction to better meet the needs of students. To obtain an equivalent result, Web-mediated materials must provide similar data to either an instructor or to another computer system for the purpose of guiding the next level of instruction. Traditional multiple choice and short answer questions can assess final solutions but fall short in addressing problem-solving questions such as “At what step did this student get off track?” or “At which steps do large groups of students fail?” One possible solution would be to ask multiple choice and short answers questions throughout the problem-solving process. However, this solution has the potential of affecting a student’s actions by requiring him to mold his own solution path to one dictated by the assessment vehicle. This limitation makes this option an inferior choice. A better solution is to use highly interactive “sandbox” tools that allow a student to pursue his own problem-solving path. This solution contains a minimal amount of biasing information that would guide the learner in any particular direction. More importantly, such tools can record additional pieces of data necessary to properly evaluate problem-solving skills and to effectively prescribe remediation. Possible data to collect are the problem-solving steps taken, the order of those steps, the time required for each step, and the dead ends pursued and abandoned. All of this can be collected unobtrusively without affecting the students' actions.

Example

To accomplish these goals, we have developed several mathematical Java™ applets that provide the tools needed by a student to solve a wide range of problems within a “sandbox” environment. This paper considers a problem-solving exercise using a statistical applet to illustrate how how sequences of behavior can be captured through the applet and used to assess student problem-solving skills. Note: This example with the live applet is available at http://www.coe.tamu.edu/publications/strader/site2001/.
Problem. Consider the following scatter plot of data from ninety-two college students who were asked to report height, weight, and gender. When data from males and females are combined, the correlation between height and weight is 0.78. However, when you look at the data for males and females separately, the correlations are 0.60 and 0.49, respectively. Using the scatterplot below combined with your knowledge of how correlation coefficients describe relationships between variables, determine which of the points are "male" and which are "female." Note. The average height for males (20 to 29) is 68.8" (S.D. = 3.0") and the average height for females (20 to 29) is 64.6" (S.D. 2.5"). How would the correlation coefficients be interpreted? In general, what cautions must be must be exercised when interpreting correlation coefficients? Why?

This problem sits on a Web page with the live applet. Each student will attempt to solve this problem by designating each point as either "Male" or "Female" so as to achieve the specified correlations. The objective of this exercise is to assess a student's understanding of correlations and in the process inform the student about potential problems with interpreting correlation coefficients when groups are combined. By having students solve this problem using the applet, we can look for important patterns within student solution processes. Figure 2 shows a subset of the sequence of steps a student might take to solve this problem.

Figure 1: Scatter plot for combined sample

The sequence in Figure 2 shows a student designating points as "Male." In the first screen, the student replaces circles in the scatterplot with the box symbol designating male and returns a correlation of 0.91. This is too high so in the second screen you can see that the student has modified the point selection to reduce the correlation coefficient to 0.62. Having achieved the target coefficient for males, the student then designates the rest of the points as "female." Clearly, the problem has not been resolved as the coefficient for females is 0.81. Presumably, the student would continue to revise the point selection to come up with better overall designations. The question is whether the modifications are systematic and informed by his/her knowledge base or more randomly targeted at an end point. Whatever solution path a student follows, a real-time record is preserved. The sequence of modifications can be replayed and form a basis for student/instructor or instructor/class discussion. Interactions between student and instructor can take place either face-to-face or at a distance with no loss of information.
The Formative Evaluation of a Computer-Managed Instruction Module: Metric Instruction for Pre-Service Elementary Teachers

A.W. Strickland, College of Education, Idaho State University, USA. strialbe@isu.edu
John Springer, College of Education, Idaho State University, USA. jspringer@ida.net
Martin Horejsi, College of Education, Idaho State University, USA. martinh@isu.edu
Jane Strickland, College of Education, Idaho State University, USA. strijane@isu.edu

Abstract: A Computer-Managed Metric Instruction Program (CMIP) providing instructional units on basic metric concepts has been developed. A blending of Gagné, et al. (1992) and the developmental theories of Bruner (1966) provides the pedagogical basis for the instruction design. The instructional design model used to create each lesson utilizes a system of "branches" allowing a student who has difficulty with a specific lesson to be routed to appropriate remedial exercises. Each unit has a companion review module for students who obtain a score that meets the pre-test criterion for that particular unit. The pre-test for the area module consisted of 15 questions, three each on the following square unit segments: kilometer, meter, decimeter, centimeter, and millimeter. Results indicate that the use of concrete materials adds a learning dimension to those students who need a transition between the "hands-on" learning modality and the more abstract learning module presented in the CMIP.

Introduction

One of the new facets of the elementary science methods program at Idaho State University is the increase in the science and mathematics general education requirements. These additional science and mathematics requirements were spawned by a survey that indicated a serious deficiency in the science content knowledge of elementary school teachers (Strickland & Horejsi, 1999).

One alarming feature found in the analysis of the survey data was the apparent lack of knowledge and understanding of the metric system within teacher work samples. A parallel survey was conducted of pre-service elementary students and the results were similar: Lack of science content knowledge and, of particular interest for this research, a serious lack of knowledge of the metric system. Two decades ago, Strickland (1980) reported a similar lack of science and metric system knowledge among pre-service teachers at Indiana University.

The solution at Indiana University was a computer-managed program using the PLATO computer-learning system. After using PLATO for five weeks (i.e., five 3-hour sessions on the system), the metric performance among pre-service elementary teachers increased by 86%, and there was a corresponding change in science content knowledge and science teaching in the elementary school classroom. Apparently, as evidenced by the survey data referred to earlier (Strickland & Horejsi, 1999), the issue of science and metric illiteracy has resurfaced.

Idaho State University has embarked on a much larger research effort focusing on the design and development of a Computer-Managed Metric Instruction Program (CMIP). The CMIP software comprises instructional units providing basic metric concepts for each of the following measures: Length, area, volume, mass, force, and temperature. Uniquely, this instructional package consistently uses a pedagogical model based on the behaviorist views of Gagné (1962, 1968, 1970), and Gagné, Briggs, and Wager (1992). While each of these theorists offers the premise that correct sequencing of conceptual knowledge in conjunction with a mastery approach leads to meaningful learning by the student, the design team for CMIP felt the most effective sequencing model would be a blending of Gagné, et al. (1992) and the developmental theories of Bruner (1967).

Bruner (1967) stresses that the effective use of information is found only when the learner has successfully translated the information into a form the learner normally uses in problem solving. Without this translation, according to Bruner, "Though it is logically usable, it is psychologically useless" (p. 53). To this end Bruner has applied a multi-branching model to learning. This model is incorporated into the metric instructional units discussed in this research.
Additionally, Rodrigues (2000) highlighted several fundamental differences between behaviorist and constructivist views as they impact multimedia development. These views are expressed in the following excerpt:

Some of the strengths of behaviorist tutorials – for example, repeat practice, reinforcement, and control – are almost the opposite to goals advocated by constructivist philosophies (Heinich, 1984), where the notions of reflection, active construction, personal relevance, and autonomy (Lebow, 1993) are considered crucial constructivist learning facets. (p.1)

The instructional design model used to create each metric lesson utilizes a system of "branches" (as opposed to linear programmed learning). For example, a student who has difficulty with a specific lesson, or who shows deficiencies in command of a subject (identified by pretest results), can be routed to a review section or to remedial exercises, meanwhile all other students progress through increasingly more difficult exercises. Thus, the system is simultaneously a "Tutor, Tool and Tutee" (Taylor, 1980). As a result, this research concentrated on the design and development of the metric area module as the first module of the entire metric system course (and to act as a prototype for the remainder of the modules).

This selection, based on metric pretest data (see Table 1), indicated a serious deficiency among the students' ability to perform calculations in determining area (mean score = 4.620) and volume (mean score = 4.440).

Table 1: Metric Unit Pre-Test Data

Metric area was selected instead of metric volume since the skills and concepts needed for the volume module were subsumed by the area module. The wide variation (SD = 2.30) in score on the metric area was an additional rationale for selecting this module to be first.

Computer-Managed Metric Instruction Package (CMIP): Unit Design

The CMIP software package (Fig. 1), has four primary elements; (1) the introduction to metrics module, (2) the pretest and skill assessment module, (3) the metric instructional module, and (4) the posttest and analysis of results module.

The introduction to metrics module is composed of an overview of the CMIP metric instruction. The student is guided through an array of examples which depict the metric system being used to measure length, area, volume, mass, force, and temperature.

The pretest and skill assessment module is designed to access the students preknowledge of the metric system, rudimentary mathematics skills and selected learner aptitudes.
Figure 1: Computer-Managed Metric Instruction Package (CMIP) flow chart outlining the elements of the metric instruction. If the student does not meet acceptable level of performance they are returned to the first unit that was below the acceptable level.

The metric instructional module consists of six metric instructional units (Fig. 2): Length, area, volume, mass, force, and temperature. Each unit describes the basic unit of measurement and explores units, which are smaller and larger than the base units.
Figure 2: Expanded flow chart of the Metric Instructional Module of CMIP. The Metric Instruction Module uses data from the pre-test module to determine the appropriate lessons for the student.

The posttest and analysis of results module is designed to measure the performance level of each student. If the performance level is acceptable then the student passes the metric course, if weakness (low performance) exists in any unit the student is guided back through that unit until an acceptable performance level is reached.
Formative Evaluation of the Metric Area Module

The metric area unit consisted of four segments (Fig. 3): (1) An introduction to the module, (2) the base unit module (square meters), (3) three modules with measurements smaller than the base unit (square decimeters, square centimeters, and square millimeters), and (4) one module with measurements larger than the base unit (square kilometers).

Figure 3: Metric Area Unit flow chart. After a brief introduction (2.1) the unit begins with the base unit of area and ends in a review and post-test (2.2) of the area unit.
The pre-test data for the metric area module consisted of 15 questions, 3 each on the following square unit segments: Kilometer, meter, decimeter, centimeter, and millimeter. The mean of the square kilometer was lowest (X = .20, SD = .09; out of 3); thus, this module was selected to be the initial module segment to be tested. The square kilometer segment (Fig. 2) consisted of several large regular shaped objects (scaled to fit on a standard monitor), such as New York’s Central Park. Central Park is rectangular in shape and made a good first example of the area calculations for large objects. After several similar examples, the instruction moved forward to irregular shaped large objects, such as a large reservoir in the geographical area. A scaled one-square kilometer area was used with the technique of summing whole and partial grid squares. The instruction produced a significant change in the performance on the module segment (X = 1.35, SD = .57; out of 3).

Summary

The analysis of the data collected during pilot test of the Metric Area module: Square Kilometer segment was critical in determining alterations needed to this module segment and additional components. This data analysis has shaped the instructional process for each of the remaining modules. While observing the students participating in the computer-managed module segment on square kilometers, it became apparent that each module must be constructed with some use of a manipulative, as well as the computer software. Apparently, the use of concrete materials adds a learning dimension to those students who need a transition between the “hands-on” learning modality and the more abstract learning module presented in the computer software.

Online Teaching Tools:
Early Results of a Survey of Online Instructors

Dr. Lucio Teles

itzoneva@sfu.ca

Abstract: As online learning becomes increasingly common and an integral part of our educational system, it is important to investigate how instructors and students teach and learn in the online classroom. This paper presents preliminary results from a research in progress which studies the use of instructional tools by online instructors. We are collecting data on the most used tools, the tasks they accomplish, and on the impact of their use as reported by instructors. The research focus is on instructor tasks which are facilitated by online tools, whether the use of these tools increases or decreases instructors' workload, according to their own perceptions, and how online instructors value the use of tools for online teaching.

Introduction

The face-to-face classroom has been the vehicle for imparting instruction to learners for the last four hundred years. Instructors teaching in the classroom have used various traditional tools to support their teaching activities: the blackboard, the chalk, print material, media material for class presentations, classroom attendance list, and many other tools which have become essential components of classroom teaching (Ong, 1982). More recently, with the advent of the World Wide Web (Web) and the online classroom, instructors are also beginning to use tools to support online teaching (Harasim, 1999; Bonk, 1999; Teles, Ashton, & Roberts, 2000). Developers of these tools claim they help instructors in the task of online teaching.

While tools are used in both the face-to-face and the online classroom, the nature and function of these tools vary from a face-to-face to an online mode of teaching. Face-to-face and online teaching have similarities but have also their own specific attributes as learning environments. Berge (1998) developed a framework that captures the specificity of instructor's tasks in online environments. He identified four roles for the online instructor: pedagogical, managerial, social, and technical. Some of these roles may have a direct impact on online teaching, and others may be presented as supportive to teaching, such as the social role (Wegerif, 1998). These four roles and the teaching tasks associated with them can be supported by tools such as the online gradebook, usage statistics on student participation in the online classroom, automatic reminders for due assignments, chat for online office hours, etc.

Some instructors state that online tools help them to teach online and facilitate classroom management while others may argue that these tools are not very useful and also they add more workload to instructors. While the use of Web tools is on the increase with online educational services and portals offering various instructor tools, it is not yet known whether these tools are being used by instructors, which teaching tasks are supported by them, and whether they help online teaching.

This paper discusses the use of tools to support online instructors. We are investigating the use of tools that facilitate the process of online teaching: online grade books and evaluation, online classroom attendance, information-sharing capabilities, creation/management of group work, assessment, interaction with instructor, etc. While there are advanced systems for student record management, to generate statistics about students, and to keep track of payments and related administrative information, these tools are not of direct interest to our research.
For the purposes of this research study an online instructional tool is defined as a software that supports the instructor of the virtual classroom in his or her online teaching tasks and activities. We are mainly interested in tools currently being used by online instructors such as ICQ (for office hours communication), usage statistics generator for class attendance (hours spent in the different areas of the online classroom, number of messages read and written), gradebook, and other related teaching tools.

Related Literature

A review of the literature on the use of tools to support the online instructor was conducted. This was done through library research restricted in most cases to the years 1997-2000 and using the Eric database, (filtered through the Information Technology Clearing House), and Web online research, using primarily the Google.com search engine. The key words used for the search were: Instructional Technology, Online tools, Faculty Development and Online Learning, Evaluation of Instructional Technology, Tools for Interactive Course Delivery; Technology and Instructors, Computer Mediated Learning. The online search yielded the most current and relevant information, and provided links throughout the academic network which pointed to known, reputable sites and scholarly research in this area.

Information technology for teaching and learning is now being widely used in education, including tools by online instructors (Frayer, 1999; Fletcher, 1998; Heinich, Molenda, Russell, Smaldino, 1999; Lee, Groves, Stephens, Armitage 1999). Although there are some studies in evaluating and comparing online software tools, (FutureU, 2000; Marshall University 1999; University of Canberra, 1999; Douglas College, 1999 and University of Manitoba, 1999; University of British Columbia; University of Alberta; University of Toronto, etc.) there appears to be little research available on how the tools have impacted instructor’s teaching activities.

Furthermore, there is not much evidence in the research literature of online tools being evaluated for their pedagogical benefits. The need very often expressed by educators, is that the online environment allows for more flexible teaching and access to resources and peers, promote collaborative student-centered learning and generally be more educationally effective (Britan, & Liber, 1999), and online tools support instructors tasks in these online environments.

In one of the few studies on the use of online tools, instructors from the Brigham Young University were surveyed on their reactions to an online course management tool used at the university (DLE, 1999). The findings show that in spite of a widespread acceptance of the potential of online teaching there is a fear by many instructors as to how they will make the transition to online teaching with the limited resources of time and money currently available. Findings also showed that instructors value tools as long as they help them to execute tasks and to save time. Tools have to facilitate the work of teaching and information-sharing, should take little time to learn, are easy to use, and have adequate university support structure in place.

There are many Web tools to support online teaching tasks, for managerial, pedagogical, social, and technical tasks. These tools offer features that supposedly make them valuable to instructors, such as:

- provide asynchronous and synchronous communication between students and instructors, and groups of students;
- allow instructors to gather data, (usage statistics tools) manage assignments, or test students via the Web;
- offer the opportunity for chats in real-time, (Olmstead, & Kontos, 1997) and
- allow instructors to continuously follow students’ progress.

Method

The study involved online instructors from different educational institutions. Our approach consisted of: (1) review the literature in the field; (2) questionnaire with selected online instructors; (3) follow-up in-depth interviews with a group of online instructors who had previously responded to the questionnaire, (4) validation of findings by a group of expert online instructors and academics.

Participants

The survey started in November 2000 and it is expected to run to February 2001. The participants include online instructors teaching online or mixed mode from Canada, the United States, Mexico, the Netherlands, Greece, Colombia, and South Africa. Formal consent was obtained from all the instructors who participated in the study.
Procedure

The online instructors were chosen from Canada and other countries. The primary source were the scholars from the TeleLearning Network of Centres of Excellence, in Canada. However, we decided not to limit ourselves to Canada and tried to reach other online instructors through different ways including listservs, newsgroups, and our Web page. The survey began by contacting potential participants by e-mail or letters to find out whether they would like to participate. The next step was to complete our questionnaire. The questions sought some background information but were primary looking for answers for our research questions: (1) Which are the tools most commonly used by online instructors to support their online teaching activities; (2) Does the use of tools increase or decrease instructor's workload, according to his/hers perception; (3) How do online instructors value the use of tools for online teaching. The next step will be a follow-up in-depth interview with selected participants to help us expand findings and areas where more information is needed. The last step will be validation of findings with the help of academics considered experts in the field.

Early Results

Early results of the study provide information about online instructional tools and how they are used by the online instructors. The preliminary results from ten questionnaire responses are reported here. The respondents are from Canada, the USA, Colombia, and Greece. The information we are investigating is: the correlation between the teaching mode and the amount of used tools; the use of online teaching tools and the desire for newly developed tools; the tools that are found to be very and somewhat helpful, and the most beneficial tools. We found that the distribution of courses taught entirely online to mixed mode was half and half. All of the instructors stated that they find the use of online tools helpful. Here are some of the comments they made: "Much functionality is not even used"; "The variety of tools certainly helps with the effective delivery of the course"; "The communication between the students and me has improved a lot"; "The question is what can you do with the tools to provide a better learning for the students."

Asked whether the expectations about the amount of online tools needed to teach online had changed after they used these tools, we found that all of them would like to have more Web-based tools to support their teaching.

The instructors also stated that the following new tools are needed: instructional design tools, role-play tools, debate tools, brainstorming tools, videoconferencing tools, conferencing with wireless application protocol (WAP), streaming video tools, dynamic learning environment tools. The tools found to be the most beneficial are: e-mail, student tracking, sharing information tools, bulletin boards, conferencing tools. The advantages found in the use of online instructional tools include: learning process enhancement, different sets of learning opportunities in the classroom, place independence, providing structure and unity to the course, offering effective course delivery and flexibility, supporting time management. The disadvantages mentioned are relatively less compared to the advantages and they consisted of: difficulty when securing information, rigid structure, and technological glitches. The following table represents the ratings of how the online instructional tools facilitate and support the instructor.

Discussion and Conclusions

The results of this early survey show that online tools support and impact instructors teaching in different ways. Results also indicate there is a need for the development of new software tools and show as well that existing tools are being incorporated into the process of process of online teaching. While online tools in many cases are found to be supportive to the task of online teaching, technical problems associated with their use often disrupt online teaching.

Further data collection from this study in the next three months may add new information and may also extend and expand early findings of this survey. This preliminary study also points to new research directions needed to be conducted on the use of online tools to support online teaching, particularly in regards to which teaching tasks are supported by these tools, how they support the instructional method and the pedagogy of instructors, and what they offer regarding the assessment and evaluation of online students.

### Web Sites Containing Evaluation Results of Online Teaching Tools

Several comparisons of course management tools have been published on the Web, as a resource for others. They provide a good starting point for selecting software for further consideration.

**Douglas College, New Westminster, British Columbia, 1999.** Available online: <http://www.ctt.bc.ca/landonline/>, retrieved June 21, 2000. This site is a collaborative effort of the British Columbia Standing Committee On Educational Technology, the Centre for Curriculum, Transfer and Technology and the Office of Learning Technologies. The site is managed by Dr. Bruce Landon and helps evaluate software for educators.

**FutureU, 2000.** [Available online: <http://www.virtualu.com>, retrieved Nov. 22, 2000]. FutureU did a comprehensive evaluation of six leading course management software packages to help academic institutions make informed decisions when they purchase or upgrade CMS products and to help developers make informed decisions when they plan for development or marketing.

**Western Washington University, Center for Instructional Innovation.** [Available online: <http://pandora.cii.wwu.edu/showcase>, retrieved Nov. 22, 2000]. Western Washington offers an excellent showcase of two online courses with details of what software they chose, how they implemented and how it contributed to a rich learning experience for students and instructors.

**Marshall University, 1999.** [Available online: <http://multimedia.marshall.edu/cit/webct/compare/comparation.html#instructor>, retrieved June 14, 2000]. This comparison provides reviews on the existing online course delivery software products categorized by developmental features, instructor features, instructional features, student tools, technical support, administrator tools, administrative features, software and hardware costs.

**University of Canberra, 1999.** [Available online at: <http://www2.canberra.edu.au/cc/flex/webct_report.html>, retrieved May 31, 2000]. Evaluation of WebCT was conducted with the notion to be used as a standard, supported university-wide online management system.

**University of Manitoba, 1999.** [Available online: <http://www.umanitoba.ca/ip/tools/courseware/evalmain.html>, retrieved June 14, 2000]. This site provides information on tools for developing interactive academic web courses and online educational delivery applications.

**TeleLearning Project 7.8: Research Spotlight on National Networks for Learning.** [Available online: <http://www.telelearn.ca/g_access/advances/spotlight.html>, retrieved June 1, 2000]. Wudeman, Owston and Shapson are conducting case studies at York University involved with Writers in Electronic Residence (WIER) and Satellite Networked Schools. Their project investigates how network innovations are implemented in the everyday practices of the teachers and the students.

**WestEd.** [Available online: <http://www.wested.org>, retrieved June 1, 2000]. One of the current projects of WestEd Technology in Education program is the Distance Learning Resource Network. It provides information for the constantly growing number of educational institutions that use distance learning and for the software developers who service the educational institutions.

### Recently Developed Online Instructional Tools to Support Online Teaching

Convene.com is a recently developed e-learning platform with built-in instructors and trainers tools. It offers the possibility of creating a customized Home Page which serves as an interface with links to personal e-mail, course materials and Web resources (school and personal related). The currently available tools for the instructors are not significantly different from
already existing ones with the difference for posting multimedia files, recorded presentations and video messages <http://www.convene.com>.

Jenzabar.com is a provider of integrated administrative software, Internet infrastructure, and services devoted exclusively to higher education. Jenzabar.com provides its Web-based Intranet application to educational institutions. The highlights include: communication, learning, organizational, and fun tools. The most valuable tools for the instructors would be: the syllabus posting with the daily remainder for the students, the calendar which automatically includes course schedule and the option to participate in a community with people with similar interests <http://www.jenzabar.com>.

MetaCollege.com provides Web-based tools that allow educators to easily develop, distribute, and archive instructional material online to supplement their classroom teaching methods, deliver distance-education courses, or build collaborative online communities. The tools are divided into two large groups: course and community tools <http://www.metacollege.com>.

Information in Place, Inc. (IIP) is dedicated to helping organizations, enterprises, and individuals create and deliver Internet-based information and services. IIP offers infrastructure software for mobile and wireless devices and customizable solutions. The company is currently developing a product called Your Information in Place Intellilink, Yiipi. It will be a browser and service system allowing anyone to create and view location-based information that can be authored and viewed by anyone <http://informationinplace.com>.

Plagiarism.org provides the online instructors and trainers with a document source analysis tools to detect plagiarism. The instructor is responsible for registering the class he/she is teaching and afterwards all the papers are submitted to a web site for plagiarism checking <http://www.plagiarism.org>.

The product developed by ThoughtShare Communications Inc. - PlanBee allows the user to map his/her web journey and save all the relevant Web addresses. It allows for filtering and extracting of information, adding personal comments, attachments. In the end the compiled information could be shared and e-mailed as a knowledge packet <http://www.thoughtshare.com>.

The product Hot Potatoes is developed at University of Victoria, Canada. It enables the instructor to create interactive multiple-choice, short-answer, jumbled-sentence, crossword, matching/ordering and gap-fill exercises for the World Wide Web <http://castle.uvic.ca/hrd/halfbaked/>.

Creative Technology produces three groups of software: teaching and learning software, and development tools. Markin is an annotation program for online and electronic teaching environments. It replaces the traditional red pen with an on-screen marking tool. PlanBee allows the instructors to produce on-screen learning exercises which could be delivered to the students as interactive Web pages. Choices is a multiple-choice quiz program. The tests are completed by the student in a password-protected environment. Word-Processor Annotation Buttons are templates containing customized button sectors for annotating sections of a document <http://www.cict.co.uk/software/>.

Inxight Software, Inc., provider of information access and content analysis software solutions, has developed tools which could be useful for the online facilitator. Summary Server extracts summaries from almost any electronic document. Thing Finder™ Server is a text analysis application that automatically identifies, tags and indexes key content—allowing end users to easily browse large amounts of unstructured text. Murax is designed to analyze relationships between concepts whilst users simultaneously could search and browse <http://www.inxight.com>.

Acknowledgments

This project was funded by TeleLearning Centres of Excellence. We would like to thank all the online instructors who participated for their collaboration and assistance on this research project.
A Model to Design Technology Teacher Training Program

Abstract: Teacher training is one of the most important factors that determines teachers' use of educational computing in classroom. On average, five to seven years of training is necessary for a teacher to become a confident user of educational technology (Hardy, 98). However, most teachers do not have enough computer skills (Dupagne, 92) and feel they have not taken adequate training to integrate computer in their classroom. The purpose of this paper is to describe a teacher technology-training model for a private high school in Turkey that incorporates the notion of instructional design and systems thinking. The training model is structured around the generic ADDIE model, which is Analyze, Design, Development, Implementation and Evaluation. However, the model provided in this paper is situation-specific and has additional elements to satisfy the need for in-service technology teacher training.

SETTING: ORGANIZATIONAL CHARACTERISTICS

The school for which the technology-training program will be designed is a private non-profit high school in Turkey. The goal of the school is to provide formal high school education and prepare its students for nationwide standardized university entrance exams. The school has 25 successful experienced teachers with approximately 300 students.

Due to the rapid diffusion of instructional technology in education, the high school management has decided to adapt computer technology in the classroom. Even though the school has an in-service teacher-training program with a little emphasis on computer technology, there is no well-designed and specific technology training model and program for its teachers. The purpose of this paper is to create a new teacher training design model to replace with the present one. This model will assist the in-service trainers in the school to form a new training to help teachers become familiar with computer technology and integrate it into their classroom instructions. For example, if a teacher teaches mathematics, he/she will be trained on how to teach mathematics with the support of computers.

PROBLEM ANALYSIS: GAPS IN THE PRESENT TRAINING PROCESS

Because of the nonsystematic procedure the school in-service trainers employ, there are numerous deficits with the current training programs indicated below:

♦ Needs assessment is not conducted to determine the minor and major gaps in teachers' technology use in the classroom.
♦ There is no job analysis conducted as to how teachers can integrate technology in the instruction successfully.
There are no established performance objectives and performance measurements pertaining to successful technology integration.

There are no defined rules specifying how to deliver the training efficiently.

There are no standards for creating training materials.

There is no quality control of training process and materials.

There is no formative evaluation process.

THE RECOMMENDED TRAINING DESIGN MODEL

The recommended model is very similar to the general instructional design process, in which planning, design, production, and implementation are the main steps (Flagg, 1990). However, to make it efficient, three categories were added to it and the sub-categories were elaborated.

The New Model
Pre-design → Needs analysis → Job/Task analysis → Design → Development → Pilot test → Evaluation

1.) Pre-Design
Establish a design team (at least one instructional designer and one Subject Matter Experts (SME) from every teaching branch, such as computer-based math instruction, computer-based science instruction etc.)

2.) Needs Analysis/Assessment
2.1. Establish the objectives of needs assessment for technology teacher training
2.2. Determine target teachers to be trained
2.3. Determine data collection techniques for the needs assessment
2.4. Determine data collection procedure
2.5. Determine data analysis methods
2.6. Evaluate previous steps
2.7. Conduct needs analysis
2.8. Determine if there are discrepancies between required performance and actual on the job-performance in teachers’ technology integration
2.9. Analyze performance problems
2.10. List evidences of the problems causing low performance in teachers’ technology adaptation
2.11. Speculate on what would be the most important problem causing the insufficient integration
2.12. Evaluate the previous steps
2.13. Determine the training solution and non-training solution to help teachers use the technology successfully in the classroom

3.) Job/Tasks Analysis
3.1. Indicate desired results from job analysis
3.2. Decide how results will be used
3.3. Conduct the data collection
3.4. Identify job requirements for teachers to successfully integrate the technology in the curriculum
3.5. Divide the job into functions, duties, and tasks
3.6. Identify entry level behaviors, attitudes and skills to successfully integrate the technology in the curriculum
3.7. Identify the minimum acceptable criteria for each task
3.8. Evaluation

4.) Design
4.1. Write technology-training objectives
4.2. Sequence the objectives
4.3. Identify the content sources
4.4. Write course title
4.5. Make course map
4.6. Sequence learning activities
4.7. Determine level of training
4.8. Choose instructional strategies
4.9. Determine instructional tactics
4.10. Prepare training material specifications
4.11. Recommend delivery method
4.12. Make delivery schedule for training
4.13. Match performance, conditions, and criteria specified in the terminal objectives and each of the learning objectives.
4.14. Develop test
4.15. Evaluate

5.) Development
5.1. Conduct research pertaining to existing materials
5.2. If there are existing materials, evaluate, arrange and modify existing materials
5.3. If there are no existing materials, write new instructional and administrative materials
5.4. Produce necessary media
5.5. Evaluate

6.) Pilot test
6.1. Select a representative sample from the teacher population
6.2. Create a realistic pilot test environment
6.3. Conduct the pilot test
6.4. Monitor the pilot session
6.5. Get feedback
6.6. Conduct debriefing session
6.7. Document result of pilot test
6.8. Make necessary modifications with instructional materials
6.9. Evaluate instructional materials for specific teaching/learning situations
6.10. Have all materials ready to distribute

7.) Evaluation
7.1. Select evaluation team
7.2. Determine purpose, objectives, audience, and subjects
7.3. Assess information needs
7.4. Create evaluation materials
7.5. Consider proper protocol
7.6. Conduct the evaluation plan

PRE-DESIGN

Pre-design is the first step in which the necessary personnel are identified to create the training program. Usually instructional designer(s) and subject matter experts (SMEs) are the key people who create the training. The SMEs should be individuals who have significant experience in teaching with the technology in different subject areas, such as math, science, literature etc. After the personnel are identified a project-planning meeting is held, and an action schedule, cost of the training and other relevant matters are determined.

NEEDS ANALYSIS

The second step, needs analysis, helps the instructional design team compare the current teachers' technology integration level and the expected level in the school in order to identify the teachers' performance gap. The purpose of needs assessment is to uncover (more precisely than performance analysis does) what the performance problems are, who they affect, how they affect them, and what results are to be achieved by training. Needs assessment is very important because all subsequent steps in the ISD model depend on its results. A needs assessment identifies gaps in results, places them in an order of priority, and
selects the most important for closure or reduction. To develop a needs assessment plan, instructional designers should first clarify why they are doing the assessment. (Rothwell & Kazans, 1998)

**JOB/TASKS ANALYSIS**

The job/task analysis is conducted to identify the functions, tasks, and skills necessary to accomplish the job, namely, successful technology integration in the classroom. Job analysis determines what teachers actually do to employ computers and identify the job norms. A task analysis is carried out to determine components of job performance, identify activities that may be simplified or otherwise improved, determine precisely what a teacher must know, do, or feel to learn a specific job activity, clarify conditions, equipment and other resources needed for competent performance, and establish minimum standards for how well job incumbents should perform each task appearing in their job descriptions. Like a blueprint, data collection tools and evaluation of data are planned prior to conducting the analysis. After the data collection, the results are illustrated in a comprehensive manner. The preferred way to exhibit the job/task analysis results is tabular form. The table should show the job title and functions, duties, and tasks associated with the job. In addition to the table, the knowledge, the skills, the attitudes and the entry-level behaviors should also be reported.

The table and the report should be used to identify the training specifications. Our main purpose is to carefully inspect the table and find out the problems associated with the job's functions, duties, tasks, skills, knowledge etc. Then, according to the findings, the training programs are designed or several non-instructional solutions are identified, such as job aids to cover those problems.

**DESIGN**

The design step includes creating the training plan. Similar to a regular course plan, the design process includes writing and sequencing the objectives, targeting the problems, creating a course content including the information to recover the performance deficits caused by the problems, considering the learning strategies and tactics for the effective learning, creating the instructional materials and delivery platforms to facilitate the delivery while creating the evaluation tool to measure the performance at the end of the training. Some criteria for the good designs would be as include: 1) training units in a harmony with objectives and content areas, 2) objectives associated with the duties and tasks, 3) instructional strategies, tactics, and activities consistent with the learner group, the content, the performance level and so on. The objectives should clarify in measurable terms what trainees should be able to do at the conclusion of the training, how well they should be able to do it and what conditions have to exist or equipment has to be available for them to exhibit the performance.

Performance objectives should contain at least two components of performance, criterion, and condition. The resulting sequence of objectives becomes the basis for an instructional outline. It is a blue print for choosing an instructional strategy and selecting, modifying or preparing instructional materials. Rules for sequencing instruction provide guidance for instructional design.

An instructional strategy is a plan for systematically exposing learners to experience that will help them acquire verbal information, establish cognitive strategy or develop intellectual skills, motor skills, or new attitudes. An instructional tactic is any instructional activity undertaken to facilitate a strategy. No, one instructional strategy works uniformly well under all conditions. To choose the appropriate strategy, consider the learners, the desired learning outcomes, the learning and working environments, and constraints on the instructional design process (Rothwell & Kazans, 1998).

Evaluation is one of the most important items in this step, because according to its results we will justify if the trainees gain the required skills, knowledge and performance levels. The proposed evaluation strategy is pre-test and posttest process. The pretest determines the trainees' knowledge before they engage in planned experiences. By the end of the planned training experience, posttest determines how well learners have achieved the terminal performance objectives (Rothwell & Kazans, 1998).

**DEVELOPMENT**

In this step the actual teaching and learning materials, such as teacher manuals, study materials, slides, computer presentation, etc., are created as specified in the design documents. The key persons are the subject matter experts and the developers. Before producing the course materials, due to cost
Effectiveness issue, research is conducted to find out if there are any ready-made materials that are compatible with the required specifications. If some existing materials are found, several modifications are performed to make them more appropriate for training purposes. If no materials are found, new materials and media will be produced. This includes storyboarding, outlining, proceeding through writing and editing, and developing visuals, tapes and other computer related media.

While using appropriate existing instructional materials, it may be necessary to organize or modify the materials in ways appropriate to satisfy the objectives. Based on the instructional strategy and media that were selected earlier, detailed outline will help summarize the content of planned learning experience or series of related learning experience. Storyboard will also be created for a visual representation, which illustrates the text, graphics, and interactivity that will appear in the training program (Rothwell & Kazans, 1998).

PILOT TEST

The pilot test aims to assure the quality of the training materials in terms of teaching and learning. According to the results of the pilot test, several revisions, if necessary, are made to improve the materials. During the pilot test, a representative sample from the target population is selected and like a real-life training environment is created. Then the test is conducted, data is collected on students' performance and attitudes, the results are discussed and evaluated, and the final modifications are made in the materials. The pilot test will capture participants' reactions to instructional materials in a setting similar to that in which the instruction will be delivered. It gives instructional designers valuable information about the effectiveness of the instructional materials by the information collected from the target trainees group (Rothwell & Kazans, 1998).

FORMATIVE EVALUATION

Formative evaluation is concerned with the quality of the instructional design process rather than effectiveness of the training materials. The plot test's scope is the quality assurance of the materials that will be used during the training. Prior to general use, instructional materials and methods should be evaluated and revised to increase their instructional effectiveness. This helps to minimize learner confusion (Rothwell & Kazans, 1998). It is advised that formative evaluation be conducted by a different team including subject matter experts and an evaluation expert or instructional designer. The formative evaluation is conducted and a suggestion report is written. The suggestion report will contain information including any necessary modifications with the segments of the ID process. As specified in the report, necessary changes are performed in the design process.

STAFFING

To conduct the instructional design process, several specialists are needed, such as instructional designer, evaluation specialist, subject matter experts, etc.

Instructional designer: Instructional designer is the manager of the process and responsible for hiring new staff, controlling the work process and writing scheduled reports to the principle of the school. Evaluation specialist is responsible for the formative evaluation conducted in the every step and in the plot test. If an evaluation specialist is not found, ideally another instructional designer can be hired for the evaluation task. Two sets of subject matter experts will be considered. The first group expert is responsible for the designing the training materials under the control of the instructional designer. Also, they are going to be involved in the production process to control the quality of media in terms of the materials' teaching capabilities. The second group of subject matter experts is responsible for conducting and evaluating the plot test with the evaluation specialist. Media developers are responsible for the material production. They work with the instructional designer and the subject matter experts. Moreover, it is possible to make an agreement with a media development company. Therefore, instead of hiring media developers, making an agreement with outside subcontractor is also a possibility.

JUSTIFICATION OF THE NEW MODEL
The main purpose is to create a teacher technology-training model that incorporates the notion of instructional design and systems thinking for the new teacher candidates as well as the experienced teachers who will integrate computer technology into their instructions. Before composing the model, many instructional design processes were reviewed. The appropriate models for training design were selected and reviewed. All steps and sub-steps were rearranged.

CONCLUSION

Our purpose is to create a technology training model and program for the high school teachers in the school in Turkey. The general instructional design model was not appropriate for this purpose because it has limitations with its four steps, which are planning, design, production, and implementation. We elaborated on this process and added three steps. The three steps emphasize team building, training (product) evaluation and process evaluation. Additionally, we elaborated on the sub-steps under the main seven steps to make the new model more systematic, clearer and effective to use.

In the new model, evaluation is divided into two different phases. Pilot training and formative evaluation activities are given more emphasis. Pilot training is concerned with the quality of training. It evaluates how well and accurately the training is created in terms of media and subject area information, how effectively it teaches, what impact it leaves on the trainees. Formative evaluation is concerned with how effectively and accurately the sub-steps are conducted.

We do not expect any obstacles in the implementation of the plan. However, this kind of training design is the first attempt in the high school. We think that the personnel in the school will naturally have specific questions and opinions concerning this project. It is important that we address any comments and/or concerns that arise, if we expect to obtain similar results as outlined in this paper. To prevent and potential negative results, we will arrange several briefing sessions with the personnel, to inform them of the benefits of instructional design. We will include examples of several successful ID applications.

Designing Web Based Constructivist Learning Environments

Emiel van Puffelen
Stoas Research
The Netherlands
EPu@stoas.nl

Abstract: A group of 18 university teachers designing and constructing a Constructivist Learning Environment (CLE) was interviewed and monitored in order to find and test optimal design of web based CLEs. The information functions of the CLE were supported by web based technology and the social / collaborative functions were designed using "face to face" interaction. The learning environment was designed for use by a group of 180 first year students with no experience in using CLEs. The results show that supporting the information functions of a CLE with web based technology can be very useful for case oriented education. It also supplied good support for efficient instructional design by a group of teachers. In addition it resulted in a shift of teachers behavior towards facilitating active learning.

Introduction

The last decade of the previous century has brought two developments with important consequences for design of instruction (Tam, 2000). The first development is the changing perception of what learning is about. Learning has long been seen as the result of knowledge transfer from teachers or knowledge transmission from information sources. Now the constructivist conception of learning has gained recognition, stressing the idea that knowledge is individually constructed by learners based on their interpretations of experiences in the world. Instructional design should thus focus on creating constructivist learning environments (CLEs) that engage learners in meaning making and knowledge construction (Jonassen, 1998). The second development is the use of information technology enabling new ways of exploring information, social interaction and constructing information sources. These two developments combine well as virtual experiences and web based sharing of results and viewpoints adds possibilities to individually construct knowledge (Rice & Wilson, 1999).

According to Jonassen (1998) CLEs should supply:

- questions / cases / problems / projects
- related cases
- information resources
- cognitive (knowledge-construction) tools
- conservation and collaboration Tools
- social / contextual support

The first four functions are dealing with information (construction) and they can be supported by web based technology. The last two functions are aimed at social interaction, and the information technology support of them is well described in the literature covering Computer Supported Collaborative Learning (CSCL). CSCL is often the main focus for the introduction of information technology in education. However it is still not very clear what advantage CSCL has compared to "face to face" implementations of collaborative learning if there is no need to bridge time or location differences. In general the first four functions mentioned above might benefit from web based technology regardless of the need to bridge time and location differences.

Purpose

The purpose of the research reported in this paper was to find and test optimal design strategies for CLEs using web technology support for the information (construction) functions.
Methods

In 1999 Wageningen University (in the Netherlands) had planned a major change in its study programmes starting with the courses for the new students arriving in September 2000. As a result of this the educational institute for environmental sciences (EIES) had to design a new introduction course for environmental science students. The institute wanted the introduction course to be case oriented with active participation of students. In addition the course had to be multidisciplinary by using input of university teachers from 14 different department groups. Stoas assisted the EIES in this task by formulating a project aimed at interactive group design using Web technology. The EIES scheduled group design sessions from April till September 2000. The meetings were at irregular intervals about two times each month. The group of 18 designing teachers was formed between March and July with most teachers participating by June. The teachers were all new to ICT supported case oriented learning, and had not been working together in this group before. The course had to be ready for use in September. It would be used by 180 first year students with no experience in ICT supported case oriented learning.

The teachers were interviewed at the beginning of the design process and after the students had finished their tasks at the end of the course. The meetings of the teachers were monitored during the design, construction and utilization phases and student satisfaction was monitored at the end using a web based questionnaire.

Results and discussion

The design phase

At the beginning of the design process the teachers had no clear idea on how to proceed and they had doubts about the available resources for the design, construction and utilization phases. However in general they showed to be prepared to “jump in the dark” and were willing to discuss instructional design based on principles they were not familiar with. In the first meetings the teachers agreed on an approach using cases build on problem specifications and information resources. In addition it was decided that the social interaction and collaborative work needed during the course would be done in group gatherings (18 groups of 10 students) of 4 hours during 7 weeks. There was a clear consensus to use a face to face approach for these meetings as that was considered essential for new students. The student groups would have to elaborate on the problems they could specify using the course cases presented on the web. The construction of group work presentations would be facilitated using general presentation software (Microsoft Power Point) and a student software training was included in the course. The students would be introduced to the course on a plenary introduction session on the first day.

By the beginning of June the teachers had thus made major decisions on all the functions of a CLE mentioned in the introduction and gathered some case material as well. Yet most group members had problems creating course content as a clear framework for the case information was missing. At that point Stoas made a design for the web based information functions, incorporating all the work the group had done so far. A simple design using web pages was selected as there was no need for student tracking or a secluded learning environment.

The construction phase

The design for the web based functions was approved and build on the web within one week. In the following weeks group discussions were based on the structure and examples on the web. Most teachers were able to provide substantial input as they had just attended a joined web page construction course (using Microsoft FrontPage). In addition to the case content, the group constructed a joint environmental science glossary. That was an important step as the 14 department involved had not confronted the students with consistency in definitions in the past. Course information functions like a work schedule, teacher contact data and a search function were added as well. Also a library containing pictures with environmental science related explanations was constructed. These pictures were described using an international standard for educational metadata (ARIADNE, 1999). This enables the collection to be part of a University wide or international database.
The course execution and evaluation phase

The course started on the 4th of September, by that time all web based information functions were completed. The design for the group work was almost finished (some parts for the last course weeks were added later) and the 18 group work rooms were made available that day. The course lasted 7 weeks and the students used the web based information functions to formulate and solve their case questions. The students assigned each other tasks and worked alone and in small groups to accomplish them. Each group room was equipped with 1-5 computers. Student couldn’t work efficiently in the few rooms with only one or two computers. The students presented their work half way and at the end. The teachers were pleasantly surprised by the quality of these presentations. A web based questionnaire on the quality of the course was introduced in the last week. The response to this questionnaire was 60% (108 out of 180). In general the course scored well with exception of the first part which had suffered from the time stress due to the late start of the design process. The teachers were all pleased with this type of education and they had liked their new role.

Conclusions

Facilitating effective group interaction is essential for designing web based CLEs as usually all the CLE facilities needed can’t be constructed by one person. A group design process requires frequent work meetings. In the first meetings the teachers can help each other in understanding new learning approaches. It is important that those discussions results in joint decisions about the instructional design. In addition the group should decide on web design standards to be used. Web based functions can be designed as soon as major decision on instructional design are taken. The construction of these functions is needed as a trigger to enable the entire design to be constructed by the group.

Supporting the information (construction) functions with web based technology can result in a shift of teachers behavior towards facilitating active learning. In addition it can create a good basis for intensive group work.

Constructing cases for CLEs is time consuming and web based support doesn’t change that much. Web based cases are an excellent use of information technology for education, however complicated case material requires combination with the social functions of CLEs in order to be effectively utilized.

The group work was done in large groups of 10 students. In general the groups reached good results but a design with more variation in group size as described by Heath et al. (1999) might be more efficient.

The CLE made the students cooperate nicely and it made the teachers cooperate in a way they had never done before.

The teachers did a wonderful job, they cooperated efficiently while executing tasks they were not familiar with. This would not have been possible without the enthusiastic support of Adri Dietvorst; Director of the Wageningen University Educational Institute for Environmental Sciences who motivated the team and supplied the first example content for the learning environment. In addition Rob Hartog of the Information Technology Group supplied very valuable input for the design of the web based parts of the learning environment. In doing this he was efficiently assisted by Steven Ottens and Oscar Vonder. Important contributions to the research part of the project were made by Annet Jager of Stoas Research by doing the interviews and monitoring teacher meetings.
Using Information and Communication Technologies to Develop a Learner-Centred Approach With Pre-Service Elementary School Teachers: An Exploratory Research.

legare@vax2.concordia.ca

Abstract: This paper presents the preliminary results of our exploratory research concerning students’ perceptions about their role as future elementary school teachers and the educational practice they integrate in the development of an integrative scenario. We have noticed that when a socio-constructivistic teaching/learning approach is used, many students still have problems assuming more freedom over their own learning experience. Indeed, they tend to fall back on their old ways of learning and they plan their lesson accordingly. We will present instructional strategies that are likely to facilitate the shift from a teacher-centred approach to a more genuine learner approach. We will shortly describe a Web site providing scaffolding tools to help students and teachers through the whole process of scenario production. In order to stimulate metacognitive processes and collective knowledge construction about the new roles of teachers, we use telediscussions in an electronic forum.

1. Introduction

The wide adoption of information and communication technologies (ICT) throughout all of our life domains push our society towards a knowledge society (Levy, 1994). Our working and learning environments are strongly transformed by ICT. Home, work and schools are all called to merge as they all make a more intensive use of these technologies. This emerging knowledge society calls for new and revised competencies for both teachers and learners (NCATE, 1997). Beyond technological competencies and probably more important, there are the pedagogical and knowledge construction competencies. Socio-constructivist teaching/learning approaches such as networked communities of learners (Brown, 1997; Wenger, 1998) are seen by many researchers as the way to rethink teaching and learning in order to meet society’s new expectations. The principles that feed this epistemological stance could be synthesised in saying that significant learning is more likely to happen in: a project or problem based activity, anchored in a real life situation that makes it a meaningful and an ecologically rich context for the student; collaborative knowledge construction activities where learners are given more control over the executive decisions about and within the learning activity; activities involving individual and collaborative metacognitive work. But these principles do not fit with neither teachers’ nor students’ experience of teaching and learning. Most of us have learned in a more traditional and directed way with little initiative and responsibility given to the learners. Teachers and learners need to be prepared and supported to make this important shift. Experience with socio-constructivist learning activities are required to develop the related competencies.

Over the past six years, we have implemented a socio-constructivist approach in the two Information and Communication Technologies (ICT) mandatory courses provided to students registered in the teacher education program at l’Université de Montréal. Although we believe that ICT provide numerous opportunities to render students more autonomy over their learning, and despite the knowledge and experience gained over the past years, we have noticed that many students still have problems assuming more control and freedom over their own learning experience. Indeed, when they are facing a novel situation or when they encounter a difficult problem, students tend to fall back on their old ways of learning (Viens & Amélineau, 1997). They seem to do the same when they plan a lesson for a specific class situation. An important challenge is then the
scaffolding of both a comprehensive understanding of socio-constructivist principles and the ability to apply these in school practice.

In this paper, we will describe in more details the context and characteristics of our teacher education strategies, Les Scenaristes Web site, the research methods, the results of the first analyses and the solutions that emerged from our experiment. Ultimately, this exploratory research project will help us refine the strategies used in teacher education in order to help students benefit from a more efficient learner-centred model of learning.

2. Context

Students registered in our teacher education programme have to take a minimum of two courses about the integration of ICT in the classroom. The first course, Les TIC en éducation (ETA1700), is a general overview of the various technologies that could be integrated in a given learning environment. The final assignment consists of producing, as a team, a complete and fully working integrative scenario that will be available on the Web, for the benefit of their colleagues and the teaching community. A scaffolding procedure is proposed for lesson planning. Scenarios should integrate the following five basic elements: motivation and contextualisation activities; teaching/learning activities: metacognitive activities; modes of evaluation; and transfer activities.

As the teams develop their integrative scenarios, individual members are invited to participate in telediscussions. For ETA1700, four themes are provided: the impact of ICT on society, the effective use of ICT in educational settings, the changing role of teachers and learners and continuing education of teachers. Since learning to use the technology is a sub-goal of the course, students are requested to make at least one contribution for each theme, as well as offer one reply to one of their colleague.

The second course, Laboratoire d'intégration des TIC (PED2000), is a full year course, offered to second or third year students and mostly at a distance. Team members are free to meet as they please. Students have to produce a more comprehensive scenario for a situation of their choice. However, prior to designing their scenario, students have to contact an in-service teacher who will let the students conduct their intervention in his or her classroom. The field experiment allows the teams to conduct a formative evaluation of their project. PED2000 students also have access to electronic forums of discussion, with the difference that no themes have been pre-determined. It is the students who create and launch topics of discussion. An on-line tutor is available to guide the students in their creative process.

Since three years, a multilingual Web site, http://facvirtuelle.scedu.umontreal.ca/scenaristes, Les scénaristes, provides additional scaffolding tools to help students through the entire process of scenario production. Scenarios are constructed and stored online so students can keep trace of their evolution. During the development process, pre-service teachers are supported by detailed questions for each of the following steps: 1-needs analysis; 2-in depth elaboration of teaching/learning strategies appropriate to the identified situation; 3-production of all related materials; 4-implementation of the lesson plan in situ; 5-formative evaluation and collective critical analyses. In addition, the Web site provides numerous resources such as a model of educational uses of ICT with four axes: Information source, Knowledge organiser and production, Teaching, and Communication; a description of 14 teaching strategies analysed to demonstrate their collaborative and student initiative potential; four scenarios presented as case examples, and so on. In ETA1700, students are asked to complete the first three steps of the model (until production). In PED200, students engage in the full developmental process, in collaboration with a school teacher who provides a real class situation in order to implement the scenario. Final products (scenarios and accompanying resources) are then posted on the Web so they can be shared with the teaching community.

3. Description of the Research

Essentially, we are aiming at discovering the links (or absence of links) between the constructivist discourse held in the forums and the application of those principles in their integrative scenarios. It is those two main sources of data—the forums and the integrative scenarios—that we are using to conduct our research. Based on the obtained results, we plan to develop instructional strategies that will use both the scenario's scaffolding tools offered by Les Scénaristes Web site and the reflective activities provided by the forums to help students harmonise their discourse with their practice.

3.1 Goals

Our goals are:
1- to identify students' perceptions about their role as future teachers while using ICT;
2- to verify the extent to which students apply socio-constructivist principles in their scenarios;
3- to explore the strength of the relationship between discourse and practice.

Ultimately, the research results will be used to improve and to enrich our scaffolding approach, which in turn will help the students not only discuss the socio-constructivist principles but also adopt them in practice. To do so, we explored the links between the discourse held in the telediscussions and the application of the principles in the integrative scenarios.

3.2 Analyses

We have proceeded to an in depth reading of all the forum messages of the two courses in search of descriptions of socio-constructivist teachers/learners' roles (student centred, student control, teacher as a guide, collaborative learning, etc.). Messages presenting such descriptions were identified and the team mates (scenario team) messages were all extracted and grouped to be analysed together. Our initial idea was to get the scenarios of these teams and to proceed to a comparative analysis. But the results of the forum analyses provided surprising data.

We found that while many ETA1700 students are indeed adopting a socio-constructivist discourse, almost no PED2000 students did. Our preliminary analyses showed that PED2000 students used forums to evaluate collaboratively their scenario implementation and to ventilate about emerging problems. Very few messages discussing the teacher/student roles were posted. The students who did, adopted a shallow perspective with very little justification or elaboration on the topic. Hence, in PED200, it would have been difficult to establish a relationship between the students' perceptions in the forums and the applications of those in the scenarios. Consequently, we decided to focus on the analysis of ETA1700 students' work.

3.3 Sampling

We selected four teams from the ETA1700 course, representing 18 students, who contributed a total of 80 messages in the forums. Two discussion themes were relevant for our analysis: They are the "perception about the role of the teacher" and the "effective use of ICT in the classroom". For both themes, students contributed 55 messages.

3.3 Criteria for Analysis

3.3.1 Integrative Scenarios

To assess the students' perceptions about their changing role as teachers, we referred to some of the criteria described in Viens (1993), as well as the general constructivist principles (Brown, Collins & Duguid, 1989; Lave & Wenger, 1991; Brown, 1997; Wenger 1998). Even though we used a Likert scale to evaluate each criterium, our intention was not to cumulate frequencies. We rather used the scales to guide our critical analysis of the constructivist aspects of each scenario. Consequently, the results are more descriptive in nature. The criteria are as follows:

Learning strategies. Notwithstanding the specific learning strategy to be used, we assessed whether during the instructional strategy the learners were « directed », « guided », « rather guided », or « free ».

Team work. We examined whether the students planned to have their learners work individually, in teams but to conduct a fragmented task, or in teams to conduct a collaborative and collective task.

Content. Did the students determine a specific content or did they leave it completely opened for their learners to decide of their specific subject, as it is usually done in project-based learning?

Pedagogical goals. Aside from the usual well-stipulated instructional goals, did the students add other learning objectives such as transversal competencies? Did they consider metacognitive processes?

Interdisciplinarity. Did the students focus on one subject matter or did they use the opportunity to integrate several disciplines?

It is to be noted that all criteria were considered simultaneously in order to assess the global constructivist flavour of each scenario.

3.3.2 Forums

For the forums we proceeded differently. First, we focused on two aspects: the positive/negative attitude toward the ICT. Secondly, we looked at the perception of the teacher's role. In addition, we attempted to assess the student's capacity to reflect critically, that is we observed whether the students were able to
develop and support their thoughts rather than merely contributing an unsubstantiated opinion (Quellmalitz, 1987; Ennis, 1987).

4. Preliminary Results

4.1 Forums

4.1.1. Attitude Towards ICT

After conducting the preliminary analysis of the telediscussions for ETA1700, we noticed that the students' positions about the integration of ICT in the classroom are not radical as one might expect. The majority seems relatively sensitive and cautious about technologies. In fact, several interventions were concerned about the fact that the computer will never replace the teacher and that the human factor is essential for the development of the pupils. In other words, aspects such as empathy, communication, emotional support are still essential for the learners' development.

4.1.2. Perceptions of the Role of the Teacher

After listing all relevant interventions, we noted three recurrent themes that could constitute categories. First, some interventions directly mentioned the role of the teacher, but did not provide further explanations or examples. The second category encompasses interventions that focus on the learner and whereby the role of the teacher is addressed indirectly. In the third group, interventions were about more specific tasks of the teacher. We chose to use these categories to present the results about the perceptions of the role of the teacher. Although not all interventions under the theme « Perception of the role as teacher » referred directly to the subject, it is interesting to discover that the perception of the role is indeed changing. The students did mention that the ICT will help shift from a traditional role of « content deliverer » to one that assumes more guidance, more facilitation. Terms such as « facilitator », « animator », « councillor », « advisor » were used relatively frequently. However, we discovered that the majority of students limited their intervention at the opinion level. For example, they only named or listed the role without providing an explanation or a definition of what they meant by « facilitator ». Furthermore, they did not establish a priori what they mean by « traditional role ». Very few went as far as mentioning « content deliverer » or « lecturer ». In other words, students talk about the changing role without defining their assumptions. No one proceeded to compare and contrast the two positions or provide an illustration to support their thought. Indeed, most participants merely identified keywords and did not attempt to engage in a more critical discussion.

Some interventions were also addressing the issue of the changing role, but indirectly. Some students talked about the fact, for example, that the ICT will provide the opportunity for the pupils to be more active in their learning process. Here, the guiding role of the teacher is implied in the discussion. Participants mention the possibility that ICT will encourage the active construction process and consequently, will contribute to a more significant learning experience. In fact, in those indirect interventions, the learners are considered to be at the centre of their learning, actively engaged in the construction of their own knowledge and experience. Incidentally, the teacher assumes the role of guide in the learning process. In sum, the students in this category seem to think that ICT can be used to favour collaboration between the learners as long as the learners' needs are respected. It seems that participants perceived the ICT as an integrated tool to teaching that favours self-learning.

Interestingly, the same group of students also discussed a specific aspect of teaching that will be affected by the technology : the impact of broader access to information. Some students recognise the fact that a wider access to information will bring new tasks for their learners. One student mentioned that their pupils will have to « clarify their own research goals, define their information seeking strategy, make choices in the information, and sort the information ». This type of anticipation regarding « transversal » competencies was certainly an interesting discovery.

However, the same students who demonstrated their critical thinking abilities, still perceived themselves as the authority figure for their students. In fact, they mentioned that it will be their responsibility to assess the quality of information gathered on the Web as well as to judge the relevance of the source. Instead of making the link between the role of guide or facilitator, as it would be expected in a constructivist fashion, it seems that the higher cognitive skills required, such as analysis and evaluation, will remain in the mind of future teachers, as their own territory.

4.2 Integrative Scenarios
Two interesting trends have been identified in this analysis. First, the students who are more able to support their opinions by providing examples, using the literature, explaining their thoughts, seem to be more capable of producing a scenario that uses a genuine constructivist approach. In fact, if all the constructivist criteria are applied whenever it is reasonable to do so, the tone used to describe the learning activity is more opened, more respectful of both the freedom of the teacher and the learners. Here, we noticed that teams who produced a constructivist integrative scenario, were constituted of at least two members who demonstrated critical thinking abilities.

In the second trend, it seems that the students who claim that the role of the teacher is changing but who do not support their opinion, do not apply their values and perceptions in their integrative scenarios. In the telediscussions, they claim to be constructivist, but they fail to transfer their thoughts in practice. Their interventions tend to be opinions and value judgements rather than supported, critical reflections. As we anticipated, the majority of the scenarios produced were meant to be constructivist. Some teams for example, will have their students work in teams but in a fragmented fashion (individual students will provide parts that will make a whole); the content will be determined and not opened for change; the learner will be rather guided in the learning process.

Two sources or information reveal the lesser constructivist approach: the instructional goal statement and the description of the lesson plan. Statements of the instructional goals in those scenarios tend to be highly fragmented, clearly measurable, well stated. Often, the students will refer to the Ministère de l'éducation du Québec programme to write the goals. There is no reformulation of the goals to suit their situation or needs. Also, there is no interpretation or critical analysis or re-evaluation of the goals. In addition, the students do not go beyond the goals officially prescribed by considering, for instance, the development of transversal competencies. The students just take the goals as they come.

The design of the lesson plan is another indicator that a scenario might not represent a good application of constructivist principles. Lessons plans tend to be very organised and directed as well. The outcomes, ensuing the instructional goals, are well planned. In fact, the pre-service teachers, remain perfectly in control of the predetermined outcomes. Despite their good intentions, the students remain in control of the learning process. The steps are not only too well defined, that are also not flexible. The outcomes of the intervention using ICT are still pre-determined. Finally, the teams did not seize the opportunity to create a lesson plan that encompasses more than one subject matter. Since the students had the freedom of choosing what to cover, one would expect a project that draws on multiple disciplines. Here too the students did not fully exploit the potential of constructivist approaches.

5. Conclusions

In this exploratory research we highlighted two trends. Students who demonstrate critical thinking abilities in telediscussions are more likely to apply successfully their values and beliefs in their productions of integrative scenarios. We also found that teams made up of at least two members who substantiate their reflection tend to create scenarios that are more constructivist. Secondly, students who do not support their opinion in the telediscussions will be less able to apply the constructivist principles to their productions. The teams are constituted of students whose interventions are opinionated rather than being critically reflective. Those teams will remain in control of their pupils’ learning.

Our analyses revealed some limitations related to team leadership and the understanding of the group dynamic. In fact, it is difficult to link one's work to a collective production without having a sufficient knowledge about how this individual influenced the group artefact. Hence, data about the evolution of the group's work and individual contributions could permit to run a more specific analysis of the collective knowledge construction processes. Nevertheless, our results suggest that scenarios production and discussions in a forum about teachers/learners roles may be used in a convergent way such as to provide rich scaffolding activities for pre-service teachers.

In conclusion, the next logical step would be to support the development of critical thinking skills in the telediscussions by having students to specifically discuss how they implement their representations of the teachers/learners' roles in their scenario. This would probably bring to front some ruptures in students representations by a process of confrontation to practical considerations. We believe that such a breakdown generative activity may be necessary to build a more coherent mental models of teachers/learners roles in socio-constructivist activities and to encourage a better transfer of the socio-constructivist principles to the development of integrative scenarios.

Abstract: CRACTIC stands for "Research Community on Collaborative Learning with Information and Communication Technologies". It is a collaborative research involving university professors, teachers and domain experts in the development and implementation of collaborative learning activities based on socio-constructivist principles. Our pedagogical model builds on having students from different schools along the St-Lawrence River to exchange questions and answers about the impact that the River have on their respective economical, social and geographical environment. Each school answering questions raised by another school and doing so, contributing to the construction of collective knowledge expressed in a community Web site. Six classrooms, matched in pairs, participate to our community. Each classroom developed a Web site presenting itself and the work done locally. We will present the theoretical foundations, the emerging model, the implementation conditions, the process of appropriation of the model by teachers and students and the outcomes of our three cycles of experimentation.

Socio-constructivist principles are raised as the basic guidelines for the use of Information and Communication Technologies (ICT) in almost every recommendation plan delivered by national orientation committees in the United States (NCATE, 1997; ASCD, 1998) and in Canada (MEQ, 2000). But there is a huge gap between the ideal vision and the day by day school's perspective. The pathway to a successful implementation of those principles in K-12 classroom activities is complex and requires numerous conditions to be met. In order to study those conditions and to develop a model of implementation that would take teachers' concerns as well as day by day classroom reality into consideration we have initiated, four years ago, a community of research on collaborative learning with
ICT. In fact, CRATIC stands for the French appellation of "Research Community on Collaborative Learning with Information and Communication Technologies". This community gather some professors and researchers of the Université de Montréal and McGill University; teachers and pedagogical support staff from a Montreal schoolboard; and topic experts from a Montreal Museum, the Biosphere. It is financially supported by a National research fund, FCAR.

The basic idea was to initiate a collaborative research community linking universities, teachers and domain experts from a Museum, and to have them to develop and implement a model of collaborative learning activities based on socio-constructivist principles (Roschelle, 1995; Brown, 1997; Wenger, 1998). The basic model that was developed builds on having students from different schools along the St-Lawrence River to exchange questions and answers about the impact that the River have on their respective economical, social and geographical environment. Each school trying to answer questions raised by the other schools and doing so, contributing to the construction of collective knowledge expressed in a community Web site. Six classrooms from different schools were participating to our community. In order to establish a stronger relation between students, to facilitate the harmonisation of teachers strategies as well as students evolution in the projects, classrooms were matched in pairs. Each classroom developed a Web site presenting itself and the work done locally. Even if a classroom was to get involved more directly with a specific other, they could access the other classrooms Web sites and communicate with every participants of the enlarged community. Exchanges were taking place along a full academic year. The activity implementation procedures contain 9 steps that guide students in the collective knowledge construction process.

The conditions of development of the model and its implementation have been observed and documented. Data sources are numerous: meeting notes and reports; classroom observations; interviews with teachers, students and school administrators; students production such as email messages exchanges and Web site produced. The model have been revised after each annual experimentation based on the gathered data.

The gathered data all points out to numerous factors that impedes the implementation of such a collaborative knowledge construction strategy. In fact, it was very difficult to have teachers as well as students to systematically apply the proposed model which implies to communicate regularly with the matched classroom. Problems came from various sources: technical, pedagogical, research related and social problems. We will shortly describe the majors difficulties that were encountered and present the solutions that we applied. Finally, the model resulting from our 4 years experience of collaborative research will be presented.

Overview of Web-Based Pedagogical Strategies

Dr. Shirley Waterhouse
Director, Educational Technology Department
Embry-Riddle Aeronautical University
Shirley@db.erau.edu
http://edtech.erau.edu/Shirley

Abstract: Preparing teachers to utilize Web-based instruction requires a focus on Web-based pedagogy, not just Web-based technology. Teachers must understand that technology should be utilized as the enabling factor, not the primary factor if Web-based instruction is to be effective in enhancing teaching and learning. The Web provides an array of teaching strategies that can be added to those commonly utilized in traditional instruction; and today's teachers must understand both. Recommended Web-based pedagogical strategies are addressed in this paper as well as how they relate to Gagne's Nine Events of Instruction as well as the American Association of Higher Education's Seven Principles for Good Practices in education.

Major Web-Based Pedagogical Strategies

There are at least four important Web-based instructional elements including: (1) Course administration, (2) Interaction with content, (3) Testing, and (4) Discussions. A review of the major Web-based instructional software products such as Blackboard and WebCT illustrates a focus on functionality to accommodate these four elements. Effective utilization of these components allows course designers to utilize a broad array of features to establish extensive Web-based pedagogical strategies. Each major component is described in more detail below.

Course Administration. Course administration components make it possible to post course information on the Web, including the course syllabus, assignments, course notes, and other course documents. Students can access information easily, and instructors can post and update important course information conveniently. Most Web-based instructional software also allows students the capability of submitting assignments electronically.

Interaction with Content. Interactive components make it possible for students to engage in student-centered learning activities and interact with course content. Direct access to Web resources allows instructors the capability of creating student assignments that require students to perform Web research and apply critical thinking skills to analyze site information and document their findings. Another major advantage of the interactive component of Web-based instruction is enhanced remediation. Course content elements such as audio or video files, simulations, PowerPoint slides, and course notes, can be reviewed by students as often as necessary.

Testing. The self-testing component of Web-based instruction provides very important learning advantages. Students can practice newly acquired knowledge and skills and obtain instant feedback on their progress.

Discussion. One of the most important functions Web-based instructional software provides students and instructors is the ability to electronically communicate. Students who may be too shy to speak out in class often do so comfortably in electronic discussions. Teamwork is fostered through electronic discussions, and the obstacles of organizing team meetings around the schedules of team members are eliminated. Electronic communications also affords instructors many advantages such as engaging in one-on-one discussions with students electronically, as well as establishing electronic office hours.
Web-based Pedagogical Strategies to Engage Learners

There are a number of factors that must be implemented to engage learners in the learning process; when learning is Web-based, special care must be taken to insure learner engagement. Figure 1 lists twelve major factors needed to engage learners in the learning process and example Web-based strategies for each. This form is provided as a planning tool for creating Web-based strategies appropriate for Web-based instructional prototypes.

Web-based Pedagogical Strategies Applied to Gagne's Nine Events of Effective Teaching

The list of Gagne's Nine Events of Effective Teaching is one of the most popular tools used by educators to insure that instruction is effective (Gagne 1985). Gagne's Nine Events can also serve as guidelines for designing effective Web-based strategies for online learning. Figure 2 is a tool that lists Gagne's Nine Events and example Web-based strategies that comply with each event. (Harris and Watchouse 2001). (Details of Gagne's Nine Events can be viewed at <http://ide.ed.psu.edu/idde/9events.htm>.)

**Web-based Pedagogical Strategies Applied to the Seven Principles of Good Teaching**

The American Association of Higher Education's Seven Principles of Good Teaching is another tool that is popular among educators and instructional designers. The Seven Principles of Good Teaching has been adapted by many educators, and one of the most renowned adaptations is the Chickering and Gamson (1991) application, The Seven Principles for Good Practices in Undergraduate Education. (A summary of Chickering and Gamson's work can be viewed at <http://www.msu.edu/user/coddejos/seven.htm>.)

Figure 3 is a tool that lists the Seven Principles for Good Practices in Undergraduate Education and provides an area for recording appropriate Web-based pedagogical strategies, depending on the learning activity.

Cognitive Learning Theory Meets Technology: 
Incorporating Research on Attention into E-Design

Joan Wines, Associate Professor of English, California Lutheran University, USA wines@clunet.edu
Leanne Neilson, Associate Professor of Psychology, California Lutheran University, USA neilson@clunet.edu

Abstract: During the implementation of a two-year faculty development grant, California Lutheran University (CLU) has explored technology's potential for improving teaching and learning. In incorporating various technologies into the design and redesign of 27 undergraduate courses, we have found that certain cognitive and physiological processes are tremendously relevant to learning outcomes. Strategic uses of new technologies that capitalize on the dynamics of these processes can, we believe, optimize a student's ability to focus and sustain attention, improve comprehension, and facilitate the transfer of content into long-term memory. To develop new design strategies that incorporate relevant cognitive theory, we have set up the generic methodology we follow in this paper: 1) examining a specific cognitive phenomenon (Attention, in this case), 2) identifying its relations to learning, and 3) imagining how its principles might be best incorporated into the architecture of an e-designed instructional project.

In 1998, the Charles E. Culpeper Foundation provided California Lutheran University (CLU) with a grant to help faculty develop and deliver curriculum in technology-infused learning environments. Our Teaching, Technology, and Teamwork groups focused on integrating good pedagogical practices into 27 e-designed courses and other instructional multimedia projects.

We now want to integrate the principles of cognitive learning as well as good practices research into other e-designed projects. We are convinced that strategic uses of new technologies can capitalize on the dynamics of cognitive and physiological processes, optimizing a learner's ability to focus and sustain attention, improve comprehension, and facilitate the transfer of content into long-term memory.

We have identified several areas of cognitive learning theory that hold promise for technology-enhanced instructional products. This paper 1) briefly examines one of these areas (Attention), 2) identifies some of its interrelationships with learning, and 3) suggests how we might incorporate relevant Attention principles into multimedia instruction to achieve better learning results.

Teachers want to get information into a student's long term memory, but too often neglect to first ensure that learners are “paying attention” when that information is being delivered. Attention is learning’s most crucial step. Educators have long known that better learning outcomes are inevitable when attention is focused, and that formal organization of content and flexible methods of delivery help direct and sustain student attention. Now, educators can use mechanical strategies to reinforce organizational and delivery methods that focus attention—something designers of ATM and other machines have been doing for a long time (e.g., that buzz directing our attention to the card slot!).

Reviewing concepts developed by Attention theorists can help us formulate strategies of incorporating Attention principles into educational multimedia design. Attentional Resource theorists propose that the number and kind of resources needed for processing information depend on the complexity of the incoming stimuli (Sternberg 1999). Simple stimuli require only a small number of resources, while the remaining resources can be used to pay attention to other stimuli simultaneously. Difficult material, requiring more resources, will limit our ability to divide attention as readily among various tasks. Practice reduces the number of resources required to attend to a task, making additional resources available for simultaneous multi-tasking.

Additionally, Attentional Resource theorists point out that the number of processing resources available is not consistent across populations and situations. A tired person, having fewer resources available, has a reduced ability to pay attention to complex stimuli. According to other Attention theorists, students will also have difficulty paying attention to verbal material when they are trying to read and listen simultaneously because when they read, they are transforming a visual format into an acoustic format (Best 1999). It follows that the acoustic processing in reading could displace the acoustic processing in listening, a physiological dynamic that needs to be considered when
designing multimedia instructional projects. Students should not be expected to read blocks of PowerPoint text and listen to an instructor at the same time, anymore than they should be expected to read handouts during a live lecture.

Because changes in attention levels are subject to the above as well as to so many other variables, instructors must continually vary delivery methods. One common way to effect variance is to increase or decrease delivery pace. The bottleneck theories in cognitive research (Broadbent 1958; Moray 1993; Treisman 1964) indicate that a “bottleneck” occurs in the presence of excessive stimuli, and information that gets stuck in the bottleneck doesn’t get processed. Complex verbal material requires slow-paced delivery because it needs time to “get through the bottleneck” and (in the Attentional Resource theorist’s context), because more cognitive resources are required to understand it.

When the delivery pace is too slow, however, students often use their “left over” resources to daydream and to drift away from the course material. Retention usually improves when delivery rate is increased, an expected result of the speech/thought speed differential: 125-175 spoken words per minute to 400-500 words processed through listening per minute. When learners have less opportunity to let attention lapse, comprehension and retention rates improve (Wines 1998). And, as Kevin Harrigan has pointed out, learners can listen to speech compressed at as much as 50% without loss of comprehension or retention (Harrington 1999). Thus, theoretically, arbitrary timing of online verbal material that would force the user to process at faster paces would focus and sustain attention simply by not giving the user an opportunity to drift.

Given the many variables that affect Attention, however, a design which gives pace control to users instead of instructors is a better option for designers who emphasize the importance of user choice and control. Many who e-design educational projects argue that the more actively engaged user learns more and learns better, and that most students have some awareness of their metacognitive processes, their learning potentials, and their limitations. Learners can, therefore, be taught to consider variables such as complexity of material and emotional and physical states, and to adjust their listening pace accordingly. They can then optimize their learning experience by deciding how to control the flow of information.

Software that gives users this control has already been developed. The DUKES computer application is a good example (Harrigan). Created to let e-designers build in variable-speech speed options, this application could be invisibly integrated into an online lecture segment, giving students the option of choosing different listening rates, e.g., remedial, slow, medium, fast paced. Questions on comprehension and tracking mechanisms could be integrated into the design to help the instructor evaluate student-learning styles and to better assess learning outcomes.

In applying Attention (in relation to listening as just discussed, as well as viewing and reading) and other cognitive principles and concepts to the e-design of multimedia instructional projects, we hope to achieve better learning results as well as a more quantitative assessment of learning outcomes.

Got Hack? Strategies to Reduce Online Cheating

Dr. Joseph Winslow
Coastal Carolina University

The purpose of this paper is to report findings from an empirical study investigating the degree to which three popular WBT development systems—scripting, authoring and enterprise—are susceptible to student “hacking.” Three questions were of primary interest to the researchers: (1) are there any differences in the number of technology-centric cheating methods students can discover between the three WBT development environments, (2) which technology-centric cheating methods are most common, and (3) what attitudes do students exhibit regarding technology-centric cheating? As WBT development tools continue to evolve, and as individual faculty take greater responsibility in the development of their own custom assessments for online delivery, answers to these questions are critical to the derivation of specific strategies to reduce online cheating.

Methods

The sample used in this study comprised all students (n=76) enrolled in multiple sections of an undergraduate Education Technology course required of Education majors at a medium-sized public suburban university. Sixty-eight percent of the participants were female; all students were either freshmen or sophomores and new admits to the teacher-education program. Students were randomly assigned to take one of three online vocabulary quizzes, one created with the web-editor and scripting application, Coursebuilder for Dreamweaver (Macromedia), another by the icon-based authoring program, Authorware Pro Attain (Macromedia), and the last with the enterprise-level integrated learning system, WebCT.

The setting for each administration was a technology classroom housing 25 Internet-enabled PCs. Each student accessed his or her individual quiz by entering an appropriate URL in a Netscape web browser. Each of the three quiz versions presented the same multiple choice items in the same order, with only minor interface design differences. Students marked their answers by clicking appropriate graphic buttons with their mouse and then submitted them for automatic grading by clicking a “Score My Quiz” button. For each administration, students were challenged to discover as many different ways possible to use technology to “cheat” on their assigned quiz. Cheating was operationally defined as either 1) quiz file and item theft, or 2) “hacking” the system to extract the correct answers, and students were asked to focus their cheating efforts accordingly. To avoid prompting, no examples were provided.

Students were given thirty minutes to discover various cheating methods and asked to generate a list describing each in specific detail. At the conclusion of the allotted time, students were surveyed for perceived proficiency and attitude. All data were coded, blind-scored, and analyzed in Excel and SPSS.

Results

Descriptive statistics indicate that students in this study (n=76) had a mean of just over 4.5 years of computing experience, with reported values ranging from one to fifteen years, but the majority within one standard deviation. On a five-item scale of computer proficiency, students estimated their own skills with a mean score of 2.8, between “basic” (2) and “intermediate” (3).

One-way ANOVA and subsequent pairwise analyses yielded significant differences between groups assigned to the three WBT development environments. Students assigned to the script-developed quiz discovered significantly more methods to cheat than students assigned to either of the other groups. Differences between the enterprise group and the authoring group were not significant.

Students discovered six different technology-centric cheating methods. The most common method used by 61% of all participants was to retake the quiz over and over until the desired score was achieved. Saving the quiz file to disk (26%) or emailing the file (21%) to a valid address were the next most popular methods. Using instant-messaging (text chat) to relay quiz answers between different student workstations...
was an effective option discovered by 20% of participating students. Fewer students (11%) realized that the internet address for the quiz file, the URL (uniform resource locator), could be used to steal the file outside of class. Only a handful of students found that the javascript source code could be parsed for correct answers. The authoring quiz file had the least number of total cheating occurrences (22); students were unable to save it, email it, or view its source code.

Almost 40% of all students in this study reported that they would cheat using one of the methods discovered if they thought they could "get away with it." Of those students, most cited the need for a grade as justification for cheating. Others explained that the ease of the technology made the temptation too great to resist. A few students reported that they would cheat simply because they could.

Discussion and Conclusion

More than 80% of students (across groups) discovered at least one cheating method. It is interesting to note that, according to the data, the authoring quiz was the most difficult to extract or hack; students were unable to save the file, email the file, or manipulate its source code. This discrepancy is easily explained by its non-standard, proprietary file format, which can only be displayed in a web browser with the appropriate Authorware plug-in. Unlike WebCT and Dreamweaver, which generate a single file for downloading, Authorware segments the quiz file into smaller pieces, each of which is arcane named and not individually viewable. In addition, the text rendered in the Authorware file is not editable, unlike that in WebCT and Dreamweaver, which allow a student to copy and paste quiz items into a word processor or emailer. Neither are there menus at the top of the window prompting students to save the file to diskette or email it to an address. Finally, Authorware does not make its proprietary source code available for display in the browser; the other programs place a "0,1,1,1" next to each correct response in the javascript code.

Perhaps the real value of this study is that from these methods specific design strategies can be derived to reduce the probability of technology-centric cheating occurrences. WBT developers might consider the following:

1) **Open the file in a window without menus and toolbars.** Creating the quiz link to open in a new window without navigation buttons, toolbars and menus inhibits students from copying the URL, emailing the file, saving the file, and viewing the source code. 2) **Limit time and scoring.** Setting the score quiz value to <1> and retaining unlimited tries per question allows a student to change his or her mind about an answer, yet preserves only one opportunity for submitting the quiz for scoring. Setting a time limit, and including a visual timer on the page, may discourage users from discovery cheating. 3) **User authentication.** Preventing users from logging in and retaking web-based assessments can be accomplished through sophisticated user authentication schemes. WebCT has this capability "out of the box," whereas Dreamweaver and Authorware require the use of middleware applications such as Cold Fusion or ASP to port quiz data to a parent database. 4) **Disable right-click.** Deactivating the right mouse button is another way to prevent a user from viewing source code or accessing edit commands like <Copy>, <Paste> and <Save>. 5) **Use an index file.** Assigning a default index file (for example, index.htm) to the root directory containing the quiz file(s) inhibits a user from accessing all objects in that directory. If a user tries to explore by truncating a URL to a parent directory (for example, www.yourschool.edu/yourname/quiz1/), the index file automatically loads, instead of listing all available files in that directory. 6) **Policies and proctoring.** Obvious but essential, stipulating specific policies and active (mobile) proctoring may decrease the propensity for some students to cheat, especially those who would use instant-messaging, email or other internet communications.

As online education initiatives continue to burgeon, the need for secure WBT development tools, and the empirically validated design principles guiding their effective use, will be imperative. The data from this study strongly suggest that the three WBT development environments used are vulnerable to security issues that facilitate cheating. The design strategies derived from these issues warrant future investigation.

Abstract
The present study explored faculty members' and preservice teachers' perceptions on addressing learning styles in different instructional environments, namely in traditional classroom and web-based instruction. This study used data from faculty members and preservice teachers at a state university in Turkey. This study reports both faculty members' and preservice teachers' perceptions on considering individual differences while designing a course for both traditional setting and web-based instruction.

Introduction
In our daily teaching practices, we observe that some students can learn easier than others and therefore they perform better on tests. This fact underlines the principle that instructional, contextual, and individual characteristics come into play during learning. In their study, Jonassen and Grabowski (1993) point out the importance of a similar principle by advocating, “student learning differs because student learning traits differ, and because the thinking process differs depending on what the student is trying to learn.” (p. 3).

If the learning traits, aptitudes for learning, willingness to learn and preferences for processing information differ dramatically, we need to recognize the need for alternative design approaches that address these differences.

Consequently, the instructional design approach is of a great value for providing learners with opportunities to learn better and effectively.

Background of the Problem
Since the advancement of technology in education, World Wide Web (WWW) has become one of the most popular tools for delivering instruction over the Internet. Such capabilities of the Web as handling text and picture as well as audio and video, promoted itself as a powerful tool for delivering instruction. Although there is a number of instructional design models that propose prescriptive approaches for Web-based instruction, only a few considers individual learning differences at appropriate level. Therefore, there exits a need for an alternative design model that conveys and considers such characteristics as learning differences, learning goals and objectives, content, user interface and so on that have a tremendous effect in web environment.

Purpose of the Study
Web-based instruction has been commonly used in distance education, especially as a supplementary delivery method for instruction for traditional courses. Hence, there is a lack of contemporary instructional design approach that fully addresses learning styles of individuals.

Learning style is not fixed to an individual, a situation or a task; it can vary by time, motivation, and learner's psychology or by other conditions of learners. Being aware of individual differences, it is
important to continuously evaluate all aspects of Web-based teaching and learning if the promise of Web-based instruction is to be fulfilled. Therefore, designing a web-based instruction by considering all variables of the instructional environment would result in more effective instruction.

The purpose of this study is to examine the perceptions of faculty members and 4th year preservice teachers of Computer Education and Instructional Technology department in a state university of Turkey. This study examined participants’ perceptions and their preferences of learning styles in both traditional and web-based instruction.

Research Context:
The learning styles theory was championed by Carl Jung, who is usually credited with first defining learning style theory. Myers and Briggs have also applied Jung's work and this work lead to a new field, understanding the differences in learning, for researchers (as cited in Silver and Strong, 1997).

The learning styles theory implies that individuals have different ways of perception, and one style doesn't represent all the individuals. So, instruction must be presented in different ways respecting these differences.

In their study of the effect of end user learning style and method of instruction on end user learning outcomes, Bohlen and Ferratt (1993) concluded, "...the method of instruction alone and in combination with learning style makes a difference in some, but not all measures of achievement, efficiency and satisfaction" (p. 280-81).

In the study conducted by Bostrom, Olfman and Sein (1988), the importance of individual differences in end-user training has been criticized from the learning styles point of view. The findings of this study suggested, "...in the design of training, it is essential to match training methods to individual difference variables" (p. 133).

Another study by Chuang (1999) investigated the presentation effects of text, oral narration, and computer animation implemented in an instructional lesson, and individual differences, which affect students’ learning in a multimedia computer environment. Chuang (1999) concluded that "subjects performed significantly better on the posttest in the animation+text+voice version, which was also the favorite interface design chosen by most of the subjects".

Assuming that technology is most effectively used in the classroom when students use technology as a cognitive tool, Cohen (1997) conducted a research about learning style in a technology-rich environment and concluded, "a technology-rich environment impacts the written and unwritten curriculum of a school. Schools should be sensitive to students’ learning styles when adopting an instructional methodology that will be used extensively throughout the curriculum".

In their studies Gilbert and Han (1999) stated, "an approach to achieve "A Significant Difference" is to provide several different instruction methods". (p. 433) So, they have developed a Web-based instruction system they called as “Arthur” which provides adaptive instruction. As an opposite view to traditional system, which defines one-to-many presentation of the lecture, this system takes several different styles of instruction from several different instructors and makes them available to each learner, which defines a many-to-one relationship. Here the web-based instruction is presented to the student by using different methods like audio, visual and text, which is expected to result in accommodating individual learning styles.

Contradictory to the findings of previous studies, Shih and Gamon (1999) found that "student learning styles and student characteristics did not have an effect on their Web-based learning achievement". They also concluded that "students with different learning styles and backgrounds learned equally well in Web-based courses and learning styles did not affect student motivation and use of learning strategies" and that "motivation and learning strategies seemed to be the most important factors in Web-based learning".

Snyder (2000) developed an instrument that teachers could easily administer to their classes to learn more about the learning needs of their students and by using this tool she investigated the relationships between academic achievement and the learning styles/multiple intelligences in her study. The results of this study showed that "many relationships emerged as being dependent" and the researcher concluded, "to be successful in our classrooms, we need to be more aware of how our students learn".

Research Questions:
This research particularly focused on the following main research questions:

1. What are the perceptions of faculty members on addressing learning styles in different instructional environments (traditional vs. web-based)?
2. What are the perceptions of 4th year preservice teachers in terms of considering learning styles in different learning environments (traditional vs. web-based)?

Research Methods:
This study used qualitative research methods for two specific reasons. First, qualitative research is an adequate method for disclosing underlying attitudes, thoughts, and perceptions when the literature suffers from lack of research on the phenomenon (learning styles and web-based instruction, which this study investigates). Second, a detailed description about the research content is needed in order to provide a complete and revealing picture to see what is going on. That’s why, this study is a ‘case study’ since the participants were selected from only one department at a state university and it is needed to present a holistic portrayal of the phenomenon (Patton, 1987).

Subjects
The subjects of this study included 3 faculty members and 13 preservice teachers of department of Computer Education and Instructional Technology (CEIT) at a state university. Since main concern of this study is to understand the phenomenon about the consideration of learning styles in traditional and Web-based instruction, we have to explore the phenomenon from multiple perspectives. To attain this goal, the subjects of this study were selected from Computer Education and Instructional Technology (CEIT) Department keeping these two issues in the mind:
1. The department is the one, which uses Web-based instruction most frequently as a supplementary to traditional courses among the departments of faculty of education in one State University,
2. For its accessibility.

Data Sources
This study extracted data from the following main sources:
1. Three faculty members
2. Thirteen preservice teachers
3. Document Analysis
Structured interviews were conducted with Faculty members of CEIT in order to understand their perceptions. These interviews were conducted according to a ‘interview guide’ which was developed and pilot tested by the researchers. All of the interviews were tape-recorded with the consent of the participants. Preservice teachers were asked to fill out a ‘questionnaire’ in order to access a wider population. This questionnaire had parallel questions with the interview guide developed for the faculty members. The questionnaire was prepared and pilot tested by the researchers in order to ensure its validity.
To obtain a more detailed vision of the preservice teachers towards the topic, a structured interview guide is prepared for preservice teachers including parallel questions with the questionnaire. For the recording of interviews, a tape recorder was used.
Finally, as the document analysis part of the study, the researchers did a comprehensive literature review.

Procedures
In this study, data was collected in the following manner:
1. Structured interviews were held with 3 faculty members.
2. Open-ended questionnaire was administered to all preservice teachers (totally 49 students of 4th year) of Computer Education and Instructional Technology Department. Of 20 students volunteered to participate the study.
3. After the analysis of results of previous step, 13 students were selected out of 20, in order to conduct more in-depth interviews. 3 focus group interviews were held with 4 students in two groups and 5 students in one group respectively.

Data Analysis:
The results obtained from interviews and questionnaire were analyzed, in order to explore faculty members’ and preservice teachers’ perceptions.
The data collected were analyzed inductively after the collection period is completed. The analyses were triangulated in terms of sources of data. According to Maxwell (1996), triangulation “reduces the risk of chance associations and of systematic biases due to a specific method and allows a better assessment of the
generality of the explanations that you develop" (p. 93). Furthermore, other researchers validated each interview transcript and interpretation. Multiple perspectives will yield people approaching situations from different point of views. Therefore, it is important for the reader to see the case from multiple perspectives and think about or judge the case by his/her own ideas. The results obtained from interviews were analyzed separately, in order to understand faculty members' and preservice teachers' perceptions. Interview data were transcribed precisely and coded inductively. The similar patterns and/or themes were outlined. After creating coding categories for the analyzed data, coding of the data was repeated according to these coding categories. Finally, the results were reported both from the views of faculty members and preservice teachers, separately.

Findings:
Throughout this section, illustrative opinions of faculty members and preservice teachers from structured interviews highlights the results.

Faculty members:

Theme 1: Faculty Members' Perceptions on learning styles in traditional learning environments:

All faculty members agreed that every student has different characteristics and talent. Every student has individual preferences coincided with their learning process. Two faculty members provided a definition for learning styles that parallels with learning theories. They also advocated that differences in learning styles could especially be tracked down by observing one's study habits or behaviors in the learning environment. When faculty members were asked about how they determine their teaching style, they all stated that such decision mainly relies on the content to be taught.

Theme 2: Perceptions of faculty members on instructional materials and strategies used in the classroom:

All faculty members reported that preferring certain teaching strategies in the classroom requires utilization of variety of teaching materials and learning tasks. Additionally, all faculty members reported that if one intends to accommodate students' learning styles in the classroom, s/he has to utilize a number of appropriate teaching strategies and techniques as possible.

Theme 3: Faculty members' perceptions on learning styles in web-based instruction:

Faculty members stated the lack of "face-to-face interaction" and "presence of immediate feedback" on the web as the most distracting feature for instruction. They also recognized the inefficiency of interactivity among all parties on the web. They also mentioned the value of utilizing all possible cognitive tools while designing a web-based instruction in order to address students' varying learning styles.

Theme 4: Perceptions of faculty members for addressing different learning styles in a web-based instruction:

Faculty members stated that the most important issue in addressing learning strategies in a web-based instruction is to consider such learning theories as cognitivism and constructivism. According to the faculty members, designing an instruction on the web is a dynamic process and this dynamism should be conveyed by the feedback provided by students.

Preservice Teachers:

Theme 1: Preservice teachers' opinions about their learning preferences in traditional learning environments:

The most common learning preferences of students in traditional classrooms could be classified from most used one to least used as; note taking, asking questions and listening to the instructor, discussion, learning in cooperative groups, reading course material and individual study.
Theme 2: Perceptions of preservice teachers about instructional strategies used in the classroom:

The most preferred instructional strategy by preservice teachers was “discussion”. Learning by doing, project-based learning, cooperative learning, questioning, discovery learning and problem solving were the other strategies favored by preservice teachers respectively. All preservice teachers also addressed that they have to be an active participants of the learning environment. Unlike other focus groups, one of the groups reported that they prefer a mix of different learning methods, and learning environment must be a representative of real life cases. Surprisingly, 14 students out of 20 ranked books as the most favored medium of instruction.

Theme 3: Preservice teachers’ perceptions about web-based instruction and their learning preferences:

All groups agreed that a web-based instruction should offer texts in different formats such as html, word, pdf and so on. They also reported that they should be able get print out of those pages whenever needed. Using different types of media such as audio, visuals, video and so on are also preferred in a web-based instruction by the preservice teachers if those features are available whenever they want.

Theme 4: Preservice teachers’ perceptions about how to adopt their learning preferences to a web-based instruction:

Preservice teachers’ responses to this question varied. For example, two of the groups addressed that web-based assessment is less valid than traditional assessment in terms of authenticity of student responses on a test and other security issues regarding to access. They also advocated that web-based instruction limits social interaction among the participants. Of 2 focus groups addressed that the sequence of instruction should be in accordance with their performance and learning pace. Navigation structure of the web-based instruction is another important future that preservice teachers emphasized. Finally, they reported that web-based instruction is more suitable for adult learners.

Discussion and Conclusion

The purpose of this study was to examine participants’ perceptions and their preferences of learning styles in traditional and Web-based instruction. Sixteen participants (3 faculty members, 13 preservice teachers) were the main focus of this study.

One of the most important findings of this study is that all faculty members recognize the importance of utilization of a number of teaching materials and learning activities in favoring certain teaching strategies for effective instruction. They also underlined the necessity for adopting appropriate and a variety of teaching strategies and techniques as possible to address students’ differing learning styles in the class. On the other hand, faculty members considered web-based instruction as a weak format for presenting content in terms of its inadequacy in providing face-to-face interaction and immediate feedback. Therefore, they suggested that all possible cognitive tools should be integrated into web-based instruction to overcome such obstacles. This finding parallels with the related literature as well (Yıldırım & Kiraz, 1999). Finally, faculty members reported that web-based instruction should provide adaptive instruction to address students’ differing learning styles. Brusilovsky and his associates (1999) also reported similar concerns; “To support the student navigation through the course, the system uses adaptive annotation...” (p. 257).

When preservice teacher were asked to identify their preferences of learning strategies in traditional classroom settings, they reported “note-taking, questioning, discussion, and learning in cooperative groups” as the most preferred strategies. Preservice teachers also favored learning by doing, problem solving and problem-based learning for effective learning. Surprisingly, most preservice teachers ranked books as the most preferred medium of instruction, yet they were majoring in computer education and were advanced on using computers. Similar to faculty members, preservice teachers also advocated that different type and format of presentation should be present on the web. They also stated that active participation is a key activity to learn effectively and different formats and medium of presentation on the web should have them actively participate in instruction. In conjunction with the faculty members’ perceptions, preservice teachers also stated that web-based instruction should provide instruction in accordance with their learning pace and performance. Additionally, they underlined the importance of navigation structure on a web-
based instruction. Finally, in contrast to faculty members’ perceptions, preservice teachers viewed web-based instruction as more suitable for adult learners.

Abstract: This paper focuses on how to use assessment tool to effectively integrate educational technology into curriculum. The authors examine the current practices in educational technology and curriculum integration and point out that successful integration of educational technology and curriculum depends on a sound system of quality assessment. An assessment model is proposed with a focus on the various stages of designing, developing and implementing the model that will enhance the integration of educational technology and curriculum in schools. Examples and case studies are discussed to illustrate how to use this model for K-12 educational technology integration. Limitations and suggestions are included for further study.

Introduction

Concern regarding how to effectively integrate educational technology into curriculum is at a high point in K-16 settings (Jones & Paolucci, 1999). School board members, policy makers, and the media are saying that educators have spent millions of dollars on technology for classrooms without being able to measure its effects on student learning. Some parents, even teachers themselves, become skeptical about the role of technology played in teaching and learning. To avoid the pessimistic forecast that the technology will simply become a passing fad in education, attentions must be paid to defining the goals for the use of technology, developing a strategic plan for technology and curriculum integration, and measuring the progress made. Sun (2000) in a recent article points out that the challenge that educational technology faces today is not what software and hardware we need to invest in our schools, but rather how to "create realistic evaluations of IT's effect on students and their academic achievement" (p. 34).

What to assess and how to assess still remain critical issues in educational technology evaluation. Studies indicate that current practices in educational technology evaluation mainly fall into three categories: (1) assessing the use of educational technology in specific content area, (2) assessing the use of educational technology in assessment itself, and (3) assessing the use of educational technology in specific learning strategies or approaches. The first category focuses on the relationship between the technology and a single subject, that is, on the effectiveness of the use of various technologies including multimedia and hypermedia in specific subject areas such as math, reading, writing, ESL education, special education (Dugdale, et al., 1998; Lindsay, 1999; Zhang, 2000). Such assessment limits itself to a specific learning situation within a single subject and hardly goes beyond its subject domain, failing to address the issue of integrating technology into curriculum as a whole. Therefore, it does not meet the needs for general purpose evaluation. The second category zeros in on the use of technology in assessment. That is, how to use technology to enhance the efficacy of assessment. Assessment under this category examines the role of online testing and computer-assisted assessment in learning (Greates & Green, 2000; Titus & Martin, 2000). Again, it fails to address the issue of an overall planning for effective integration of technology into
curricula. The third category has in recent caught the attention of educators as performance-based learning, authentic learning and other types of constructivist learning approaches become the fad in education (Bonnie, 1994; Carlson, 1998; Russell & Butcher, 1999). The role of technology has been examined to create an authentic, real life situation in which learners can engage in meaningful and constructive learning. Although assessments in the above three categories have contributed to the understanding of the relationship between assessment and technology, they, nonetheless, fail to provide a holistic picture of how technology can be effectively applied to subjects across the curricula. In other words, what is the common denominator with which educators are able to evaluate their practice in educational technology and curriculum integration? Evaluating educational technology should consider variables that are common to all subjects and that are applicable to integration across all curricula.

Current practices in educational technology tell us that what teachers need most is not how to use technology, but rather how to use it effectively. Oftentimes, efforts to integrate educational technology into curriculum fail to yield desired results because such efforts are not garnered by a sound system of quality assessment. The term “quality assessment in educational technology” means using appropriate assessment tools and methods to evaluate various stages in educational technology and curriculum integration. This paper will, therefore, address the following issues which are vital to our current practices in integrating educational technology into curriculum: (1) The needs for using assessment as an effective tool to enhance integration of educational technology into curriculum; (2) Ways of using various assessment methods to align educational technology with curriculum standards; and (3) Ways of teacher using assessment to create an effective learning environment with educational technology.

Needs for Assessment in Educational Technology

With the rapid introduction of computers into schools, routine access to multimedia and hypermedia resources by instructors becomes possible. Among many of technology users, three types of users typically represent those who are currently using the technology in today’s classrooms. They are: (1) follow-the-national-and-state-mandate users, (2) follow-the-fashion users, and (3) self-initiated users. The first type of users are passive in using the technology, simply follow the national and state mandate and use the technology in teaching as required by the school or the district. The technology therefore plays a very limited role in instruction under these circumstances. The second type of users are characterized by an “overnight” enthusiasm for the use of technology. Urged by their colleagues or peers who have integrated technology into teaching, they become enthusiastic about the technology and begin to use technology in their classrooms. However, their enthusiasm for technology is a short one and wanes quickly as they encounter difficulties in the process of using the technology. The third type of users are adamant about putting technology in their classrooms. This is a type of “I want to do it” users. Yet their technology and curriculum integration lacks a systematic planning and is not garnered by a sound system of assessment. Oftentimes, they found themselves in a situation where the result was only worth half of the efforts made. Obviously, if technology is going to play a positive role in teaching and learning, if learners are going to benefit from technology in their learning, if teachers want to create a creative and constructive learning environment, it is imperative to establish a sound system of quality assessment that evaluates “how teachers are using technology in the classroom and the general academic achievement that results from their instructional technology (IT) practices” (Moersch, 1999, p.41).

The National Educational Technology Standards for Teachers (NETS•T) Standards IV states that teachers “apply multiple methods of evaluation to determine students’ appropriate use of technology resources for learning, communication, and productivity” (ISTE, 2000). The challenges that we all face today are: how do we use methods of evaluation to determine students’ use of technology? And how do we know that teacher’s use of technology in classroom is working? There are various models that address the issue of integrating technology into curriculum. Bowens (2000) introduced a technology-integration model known as The RAC Model which consists of three phases: Research, Analysis, and Communication. The RAC Model starts with engaging students in gathering information by researching through various media including traditional textbooks, film/videos, Internet, then involving them in various higher level thinking activities such as analyzing and categorizing information, and finally using variety of technology to communicate the results. Although the Model discusses the role of technology in higher level cognitive learning, it fails to establish the connection between curriculum objectives and the use of technology. In Bowens’s model the functions of technology are not examined to provide a strong rationale for its use in
curriculum implementation. What has happened is that the users move directly from the stage of curriculum objectives to the stage of technology activities, that is, using the technology without understanding exactly why a particular piece of technology is used and what the functions are that will ensure the successful implementation of the curriculum objectives.

Morrison et al. (1999) proposed an Integrating Technology for Inquiry (NTeQ) model which addresses the issue of technology functions in curriculum integration. Morrison et al.'s model provides an excellent tool for teachers to integrate educational technology into curriculum. Yet their model regards assessment as a separate entity. The assessment is placed at the last stage of the NTeQ model. In other words, NTeQ Model adapts a summative approach rather than a formative one in assessing technology and curriculum integration. However, the authors believe that the assessment should be an ongoing process which must be built into every stage of technology and curriculum integration.

**Model of Assessment**

Being aware of the challenges that teachers face in their technology and curriculum integration and realizing that successful technology and curriculum integration depends on a sound system of quality assessment, we start to develop an assessment model which is based on five guiding principles: (1) student-centered, (2) focus on standards and objectives, (3) focus on students' ability to construct knowledge, (4) encourage higher level thinking, and (5) encourage reflective thinking. After an extensive study on national and state standards, we define two types of knowledge and three types of skills as the basic knowledge framework for evaluating teachers' use of technology and students' performance in a technology-integrated curriculum. The knowledge and skills include: (1) Declarative knowledge, (2) Procedural knowledge, (3) Complex thinking skills, (4) Effective communication skills, and (5) Collaboration/Cooperation skills. We believe the types of knowledge and skills we define are applicable to subjects across all curricula.

Our assessment model (EEAER Model) contains five stages: (1) Evaluate objectives, (2) Examine technology functions, (3) Assess technology-rich activities, (4) Evaluate learning outcomes, and (5) Reflect on learning experience (Figure 1).

**Various Stages in Assessing Educational Technology and Curriculum Integration**

![Figure 1: EEAER Model of Assessment](image)

- **Evaluate Objectives** Successful implementation of technology and curriculum integration starts with careful planning which clearly defines the curriculum objectives. Assessment is to ensure that curriculum objectives meet the standards. The evaluation of objectives, therefore, focuses on: (1) alignment with standards, (2) the role of technology in instruction, (3) the role of technology in learning, and (4) knowledge and skills covered. We used assessment tools such as checklist, matrix, questionnaire, Likert's rating scale to assess whether the objectives are aligned with various standards and criteria.

- **Examine Technology Functions** Technologies which apply well in one learning situation may not work well in other learning situations. Some students may benefit from a specific computer software...
whereas others may not benefit from it at all. The complexity of various functions of technology determines that the process of implementing a technology-integrated curriculum must be a complex one. Therefore, teachers need to identify the functions of technology and understand what software to use and how to use. For example, teachers may look at the functions of educational software by examining the role it plays in learning, whether it belongs to a productivity tool or a mindtool (Jonassen, 2000). If it is a mindtool, what specific function does it have? Is it a concept mapping tool, or a data processing, or a graphic/data processing tool? How well does it meet the curriculum objectives?

Assess Technology-rich Activities The technology-rich activities stage consists of three sub-stages: (1) Pre tech-rich activities. Students identify problems, plan how to collect, analyze, and categorize data; (2) Tech-rich activities. Students learn to use technologies and engage in higher level thinking activities via technology; (3) Post tech-rich activities. This is the enrichment stage where students engage in peer review, exploring other forms of content delivery, and examine how their knowledge becomes transferable to other learning situations.

Evaluate Learning Outcomes Four learning outcomes are essential for evaluating technology and curriculum integration: (1) Core technology skills (Coughlin & Lemke, 2000), (2) Cognitive and metacognitive skills, (3) Social skills, and (4) Attitudes. Coughlin and Lemke (2000) defined core technology skills as hardware, network, information tools, application tools, and multimedia/presentation. Cognitive and metacognitive skills include reasoning, analyzing, synthesizing, creating, constructing, problem solving (Marzano et al., 1994) and self-awareness, goal setting, and strategic planning. Social skills consist of collaboration, communication, contribution to group goals, etc. Finally, attitudes means students' motivation and disposition to learning, interest in using technology, and ability to face challenges in learning. Again, rubrics, portfolio, checklist, questionnaire, interview, observation are viable tools for assessing learners' learning outcomes.

Reflect on Learning Experience Oftentimes, assessment is a teacher-dominate process. Our assessment model tries to include students in the evaluation process. This will create in students a sense of ownership and motivate them to learn. In this stage students reflect on the technology and content learning, the technology and cognitive skills, and the transferability of knowledge to other learning situation via technology.

The EEAER assessment model is a dynamic, self-generating model in that each stage is an on-going, formative assessment process that detects and self-corrects errors in its integration of technology into curriculum. For example, when an assessment tool like checklist is used to assess the software functions and finds that the software selected is not the right tool for carrying out the objectives, other software will be chosen from the checklist to meet the requirements. Thus the assessment tool is not a passive tool that simply inspects, it is, instead, a dynamic tool that helps to form instructional decision based on standards. The five stages in the EEAER Model are an on-going, cyclic process in which the stages are interwoven and interacting with each other. For instance, the technology-rich activity stage may provide some feedback to the objectives stage which will be revised and which will, in turn, further affect the use of technology and the role of technology in learning and teaching.

Case study: the implementation of technology and curriculum integration with EEAER model

We have applied the EEAER model to several undergraduate and graduate courses. The results are positive. The students feel they understand better the functions of the technology, the relationship between technology and curriculum, therefore, are better users of technology in teaching and learning. A typical example is a graduate course we offered in the summer of 2000 in which we applied the EEAER model to integrate technology into curriculum.

The course is a graduate seminar entitled “Bridge building between community and school using educational technology.” It was designed to help the students become aware of the issues regarding school and community collaboration, explore ways to bridge school and community via technology, and appreciate the benefits of using technology as an effective tool to collaborate school with community. Fourteen graduates enrolled in the seminar. Among them eleven from elementary schools and three from junior high. Except one graduate student who was at administrative level, the rest were teaching at various grade levels in the subject areas of language arts, reading, math, science, social studies, etc. The course
objectives focused on integration of technology into the content area. The students were to use Web technology to create an instructional Web page which served as the link between the school and the community. The functions of Web technology were examined and assessed to determine if it fit the objectives and met the purpose of teaching and learning. Students also engaged in brain storming, discussing pros and cons related to the use of Web technology as a tool for school and community collaboration. They planned how to design and developed their Web pages. The instructors taught the basics in Web construction. But it was the students who decided what information should go into their Web pages and how their Web pages should be designed and developed. The students examined each other’s Web pages and engaged in an informal peer evaluation which became part of their valuable learning experience. Finally, students presented their projects before their peers. Comments were made regarding the content, the design and the techniques of their Web pages. In an aftermath course evaluation the students reflected that they learned a lot, understood better the content and issues and were able “to create a nice Web page.” Others commented they saw “the possibilities available to teachers for use in the classroom.” The EEAER model was integrated into the various stages of course design and development. Various assessment tools were used to align objectives with standards, examine the functions of technology chosen, garner the activities in which technology-integrated curriculum was implemented, and evaluate the learning outcomes by checking students’ performance in a technology-rich learning environment. By incorporating EEAER assessment model into the technology-rich curriculum we find that

1. instructors are able to align the use of the technology with standards; understand better the relationship between technology and curriculum, and use technology more effectively to achieve curriculum objectives;
2. students who use the technology become more goal oriented and know how to use technology as an effective tool to enhance their learning;
3. the use of model motivates the instructor to teach and the student to learn as the instructor knows better how to successfully integrate technology into curriculum and the student knows better how to learn more effectively with technology.

The EEAER assessment model is applicable to any subject. The model empowers the teachers by allowing them to easily and appropriately incorporate technology in their classrooms, assessing the students’ academic strength and weakness as well as their abilities to collaborate and communicate in a technology-rich learning environment. It also enables the teachers to evaluate how well they use technology in the classrooms.

Conclusion

The EEAER assessment model is a useful tool for K-12 teachers who are eager to but do not know how to infuse technology into curriculum. It is a tool that can be applied to subjects across all curricula. It provides the framework for teachers to go beyond the mere acquisition of technology for their classrooms to addressing the bigger question: How can technology be used to effect change and improve student learning and achievement?

Realizing that the model has a potential for helping teachers to improve their use of technology in classrooms, we also notice that the study is still in its fluid stage. It needs to be implemented in a more diverse population and learning setting so that the model can reach beyond its present study scope to generate findings that are significant at a more general level. We hope that our study will serve as a stepping stone which will attract those who are interested in building a sound system of quality assessment that will garner teachers’ use of technology in classrooms and their integration of technology into curricula.

**Acknowledgements**

The authors would like to express their thanks for the support from Goals 2000 Preservice Teacher Development Grant which helped shape this study.
Each year I look forward to the international proposals and then later to the papers sent, now electronically, from around the world. Initially any paper from outside the United States found its way into this section, but each year as we became more and more an international organization, as STATE became SITE, we looked for papers that told of IT in teacher education across national boundaries. Every year I have enjoyed a ‘world tour’ of IT and teacher education, marveling at the fascinating differences and the wonderful commonalities that we share. This year’s annual sees a change in format due to the large number of accepted proposals and the quick turnaround time. All of the papers within each section are listed alphabetically by lead author; however, section leaders have been encouraged to address them in logical groups, providing a ‘mental’ arrangement no longer possible in book form.

There are a number of papers this year that exemplify multinational perspectives and I have grouped them accordingly. Another packet of papers provide us with virtual windows on IT within individual countries. Several articles focus of IT with specific types of teachers. Finally, two papers address, to some extent, a more people-to-people view.

**Multinational perspectives**

Five papers represent the findings of panel members from the Project for the Longitudinal Assessment of New Information Technologies (PLANIT): 2000-2001, and should be read with this in mind. These researchers have gathered data about the impact of information technology on teachers and learners using a common set of instruments.

- **Magoun and Owens**, University of Louisiana-Monroe, USA, evaluate a project in Louisiana involving girls in research opportunities in computing.
- **Knesek and Christensen**, University of North Texas, USA, examine teacher and student attitudes toward computers in a suburban Texas school district.
- **Morales**, Institute of Latin American States for Education, Mexico, reports a similar study among students and teachers in the Mexico City area that marks a three-year Mexican contribution to PLANIT.
- **Khine**, University of Brunei, Darussalam, looks specifically at preservice teachers’ attitudes toward IT in Brunei, noting an interesting variation between home computer owners/users and those without, those without being more positive in the impact on student learning.
- **Palitawanont**, Burapha University, Thailand, explores attitudes in Thailand of students, teachers, and university faculties.

While the papers mentioned above spanned locations around the globe, the work of **Darkwa**, University of Illinois Chicago, focuses primarily on one very large continent, Africa, and the issues and challenges of creating virtual learning communities in incredibly diverse and difficult situations. Suggestions are given for overcoming the challenges confronting technology-based education in Africa.

**Freeman, Holmes & Tangney**, Trinity College Dublin, report on the curriculum, assessment and the use of ICT as tools to reshape learning in Finland and Sweden. The authors emphasize how Ireland could benefit from following the examples provided by these Scandinavian countries. The authors also provide a rich list of references, the majority accessible via web sites.

The next paper spans the Atlantic reporting on a collaborative effort by a South African University and an American University. The authors, **Kagima and Zayed**, University, United Arab Emirates; **Thompson and Phye**, Iowa State University, USA; and **Van Wyk**, University of Stellenbosch, South Africa, describe a project designed to enhance faculty capacity to meet a number of growing needs including the challenges of providing higher education to in-service teachers and practitioners.

**Virtual windows on IT**

The first two papers I recommend in this subsection examine IT inservice programs in the Western Hemisphere.

- **Valeke**, University of Ghent, Belgium, and **Chihuiza**, Escuela Superior Politecnica del Litoral, Ecuador; report on part of a six-year project to improve Ecuadorian elementary education. A sub-project focused
on the analysis of video materials and surveys that research the current dominant teaching-learning strategies adopted and promoted by teachers in the project. The second of these papers is authored by Jenkins, Gilbón, and Contijoch, National Autonomous Univ. of Mexico, Mexico. They explore the challenges language teachers now encounter and describe a project designed to address these needs through a model which combines the applied linguistic content with experience in the use of educational technology.

The next paper provides a critical analysis of the integration of technology in pre-service teacher education in New Zealand. White, University of Houston, USA notes while the country has made great strides there is a continuing issue of professional development of teachers and actual application of technology in the schools.

Chinese teachers have made an impressive progress in using multimedia in their classrooms, reports Ouyang, Kennesaw State University, USA, and Yao, Texas A&M University-Commerce, USA. These teachers participate in training to enrich their own technological skills, and utilize multimedia to improve teaching and learning.

Two articles examine IT in Malaysia. The first, by Luan, Bakar, Tarmizi, and Hamzah, Universiti Putra, Malaysia, describe the development of a group of assessment tools to evaluate teachers’ IT preparedness in three domains: the teachers’ actual IT skills, their knowledge about IT and their attitudes toward IT. They also describe what the instrument attempts to measure, how it is administered and present results of phases one and two of the study. The second paper, by Bakar and Mohamed, University Putra Malaysia, report a descriptive correlational study of vocational trainee teachers attitudes towards the integration of computers in teaching.

Lee and Wu, National Taiwan Normal University, Taiwan, provide us with an overview of IT in education in Taiwan, noting the dramatic increase in IT and the tremendous support given by the Ministry of Education of Taiwan.

People-to-People

In many ways the final two papers explore personal connections, one in a ‘virtual exchange program’ and the other in a real exchange, between international IT students and their hosts. A description of a “Virtual Exchange Program” is given by Junghans, Montana State University, suggesting this as a way to introduce an intercultural experience into the foreign language classroom that would directly stimulate and provide for an interest in contemporary German culture.

In the article, “Views from an Asian Bridge: How International Students See Us and Still Survive” Cornell, Lee, Chang, Tsai, and Tao, University of Central Florida, USA, and Ku, Arizona State University, describe the problems international students encountered and efforts being made to resolve them. While the setting of this last article is the US there are lessons are universal. Several in my family have studied in other countries, the UK and France, to be specific, and they had concerns and experiences not unlike those mentioned in this paper. Any student in a foreign land encounters similar problems and, one hopes, similar pleasures.

Abstract: This paper is a report of a study conducted to assess the attitudes of Malaysian vocational trainee teachers towards the integration of computer in teaching. One hundred and thirty trainee teachers participated in the study of whom 12.2% was male trainees and 87.8% was female trainees. They majored in agricultural science (13.7%), home science (17.3%), economics and accounting (22.3%), others (46.7%). Their minors areas were living skills (25.5%), business studies (70.5%), and economics (4.3%). In general, vocational trainee teachers had a positive attitudes towards the integration of computers in teaching. However, the attitudes towards the integration of computers in teaching did not differ among students with different majors and minors. Majority of them planned to integrate computers in teaching. A significant correlation was observed between their attitudes towards the integration of computers and their plan to integrate computers in teaching. They believed that all trainee teachers should be required to enroll in a computer class while in teacher training.

Introduction

Microcomputers has started to revolutionize the delivery of education in Malaysia when the Ministry of Education Malaysia initiated a computer in education project for Malaysian secondary in 1983. At that time twenty secondary schools were selected to participate in a pilot project called 'An Introduction to Computer' (Abdul Rahman Abdullah, 1986). The purpose was to equip students with basic knowledge of computers and it's applications. However during the 80's the integration of computer in the school curriculum was not as intensive as it was in the late 90's. During the late 90's the Government of Malaysia emphasized the importance and the role of information technology for national development. In fact, information technology has become a dominant feature of the National Policy. As emphasized in the Seventh Malaysian Plan, there will greater demand for workers with computer and information technology skills as a result of a greater use of information technology the operation of both government and non-government organizations. Preparation of workers with knowledge and skills in computerization begins in schools. Then only, computers became an important component of the school curriculum.

The Government is committed towards the use of computers in the delivery of education and as such a hefty sum of RM 12.5 billion was allocated to the educational sector in 1998. The large budget allocation was intended for the initiation of the infrastructures development and training needed to prepare students for the information age. Currently, many schools (both primary and secondary) has at least one computer with an access to the internet. To emphasize the seriousness of the Malaysian Government in preparing knowledge workers, the government through the Ministry of Education has embarked on the
project called SMART SCHOOL project whereby technology will be extensively used to support and enhance teaching-learning. The SMART SCHOOL project is aimed at re-inventing the teaching-learning process and promote creative and critical thinking among students through the extensive use of technology, the Internet and multimedia courseware. Currently, 90 schools have been transformed into SMART SCHOOL. The Ministry of Education Malaysia intends to have all its 10,000 school in Malaysia to be renowned as SMART SCHOOL by the year 2010.

The excitement to integrate computers in education is not without basis. According to Roblyer, Castine, and King (1988), research findings have made it clear that computer applications have undeniable value and have an important instructional role to play in classrooms. Others (Bruner, Buchsbaum, Hill, & Orlando, 1992; O'Brien, 1991; Papert, 1993) have affirmed that computer technology provides abundant opportunities for students to build or modify their personal knowledge through the rich experiences that technology can afford. Computer technology has the capacity to affect the efficiency and productivity of education (Yang, H. H, Mohamed, D. & Beyerbach, B., 2000). In fact, Pelgrum and Plomp (1991) observed that there was a phenomenal infusion of information technology in school worldwide and Malaysia is no exception.

The success of the integration of computers in teaching depends partly on teachers’ knowledge about computers, their skills in using computers and their attitudes towards the integration of the computers in their teaching. As Fouri and Gioia (1991) indicated, teacher’s attitude towards computers influences teacher’s willingness to use computers as a professional tool or the introduction of computer applications into the classroom. Woodrow (1992) also stated that positive teacher attitudes toward computers are widely recognized as a necessary condition for effective use of information technology in the classroom.

The question is ‘What is the attitude of Malaysian vocational trainee teachers towards the integration of computers in teaching?’ The answer to this question is needed if the integration of computer in Malaysian school is to be successful.

Objectives of the study

The objectives of the study was to assess the UPM vocational trainee teachers attitudes towards the integration of computer in teaching. The study also attempted to examine the relationships between trainee teachers attitudes towards the integration of computers in teaching with several selected variables such as: (a) level of confidence, (b) level of knowledge about computers, (c) interest towards computers, (d) whether or not they have their own computers, and (e) do they plan to integrate computers in their teaching.

Methods

The present research employed a descriptive correlation research methodology. Two hundred vocational trainee teachers who underwent a 12 weeks teacher training program were mailed the research instrument. They were requested to return the completed instrument within two weeks period. One hundred and thirty-nine completed questionnaires were returned giving a response rate of 69.5%.

The research instrument used to solicit the needed information consisted of attitudes items, one question each on gender, major or minor areas of study, academic achievement, interest towards the integration of computers in teaching, level of confidence and knowledge about computers. Trainee teachers attitudes towards the integration of computers in teaching was assessed using a 5-point Likert Scale (5=strongly agree; 4= agree; 3=moderately agree; disagree; 1=strongly disagree) Originally, the measure consisted of 36 items. However, based on the pilot test results 5 items were eliminated. The final questionnaire consisted of 31 attitudes statements. The 5 items were eliminated because of either the statements have near zero correlations or negative correlations. According to Mueller (1986), items that have near zero correlations negative correlations should be eliminated form the scale. These items did not contribute to the variance in the attitudes towards the integration of computers in teaching. An analysis of the responses from 30 trainee teachers who did not participate in the study yielded a reliability coefficient of 0.90 for the attitudes scale.

Results
A total of 139 trainee teachers responded to the survey. The respondents consisted of 12.2% male and 87.8% female trainee teachers. Their major areas of study were agricultural science (13.7%), home science (17.3%), guidance and counseling (23.0%), Malay language (15.1%), economics and accounting (22.3%), science and mathematics (8.6%). Their choice of minors were living skills (25.5%), business studies (70.5%), economics (4.3%). Their academic achievement as measured by grade-point average ranged between 2.00 and 3.74 with a mean of 2.91 (sd=.41). Some of the respondents have used computers for more than 10 years while some have just started to use computers about two years ago. On the average trainee teachers have been using computers for about 5.2 years with a standard deviation of 2.73 years. About one-half of the trainees (53.2%) own a computer.

The study showed that trainee teachers were not very confident in using computers (mean=3.71 on a scale of 1-5, sd=.55). They had quite a low level of knowledge about computers (mean=3.47 on a scale of 1-5, sd=.57). They had quite a high level of interest in using computers (mean=4.12 on a scale of 1-5, sd=1.01). Majority of the respondents planned to integrate computers in their teachings (93.5%). All of them believed that a trainee teacher should be exposed to a computer course while in training. The study also found that 61.20% the respondents had taken computer classes beside the computer classes offered by the Faculty of Education, UPM. The study showed that 59% of the respondents did not enroll in a computer course offered by the Faculty of Education, UPM.

Vocational trainee teachers attitudes' towards the integration of computers in teaching was assessed using a questionnaire consisting of 31 attitudinal statements. The total score obtained by the respondents ranged between 89 and 145. The total scale mean was 103.8 (sd=.836). The median was 104 and the mode was 105. The items mean was 3.95 on a scale of 1-5 (sd=.33). In general, trainee teachers tended to agree with most of the statements. Fourteen statements (45.0%) had a score of 4.0 and above, 12 statements (38.7%) had a score between 3.5 and 3.9 and eight statements (16.3%) had a score between 3.0 and 3.49 (Table 1).

Table 1: Means and sd. of vocational trainee teachers attitudes towards the integration of computer technology in teaching (n=139)
(Scale: 1=strongly disagree, 2=disagree, 3=moderately disagree, 4=agree, 5=strongly agree)

Item means=3.95, sd.=.33
Scale mean=103.8, sd.=8.36

A correlation analysis was conducted to determine if any relationship between trainee teachers attitudes towards the integration of computers in teaching and selected independent variables existed. Low significant correlations were found between trainee teachers attitudes and their level of knowledge about computers (r=.21, p<.05); level of confidence (r=.20, p<.05); and their intention to integrate computers in teaching (r=.20, p<.05). No significant correlations were found between the attitudes towards the integration of computers and whether or not the trainees own a computer, the number of years they have been using computers, and their interests towards computers. A One-way ANOVA test was performed to determine if there was any difference of attitude among students of different majors. It was found that attitude towards the integration of computer in teaching did not differ among trainees of different majors (F(6,138) = 1.902, p >.05) and among trainees with different minors (F(2,134) = .174, p>.05). The study also showed that attitudes towards the integration of computer technology in teaching did not differ (t(136) =-.31, p>.05) among students who have or have not taken a computer course offered by the Faculty of Education, UPM (mean=118.9, sd.=10.22; 118.3, sd.=11.79, respectively).

Conclusion

The following conclusion can be drawn from the study:

1. The study has shown that in general vocational trainee teachers had a positive attitudes towards the integration of computers in teaching. Thirty-three percents of the respondents obtained a score of 125 and above. They can be classified as having positive attitudes towards the integration of computers in teaching. About 60% of the respondents obtained a score between 96 and 124. They can be classified as having a moderately positive attitudes towards the integration of computers in teaching.

2. The vocational trainee teachers do not have a high level of knowledge about computers. Their level of knowledge about computers is about average (mean=3.47). A significant correlation was found between their attitudes towards the integration of computers in teaching and their level of knowledge about computers.

3. The vocational trainee teachers were not very confident in using computer (mean=3.71). A significant correlation was found between their attitudes towards the integration of computers in teaching and their level of confidence in using computers.

4. The vocational trainee teachers had a high level of interest towards computer technology (mean=4.12). However, no significant correlation was found between their attitudes towards the integration of computers in teaching and their level of interest towards computers.
5. The trainee teachers believed that all trainee teachers should have been exposed to a computer course.

6. The attitudes towards the integration of computers in teaching did not differ among students of different majors and also among students of different minors.

7. The majority of the trainees planned to integrate computer technology in their teaching.

Abstract: Increasing numbers of international students are entering the graduate programs in the area of Instructional Technology at the University of Central Florida. With this influx comes a series of communications and miscommunications between American faculty, staff, and students with their Asian and other international peers. This article and presentation describe the problems encountered and efforts being made to resolve them. It is our hope that other faculty, staff and students from North America will benefit from our experiences.

The Problem

Faculty and staff at our universities require a substantial amount of information to adequately advise international students who wish to enter instructional technology graduate programs. We choose instructional technology because this is the area in which we work. We feel that, within our field, members share a common bond that is unique, and this sharing needs to be passed on to any and all who might be able to assist our future and current students from abroad.

Like many of our academic peers, we encounter a range of experience among our faculty in advisement of new international students when they are studying with us. While some of this deficit rests with routine logistics involved with assisting international students, i.e., knowing details related to immigration, course load requirements, and related visa status, other elements present themselves in more unique ways.

A survey of faculty and staff in many programs reveals a lack the background and knowledge required to properly assist our international students.

A telephone and face-to-face series of interviews was conducted during May 2000, among fifty faculty members at the University of Central Florida (UCF) across all five colleges, to determine the extent to which they had previous international experience (Cornell, 2000).

In addition, during an International Studies Summer Workshop, also at the University of Central Florida, a 14-point questionnaire was given to over 100 faculty members related to faculty perceptions of international issues.

The findings obtained during both surveys revealed a wide and disparate diversity of attitudes, initiatives, and previous international experience, as might be expected from most academic institutions. Given that our institution has a strong international focus reflected in its strategic plan, these concerns were of interest to those of us who emphasize international outreach in the recruitment and retention of such students.

The telephone and face-to-face interviews asked respondents:

Do you have a valid passport?
When and where was your last trip abroad?
Have you had international students in your classes in the past?
Do you currently have international students in class?
Do you know the current status of your international students' I-20?
Do you know the visa designation of your current international students?
Are international students enrolled in your academic program major?
If so, how did they find out about your program?
If so, what information and services did you provide or arrange on behalf of your international student, before, during, and after completion of their program?

Questions in the second questionnaire (2000, Office of International Studies) asked faculty:
To what extent are you conscious of cultural differences among your students?
To what degree do you encourage diverse values?
What initiatives do you take in dispelling prejudices, stereotypes and misconceptions among students?
Do you recognize your own cultural biases?
What measures do you take to insure that your own prejudices or stereotyped thinking influences expectations from your students?
To what degree do you encourage students' mutual respect and open communications?
Do you search for ways to overcome student reluctance to recognize and discuss cultural/ethnic questions?
To what degree do you adjust your own teaching methodologies with students from differing cultures?
Do you demonstrate that academic expectations are equal for all students, regardless of cultural background?
Do you encourage the formation of cooperative learning groups that reflect diverse cultural and academic performance levels?
Do you include specific world areas and topics within your curricula?
To what extent do you keep up to date on issues and content related to world areas?
Do you feel that institutional resources related to international issues are adequate to meet your teaching needs?

Rather than dwell on the findings of these surveys, the aim of this paper and presentation is to accept the root cause of specific issues identified and to devise means through which they might be addressed. In this regard, we turned directly to our students and had them describe their own survival strategies while studying with us.

Using Maslow as our metaphor, we sought the advice of Dr. William G. "Bill" Huitt, Professor of Psychology and Counseling at Valdosta State University (Huitt, 2000). He generously provided us with a number of citations of his work and complete presentations related to Abraham Maslow and this provided us schemata or rubric upon which we placed our approach.

We took Maslow’s Hierarchy as a framework and asked our students to move through it, step-by-step, while they considered their own presence with us. It is the impact of commentaries by our students that constitutes the majority of this paper, for their voices, when heard by concerned faculty, staff, and fellow students, sing. Through these students, all of whom are Asian, we experienced their fear, anxiety, loneliness, isolation, and more. We also learned of their passions, their excitement, and joy of discovery. Together we present a quilt of numerous colors and textures.

It is our contention through this discussion, that the comments made, with some adaptation, may also be extrapolated to students from non-Asian nations, for such problems appears to us to be universal.

**Physiological needs** form the base of our model for it constitutes the first step along their path toward accommodation into our university culture. Neither this fundamental needs set nor those that follow necessarily lead to assimilation.

---

**Food**

What to eat? That posed a real challenge for our students. The immediate problem is to satisfy hunger pangs, and then to seek out sources of food that are as close as possible, to food consumed at home. Fortunately for students coming to Central Florida, there exists a wide variety of international cuisine from which to select, two of which are literally across the street from our campus. Such may not, however, exist among many of the smaller academic communities where international students might settle.

For many of our newly arrived international students, their first trip to an American supermarket posed a mixture of confusion, awe, and disbelief that such a preponderance of selections was available to them. What to purchase and to what extent it resembled their customary dietary needs posed a dilemma for many. Of course, there was always the option of indulging in a hurried trip to one or more American fast food establishments, as many did, only to find several hours later that their digestive system went into open rebellion.

Some of our new arrivals, accustomed to Asian cuisine, found limited availability of chop sticks, and had to conduct a rapid self-tutoring as to how to adapt to knives, forks, spoons, glassware, and only a single entrée.

Fortunately, most students adopted conventional American ways of eating with minimal problems, often within twenty-four hours of their arrival. They also, and with equal speed, located a variety of ethnically compatible sources of nourishment and continue to patronize such establishments with joy.

---

**Shelter**

Where will I live? That posed an immediate problem for our students. Our institution, like most in North America, has a well-established student residence office. There are a wide variety of choices for graduate students, most of which are adjacent to our main campus. This, however, is of little comfort when one walks off the plane after having flown twenty-four hours or more and the ravages of jet lag render them nearly immobile.
Typically, our arriving students have established contact with others from their country, and we hope one or more such contacts are there to meet them as they walk off the plane. In some instances, individual faculty members provide their new students with a few days of respite in their homes before the hunt for a new home has to begin.

Personally, I must admit that my own home has been functioning as a kind of international halfway house for some years now, and is likely to continue for some years to come. Not all faculty are as welcoming and, should no one be at the airport to meet a new student, problems can and do arise.

The immediate question raised by most is how far from the University will I be? The second question relates to how to get from their new home or apartment to campus, thus opening yet another series of questions as to available transportation, costs of same, and the wisdom of buying one’s own vehicle, be it a bicycle, moped, motorcycle, car or to simply take the bus or walk back and forth. All possibilities exist in and around most campuses but the questions posed are sure to arise soon after the student has recovered from their trip.

Clothing

What to bring? Often questions arise as to what type of clothing one will need, especially if one has come from a culture where specific dress conventions are followed. Islamic customs may pose unique problems for female students, as one example. Most students coming from one of the “Five Dragons” nations (Japan, Hong Kong, Singapore, South Korea, and Taiwan) increasingly wear Western clothing, much of it designer-label, so compatibility with North American standards is less and less problematic.

It was noted by the lead author, during a trip to China in December of 1999, that clothing styles among the younger citizens likewise reflects a Western motif. Where to buy new or replacement clothing sooner or later poses a problem for some, depending on what the international student brings with him or her. In this regard it is important to communicate with the prospective arrival as to appropriate clothing to conform to existing weather patterns. What we would recommend to one of our students will differ considerably from that of a student about to arrive in Minneapolis or Boston.

Safety needs form the second tier of our hierarchy, once the more primal needs have been addressed. Typically, either before a student arrives or once they are at the university, questions arise, i.e., “Just how safe will I be in this new environment?” Given the plethora of American mass-media content delivered abroad, small wonder that so many unanswered questions are posed, questions that North Americans take for granted, having lived through many prior experiences.

CNN aside, and in deference to the influence of innumerable media epochs laden with blood and gore, our international students need reassurance that in most of America, life is reasonably tranquil. Our citizens do not sport six guns in holsters strapped to their legs, (some Western States being an exception), and that in reality, American life can be quite peaceful, routine, and to some, boring.

As with any new environment, common sense dictates that caution be taken when walking alone at night, when in some “less-chance” neighborhoods, and that yes, the police will be your friend unless you break our laws.

“How safe is my new home or apartment?” A common question with no simple reply. Even in the best of neighborhoods, theft and mayhem occur, and few can predict when such events will happen. Once more, common sense must prevail, and admonitions made regarding security of one’s premises and person.

Once our students get into a familiar routine, and gain acquaintances, of both fellow nationals and of Americans, major concerns related to safety evaporate. This feeling may change should some untoward event take place so it is advisable to alert the students to avoid complacency lest they become vulnerable.

Belongingness and Love Needs

How can I belong? This question, while not always vocalized, remains foremost as this step of the hierarchy is encountered. Often a decision is made by the international student to either stay with my own kind or integrate. Because cultures other than ours differ greatly, there may appear to be reluctance for our international student to mix much with their American counterparts. This behavior may often be the result of natural shyness, homesickness, lack of English language skills, fear of being around those different from themselves, or a myriad of other scenarios.

Dating or Miss-dating?

It is not uncommon for our international students to experiment with dating American students, once they have overcome their initial discomfort with being in the new environment. On more than one occasion, hearts will be broken and
alliances severed. At other times, true and lasting relationships are formed, the bonds of which will last a lifetime. Marriage is often a goal for some of these students, and frequently the student will share such confidences, once a mutual trust has been established. It is here that the role of surrogate parent comes into play as well as the ability to discern if the intended relationship is mutual between the two parties and if the ultimate intent is one of love and affection or, as does happen, an expedient means through which to obtain a Green Card. Tact and empathy become valued attributes during such times and the question then becomes, "How much looking before I leap?"

Esteem needs entails more than being liked by others. It also address questions of self-worth, of feeling one is valued by others, and certainly, of beginning with valuing of self. To we rather brash Americans, such reflections of ourselves seem second nature but to those from other cultures, indulgence in one’s self is considered in poor taste. In these times of self-assertiveness, our emphasis on introspection, self-development, and need for esteem may appear strange to those from abroad.

The need to know and understand follows in our model and presents its own set of questions. These issues are not solely the purview of international students as their American counterparts voice similar concerns. Among them are:

- How do I know I know something?
- What should I know and how to learn it?
- "Knowing" not = to "Understanding"
- Acting on what I both know and understand.

Aesthetic needs begins the climb from more fundamental needs to those wherein the quality of life begins to emerge as being of importance. Some of our international students bring with them a finely tuned sense of aesthetics while others may ask, "Who needs them?"

Once the international student feels comfortable in immersing himself or herself into the mainstream of American academic life, both social and professional interests rise and decisions are made as to concerts vs. football, plays vs. parties, and inter-cultural collaboration. The question then becomes one of achieving a balance.

Self-actualization moves our model components up closer to the pinnacle and the major issue here is have I reached this level? How do I know? How do I know the "real" me? Do others know the "real" you? What are my next steps?

Transcendence is the true shining beacon of both Bill Huitt and Abraham Maslow, to say nothing of Mother Teresa. It is Nirvana for some, unachievable for many, and beyond the imaginations of most. It is the spiritual counterpart of being a mental giant yet, if applied with reason and care, maintains the qualities of caring, empathy, and more. Our international students may have already reached such a deified state and we would be unaware of it, because we are often unaware of them where they really are.

Faculty and Staff Role

There are many things faculty and staff can do to enhance the experience for our international students. Consider these experiences opportunities for mutual growth as you consider their impact.

Expectations of both faculty and their international students will vary but it is worth noting that:

- My expectations of the man may say more about me than about him.
- What I expect depends upon where I come from and the meanings I give to what I experience. Expectations occur on many different levels, from concrete, explicit to implicit and subconscious ones. When the expectations of who we are communicating with meet our own, there is mutuality of meaning (1998, Trompenaars and Hampden-Turner, p. 21).

In searching for the author’s meaning as quoted above, we need remain aware that:

- International students may be scholars but may not be too adept at “life” skills.
- Clarification is critical - what international students “know” may be inaccurate.
- Referral to other agencies and sources is invaluable.
Mentoring becomes memorable.

To facilitate transitions from homeland to North America a number of logistics items are worth noting.

**Before a student arrives** there remain innumerable questions unanswered and often it is the faculty member who can and does supply the answers. The questions may relate to programmatic and/or personal issues that need resolution.

**Legal stuff** involves providing assistance in applying, advising how to properly complete an I-20 application, clarification of various visa types such as F-1, J-1, H-1, how to obtain assistantships, tuition waivers, etc.

Conventional wisdom says that the American Embassies and/or Consulates, and the University’s International Student Office should provide the most accurate help in navigating these legal waters but in truth, small yet critical items frequently are omitted.

**Personal stuff** may be supposedly simple as advising the international student about what to bring, what to leave behind, and what items might be sent later. Keep in mind that the international student has very little understanding of what they will need in North America and what items might best be left at home.

Arranging housing should be done in concert with the University’s Office of Student Housing, as most such offices will have the latest information as to availability, price range, and suitability. This is important information to have but equally important is that the housing located be in harmony with the international student’s needs, and this is difficult for a busy housing office to determine.

**When a student arrives** involves assuring the student that someone will be there to meet, greet, and assist them in settling in. As was previously mentioned, if there is sufficient room in a faculty member’s home for a day or two, such a welcoming is never forgotten.

**While they are entrusted in your care** relates to what happens when they have settled in and are ready to come to the faculty member for advisement in the program. Care must be taken not to overwhelm the new international student, as their previous academic system may be totally different from the one in North America. Everything is new and everything is confusing.

Insuring that legal and financial affairs are addressed is most likely the task of the admissions office and the International Student Services Office but faculty should be alert to the many nuances involved in seeing that all papers are legally in order. Doing so protects both the institution and the student.

Making international students part of the technology studies “family” can be extremely rewarding for the international student. Consider that they have left their own families and friends behind, know very few people upon arrival, and this leaves only the students with whom they will be taking classes.

It is advisable to assign a peer mentor for the newcomer who can assist the student in transitioning from past to present. It is our feeling that, where possible, the peer mentor should be someone from the same geographic area from which the student comes. If not, then the peer mentor should be someone who has traveled abroad, and can thus empathize as to how being alone in another country feels.

Helping overcome difficulties that arise can be an issue, especially if the faculty member has no prior experience in dealing with international issues and concerns. The more the faculty member knows about the culture and customs of the new student’s country the better.

**Upon their departure** and the student has completed their academic program with you, the story has not ended. In fact, it is most likely just beginning for, if your student has met with success, it is the beginning of a lifelong relationship. Often such relationships lead to visits abroad to the student’s home country or exchanges of faculty between his or her institution and yours or the infusion of many more students from that nation. Our field of instructional technology is close-knit and long lasting.

**Summary**

Maslow’s Hierarchy served us well as a suitable rubric upon which to place our discussion and, in doing so; it has allowed us to see our students as they see us. Beyond all doubt, faculty, students and staff benefit equally. While the context of this article relates to those who come to us from overseas, what is true for our international students is true for ALL our students.

Creating Virtual Learning Communities in Africa: Issues and Challenges
Osei K. Darkwa, Ph.D., University of Illinois at Chicago, 1040 W. Harrison Street, Chicago IL 60607: E-mail: Darkwa@uic.edu; phone: (312) 996-8508.

This paper discusses the growing application of information communications technologies in Africa and other parts of the world. It examines the growing global information technology revolution and how it is transforming educational institutions. It then discusses the state of distance education in Africa, identifying the institutions offering distance education and the nature of the delivery platform used. The prospects and challenges in introducing distance education to tertiary institutions in Africa is discussed. Finally, it offers suggestions to overcome the challenges confronting technology-based education in Africa.

Introduction and background

The new information revolution has enabled academic institutions to provide a flexible and more open learning environment for students. The convergence of new information technologies such as telecommunications, computers, satellites and fiber optic technologies is making it easier for institutions to implement distance education (Harasim, 1993). Indications are that distance education in higher education will continue to grow (Hanna, 1998; National Center for Education Statistics, 1998; Rahm & Reed, 1998; Roberts, 1996). Over the past few years, the World Wide Web (WWW) or Information Superhighway has emerged as a locus of innovative instructional modalities in higher education (Patterson & Yaffe, 1994).

Higher education in Africa is facing a critical challenge to meet new demands for the 21st century. Africa has a population growth rate of 2.3%. This means that those seeking access to education at all levels-primary, secondary, and tertiary-will increase. In spite of this fact, educational institutions in Africa are not expanding enough to accommodate the increasing number of students seeking access to higher education. Africa needs a kind of education that would make it more responsive to challenges confronting the continent. Until such time as tertiary institutions in Africa have the resources for their own expanded traditional tertiary institutions, it would be in the interest of the continent if alternative ways of providing access to higher education via distance education is explored. Distance education makes it possible for students anywhere who have Internet and Web connection to enroll in on-line courses.

Even though the application and use of information technology in education in Sub-Saharan African has been severely underutilized, over the past few years, Africa has seen a tremendous growth in the use of technology on the continent. The past few years have seen pioneering efforts in a number of African countries to apply information technology to higher education. Among the countries are Botswana, Madagascar, Namibia, South Africa, Tanzania, and Zimbabwe. Countries such as Cote d'Ivoire, Togo, and Congo are joining the distance education bandwagon by establishing pilot virtual programs.

Distance education could be used to make it possible for African secondary school graduates, only a fraction of whom can be accommodated in African tertiary institutions, to enroll directly, and without leaving their homes, in on-line colleges and universities on the continent and around the world. Such form of education offers several advantages over the traditional educational system. Among them a) virtual access to faculty in higher institutions around the world, b) introduction of new interactive pedagogical techniques (e.g., more hands-on learning opportunities, etc); and c) the linking of institutions in cyberspace where resources could be shared by people and institutions in physically unconnected places.

But what are the prospects and challenges confronting African educators as they explore the power and applicability of new information systems to education. This paper addresses those challenges. First, it begins by discussing the growing global information technology revolution and how it is transforming educational institutions worldwide. It then discusses the state of distance education in Africa, identifying the institutions offering distance education and the nature of the delivery platform used.

The Promise of Distance Education

African educational institutions are confronted with several challenges; the challenge in training a cadre of highly qualified professionals to fuel development and address the challenges confronting the continent; the challenge of inadequate educational resources; brain drain and the loss of the best talented faculty to the outside world; the challenge of providing a more flexible educational system for students; and a host of other factors. Given the above challenges, it is highly unlikely that current educational institutions on the continent will be able to provide access and affordable education to all those seeking access. Even though tertiary institutions have a responsibility to produce scholars to fuel national development, higher institutions in Africa are constrained by space, time, and money. Against the backdrop of these factors, there is the need for the adoption of innovative learning methods that will permit the delivery of education to the majority of people who are looking for access to higher education.

Distance education appears to offer an option for African students in search of higher education but are not in a position to afford it. Distance learning can provide instructionally effective, highly interactive learning experience that are flexible, equitable and responsive to individual needs. (Rogers, 1996). Studies show that distance education is more cost-effective than
traditional programs, especially with large student enrollments and a good support system for students (Daniel, 1996). Unit costs per student is below that of conventional programs (Daniel, 1996).

The promise of ICTs on the continent is enormous. Emerging Information Communication Technology (ICT) holds much promise for breaking down the traditional barriers that have limited access to higher education. If this approach to educational development is used judiciously, it will open up new frontiers to learning; enrich collaborative research among African universities and between universities in Africa and other parts of the world; promote cross-national, multi-disciplinary perspectives in educational practice, and thereby equip students, faculty, and administrators with tools and resources that would enable them to successfully engage the academic world of the 21st century. Today, through distance learning strategies and computer applications, we can expand the content, extend the reach, and increase the effectiveness of existing academic programs. Through emerging communication technology, effective computer delivered coursework could be developed; and improve access to scientific and technical information.

Institutions With Distance Education Projects in Africa

Distance learning techniques are increasingly being employed by a growing number of higher institutions in Africa. While most of the on-going distance education initiatives on the continent have been used to upgrade the quality of basic education (ADEA, 1999), some countries are taking bold initiatives in piloting Internet-based, video-conferencing, and other forms of multimedia (ADEA, 1999). The University of Abidjan and the African Virtual University are good examples. Also, the Teleus program in Cameroon uses Internet-based courses in its science program. The FORST program links Benin and three other countries with McGill University in Canada. And the RESAFAD program in Djibouti provides teacher training from French universities (ADEA, 1999). For the majority of the institutions, the delivery platform to date has been text and correspondence based. This is supported by print material. Four institutions in South Africa provide distance education courses--Technikon SA, the Technical College of South Africa, Vista University, and the University of South Africa (UNISA), the oldest mega-university. Its distance education program to off-campus students was started in 1946 (ICDL, 1995; Wiechers, 1995), with an enrolment of over 130,000 in 1995 (Wiechers, 1995). This represents over one-third of all university enrolments in South Africa. These schools enroll over 225,000 students annually (Butcher, 1998). UNISA uses print material, audio cassettes, and community radio

The most ambitious distance education initiative on the continent to date is the African Virtual University (AVU) Project. This is the first satellite based attempt to harness the power of information technologies to deliver university education in the disciplines of science and engineering, non-credit/continuing education programs and remedial instruction to students in Sub-Saharan Africa. In the words of Baranshamaje (1996), it represents the quintessential instruments for sharing resources at affordable prices to large numbers of people (p. 3). The AVU project will deliver instructional programs, strengthen the capacity in African partner institutions, implement a network infrastructure, and implement a digital library program (Baranshamaje, 1996).

About five Anglophone and five Francophone African countries are participating in the initial pilot phase. The project will be extended to other African countries during the third and final phase (AVU Executive Summary, 1997). Another virtual university program supported by the World Bank and the Agence de la Francophonie is the Universit francophone project.

Challenges In Implementing Distance Education in Africa

While distance education holds promises, a number of obstacles will have to be addressed before it can be fully utilized on the continent. The following section addresses the challenges.

One of the major challenges in promoting distance education on the continent is technological constraints. Telephone and other communication infrastructure beyond the cities remain inadequate. Connectivity beyond the major capital cities poses a potential problem in creating a national distance education strategy. Even though Africa has about 12% of the world’s population, it has only 2% of the global telephone network and over half of the lines are in the cities (Marcelle, 1998). Telephone density is less than 2 lines per 1,000 inhabitants, compared with 48 per 1,000 in Asia, 280 per 1,000 in America, 314 per 1,000 in Europe, and 520 per 1,000 in high income countries (International Telecommunication Union, 1996).

Another challenge is the lack of a trained cadre of professionals to support the implementation of distance education. The effective use of distance learning technologies demands that faculty be properly trained in using distance education as a delivery mode. To date, few African scholars are familiar with teaching in an on-line (virtual) environment. And this poses a major challenge in introducing distance education on the continent.

The absence of clearly defined national distance education policies in most African countries poses another challenge. Policies are needed to provide a framework for the development of distance education in the various African countries. With the exception of South Africa, few African countries have a clearly defined national information or communication policy to guide the development of distance education and technological development in their respective countries. The absence of such a policy is a clear obstacle to the development of distance education on the continent.
Access to connectivity remains one of the major challenges in Africa. Students would need access to a computer that can send and receive messages using a "browser" such as Explorer 3.0 or higher, or Netscape. They would need an email program, which might be "hotmail" or a similar program. They might need a word processing program. They would need connection to an Internet Service Provider (ISP). They might need, depending on the course, access to a VCR to play videotaped instruction, and perhaps tape recorded lectures. They would need in some cases commercial textbooks. And all these cost money.

The Association for the Development of Education in Africa (1999) lists additional limitations. Among them are a) the lack of high level political support for distance education by political authorities in Africa, b) the lack of recognition of distance learning by the public service in its assessment of employee qualifications, c) the availability of professionally trained distance learning personnel, d) the lack of follow-up and support programs, e) limited budgets, and f) poor domestic infrastructure.

Closely related to connectivity problems is financial. ISP services are expensive in Africa. The connecting colleges charge tuition, in some cases by law very high tuition to students taking those courses. A source of financial support would be needed from some source. For example, multilateral agencies such as World Bank; the United States Agency for International Development (USAID), and national institutional donors such as churches and employers have a role to play in exploring funding sources.

Another challenge to overcome is cultural bias. Current research into distance education has focused on the process as a western social/cultural/educational constructs, and is being viewed by some as a way to export this worldview to other nations more efficiently and quickly than by other media currently available. (Moore and Thompson, 1990; Barker et al., 1996; Bork, 1993). Distance learning, by its very nature, involves more than just the transmission of information, but also the transmission of cultural/social paradigms between and among the participants. This transmission is a very important facet of any design of a distance learning curriculum that is sensitive to the cross-national cultural experiences (Cummings and Sayers, 1990, 1996; Sayers, 1991; Spiro, 1995). To date, most of the distance learning models have been developed and tested outside of Africa- in American, Canadian, or European educational environments. Without diligent research focusing on localizing content, this might pose a problem (Cummings and Sayers, 1990; Owston, 1997; Sayers, 1991). To date, few scholars or technocrats supporting the push for information technology access for schools have examined questions regarding the possible effects information gained, via the technology, may have on the culture and traditions of a people (Asante, 1992; Ani, 1994). Clearly, there is the need to address cultural issues so that distance education effort on the African continent would not be seen as an attempt by foreign institutions to extend their influence to the continent (some may view it as cultural imperialism).

Clearly these needs would at the present time make taking on-line courses difficult or impossible technically for those who a) do not have or can not get access to the computer, modem, ISP, and this would mean, the majority of Africans. Potential students in the larger cities that have ISP access, and which have or might have "community or church learning centers" or other ways of providing the needed technology, might be served quickly if the other issues can be attacked.

Closely related to connectivity problems is financial. ISP services are expensive in Africa. The connecting colleges charge tuition, in some cases by law very high tuition to students taking those courses. A source of financial support would be needed from some source. For example, multilateral agencies such as World Bank; the United States Agency for International Development (USAID), and national institutional donors such as churches and employers have a role to play in exploring funding sources.

Fortunately, Africa is awakening to the potential of information technology to take advantage of the opportunities offered by distance education. The efforts of national governments and international donor agencies have contributed to this situation. For example, the United Nations Economic Commission for Africa Pan African Development Information Systems (PADIS) Initiative aims to establish low-cost and self-sustained nodes to provide access to electronic mail in 24 African countries. Another is the African Information Society Initiative with its primary goal of building information and communication infrastructure in Africa. Similarly, the United States Agency for International Development (USAID) Leland Initiative aims to provide 20 African countries with connections up to 128 kilobits. In addition, the program will provide assistance with materials, expertise, training and free internet access for a limited period.

In addition to the above initiatives, professional organizations have emerged to champion and promote distance education on the continent.

Addressing the Challenges

Established institutions have a role to play in addressing the challenges in creating distance education on the continent. For example, religious organizations have a commitment to outreach, to service, to mission. They often have a room or two that is not occupied on days other than worship days. One of these rooms in the church can become a telecentre, a community learning center, and its services offered to the community surrounding the church as well as its own congregation.
distance education is spreading among African students and educators. The activities of community-based groups and Zimbabwe have made recent statements pledging their support to distance education. Awareness about the potential of sharing facilities and offering joint programs. This will go a long way to reduce the start up investment costs for the information infrastructure needed to launch distance learning initiatives on the continent.

Since the concept of distance learning and educational technology is still emerging on the continent, a learner support system needs to be put in place to assist students to comprehend all the technical details needed to make effective use of the technology. Research shows that distance learning requires a lot of self-discipline on the part of the student; student isolation tend to be high, compared to conventional learning (Potashnik & Capper, 1998). Strategies for reducing drop out should be put in place to ensure successful completion of programs.

There is the need for higher institutions on the continent to form partnerships with business, industry, and government to help promote distance education on the continent (Darkwa, 1999). These bodies will be very crucial in helping to advance the development of distance education. The private sector will help develop the technology for the delivery of distance education; the government will help formulate national policies to promote distance education, while academicians will help develop locally-based content (Darkwa, 1999).

Institutional linkage programs between African institutions and foreign partners who are pioneers in applying distance education is needed. Such programs will offer African students the opportunity to take courses on-line, without leaving the shores of their countries.

Creating awareness about the potential of distance education is needed to expose its potential. African Ministries of Education have a responsibility to assist in facilitating this process. Additional efforts could be made to explore the establishment of the necessary infrastructure to support the delivery of distance education courses outside the boundaries of the universities.

One of the major obstacles to expanding the incorporation of distance education into the educational system in Africa is the lack of a well-developed telecommunication infrastructure on the continent. The telecommunication industry is not very active in the provision of telematics services. Besides, telecommunication services are limited to urban areas in Africa. Rural telecommunication infrastructure is highly underdeveloped. This implies that rural institutions are less likely to benefit from the advantages offered by information technology. This calls for an extension of the telecommunication infrastructure to be extended to the rural areas of Africa.

The need for faculty training is essential if Africa is to make any significant headway in applying DE technologies for social work education. Faculty training could be done in conjunction with private information technology institutions and relevant academic departments who have expertise in these areas. The training could be offered by renowned experts in both the public and private sector who have distinguished themselves in the use of emerging communications technologies.

Steps should be taken to advance and support the use of information technology and move rapidly and aggressively to develop programs of the highest quality to advance the promotion of technology-based development on the continent. This should be seen as an act of strategic that touches on the future of higher education on the continent. We hope African educational policy makers will explore, encourage, and promote the development and use of emerging communication technologies at all levels of our educational spectrum.

Invariably, the decision to develop the infrastructure needed to launch distance education initiatives on the continent is primarily a political one. This need to build the continent's distance learning capacity has been echoed by interest groups on numerous occasions. It is time to translate words into action by putting structures to help promote distance education. If the authorities in key decision making positions fail to act, there is little hope for seeing progress in this area. Without this, it will be over-optimistic to expect far-reaching changes in the telecommunication infrastructure of Africa. This calls for a commitment on the part of African political leaders to address the telecommunication imbalance in the country. Without that, very little progress will be made in this area. This requires a whole-hearted political commitment to this cause.

Future Prospects

In spite of the challenges confronting the advancement of distance education on the African continent, there is a growing interest in the concept. Several African leaders are increasingly becoming aware of the potential of distance education in addressing educational challenges. The political leadership in countries such as Burkina Faso, Ghana, Kenya, Tanzania, and Zimbabwe have made recent statements pledging their support to distance education. Awareness about the potential of distance education is spreading among African students and educators. The activities of community-based groups and
academic organizations such as the Ghana Computer Literacy and Distance Education, Incorporated (GhaCLAD), the African Distance Learning Association, the Association for the Development of Education in Africa (ADEA), the Commonwealth of Learning, and the Working Group on Higher Education (WGHE), African Association of Universities (AAU), the West African Distance Learning Association, the Acacia Initiative, the African Information Society Initiative (AISI), and WorldLinks have contributed to this awareness. Multi-country cooperation in launching distance education initiatives (e.g., the cooperation between Mauritius and Madagascar, and between Cote d'Ivoire and Burkina Faso), and the creation of non-university-based distance learning programs are likely to be the norm. National organizations have emerged in some African countries to promote distance education. An example is the National Association of Distance Education Organizations of South Africa (NADEOSA). The activities of such organizations are having a tremendous impact in shaping the future of distance education in Africa. The future looks bright for the evolution and development of distance education in Africa.

Conclusion

Effective measures to sustain distance learning initiatives needs to be considered. While donor funds could be used as the basis of establishing distance learning programs on the continent, sound financial planning by African educators to ensure that funds will be available to continue offering distance education programs when donor funding dries up. Tuition has traditionally been where most of the revenue to sustain distance learning initiatives have come from. In addition to this source of funding African stakeholders interested in launching distance learning initiatives could pool resources together to share facilities and offer joint programs. This will go a long way to reduce the start up cost investment in information infrastructure needed to launch distance learning initiatives on the continent.

Universities without walls have a lot of appeal to Africa, given the multiple economic constraints confronting the continent. On-line universities without walls will enable Africans to increase enrollment levels, gain access to up-to-date educational materials through on-line libraries, provide virtual access to the best faculty around the world, share resources, and become part of the global learning community.

Since the concept is still emerging on the continent a leaner support system needs to be put in place to assist students confronted with challenges. Strategies for reducing drop out should be put in place to ensure successful completion of programs.

Africans need to examine the pedagogical effectiveness as well as the cost of each of the available delivery platforms to ensure that it has the capability of meeting the educational needs of institutions that make use of it.

The complexities for introducing distance education to the continent is enormous. But, this initiative appears to represent hope for the millions of Africans who are looking for access to higher education. It is our hope that through distance learning opportunities, fewer Africans will leave the continent for better opportunities elsewhere. The hope is that we can become a team of friends and devoted collaborators, pooling our experiences, resources, and connections to serve the African continent.

 ICTs for Learning
An International Perspective on the Irish Initiative

e-mail Tangney@tcd.ie Web www.crite.net

Abstract
"Where the appropriate systems of support are in place, then ICT can be experienced as a 'transformative technology' both for staff and for students [Comber & Lawson 1999, p 51].

Around the world governments are investing heavily in promoting the use of ICTs within the school system. Our research explores the Irish Policy Framework (IT 2000) and the National Action Strategies of two European countries, Finland and Sweden. The focus is on curriculum and assessment, and evaluation of the use of ICTs in the classroom, as these are key factors in forming policies to influence the use of ICTs as tools to reshape learning. An underlying aspect of the research is that, due to the use of ICTs by governments for the dissemination of their national strategies, concerned individuals can be empowered to compare and contrast policies, identify best practice and make a contribution to the formation of the policies of their own nation by publishing in turn their research.

The Irish Initiative - An Overview

In 1997, the International Data Corporation (IDC), ranked Ireland in the third division (position 23) with respect to the country's preparedness for the Information Age [IDC 2000]. Recognising that Ireland was lagging significantly behind, the Irish Government's Schools IT 2000 initiative was launched in November 1997 to redress the balance in the area of education [DES 1997]. IT 2000 has yet to be fully evaluated but the implementation of the programme allows for its comparison to similar initiatives in other countries so as to assess and expand the programme.

IT 2000 is a policy framework for the integration of ICTs in first and second-level schools. The core objective of the policy was to put in place an infrastructure to ensure that: 'pupils in every school should have opportunities to achieve computer literacy and to equip themselves for participation in the information society; support is given to teachers to develop and renew professional skills, which will enable them to utilise ICTs as part of the learning environment of the school' [DES 1997, p. 2-3].

In order to achieve these aims, IT 2000 sought to target action on: classroom resources and infrastructure, teacher skills development and support, policy and research. A key objective was to 'bring about a national partnership involving schools, parents, local communities, and third-level institutions together with public and private sector organisations to meet the project's ambitious aims' [DES 1997, p.2]. In order to manage the implementation of IT 2000, the National Centre for Technology in Education (NCTE) was set up in March 1998. A key aspect of the plan was that a policy formulation unit was to be set up within the educational ministry to act as the focal point for the formulation of policy in all educational ICT related matters.

Since the launch of IT 2000 in 1997, the profile of ICTs within the country at large and the education system in particular has been raised significantly. Most schools are connected, by at least a dial-up line, to the Internet and over 40,000 teachers have participated in at least one course in computer literacy training. A national educational portal (Scoilnet2) has been set up and funding has been provided for selected schools that are engaged in ambitious ICT related projects.

How effective IT 2000 has been in improving the quality of learning, or to what extent ICT has been integrated into the teaching process, are important questions to ask at this stage but the lack of a large scale integrated approach to assessment should not preclude valid individual assessment of government needs.

3 The Schools Integration Project (Support Infrastructure strand) of IT 2000 has produced the best examples of learning with technology. See www.sip.ie for details.
policy. The increasing use of ICTs to disseminate information provides a platform for a widening of the idea of action research so that teachers can learn from reflecting on and assessing their own practice, this should be further expanded to include the role that individuals within a system can have in reflecting on and evaluating their own environments.

We believed initially that ICTs within the classroom is still largely confined to the ‘early adopter’ category and that severe challenges are in store in any attempt to spread the use of ICTs into the ‘late majority’. We decided to check our initial impressions and benchmark Ireland’s progress on the treatment of the key issues of evaluation, and curriculum and assessment, compared with that of ‘leading countries’ in the area of ICTs and learning.

**Scandinavian Initiatives**

Finland and Sweden are, among two of the Scandinavian countries, regarded as having a progressive approach to Information Society issues in general and education in particular. They are also comparable to Ireland in terms of population and economic climate. Unlike Ireland these countries have had substantial investment in educational action strategies for ICT going back to the early 90’s, moreover, they have had the time to learn from evaluations of their previous strategies. Their current strategies for Education are action strategies, which clearly articulate a vision for the reshaping of the curriculum and the organization of learning.

**Finland**

Finland’s most recent National Plan (2000-2004) is a concerted effort to implement a comprehensive action strategy aimed at reshaping the role of learning within, and outside, the school system. The focus of the strategy, “Education, Training and Research in the Information Society. A National Strategy for 2000 – 2004” is on education, training and research [Finnish Ministry of Education 1999]. While a strategy, of itself, does not create educational change, the commitment on the ground may be furthered with strong signals from the top that in turn support bottom up initiatives. In terms of equality of opportunity, the plan safeguards corresponding standards for both students and teachers. The Finnish strategy provides students and teachers with a detailed framework for the organisation of learning, in contrast with the Irish framework, which appears to lack this dimension in its planning. Furthermore the strategy is a learning and motivation campaign for the population as a whole. It focuses not just upon formal education, but also on all sectors and includes all citizens, from the very young to the elderly. One of the key aims of the Information Age is empowerment of the individual in terms of life-long learning. This is emphasised in the Irish Government’s action plan for implementing the Information Society, where it is stated that, ‘...developing the concept of lifelong learning, of extending access to the formal educational infrastructure to those outside the formal education process and of identifying further options to introduce new learning possibilities for the population in general’ [Government of Ireland 1999]. ‘Learning to learn’ is one of key indicators in a recent EU report on the quality of school education [EU 2000] and the Finnish strategy recognizes this importance and that students and teachers need to improve their skills in the area of communication and in the acquisition of, and management of, information.

**Sweden**

Support from the top has been recognized as one of the key factors in achieving innovation in the Information Age and the Swedish IT Commission has played a highly influential role in supporting governmental developments in this area. The present commission, appointed in May 1998, is chaired by the Minister of Industry and Commerce. An interesting aspect of the Swedish Information Age initiative has been the setting up of a Youth Council to encourage discussion on the future society from young people’s perspectives and, in addition, to propose political actions to respond to the progression towards a future society based on the use of ICT.

In 1998, the Swedish Government submitted to Parliament the report “Tools for Learning - A National Programme for ICT in Schools. [ITiS 1997]. The Delegation for ICT in Schools was given the task of planning and implementing the programme, which became known as the National Action Programme 1999-2001 [ITiS 1998]. The emphasis of the plan is on teaching with technology, rather than teaching about technology, emphasised by Wärnersson stating that: ‘The new technology will not replace teachers, textbooks or the classroom. It will supplement them by creating new combinations of
opportunities and help to put pupils' learning in the very centre.' [The Minister for Schools and Adult education 2000] It is based upon a revised curriculum and subsequent changes in the learning environment. In scope it covers pre-school, compulsory school and the upper secondary school. The implementation plan was initially expected to involve 60,000 teachers (40% of teaching workforce) but has recently been increased to reach 73,000 teachers.

From Policy Framework to Action Strategy - Issues

As previously stated IT 2000 has had a significant impact on the Irish education system. From the strategic point of view, however, a number of aspects of IT 2000 bare reflecting upon and these are now discussed with reference to the Scandinavian initiatives.

Overall Scope and Aims

The original IT 2000 framework document stated that, 'among the most important outcomes of the framework will be a comprehensive national policy on the role of ICTs in Irish schools together with a strategic action plan specifying the activities and resources necessary to fully implement the policy' [DES 1997 p.22]. A policy unit, however, was not formally set up until October 2000, which meant that an air of uncertainty surrounded much of the implementation work of the program.

One of the key aims of the Information Age is empowerment of the individual in terms of life-long learning. This view is echoed in much of the Information Society literature, for example [ISC 1999, 2000]. The focus of IT 2000 has however been upon first- and second-level schools within the formal education system with other areas receiving attention only from parallel initiatives if at all. This contrasts sharply with the Finnish strategy, which embraces all learners from the very young to elder citizens.

At the outset of planning in Ireland it was acknowledged that integrating ICTs in learning is a complex process. It was also accepted that revolutionary approaches and 'quick-fix' solutions involving extensive expenditure on hardware and software can carry the very high risk of large-scale waste and furthermore of outright failure [DES 1996]. With this awareness incorporated into the overall policy, IT 2000, nonetheless, allocated 60% of its total budget on equipment and infrastructure. One justification for this was the relatively low base from which schools were starting.

The most recent data available from the NCTE states that the total number of computers in schools has increased by 65% since 1998, with the current student to computer ratio at Primary level being 18:1 and Post Primary 13:1. All schools are now connected to the Internet by at least a dial-up line. 69% of Post Primary schools have an ISDN line and 62% of all schools have Internet access on more than one machine.

According to an international survey carried out by Angus Reid, 78% of Swedish students, between 12-24 years, are using the Internet from school (nearly three-in-four students in Sweden say they use the Internet from school, a proportion roughly equivalent to the level of home Internet access). More than nine-in-ten students who have Internet access report using the World Wide Web to complete their school assignments. [Angus Reid 2000].

Evaluation

Evaluation of the effectiveness of the use of ICTs for learning is a fundamental concern at present, particularly as there is a remarkable absence of reliable data on the use and effects of ICTs in European countries. One of the key recommendations of a European report, focussed on how learning with ICTs is changing (13 countries), was that EU 'central ministries and regional authorities should co-operate in gathering, analysing and disseminating data, not only on inputs into the system such as pupil/computer ratios, but also on process variables such as deployment and pupil/teacher access time and actual

4 Ms Wärnerson, Minister for Schools and Adult education, in a foreword on ITIS website: http://www.itis.gov.se/english/back.html#A National Action programme for ICT - why?/
outcomes’ [Becta 1998, p17]. Government supported initiatives in Finland and Sweden are to the forefront in this regard, while to date most of the studies of IT 2000 have been quantitative rather than qualitative in nature.

Prior to and during the period of the Finnish National Strategy 1995-1999, significant funding was made available to schools, universities and vocational institutions in order to purchase ICT equipment to network schools and to fund teacher training. The Finnish Parliament’s ‘Committee for the Future’ adopted ‘ICTs in Teaching and Learning’ as one of its evaluation projects and asked the Finnish National Fund for Research and Development (Sitra) to administer it. Hundreds of pupils, teachers, decision-makers, researchers and officials participated in the project. Various reports focused upon: universities, kindergartens and institutions of general and vocational education, lifelong learning and digital learning materials. In addition to eight reports published in Finnish, a final report was published in English entitled ‘The Challenges of ICT’ [Sitra 1999]. The important value of these reports is the extent to which they were able to inform subsequent policy formation.

The Swedish National Agency of Education (Skolverket) plays a strong role in ensuring the collection and analysis of data from ongoing learning projects in the schools. Follow up research activities are undertaken by a special research unit within the agency. Skolverket also sponsors the research programme ELOIS (Students, Teachers and Organisations around Information Technology in School), which is an extremely important participant in the evaluation of ongoing activities [ELOIS 2000]. The work it produces includes annual reports on the influence of ICTs on the role of student, teacher and organization of work. The agency is supported in this work by eleven centres across Sweden. In addition to four quantitative studies (supply and resources of computers), extensive qualitative reports with information on international experiences are also available, [Skolverket 2000]. Further information is available from the Foundation for Knowledge and Competence Development (KK-Foundation), established in 1994, which has put in place a web-based database of projects. The projects are used to evaluate and test innovative activities using ICT as a pedagogical tool. The wide and varied experience of involvement in over 250 projects, ranging from Teaching Materials to Disability and ICT, are disseminated to aid in influencing future developments [KK 2000].

Thus it can be seen that substantial qualitative studies are central to the two Scandinavian initiatives. Ireland could benefit from following such examples.

Curriculum, Assessment and Learning Environment

Curriculum and assessment are at the heart of any educational system and to a large extent shape the nature of the learning environment. A key objective of IT 2000 was the introduction of curriculum innovations to enhance learning through the use of ICTs in the classroom [DES 1997 p. 26]. This development was to be achieved through co-operation with the National Council for Curriculum and Assessment5 (NCCA). While one of the principles of NCCA policy is that all learners should use ICTs in relevant curriculum contexts, [NCCA 1998], there is only limited mention of ICTs in many of the revised curricula. This holds particularly true for the new Primary Curriculum6, Junior Certificate and Leaving Certificate7 curricula. This has very serious implications for the organisation and reshaping of learning in Irish classrooms. The syllabi afford great freedom to innovate, the process, however, is not credited in national assessments. While there is much talk about the benefits of life long learning, Little (1991) referring to the Irish educational system notes that ‘For many learners at second and third levels the most important thing is not that they should learn, but that that they should get good qualifications’ [Little 1991, p. 47].

Teachers understandably see the curriculum, and particularly assessment requirements, at second level, as not yet strong enough to make the integration of ICTs an imperative for schools. Evidence of this is

5The National Council for Curriculum and Assessment (NCCA) is the body responsible for advising the Minister for Education on matters related to the curriculum and assessment procedures for primary and secondary level education.

6A new Primary School Curriculum was introduced in 2000.

7The Leaving Certificate is the national-wide state examination taken at the end of secondary-level education. For most students the results of this exam is the sole criteria taken into account for entry to 3rd level education.
found in a recent survey of Irish post-primary teachers, where it is reported that just 29% of the teachers surveyed had used ICTs in teaching [Mulkeen 2000]. Conway argues that 'IT 2000 underestimates the curricular scope of computer literacy and although it is not a curriculum document, the inattention to the curricular scope of ICT integration is problematic' [Conway 2000]. Austin et al [NCTE 2000, p. 88] argue that if the intention is that ICTs will have a catalytic effect on classroom practice, policy must play a critical role in ensuring that curriculum and assessment systems accommodate this change.

In Sweden, since 1992, there has been a major shift in focus from teachers teaching to pupils learning. The new curricula and syllabi state that all subjects should integrate the use of computers as a tool where appropriate [ITiS 1998]. In line with this, assessment structures and the organisation of learning and the leaning environment have also been modified. ICTs are seen as powerful tools to promote the transition from one teacher to one classroom to teams of teachers working together with larger groups of students.

"Evaluations of ICT projects in schools provide strong evidence that only when the organization of work has been changed can the introduction of ICT fully support the learning of children." [ITiS 1997]

An outstanding example of a collaborative and integrated learning environment is the Swedish Färila Project, where classrooms have been replaced with open areas and the traditional teaching style replaced by a more collaborative learning focus. All students have access to a personal portable computer. Just 16% percent of time is spent studying with a teacher, reduced from 42% in 1995 [Knut 2000]. This radical overhaul has contributed to the raising of grades in one particular school from one of the lowest in the country in 1993, to being a school with one of the highest grades in 2000.

Across Sweden inter-disciplinary, problem-based and pupil-oriented development projects are planned and carried out together by pupils and teachers working in teams. The aim is to promote and develop the learning approaches of students and teachers. A pedagogic facilitator appointed by the municipality supports the teams, but using each other’s knowledge is prioritised. Furthermore, each one of the teachers was supplied with a multimedia computer for the home. The idea behind this is that teachers who use computers at home will use it as a professional and pedagogical tool. Local conditions and the individual desires and needs of participants are taken into consideration in the planning of training for students and teachers. Active involvement of Head Teachers is strongly encouraged and supported. The work of schools involved must be organised in such a way for the team to be able to work effectively on a joint development project. The school must ensure that it has in place technology of appropriate capacity and of sufficient quality to support the work of the team. Organized technical assistance for the participants is at hand to ensure that ICT functions as a working tool in the classroom, [ITiS 1998].

Similar characteristics can be found in the Finnish strategy, which places strong emphasis on the participation of students. The plan acknowledges students' information technology skills and encourages their participation in the practical operation of educational establishments. Even more importantly the involvement of students in the preparation of teaching materials is encouraged. Students, especially female ones, are encouraged to participate through the awards of scholarships, fees and involvement in competitions arranged with appropriate business sectors. In keeping with the emphasis of the role of the learner, the curriculum has been changed. The Finnish policy, moreover, emphasises a move from the classroom to the development of an open learning environment. There is a specific action in the plan devoted to the planning of education and educational establishments and their influence on the teaching and the learning environment.

**Conclusion**

Bearing in mind, 'that among the most important outcomes of Schools IT 2000 will be a comprehensive national policy on the role of ICTs in Irish schools together with a strategic action specifying the resources necessary to fully implement the policy'. Ireland has much to learn from developments in Finland and Sweden [DES 1997, p4]. IT 2000 noted the high ranking of small countries and, in particular, the fact that all these countries had national strategies for integrating ICTs [DES 1997, p.14].

---

8 The Färila school website is at: [http://www.farila.ljusdal.se/farila_sks/](http://www.farila.ljusdal.se/farila_sks/) (Information available in Swedish only).
In Finland and Sweden, the National Strategies have played their role, but even more importantly comprehensive action plans have been developed arising from in-depth evaluation of learning with ICTs in both countries. Finally, evidence of the recommendations of the evaluation of ICTs for learning is evident in the incorporation of an adjusted rethinking of curriculum, assessment and learning environment in the action plans of both countries. In summary, both action strategies have evidently prioritised the pedagogic and catalytic goals for integrating ICTs alongside, but not above the social, vocational and economic benefits of their use.

"...many countries are just at the start of a very long and challenging road ahead, but it is intended to make that path somewhat easier by distilling the wisdom from what others have learned and sharing the results." [Becta 1998]

Abstract: Given the recent rapid changes in the educational field in Mexico many language teachers face new challenges for which even recent graduates of training programs may be ill-equipped to deal with effectively. Among other new challenges, teachers are being expected to take an ever more active role in syllabus, program and materials design. They are also increasingly expected to be able to manage new technologies. In order to participate they need to transform themselves from technicians to professionals and to do this they need updating in the theoretical and practical bases of their field. This project, sponsored by the National University's Support Program for Institutional Projects for the Improvement of Teaching, hopes to address these needs through a model which combines the applied linguistic content with experience in the use of educational technology.

Objective

The project's objective is to design a distance-learning teacher-education model, including courses, that might serve as the basis for in-service development of language teachers at the high school and university levels, in the area of applied linguistics. The goal of the project is to create a learning community among course participants. They will experience (in many cases for the first time) the use of educational technology to support their learning and will become both independent and collaborative learners. Proposed activities will encourage interactivity within the learning community; participants will inevitably discuss, argue and share their beliefs and ideas about their own teaching. In the long run we hope to create colleagues not only former students.

Background

Since 1980, the Foreign Language Center at the National Autonomous University of Mexico has trained more than 800 foreign language teachers. These teachers work at both public and private high schools and universities. In conjunction with the Graduate Program in Linguistics, the center offers both a Masters in Applied Linguistics and a Doctorate in Linguistics.

This project is part of a university-wide program to benefit researchers and teachers. In an effort to respond to teachers' needs for better professional development, a group of researchers at the Foreign Language Teaching Center proposed designing a Distance Learning Diploma in Applied Linguistics that, to
The project was inspired by the previous work done on distance education and most particularly on the work of Dulce Gilbón Acevedo who with Karen Lusnia designed the first course in distance education for professors at our center (Lusnia & Gilbón 1998) and most especially on the work done by Dulce Gilbón for her master’s thesis on the need and possibilities for graduate education in applied linguistics. (Gilbón 1998) On these foundations the project was designed and approved, and with the new year we began to work in earnest.

The program

The program consists of a series of courses related to the most salient areas in the field of Applied Linguistics, i.e. Introduction to Applied Linguistics, Psycholinguistics, Sociolinguistics, Evaluation, Reading Comprehension and Linguistic Aspects in Communicative Approaches. At the very beginning, a course called “How Do I Learn Applied Linguistics through Distance Learning?” is required. This is a 30-hour course to give an orientation to the use of educational technology and to teach some basic information on Applied Linguistics. This course has been piloted once and although it has been well received is being revised.

The program is in a sense open ended. These courses, or modules, are basic to teaching situations of the participants but as more modules are created it is hoped that the teachers can design a program that fits their own needs.

The model

The development of the teacher-education model has taken the following issues into account:

a) Teacher development. Continuous teacher education is absolutely necessary for high school and university teachers. Both the model and course content have to meet their needs.

b) The design of the program. A constructivist/collaborative perspective seems to be the most promising.

c) Materials development. Both printed and on-line materials will be used. If necessary, CD-ROMS, cassettes and videocassettes will also be developed. The criteria for the use of media must be based on the goals and needs of the participants on the practicalities of their situations.

d) The role of educational technology in all of the above

In the research team’s view, a teacher-education model is a symbolic representation of the teaching-learning process. However, a model can be interpreted in different ways, as it is only a way of looking at interrelated issues. The same model can be interpreted at different levels: epistemological, theoretical or methodological. In the development of this model we refer to those theoretical issues that have been considered up to now and that have been fully discussed by the project team.

Although the final model is still a rather vague and heuristic one, the discovery process of the interaction in the development team has lead to a reconstruction of views even among those of us who have taught instructional design. Some of the models we have discussed have been algorithmic, some impressionistic but the above elements have appeared in all.

Teacher development
Teacher development is a continuous process. It can be an independent process in the sense that it is the teachers themselves who want to take part in a development program. Teachers will come to the program with their own experiences, with background knowledge about each of the courses, and with expectations and ideas about what teaching is, and about the use and usefulness of educational technology. In the learning process itself, they will be confronted with new knowledge that will help them to think about their teaching practice and their attitude towards the program. Course activities will lead teachers toward learning by doing and experiencing, and reflecting on what has been learned. (Scrivener 1994, Díaz Barriga & Hernández 1998)

It is also important to consider at this point the fact that teachers are adult learners who, by definition, grew up without the most recent technological innovations; inevitably, some will resist the change from print to “on-line”. They can be expected to take time adjusting to the virtual classroom. Thus, the project cannot rely exclusively on multimedia technology. The goal is to introduce or seduce the participants into seeing the advantages that they can achieve by the use of the technologies. In our pilot of the first course these issues emerged as might be expected but the trend was definitely positive and the web based activities were a “hit”.

Applied Linguistics

The field of Applied Linguistics has not yet been well defined. Some authors still see it as part of Linguistics. (Barriga y Parodi 1998) Nonetheless, in general, it can be considered an interdisciplinary area that tries to solve problems related to language. A look at the topics of international academic events shows its breadth: bilingualism, language therapy, curriculum design, intercultural communication, and so on; however, it is not the number nor the kinds of topics that Applied Linguistics deals with, but rather the interest in identifying uses that leads to the development of theoretical models that can help in the explanation of problems related to language. The theoretical aspects of the field are precisely those that participants need to justify their projects and to participate fully in the roles they are acquiring. All teachers who participate are credentialed teachers and many have years of experience.

Distance Learning

Distance Learning makes learning possible through the virtual classroom which, according to Porter (1997), should ideally recreate an effective learning environment creating the conditions and providing students with the tools in order to respond to their expectations and needs. Distance learning is, according to Harrison (1999), often applied to the materials and media that allow people to learn away from a source of expertise or training. Therefore, we also have to consider that technology is a support, a tool that will be used by teachers and learners to have access to knowledge but at the same time we can learn with technology and from technology. Therefore we must review carefully what we want from it.

There is a direct link between distance learning and self-directed learning. Self-directed learning describes a particular attitude to the learning task, where the learner accepts the responsibility for all the decisions concerned with his learning but not necessarily undertake the implementation of those tasks (Dickinson, 1987). Here, we can realize that the learner is an autonomous and independent one, but the process he/she has to go through is neither easy nor fast.

The role of educational technology

In recent years, there has been a consciousness raising wave towards the way technology should be treated in schools. Jonnassen, Peck and Wilson (1999), under a constructivist perspective, amongst other issues, assume that:

- Technology is more than hardware. It consists of the designs and environments that engage learners.
- Learning technologies can be any set of activities that engage learners in active, constructive, intentional, authentic and co-operative learning.
- Technologies support learning when they fulfill a learning need.
From these ideas we can see that working under a constructivist perspective serves as a guide to develop appropriate methodology (clear objectives, activities, assessment and self-assessment techniques) and appropriate materials to implement the mentioned courses. In order to make a right link with all these aspects it is necessary a clear understanding of the whole constructivist paradigm.

Virtual Exchange Program:
Coming to a Computer Near You?

Chris Junghans, Ed.D. candidate
Montana State University
Bozeman, Montana
junghans@montana.edu

Abstract: In the spring of 2000, a "Virtual Exchange Program" was piloted by the Koerber Foundation’s Transatlantic Classroom project. The intent of the program, initiated by the author, was to allow American high school students of German to electronically correspond with Americans of the same age who were in Germany on a one-year, U.S. Congress-Bundestag Exchange Program.

Introduction
Since the medium for the American-to-American correspondence about Germany transpired primarily in English, the rationale for this pilot program was not based upon teaching Americans German. The program sought to introduce an intercultural experience into the foreign language classroom that would directly stimulate and provide for an interest in contemporary German culture.

Findings
American exchange students in Germany corresponded with high school students of German in America (in Bozeman, Montana). Highlights of their correspondence, conducted via an electronic bulletin board, have been archived at:

http://www.tak.schule.de/amvoices.htm

Based upon the author’s five years of experience in American-German K-12 email exchanges, the American exchange students in this pilot program appeared to notice things while in Germany that native students would not notice or would not recognize as worth sharing. This was the general finding of the pilot Virtual Exchange Program, which sought to multiply the positive intercultural learning that takes place when students are able to study and live abroad.

Plans
This spring (2001), the Virtual Exchange Program pilot sponsors would like to expand the program to include more Americans, both at home and abroad. They would also like to begin to build a program for German students of (American) English to electronically correspond with German students on exchange programs in America.

The Virtual Exchange Program, as piloted, may eventually become a comprehensive website that allows students in America and Germany to find "virtual connections" to students on exchange in the target culture. The website would offer both links to information about U.S. states and German Bundeslaender, as well electronic bulletin boards creating electronic access to exchange students in those regions.
An Overview of Information Technology on K-12 Education in Taiwan

Greg C. Lee and Cheng-Chih Wu
Department of Information and Computer Education
National Taiwan Normal University
Taipei, Taiwan 106
{leeg, chihwu}@ice.ntnu.edu.tw

Abstract: Under the support of the government’s National Information Infrastructure project, ease of Internet access has increased dramatically at all levels of schools in Taiwan in recent years. In an effort to speed up preparation of tomorrow’s teachers to use technology (PT3), the Ministry of Education of Taiwan has launched several multi-million U.S. dollar projects to facilitate and to promote the use of information technologies in the classrooms and in teaching across all subject areas. Those national efforts are directed at improving networking infrastructure, the computing environments, the digital educational resources, and on teacher training. In this paper, we will report the endeavors undertaken, the accomplishments, the current and on-going PT3 related projects in Taiwan and discuss the issues that have emerged.

Introduction

Under the support of the government’s National Information Infrastructure project, ease of Internet access has increased dramatically at all levels of schools in Taiwan in recent years. In an effort to speed up preparation of tomorrow’s teachers to use technology (PT3), the Ministry of Education (MOE) of Taiwan has launched several multi-million U.S. dollar projects to facilitate and to promote the use of information technologies (IT) in the classrooms and in teaching across all subject areas. In 1999 alone, over $200 U.S. million dollars were subsidized to expedite the process of modernizing all K-9 schools with IT equipments and to broaden the scope of teacher IT trainings. On the infrastructure side, all K-12 schools (3555 in all) now have at least one multimedia PC lab. Furthermore, all are connected to the Internet. Funding is also being appropriated to install IT equipments in all the classrooms. On the teacher training side, several venues are being explored to increase teachers’ IT awareness and proficiencies. Lastly, collaborative effort among 80+ selected K-12 schools has been under way since early 1998 to amass educational resources in various subject areas, making Chinese instructional resources readily available on the Web. It is hoped that with the aid of computer technology, the educational resource gap between urban and rural schools may be bridged. In this paper, we will report some of those projects and the issues that were encountered.

Current State of NII for K-12 Schools

Information Infrastructure

1. All K-12 schools are connected to the Taiwan Academic Network (TANet).
2. K-12 schools to TANet Bandwidth: using ADSL technology, upload at 384Kbps, download at 1.5Mbps.
3. TANet Backbone Bandwidth: OC-3 (155Mbps) around the Taiwan Island.
4. TANet to Internet Bandwidth: One T3 (45Mbps) and two T1 (1.544Mbps) trunks to the U.S.

Instructional Computing Equipment at K-12 Schools

1. PC Lab: For each K-12 school, there is one PC lab per 35-40 classes. The PC lab is equipped with enough multimedia PCs, typically 25 to 40, so that every student in the class can have access to one PC. Each PC lab is also equipped with at least one scanner, one digital camera, one laser printer and an instructional broadcasting system. (Project completed in June 1999)
2. IT enabled classrooms: For each regular classroom, installation of one PC/Notebook and one LCD projector/digital TV is being planned. In addition, those PCs/Notebooks will be connected to the campus network so that access to the Internet is possible.

Digital Content Resources for K-12 Teachers and Students

1. CAI software: The MOE sponsored projects have develop over 650 CAI/CAL titles across all subject areas to supplement classroom instructions. The project is on-going and was first initiated in February 1993.

2. NERC: The National Educational Resource Center (NERC) was set up in February 1998 to provide instructional resources for all teachers of all subject areas. Eighty K-12 and vocational schools were selected to develop Chinese instructional Web contents. Besides the instructional materials, the test banks, the other resource links, and contents on local cultures and places of interests, each school maintains a discussion forum to provide timely assistant to all users (teachers and students alike). NERC has an annual budget of U.S. $4,000,000 dollars and currently houses over 30 GB of data.

3. EduCity: EduCity provides an environment for social learning on the net. Virtual elections, distance learning courses, and electronic journals can all being offered in this virtual environment. This is an on-going project that was first initiated in July 1999.

Preparing Tomorrow's Teachers to use Technology (PT3)

1. In an effort to prepare teachers to use technology, the MOE annually sponsored on-the-job IT training courses to teachers through colleges and universities in Taiwan. These courses range from introductory hands-on courses to theoretical advanced network management courses. In 1999 alone, over 8000 teachers have taken advantage of 173 courses.

2. In the 1999-2000 school year, special funding was appropriated to all K-9 schools to provide basic IT training to all teachers and administrative staff within the school. Recent spot checks on school personnel have shown an increase of IT awareness by the teachers. However, the level of IT competency differs greatly from school to school.

3. The MOE is initiating a new project to set national norm on IT proficiency for all K-12 teachers. Upon completion of this project, all incoming teachers will need to be IT-proficient with respect to the standard set forth in this indicator. Furthermore, this indicator will also serve as a measuring stick for evaluating the effectiveness of within-school IT training. Final indicator is scheduled to be completed by June 2001.

Issues and Discussions

Being the principle investigators or project leaders of several of the above mentioned projects, we have observed several interesting issues relating to preparations of teachers to use technology in the classrooms.

1. With the MOE pressing ahead with installing IT equipments into each classroom, we need to think whether having IT equipments in regular classroom is the proper physical setting for doing IT-integrated subject teaching. Or perhaps setting up specialized IT equipped classrooms is a better way to accomplish the same goal.

2. Is regular classroom + IT equipment the proper physical setting for doing IT-integrated subject teaching?

3. What are the K-12 school administrators' views on IT integration? Do they support IT integration? What roles are they willing to play in this IT revolution?

4. What are the teachers' attitudes toward using IT in the classroom? Do they all embrace the idea? Or are they being forced upon by the administrators?

5. The second information technology in education study (SITES) by International Association for the Evaluation of Educational Achievement (IEA) has concluded that adequacy of teacher training is still the major problem faced by most nations. With the multi-million dollars projects at the national level, it is hoped that the teachers in Taiwan are more acquainted with the use of IT in their classrooms.
Evaluation of the Girls Research Opportunities in Computing (Girls R.O.C.)

A. Dale Magoun, Ph.D.
Charlotte H. Owens, Ed.D.
Department of Computer Science
The University of Louisiana at Monroe
Monroe, Louisiana USA
csmagoun@ulm.edu

Introduction
The Department of Computer Science at the University of Louisiana conducted the NSF/Girls R.O.C. program that was a three-week summer residential project during the month of July 2000. Twenty-four middle school girls were recruited within a 90 miles radius of the campus and experienced a variety of hands-on activities that exposed them to software applications that are used in research, business, and the home. The participants lived on campus with six female undergraduate science majors that served as their mentors/counselors. Activities for the girls included the following: an orientation to campus and dormitory life, defining and developing ways in which the computer is used as problem-solving tool, and becoming familiar with ways the computer and the Internet can be used for research purposes.

Activities
During the first week students were introduced to software packages such as Windows 98, MicroWorlds, Netscape, and Office 2000. MicroWorlds served as a useful tool for introducing programming concepts to the young scholars, and facilitating hands-on experience with artificial intelligence and graphics applications. The Office 2000 Suite introduced business software packages to the participants that included a word processor, a database manager, presentation software, and spreadsheets. A camp newspaper was created using Word 2000 while PowerPoint was utilized by the four research groups to present their research findings at the closing day symposium. In addition to the classroom and lab activities, several field trips and evening seminars with outstanding scientists were conducted.

Research Groups
The twenty-four girls were divided into three research teams and assigned to a research project adviser. The research groups were: Software Engineering (SE), Data Mining (DM), and Expert Systems (ES). Software Engineering investigated the software development models and implemented a small system to familiarize the participants with proper SE techniques. The Data Mining group used Excel's data analysis tools to test hypotheses and to make inferences about their experiments. The Expert Systems group studied the area of artificial intelligence and expert systems that familiarized them with problems that are non-numeric. The solutions to these problems used the stepwise refinement method for system development. During the three follow-up visits to the ULM campus during the Fall 2000 semester, the participants have developed science fair projects and updated their web pages. The URL for the Girls R.O.C. site is http://cs.ulm.edu/~girlsroc.

Evaluation Procedures
The Computer Attitude Questionnaire (CAQ) was administered to the participants at the outset of the 3-week program (pre-survey), at the end of the 3-week program (post-survey), and 10 weeks after the completion of the program (follow-up survey). Prospective studies, such as this, are studies in which the same characteristics are measured on subjects that are followed forward through time and are referred to as repeated measures experiments.

To assess attitudinal changes over time, a multivariate analysis of variance was performed using a one factor repeated measures design. The Wilk’s Lambda test statistic ($F = 2.1872$, $p-value = 0.0115$) indicates that differences in attitudes are present among the three survey times. Table 1 below shows the average responses, the individual $F$-test statistic and its associated $p$-value for each of the subscales.

Significant Subscales
The subscales where significant effects over time were observed are in both the Young Children's Computer Inventory (YCCI) and the Technology Proficiency Self Assessment (TPSA) areas. Significant effects were observed in the YCCI subscales of Study Habits (F = 4.21, p-value = 0.0236) and Creative Tendencies (F=4.44, p-value = 0.0196). According to Duncan's Multiple Range procedure, the attitudes of these students did not show any evidence of change over the 3-week program; however, when measured at the 10-week follow-up portion of this study, a significant increase in their attitudes was observed.

When considering the subscales of the TPSA, changes in student attitudes were observed in all characteristics. In each of these, the end of the 3-week program significantly improved their attitudes in the TPSA subscales and these positive changes are still present at the 10-week follow-up period. The attitudes of the participants were significantly improved in the areas of E-Mail (F = 6.26, p-value = 0.0050), the WWW (F = 11.90, p-value = 0.0001), Integrated Applications (F = 14.64, p-value = 0.0001) and Graphics (F = 4.67, p-value = 0.0163).

Summary and Conclusions
A major facet of the Girls R.O.C. program was to increase female awareness and to foster better attitudes toward the latest technologies in computer science. The CAQ subscales measure the attitudes of students as it relates to various topics. While some are closely tied to their local school environments, others relate to the confidence level with which they have gained through the exposure to technology during the three-week Girls R.O.C. program. The ratings from the surveys provided evidence that changes in the participants' confidence in using E-Mail, the WWW, Integrated Applications and Graphics were greatly improved as a result of the three-week interactive program. Furthermore, the ratings also indicated that the participants' attitudes toward technology as taught in their local environments did not change over the thirteen-week period of this study. This latter finding supports the findings of other studies about the importance of introducing female students to technology at an earlier age. As such, to affect change would mean that one would have to change the attitude of the teacher in conjunction with the attitude of the student.
Teacher and Student Attitudes Toward Computers, 1999 - 2000: Findings from a Suburban Texas School District

Gerald Knezek
Rhonda Christensen
Institute for the Integration of Technology in Teaching and Learning (IITTL)
University of North Texas
Denton, Texas USA
gknezek@unt.edu

Abstract: More than 500 teachers and 3,000 students were assessed regarding proficiency and attitudes toward technology in a large suburban school district in Texas. In addition, 5000 parents in the district were surveyed regarding the use of technology at home and the support for technology access in the schools. Key findings from this study are provided in this paper. Additional detail is available in a 132-page publication compiled by the authors (Knezek & Christensen, 2000).

Introduction

More than five hundred teachers in a northern Texas suburban school district completed a Needs Assessment (NeedSnap) survey, the Teachers' Attitudes Toward Computers (TAC) questionnaire, the Teachers' Attitudes Toward Information Technology (TAT) questionnaire, the Technology Proficiency Self Assessment (TPSA), and the Stages of Adoption form in the fall of 1999 and spring of 2000. The TAC and TAT measure attitudes toward computers and new information technologies. The TPSA measures skill levels within the major areas specified by the International Society for Technology in Education (ISTE) standards, while the Stages instrument records an aggregate assessment of the overall level of technology integration of the respondent. The NeedSnap measures teachers' beliefs and needs regarding technology, as well as level of classroom use. Students in grades 1-6 completed the Young Children's Computer Inventory (YCCI) while students in grades 7-12 completed the Computer Attitude Questionnaire (CAQ).

Teachers' Proficiency, Needs, and Beliefs about Technology

Analysis of the technology proficiency data indicated that professional development activities carried out during the 1999-2000 school year were highly effective in advancing the skills of teachers. The impact was strong (p < .001) in all four areas assessed: E-mail skills (pretest mean = 3.81, post = 4.23), WWW skills (pretest mean = 4.09, post = 4.43), classroom use of Integrated Applications (pretest mean = 3.46, post = 3.80), and incorporating methods of Teaching with Technology (pretest mean = 3.74, post = 4.02). Teachers advanced as a group approximately one stage of adoption on a six-stage scale, moving from: Stage 4: Familiarity and confidence (I am gaining a sense of confidence in using the computer for specific tasks. I am starting to feel comfortable using the computer; mean = 4.44) and moving toward: Stage 5: Adaptation to other contexts (I think about the computer as a tool to help me and am no longer concerned about it as technology. I can use it in many applications and as an instructional aid; mean = 4.86).

Teachers' general beliefs remained reasonably stable from the beginning to the end of the school year. Specific needs that changed to a great extent from the fall to the spring were: 1) a lesser need for training in how to use the computer and 2) a greater need to be trained in teaching techniques and strategies to integrate technology into the curriculum.

Student Preferences, Attitudes and Technology-Related Skills

Data gathered from approximately 1600 grades 1-6 students in eight district elementary schools indicates that high technology-integrating teachers at the first grade level rapidly influence the preference of their students toward using computers over the more passive medium of watching television. Across grades 1-3, looking at the classroom environment from a pre-post perspective, we found that among teachers who were low integrators of technology, student Attitudes Toward Computers (p<.001), Attitudes Toward School (p<.05), Computer Importance (p<.01) and Computer Enjoyment (p<.02) declined significantly from the first to the last six-weeks of school. However, the students of the teachers who had been previously identified by their principals as high integrators of technology also had a significant decline in Attitudes Toward School (p<.02), yet increased significantly for Computer Enjoyment.
The general impact of technology integrating teachers over several months, across grades 1-6, appears to have been the greatest in the area of Attitudes Toward Computers on students without computers at home.

Student dispositions as a whole tended to decline from the younger grade levels to older grades (grade 1 to grade 6). This is similar to trends found in past studies (Knezek, Miyashita, & Sakamoto, 1995; Christensen, 1997). Although all measured attitudes declined, the three indices related to computers declined less across grade levels than other learning-related dispositions.

With respect to student dispositions by gender, girls were significantly higher than boys in Empathy (p<.001), Computer Enjoyment (p<.05), Attitudes Toward School (p<.001), Motivation to Study (p<.05), and Study Habits (p<.001) as of fall 1999. During spring 2000, the girls remained significantly higher than boys in Attitudes Toward School and Empathy, while boys became significantly higher in Motivation.

Based on information gathered from approximately 1400 students in grades 7-12 during 1999-2000, secondary school students appear to have positive attitudes toward information technology and most learning-related dispositions. Their information technology skills showed healthy growth during the 1999-2000 school year, to a point where they approached the level of their teachers. Their relatively-low (and declining with increasing age) ratings on attitudes toward school are consistent with studies conducted at the elementary school level and findings from earlier studies using the same scales (Christensen, 1997; Knezek, Miyashita, & Sakamoto, 1995).

Parent Access to Information Technology

Five thousand ninety-three (5,093) surveys were completed by parents of elementary, middle, and high school students from the district's 12 schools during the fall of 1999. Most parents reported having access to a computer (93%) and the Internet (82%) at home and making the same facilities available to their children. Parents indicated broad-based support for the idea of accessing school-based information electronically, and the idea of students enrolling in web-based courses was well received. The majority of these parents appeared to be immersed in the technology of the information age.

Teachers and Students’ Attitudes Toward Computers in México
Results of Phase 2000

Cesareo Morales
Instituto Latinoamericano de la Comunicacion Educativa
Mexico City, Mexico
cmorales@paz.ilce.edu.mx

Introduction
The year 2000 marks a three-year Mexican contribution to the International PLANIT study, and is now focused on the attitudes toward the computer and related topics of Mexico City Secondary School Teachers and Students. In previous years our samples included the countryside and various cities from around the Country, but researchers realized that the condition and the context of teachers and students of such a big metropolitan area as México City were special and so those individuals were being under-represented in our study. The administration of instruments was conducted during the Spring of 2000 (May-June) by the same researchers who have been participating in these series of studies since 1998. The results showed a few surprises but most of them supported the previous data.

Sample
There were 762 teachers (Male=324, Female=438) and 753 students (Male=385, Female=368) from three different School Systems: Public Regular, Public Technical and Private Schools of the México City’s 16 political districts.

Instruments
In order to measure the attitudes, two instruments were administered: The Teacher’s Attitude Toward Computer Questionnaire (TAC, Knezek & Christensen, 1996) and the Computer Attitude Questionnaire (CAQ, Knezek & Miyashita, 1994), validated for the Mexican population (Morales, Turcott, Campos & Lignan, 1998; Morales, 1999).

TAC’s six factors were: a) Enjoyment / Utility; b) E-mail; c) Frustration / Anxiety; d) Learning / Productivity; e) Positivity / Negativity, and f) Negative Impact of Computers. CAQ’s six factors were: a) Enjoyment; b) E-mail; c) Frustration / Anxiety; d) Preferences; e) Self-Learning, and f) Empathy.

Variables
The most important variables selected for the analysis of Teachers’ TAC were: Age, Gender, Computer at Home, Internet at Home, Years of Service, Computer Experience, Frequency of Use, School System and Stage of Adoption. On the other hand, the selected variables for the CAQ analysis were: Age, Gender, Computer at Home, Internet at Home and School System.

Results
In terms of the general results, we found a favorable attitude toward computers among teachers and students of México City, as previously found in 1998 and 1999. On the other hand, the access to technology was much higher than last year’s teachers and students of the rest of the Country:

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>1999</td>
<td>12%</td>
<td>16%</td>
<td>40%</td>
</tr>
<tr>
<td>2000</td>
<td>22%</td>
<td>26%</td>
<td>40%</td>
</tr>
</tbody>
</table>
ANOVA Results

Teachers
Across factors, the most significant variables responsible for the differences were:
- Gender: Male teachers seem to be more positively oriented toward the computer;
- Stage of Adoption: Teachers in the Application and/or Integration stages seem to perceive more positively the computer than those in the Consciousness stage;
- Computer Experience: Teachers with experience of five years or more using computers seem to have a better attitude than those with no experience;
- Frequency of Use: Teachers in daily use seem to be more positively oriented toward the computer than those who use it occasionally.

The big surprise in these data was the Gender variable, which marked differences in all factors, and yet in 1999 no differences were found. On the other hand, Adoption of Technology seemed to be related to computer experience, frequency of use and level of technology training.

Students
In contrast with the teachers' results, students showed only a few differences, and not very consistent across the factors. Only two variables had more than one difference:
- Age: 18 year old students rated higher than those 17 years old in Self-Learning, while 13 year old students rated lower in Frustration/Anxiety than those 18 years old.
- School System: Students from General Secondary Schools rated higher in E-mail and Computer Enjoyment than those from Private Schools.

Preservice Teachers' Attitudes Toward Information Technology in Brunei

Myint Swe Khine
Faculty of Education
University of Brunei, Darussalam
mskhine@nie.edu.sg

Introduction
Brunei is one of the 35 countries in the world that has a population of less than half a million and is categorized as a micro-state. The country is situated on the northwest coast of Borneo with an area of approximately 5700 sq.km. According to the 1999 census the population of Brunei stands at 331,000. The University of Brunei was established in 1985 and the number of students enrolled in the university reflects the small population of the country. Teacher training is a major thrust of the Institute of Education within the university and each year 100-150 students are taken in for the three year certificate training program. Female students tend to choose teaching as their profession.

The formal school system in Brunei has adopted a 6-3-2 pattern. 6 years of primary education (Grade 1 - 6), 3 years of lower secondary education (Form 1, 2 & 3), 2 years of upper secondary education (Form 4 & 5).

The language of instruction at the secondary level is English. At the end of Form 5, General Certificate of Education (GCE) 'O' level examination is conducted. Subjects covered in this examination include English, Malay, Mathematics and pure science subjects such as Physics, Chemistry, Biology, Combined Science, History, Economics and Geography.

Not all students use computers at school and the students who participated in the survey are average students. Elite students go abroad to study Medicine, Law and Engineering subjects.

Brunei has good communication infrastructure and BRUNET, the only Internet service provider has 14,000 users. In a country with only 70,000 household, this figure translated into 20% of the population who are using Internet.

Findings Regarding Teachers' Attitudes Toward Computers
One hundred forty-eight first year teacher education students completed the Teachers' Attitudes Toward Information Technology (TAT ver. 2.0) semantic differential scales of Electronic Mail (EmailT), World-Wide Web (WWWT), Multimedia (MMT), Teacher Productivity (ProdT) and Productivity for Classroom Learning (ProdCL) during 1999. Internal consistency reliabilities for the scales compared very favorably with those reported for USA data by the authors of the instrument (Knezek & Christensen, 1998). For the Brunei data, Cronbach's Alpha ranged from .90 to .92 for the individual scales. Mean ratings for most new information technologies were quite positive. No significant differences were found among the university students on any of the five measurement indices based on gender or arts versus sciences as a major field of study. Few differences among the students were found with respect to various background variables. One interesting exception to this trend was the students' perceptions of how useful the computer would be for student learning in the classroom. If the Brunei students had a computer at home they were fairly positive in their beliefs that the computer would be useful for student learning in the classroom (5.88 on a scale of 1 = least positive to 7 = most positive), but if the university students had no computer at home they were even more positive (6.20 on a 1 to 7 scale). The difference between the two groups reaches statistical significance (f = 4.36, p = .038). Perhaps the most significant finding from the Brunei pre-service educators, overall, is their overwhelmingly positive attitudes about teaching and learning with technology, which appears to vary little based on gender, field of study, or even access to technology at home.

Analysis: t-test and ANOVA

- Comparison of gender in co-educational school: significant differences in these areas of Computer Enjoyment, Empathy, School, and Anxiety. Girls tend to have better attitudes in these areas.
- Comparison of gender in all three schools: significant differences in: Computer Importance, Computer Enjoyment and Empathy also girls tend to higher attitudes in these areas.
- Comparison school types: significant differences in these areas: Computer Importance, Computer Enjoyment, Motivation/persistance, Study Habits, Empathy and creative tendency. Non-coeducational schools for girls have more positive attitude than either the non-coeducation schools for boys or the co-education school.

II. Teachers’ Attitudes using TAC (ver 4.0)

- Targeted population: teachers representing every subject taught in the above three schools.
- School 1 Chonchai Secondary School 101 teachers (33 males, 58 females)
- School 2 Chonkanya Secondary School 72 teachers (12 males, 58 females)
- School 3 Rayong Witayakom Secondary School (37 males, 55 females)
• Analysis (using the Scoring TAC v3.0) into 7 areas: Computer Importance, Computer Enjoyment, Anxiety, Enthusiasm, Productivity in the classroom and E-mail.

Results
• Gender: There found no different attitudes in these areas between males and females teachers.
• Frequency of Use: Teachers who daily use have better attitude.
• With the results of this surveys found that 56 % have computer at home and 17% use internet at home.
• Only 7% use computer Daily, 9% use weekly, use occasionally 25% and do not use 59%.

III. Faculties Attitudes' toward IT (FAIT v1.1)
• Targeted population: Faculty representing Colleges of Education from universities:
  Chulalongkorn University, Bangkok received 64 cases from 173 faculties
  Kasertsat University, Bangkok received 32 cases from 110 faculties
  Prasarnmith University, Bangkok received 41 cases from 129 faculties
  Burapha University, Chonburi received 38 cases from 63 faculties
• Data were analysis into 5 factors according to the scoring of FAIT1.1

• Education: Ph.D. ( 94 people, 53.7%)  Masters ( 79 people, 45.1%)  Bachelors ( 2 people, 1.1%)
• Age are vary the most frequency are more than 55 years old -thirty percent.
• Anova Results
  1. Education: Faculties who earn higher degrees have better attitudes and have less anxiety about computers.
  2. Middle-aged faculties (35-49) have a better attitude, less anxiety toward, and better enjoyment of computers and information technology; and a better appreciation of using e-mail in the classroom than older faculties.
  2. Faculties who use computers more often have a better attitude than those who use computer less.
Abstract: Multimedia describes any system that unites two or more media into a single product or presentation. Along with the increasingly developed computer technology, it is believed that multimedia is the best single set of technologies to promote among teachers to improve the way they educate students. Facing the challenge of large-sized classes and lack of multimedia resources, Chinese teachers have made an impressive progress in using multimedia in their classrooms. They are taking the advantages of national centralized curriculum, design and develop multimedia courseware to accompany with the textbooks. Collaborating with media specialists, they have been directly involved in multimedia courseware development. Supported by administrative bodies, they participate in training, enrich their own technological skills, and utilize multimedia to improve teaching and learning. The schools, like Danyang Experimental Elementary School, Yangzhou International Elementary School and Nanjing's Beijing East Road Elementary School are setting up a good start, although there still exists a great unbalance in utilizing advanced computer technology among Chinese schools and teachers.

Multimedia describes any system that unites two or more media into a single product or presentation (Lockard, Abrams and Many, 1997). In the field of education, multimedia has been used to describe audio-visual teaching aids since the early 1960s, almost twenty years before microcomputers entered the classrooms. Today, multimedia has become closely associated with the computer-based, instructional delivery systems for improving teaching and learning (Poole, 1997). Multimedia encapsulates works, pictures and numbers in many ways such as full motion video, still images, text and sound to make the delivery more meaningful. Along with the increasingly developed computer technology, it is believed that multimedia is the best single set of technologies to promote among teachers to improve the way they educate students. However, multimedia is one of the instructional vehicles, it is only an instructional tool. Its effectiveness does not solely depend on the multimedia itself, but its users, teachers and students. Of course, there is a certain excitement in promising new ideas and powerful innovations that allow teachers and students to explore the multimedia instruction and learning, but little research has been done on the effectiveness of teaching and learning with multimedia environments (Grabe and Grabe, 1998). From a global perspective, this paper is to examine the implementation of multimedia in Chinese elementary schools to see how multimedia assists teaching and learning in the large-sized classes that are usually as three times large as those in the United States.

Fifty-four third graders have entered the classroom sitting at the desks in rows. The teacher is standing in front of the class getting ready to deliver the instruction. Multimedia station including a Pentium III multimedia computer, a VCR, a data projector, and speakers is in function for the class to use. This is a third-grade Chinese language class to be delivered with multimedia implementation in an elementary school in Southern China. Following the respect greetings "Good morning, teacher!" and "Good morning, class!" the teacher states the purpose of the instruction that they would have the lesson of "The Lotus" on that day. The teacher brings up a few questions about the
knowledge of lotus and asks students to describe their experience in the park and what they have seen on the lake, but only few students can give satisfactory answers. The teacher then turns on her multimedia station and the projector. Beautiful animated lotuses are projected on the screen and lovely soft music is played. The texts in Chinese are highlighted and read with excellent standard Chinese tone. Obviously, the fifty-four children have been highly motivated to learn about "The Lotus." With three key words, "smell," "look" and "think," the teacher facilitates the discussion about the characters of the lotus and its symbolic meanings towards human being. Honesty, collaboration, and the value of life are integrated in instruction and learning. The animated images are paused while the discussion is in progress. Students read aloud after the narrator along with the textures displayed on the screen. The teacher guides individual silent reading and integrates listening, speaking, reading, and writing activities in the classroom with the aid of multimedia presentation. Within this multimedia-learning environment, students have had group discussion, participated in a dramatic play, and actively involved in various learning activities. Corresponding to the learning outcomes, students have mastered the reading of the text and completed creative paragraph writing with the phrases and sentence structures learned in the class within a fifty-minute lesson.

Clearly, it is a very successful lesson. Technology is no longer an individual showcase, but a common tool to improve teaching and learning in Chinese elementary schools. Based on the recent visits to Danyang Experimental Elementary School, Yangzhou International Elementary School and Nanjing's Beijing East Road Elementary School of the People's Republic of China, it has been found that multimedia has been successfully implemented in the classroom teaching. The success is evidently attributed to the matching of the contents of multimedia courseware and the contents exactly being taught in the class, instructor's involvement in designing and developing multimedia courseware, and the emphasis of teacher's technology training and implementation in the classroom.

The contents of multimedia courseware packages

The Chinese schools have a national centralized curriculum, unified textbooks, and an emphasized mastery of learning. Although multimedia resources in Chinese elementary schools are comparatively fewer than that in the United States, it is found that the contents of limited numbers of multimedia courseware packages utilized in the classrooms are directly matching with the contents of school textbooks. The courseware "The Lotus" that the third grade teacher has implemented in her class is one of the good examples. It is designed and developed specially for the text version of "The Lotus" in third-graders' textbook. Its images, textures, and audio features serve the needs of teaching and learning in the classroom. With the implementation of that multimedia courseware in the classroom, students can be highly motivated to learn how to read, talk and think. The multimedia has integrated "listening, speaking, reading and writing" activities for a successful language arts class. To name a few more, "Bei de Ren Shi " (The Understanding of the Times of) and "Yuan de Mian Ji " (The Area of the Circle) are also excellent examples of matching the contents between courseware packages and textbooks. "Bei de Ren Shi " is a multimedia courseware to help younger children understand the concept of "times" and to learn how to solve problems of the "times". The contents of this courseware match exactly the contents of the section one, unit six in the second graders' mathematics textbook. When given the information that a squirrel is three years old and is three times younger than an elephant, the second graders can figure out effectively how old the elephant is with the assistance of that multimedia courseware. "Yuan de Mian Ji " is designed to illustrate the concept of circles and to facilitate six-grade students to learn how to measure and calculate the area of a given circle and to learn how to solve related math problems. Again a good match of the content areas between the courseware and the textbook is found. The contents of the courseware, "Yuan de Mian Ji " are closely connected to the contents of the section two, unit four in the sixth graders' mathematics textbook. This type of matching nature promotes teachers to consider the implementation of multimedia courseware in their teaching, assists teachers to achieve their instructional objectives, and facilitates the process of improving students' learning achievements.
Teachers' involvement in multimedia courseware development

In China today, government education commissions at all levels, county, city and province, encourage teachers' involvement in multimedia courseware development and support such development by rewarding and honoring excellent courseware packages and their developers. This administrative action has greatly motivated teachers to be involved in multimedia courseware design and development. Chinese teachers have been involved in the design of most multimedia courseware at different academic levels, though with limited multimedia resources. In some Chinese elementary schools, teachers have learned to use such multimedia-authoring tool as Authorware to design and develop multimedia courseware collaborated with media specialists. The courseware "The Lotus," "Bei de Ren Shi " (The Understanding of the Times of) and "Yuan de Mian Ji " (The Area of the Circle) are all the products of the collaboration between the teachers and the media specialists. Danyang Experimental Elementary School organizes a multimedia teaching demonstration and discussion every month, conducts a multimedia courseware development-competition every semester, and compiles a faculty's essay collection every academic year. Yangzhou International School and Nanjing's Beijing East Road Elementary School encourage and support teachers to participate in the courseware exhibitions on campus, submit their products to city, provincial and national competitions. All these three schools today own multimedia courseware developing labs where teachers can contribute their expertise of teaching and practice on courseware design and development. Each campus has networked cable TV, language labs, and multimedia classrooms. Teachers share with each other their multimedia resources and implement the courseware developed by themselves into their classroom teaching and learning. Campus radio on the other hand helps reinforce the multimedia implementation at each school. As a result of teacher involvement in multimedia courseware design and development, multimedia courseware implementation in elementary schools in China has turned out to be quite a success. Because of the direct involvement, teachers know what they need in the classroom and know how to teach with the integrated multimedia.

The emphasis of teacher training and the implementation strategies

Computer technology, no matter how advance it is, it is an instructional tool; using multimedia, no matter how exciting we feel, we should know how to use it effectively. Like many middle schools and universities in China, Chinese elementary schools have put teachers training on the agenda and emphasized the effective implementation. The school knows that it would become a formality of using technology in the classroom if there had not a team of teachers who were education technology literate. In the past two years, all teachers in Jiangsu province have been required by provincial educational commission to receive training in technology and to pass the technology competency tests. The competency tests include primary level, intermediate level and advanced level. A majority of teachers attend the training classes at weekend, during holidays or summer vocations; a few of them go with self-study track. Out of the training, teachers devote their after-school time, entertainment time and even their valuable dating time to practice at computers. It is told that all teachers in Danyang Experimental Elementary School, Yangzhou International Elementary School and Nanjing's Beijing East Road Elementary School have passed their primary competency tests, quite a number of them are at the medium level and a few have reached advanced level. The purpose of receiving training is to use technology in the classroom. Teachers in the schools mentioned above are encouraged and supported to implement their new technological skills in classroom teaching. This type of implementation has put the emphasis on the clear instructional objective(s), integrated learning activities, and students' academic learning achievements. In schools, implementation strategies are discussed, models of teaching with multimedia aides are demonstrated, and teaching experience is shared among teachers in a timely manner. It is clear that the teacher training and the emphasis of student learning achievement have made the multimedia implementation become more meaningful and effective.

In summary, facing the challenge of large-sized classes and lack of multimedia resources, teachers in China have made an impressive progress in using multimedia in their classrooms. They are taking the advantages of nationally centralized curriculum to design and develop multimedia courseware to accompany with the textbooks. Collaborating with media specialists, teachers have directly involved in multimedia courseware development. Supported by administrative bodies, teachers are encouraged to
participate in training and enrich their own technological skills and utilize multimedia to improve teaching and learning. Schools like Danyang Experimental Elementary School, Yangzhou International Elementary School and Nanjing's Beijing East Road Elementary School are having a good start; however, there is one thing needs to be pointed out that these three elementary schools are all key elementary schools in China. They have more funding resources and can afford the cost of hardware, software, training and follow-up support. They also have more advantages to recruit excellent faculty and staff members as well as students. For the majority of elementary schools in China today, there is still a long way to go to implement multimedia in classrooms. There exists a great unbalance in utilizing advanced computer technology between schools, as well as among the teachers. The reality is that quite a number of Chinese elementary schools do not have multimedia classrooms and labs. Some schools do not even have a computer yet. In those schools, teachers have not had an equal access to the advanced technology and students still rely on the textbooks and pencils. But what is happening at Danyang Experimental Elementary School, Yangzhou International Elementary School and Nanjing's Beijing East Road Elementary School today will be seen in other Chinese elementary schools soon along with the advances of computer technology and political-economic reform in China.

An introductory internet skills program for teacher education: or from practice to theory: a case study

Cameron Richards, Instructional Science Academic Group, Singapore National Institute of Education, Nanyang Technological University. email: crichards@nie.edu.sg

Mita Bhattacharya, Instructional Science Academic Group, Singapore National Institute of Education, Nanyang Technological University. email: mitab@nie.edu.sg

Abstract: This case study presentation will report on how the presenters successfully responded to the 'just-in-time' challenge of putting together an inservicing 'introductory technological skills' course for a 'difficult' group of teachers. The particular course which will be the focus of the presentation provided the specific opportunity for the two presenters to bring together their convergent but differing international experiences in teacher education to try and distil the key principles and practical requirements for developing an effective introductory internet skills program. Although many of the students undertaking this course began with little knowledge of computers let alone the internet, they all achieved in a short time (2 hours X 14 weeks) a basic and convergent competency in a range of generic internet skills: internet communications, online information literacy using browsers and search engines, developing animated powerpoint presentations and webpage learning resources, and other associated skills like FTPing and scanning graphics. Indeed, some of the initially less confident and even reluctant teacher-learners quickly became adept at using what for them was a completely new medium.

In other words, the presentation will cover some of the approaches, methods and activities used to transform reluctant or intimidated learners into keen users of the internet. This session will identify and discuss the kinds of simple practical skills and activities that can be linked together in progressive contexts of applied, relevant, and even 'real-life' learning to achieve a 'spiral curriculum' of effective reflective practice using the internet. The organization of the presentation will be as follows:

(i) an initial outline of the context of the challenge faced by the presenters;
(ii) an overview of how the presenters responded by developing this particular program in terms of 'show-and-telling' teacher-learner artifacts, anecdotes and other action research data;
(iii) a reflection on the course as case study, and about the key principles or strategies and kind of activities required to conduct an effective introductory internet skills course.

Note that this is an abstract for a Presentation which will complement two other papers by the presenters – 772 and 1033
An Instrument to Measure Malaysian Teachers' IT Preparedness

Abstract: The Malaysian Ministry of Education plans to turn approximately 10,000 primary and secondary schools into Smart Schools by the year 2010. This means that in the next decade, all teachers must be fully prepared to teach in all the Smart Schools nation-wide. The pressure on teachers has, therefore, become urgent. For this reason, there is a growing educational interest in the assessment of teachers' IT preparedness. In this paper, we examine the need to develop an instrument that is able to assess teachers' IT preparedness. IT preparedness in this study is measured in three domains: the teachers' actual IT skills, their knowledge about IT and their attitudes toward IT. We also describe what the instrument attempts to measure, how it is administered and present results of phases one and two of the study.

Introduction

Malaysia is considered to be one of the fastest developing nations in South East Asia. Indeed, it has a national ambition called Vision 2020, the purpose of which is to attain developed-nation status by the year 2020 (Mahathir, 1998). To achieve the substance of Vision 2020, the government has set up a blue print for the Multimedia Super Corridor (MSC). The MSC is a massive 750-square-kilometer high-tech information zone encompassing the Kuala Lumpur City Center (KLCC), Putrajaya (administrative center) and the Kuala Lumpur International Airport (KLIA). The infrastructure of the MSC area emphasises what the Prime Minister has described as providing high-powered networking, efficient transportation, satellite telecommunications and intercity connections. To spearhead the development of the MSC and give shape to its environment, seven initiatives for multimedia applications have been identified. These initiatives are borderless marketing, smart schools, electronic government, multi-purpose card, telemedicine, research and development as well as worldwide manufacturing webs. Of these, the smart school initiative is regarded by the Prime Minister as a specific response to Malaysia's need to make the critical transition from an industrial economy to a knowledge-based society (Mahathir, 1998). This initiative will enable Malaysia to produce skilled people who will be able to harness the benefits and the potential of IT needed to attain the "smart" Malaysian society in 2020.
The Need to Measure Teachers' IT Preparedness

The pilot Smart Schools that started operation in 1999 will act as a nucleus for the future Smart School teaching concepts and materials, skills and technology. By the year 2010, if the 1997 planning is followed, all 10,000 of Malaysia's primary and secondary schools will be Smart Schools (Smart School Project Team, 1997). This means that in the next decade, the entire population of approximately 450,000 teachers in Malaysia must be fully prepared to teach in all the Smart Schools nation-wide. The pressure on teachers to become IT literate as well as to understand the education implications of the new technology has, therefore, become urgent. It is now envisaged that all teachers will become skilled in the use of IT and the integration of IT in the teaching-learning process (Smart School Project Team, 1997). This is important because all teachers will have to use IT in the classroom. However, before they can integrate this new technology, these teachers must be trained to be skilled and be knowledgeable about IT with the right attitudes.

The Smart School Project Team (1997) stressed that a comprehensive teacher education programme incorporating best practices in technology supported learning will be critical to the success of the Smart School concept. The training will enable teachers to carry out their responsibilities as facilitators in the classroom, as they will be equipped with specific IT skills and knowledge as well as with the right kind of attitudes. For this reason, teachers must be assessed thoroughly by the educational authorities before they teach in schools to determine if they are IT prepared. With the implementation of Smart Schools nationwide, there is a growing educational interest in the assessment of teachers' IT skills, knowledge and attitudes. An instrument, therefore, is needed to assess Malaysian teachers' IT preparedness.

Theoretical Framework

Evidence supported by the Technology Acceptance Model (TAM) (Davis, 1989; Davis et al., 1989), Adaptive Control of Thought (ACT) theory (Anderson, 1983), and Wilson's (1990) framework has substantiated the claim of this research that these three domains (skills, knowledge and attitudes) should be measured to represent IT preparedness.

![Figure 1: The Technology Acceptance Model](image)

Davis et al. (1989) strongly suggested that the TAM can explain the usage of IT (Fig. 1). This model has strong influences of Fishbein and Ajzen's (1975) theory of reasoned action. It shows that beliefs influence attitudes, which in turn lead to behavioural intentions and ultimately the actual system use. Suffice to say, this model posits that actual system use is determined by the user's attitudes toward it. The actual use can be measured in terms of the user's performance or more specifically the knowledge and skills of the system (Speier et al., 1997).

The ACT theory by Anderson (Anderson, 1983) explains how cognitions can produce action. The ACT theory is one of the most influential explanations of skills acquisition in cognitive psychology. Essentially, Anderson distinguished the learning skill in relation to two different types of knowledge that are:
- Declarative knowledge which consists of facts about the world which can be put into words;
- Procedural knowledge which refers to how we do things.
Anderson (1983) suggested that the first cognitive stage of learning involves acquiring declarative knowledge that is relevant to the skill. Preece et al. (1997) likened this stage to learning a computer. Examples of this stage include activities such as memorising things to select an option from a menu, moving the cursor to the required option using the mouse and then clicking twice rapidly in succession on the mouse button.

From the acquisition of declarative knowledge, an associative stage occurs which connects the different elements needed for performance. The elements are strengthened at this stage (Anderson, 1983). This would include things like learning how to move and 'double click' the mouse.

Lastly the autonomous stage comes into play where the skill becomes more automated and rapid (Preece et al., 1997). The declarative knowledge becomes second nature to the performance of the task and ceases. According to Preece et al. (1997), learning to use a computer system, therefore, can be viewed in terms of the acquisition of a skill where declarative knowledge changes into a skill.

Wilson (1990) somehow made the connection between the three variables when he stressed that teachers' IT preparedness should be measured in terms of skills, knowledge and attitudes.

The Instrument

The instrument is constructed in our national language, Bahasa Malaysia. Three domains are measured in this instrument. They are skills, knowledge and attitudes. The instrument comprises Parts A, B and C. Part A is paper based while Parts B and C are web based. Part A of the instrument measures the teachers' actual IT skills. The skills are measured in terms of the teachers' ability to execute a series of 74 tasks. Most of the tasks are based on the North Carolina State Board of Education’s Educator Technology Competencies (North Carolina Public Schools Info Web, 1999). The North Carolina Board’s Educator Technology Competencies are used because Malaysian authorities have recommended no detailed or clear competencies.

The tasks are measured in two dimensions. The first dimension comprises content categories pertaining to productivity tools (word processing, spreadsheet, database and presentation), World Wide Web (WWW) and electronic mail while the second dimension comprises task categories (basic operation, management and design).

Part B measures the actual knowledge about IT. It is measured in terms of 25 multiple-choice questions. Of these, two items are adopted from Deakin (1998). The questions are constructed in two dimensions. The first dimension comprises system hardware, system software, WWW and electronic mail while the second dimension comprises the three lower levels of Bloom’s Taxonomy.

Lastly, Part C measures the teachers' attitudes toward IT and consists of two dimensions as well. The first dimension consists of specific software applications, software applications in general, computer and IT in general. The second dimension consists of confidence, usefulness, anxiety and aversion. This part comprises 36 five-point Likert’s scale statements. Twelve statements are adopted, translated and adapted from Loyd and Gressard’s (1984) Computer Attitude Scale and Christensen and Knezek’s (1998) Teachers’ Attitudes Toward Computers Questionnaire (TAC).

Administration of the Instrument

Two phases of instrument testing were carried out. The participants for this study were student teachers from Universiti Putra Malaysia who had taken the “Information Technology in Education” course (EDU 3033).

Two sub-samples were involved in phase one. There were two assessments in phase one. The first sub-sample comprised 22 student teachers while the second sub-sample comprised 15 student teachers. At the beginning of the test, the participants were briefed about the assessment that was being carried out. We had the full cooperation of the course instructor who encouraged the student teachers to participate in the assessment. The participants were required to attempt Part A of the instrument, followed by Parts B and C respectively. Each student was given a desktop to work on, access to the Internet and a piece of diskette to save their work into. The participants were required to save their work only for Part A in a floppy diskette. The answers and responses of the participants in Parts B and C were collected via electronic mail. Both assessments took place in our faculty’s computer laboratory. The assessments lasted for three hours. Participants in the first session detected several errors in the instrument. For that reason, we were able to correct the errors before the second session took place.
The revised version of the instrument after item analysis was sent for phase two. Forty-nine student teachers participated in the study. Nine and 10 out of 49 students did not attempt Parts B and C respectively as they encountered problems with the Internet connection. So they were not able to access the WWW after completing Part A. Results from phases one and two were used to calculate the internal consistency coefficients. Item revisions and elimination were also carried out based on the results of item analysis from both phases. Item difficulty was calculated for Part B while item discriminant was calculated for Parts B and C. Items accepted ranged between 0.3 and 0.9 for item difficulty and had values greater than 0.3 for item discriminant.

Results of Phases One and Two

Table 1 shows that the reliability coefficients for the subscales are high except for knowledge. The low values are expected because this subscale is measured by a small number of items. For this reason, the reliability estimates are corrected by the Spearman Brown’s prophecy formula. The corrected reliability coefficients are comparatively high. The reliability coefficients clearly suggest that the instrument has high internal consistency.

Table 1: Internal Consistency Coefficients

To ensure that the instrument will be valid and reliable, classical procedures for test construction will be closely followed in the third and fourth phases of the study.

Conclusion

IT offers great potential and benefits in the teaching-learning process. However, before the students can benefit from IT, teachers must be trained to use IT. There is great urgency to bridge the digital gap among Malaysian teachers now. Teachers, therefore, must have the right IT skills, knowledge and attitudes to reap the potential of IT. The instrument that is currently being validated can provide valuable information about the teachers’ IT skills, knowledge and attitudes as well as to teacher education programmes that are working toward these competencies.

Abstract: The Ecuadorian educational setting promotes teaching strategies that are still built upon traditional educational models. The potential of new learning models and information technologies is neglected and little interest is shown in including ICT as a catalyst to foster innovation of education in general. This paper is about an Innovation Educational Program for elementary education in the Santa Elena Peninsula in Ecuador. The project seeks to develop creativity, critical-thinking and problem solving in primary school children with the support of ICT. A major part of the project is focused on teacher training. The study monitors and follows teachers and pupils during a 6-year period. In this paper part preliminary results of the teacher-focused studies are presented. This sub-project focused on the analysis of video materials and surveys that research the current dominant teaching - learning strategies adopted and promoted by teachers in the Peninsula Project.

Introduction

Today’s society is qualified as the information society (Mojica 1999) and the people living in this society are the ones that are in the midst of a third major revolution in human civilisation (Negroponte, 1995). According to Oblinger and Rush (1997) we are living the Information Revolution. Nowadays, the volume of new information is increasing at such a rapid pace that the class of 2000 is exposed to more new data in a year than their grandparents encountered in a lifetime. Knowledge doubles every seven years and ten thousand scientific articles are published every day (Forman, 1995). Yet, are we prepared to dominate all the information surrounding us?

The exponential growing of information urge the individuals of the 21st century to move from a materialistic and physical reality to more of a mental and informational reality—the source of survival will become knowledge rather than physical capital (Lombardo, 1998.) Therefore, the man of the future is challenged to handle three abilities: a) to access information; b) the capacity of prioritise and c) to think critically and analyse the information he reaches (Mojica, 1999.) This challenge is not possible only by exposing the children to the Information and Communication Technologies (ICT), since technology by itself would not create these skills in the pupils. If we are going in the wrong direction, technology will not help us to find the right direction (Ehmann, 1995). Dede (1996) says that technology can help transform schools but only if it is used to support new models of teaching and learning. Therefore, technology will work best if it is seen as a tool, the means, and not the goal of the educational process. As Land and Coe (1998) stated: “Technology works best when learning includes the process of finding data, information or artefacts; making decisions based upon data; and communicating those findings to others. Information Technology as a tool works best when teaching includes the management of a learning environment that sets up environments in which students can work individually an in groups in data collection, decision-making, and communicating within the context of real-world tasks.”

The academia throughout Universities, High Schools and Elementary Schools in general has to be committed to participate in the process of preparing the 21st century people to dominate the information age (Chiluiza & Pelaez, 2000). The ones called to be the means of this challenge are educators. Teachers have to learn good practices of teaching in order to help in the transformation of new schools in places where the learner learn how to work collaboratively, inside and outside the classroom, with his/her teacher and partners, through active learning techniques and reflective learning (Chickering and Ehmann, 2000). All these characteristics go in line with the new learning
models (such as constructivist model) which promote an active learner and a teaching-learning process centred in the pupil and not anymore in the teacher.

This paper is about the Innovation of Primary Education in the Santa Elena Peninsula (IESEP), an educational project, in rural Ecuador. The project is set up by the Escuela Superior Politécnica del Litoral (ESPOL), an Ecuadorian University and forerunner in (educational) technology. The project seeks to develop creativity, critical-thinking, problem-based learning and collaborative work in primary school children with the support of ICT. Next, the project looks for increasing the number of children that continue higher education after secondary school level. A major part of the project is focused on teacher training. A core group of teachers that receive special training - 40 from a network of 20 schools - will be in charge of the further training of all academic staff in their own and other schools. A cascade-effect will be provoked in the school system in the Peninsula region as a sustainable professional developmental model.

The software tools that are being used - by teachers and pupils - are LOGO-Microworlds and LEGO-Mindstorms. The project will gradually include Internet and databases access to the participants in the IESEP Project. In order to reach the objectives of the project the teachers of the participating children were enrolled in an educational program to train them in the use of ICT and the integration of these technologies in their classroom practices. Previously, the IESEP team needed to assess the educational and technological needs of the teachers to design an appropriate training program for the context of the Peninsula region.

Purpose

This study seeks to identify the common educational characteristics of the rural teachers of the Ecuadorian coastal region and the context surrounding these teachers. Besides, the purpose of the study is to research the current dominant teaching-learning strategies adopted and promoted by teachers in the IESEP project. Considering the educational reform that is promoted in Ecuador since 1992 is based on the social constructivistic pedagogical paradigm, the main questions to be answered are: Do the Peninsula teachers are upholders of this pedagogical paradigm? And do these teachers have a sounded understanding of what they mean by being constructivistic educators?

Additionally, the researchers wanted to identify the educational needs of these teachers; to design a targeted training based on the actual needs of the group. Thus, as suggested by Knezec and Christensen (2000) the developed plan would move the group from a lower stage of technology integration to a higher one.

Theoretical Framework

The learning theories that frame the present study are behaviorism, cognitivism and social-constructivism. To behaviorist learning is essentially a matter of storing information for later recall. Under this paradigm the teacher plays the central role in the classroom, transmitting knowledge to learner who only have to absorb information. The student’s role is reception and compliance. In this model the teacher’s performance in front of students is critical, the effectiveness of teachers is evaluated for the ability to establish “effective” eye contact, use different kinds of questions, pause in explanations to allow pupil reflection, use of a variety of concepts, and redirect student questions (Marsh, 2000). These characteristics are the ones that were considered to identify a teacher as promotor or adopter of the behaviorism learning theory.

The cognitivist school made mental processes the primary object of study and tried to discover and model the mental processes on the part of the learner during the learning-process. Knowledge under the cognitive theories is viewed as symbolic, mental constructions in the minds of individual, and learning becomes the process of committing these symbolic representations to memory where they may be processed. Eggen and Kauchack (1992) propose the following as active teaching-learning strategies that the cognitivist teacher promote in the classroom; however, the cognitivist paradigm knowledge is still viewed as given and absolute just like the behavioristic school:

- Make questions to the students, especially those questions that the students ask when they are learning.
- Make the students paraphrase the information instead of reciting it by memory.
- Construct lessons from the analysis of examples and practical applications, instead of departing from definitions.
- Solve problems
Develop practical classes and send homework
Write articles, essays, etc.
Develop practical activities.
Elaborate tests and questionnaires that require more than a simple memorisation or recall.

In regard to the constructivistic theory besides Piaget, constructivists have embraced other theorist, especially the Russian psychologist L. S. Vygotsky, who considered and individual’s cognitive system to be a direct result of and inseparable from social life. The individual’s psychological processes are always bound to the culture in some way because the individual uses a particular “set” of cultural tools, thus mental constructs are delimited by one’s culture. Is in this social level where sign mediated memory, voluntary attention, and concepts are developed on the basis of internalisation of external activities (Marsh 2000). Then, the question is how this theory influences educators and education? Educators may have greater influence in his/her students, as they concentrate most of the social pupil’s time at schools. The social setting of the school and the classroom is of much greater importance than it has been generally considered in educational research and practice. Teachers can incorporate ICT to transform learning through a social context that reflects a change from knowledge transmission to student-centred learning, which promotes individual and shared construction of meaning. Computers can lever the classroom environment through co-operative learning, collaborative project-based schoolwork; thus, the resulting effect is a class where students are active, self-regulated, reflexive, involved and facilitating rather than passive spectators while the teacher plays the role of a coach, a facilitator of the teaching – learning process (Seels 1989).

Methods and data sources

In order to attain the purpose of the study surveys, interviews, class observations and video analysis were used in the research. The subjects of our investigation were 40 teachers from 20 schools of the IESEP school network.

Surveys and Interviews

Firstly a survey was distributed among 40 teachers during a meeting session and was collected the same day. This anonymous survey intended to describe the following educators' characteristics: average age, sex, years of experience, educational level, self-qualification of the learning model adopted by the teacher, attendance to continued education, previous experience with computers or technology. Additionally, the survey collected the following school context characteristics: number of students per classroom, technology infrastructure available at school or home and the way teachers select support or reference materials.

Secondly, in a later meeting a non- anonymous survey was filled-out by all the educators participating in the IESEP project. The survey contained 18 close-ended and 3 open-ended questions related to 3 close-ended questions. Each close-ended question was graded over 5; thus, a figure near 5 indicated a tendency to promote a specific type of activity. The questions were classified in 6 activities-group, each group represented a learning model or strategy promoted by the teacher.

The surveys were collected again the same day they were distributed. In this opportunity the answers found in the survey were discussed with each teacher during a later programmed interview. The purpose was to identify explicitly and deeply the type of activity promoted by the teacher in the classroom and whether the educator was able to explain the adoption of such performances. Thus, the researchers could assess the level of reflection and understanding the teacher has upon the educational practice he/she adopts.

Class Observations and Video Analysis

Through these methods the researchers went to the field to gather live-data. Ten teachers were asked to let the research team to observe and videotape their performance in the class. An observation list was accordingly designed with respect to the questions of the second survey. The list was used in order to tick activities that were or were not adopted by the teachers during the class. The video analysis was accomplished with the participation of an external researcher to do a more objective analysis.
Results

Descriptive data about the teachers and schools participating in the IESEP school network was collected through surveys; learning models promoted and adopted by teachers and level of reflection upon their teaching practice was gathered from the three methods applied in the study. These data is briefly discussed below.

Surveys and Interviews

The descriptive data gathered from the surveys about the teachers indicate that the majority of the IESEP teachers are men, the average age is 42, and the average teaching experience is around 19 years. Whereas the educational level 58% obtained their educational/pedagogical degree at the university and 20% followed a pedagogical training in post – high school institutes, the rest has a non-formal training in the educational area.

In reference to the learning model 43% auto-qualified themselves as constructivist, 44% behaviorist and constructivist, 6% considered themselves as behaviorist, and 7% mentioned other paradigms. 80% of the latter said they adopt the paradigm promoted by the Ecuadorian educational reform; paradoxically, they couldn't remember the name of the driving theory. Even though, 55% of the participant teachers has been linked to programs for continued education (no training the rest) the majority of them (89%) did not have any previous experience with ICT or computers, 11% stated they have medium to high experience in the use of office-support software.

In the school context, an average of 50 students per classroom was found. One out of the twenty schools (2.5%) had computers; but, very outdated ones (no hard disks). Computers are used in administrative tasks and/or for academic usage. The latter includes technology as another subject in the curriculum and does not integrate it as part of the whole curriculum. Only two teachers have computers at home and the reference material is the one chosen by principals or the designated by the Educational Ministry.

According to the chosen answers in the second survey very high indexes over 5 were reached for each of the set of activities. On the behaviorist, cognitivist, and constructivist sets the averages were 3.56, 3.76 and 4.16, respectively see [Figure 1].

Next the researchers interviewed the educators in order to find reflexive and coherent answers according to the survey results. Unfortunately, only one of the interviewed teachers where more coherent with the results obtained in the surveys and the paradigm he promoted in classroom. Teachers could not explain why they chose some activities completely opposed to other ones, or from complete different approaches.

Class Observations and Video Analysis

This data source provided the researchers with important evidence referred to the learning paradigm the Ecuadorian teachers adopt. The videos were analysed focused in the following type of activities: (1) behaviorist-related activities, (2) cognitivist-related activities, and (3) social – constructivist related activities.
Teachers adopted most of the times the central role in the classroom, promote individual activities, rely their activities in concept definitions, drill and repetition. They neither foster the use of other sources of information nor bring past experience to the classroom. Group-based learning is almost avoided due to the high number of students in the classroom, and when used the group community does not exist, all you can see is agglomeration of children trying to solve a problem in a very unguided way. Since, the teacher remains in front of the class instead of supporting kids in their tasks. This latter is aggravated with the lack of enough material to make all the students engaged in specific activities. The developing of project-based activities is neglected, since in their words “there is no time or resources to promote that kind of ideas.” Finally, teachers still consider children as repositories of information and not as possible self-regulated or reflexive subjects able to construct their own knowledge.

Analysis and discussion

This analysis will be unfolded in two topics: the educational model adopted by Ecuadorian teachers and the educational and technological needs of these educators.

The Ecuadorian educational model

The results obtained with surveys greatly contrasted with the ones obtained from interviews and much more with the video analysis of classroom’s activities. According to the surveys more than the 50% of the teachers have participated in continuing education proposed by the Ministry of Education it would be reasonably to find well-prepared teachers executing a practice in-line with the model the educational reform promotes. But, what researchers found supported by the use of qualitative and quantitative data analysis was a very contrasting reality. Teachers performed a more behavioristic class than a constructivistic one and self-categorised themselves as a mix of behaviorist and constructivist educators (44%).

Educational and technological needs

Teachers from the Peninsula region suffer from a clear weakness - they do not have a deep understanding of the pedagogical paradigm the educational system urges them to adopt. They keep considering students as receivers of information whilst the cognitive and social construction of knowledge is almost neglected; since, the memorisation of content tends to be the primary source for evaluation and educational success. They do not reflect on their educational practices. Ecuadorian educators follow the textbooks the system suggests, they remain as the basic unit of instruction, and few of them refer their students to other information sources. Teachers make efforts to work in a group-based learning approach; nevertheless, their practices do not reflect planned and organised tasks with specific goals to achieve in the classroom setting. They adopt in this a pragmatic and empirical attitude. Therefore, they need a program where they learn the following:

To centre their teaching practice on the learner
To redefine their teaching role as facilitators or coaches in the classroom
To promote the construction of knowledge in view of the social context of pupils and teachers in the Santa Elena Peninsula area.
To develop abilities to work with computers and the programs the project adopted.
To promote self-reflection and critical thinking

Conclusions

The focus of this study was to identify the common educational characteristics of the Ecuadorian coastal rural teachers, specifically the teaching-learning strategies adopted and promoted by these teachers. Besides, the description of the characteristics of the educational context where the educators develop their activities was other of the goals of this study and the identification of the educational and technological teachers’ needs. All the goals were achieved successfully. Evidence that the teachers of the Ecuadorian coastal region are not upholders of the social - constructivistic paradigm is the fact that they obtained high rates in all three categories of teaching-learning strategies studied. Teachers do not have a deep and thorough understanding of what they mean by being constructivistic, since they could not explain their performance over what they answered during the surveys and interview sessions. They do
not reflect on their educational practice and/or use a specific frame of reference. Qualitative data analysis in this study was the key in these latter findings.

In regards with the educational and technological needs of these teachers, the researchers found the educators needed a program in which they learn to be social-constructivist teachers; since, they are not able to promote strategies they do not understand. The researchers find the teachers have to have opportunities to share with others their successes and failures in order to learn with and from others; thus, workshops, conferences and reflective practice have to be encouraged for the quality of teaching – learning in the project. Finally, the IESEP team has a major challenge, teachers have to learn while getting involved in what is significant learning for them, they will learn more efficiently by doing or experiencing (Davis, 1998). Unless what is learned can be applied to actual work or life situations the learning will not be effective or long lasting.

Critical Kiwi Chronicles: Technology and Teacher Education in New Zealand

Cameron White, Ph. D.
University of Houston
Department of Curriculum and Instruction
U. S. A.
cswhite@uh.edu

Abstract: This paper provides a critical analysis of the integration of technology in pre-service teacher education in New Zealand. New Zealand has made great strides in reforming curriculum both at the pre-college and teacher education levels. As a result, the country has decided that technology has a vital role to play in the teaching and learning process. As a result teacher education institutions have made great strides in course development, online offerings, and internet resources for prospective teachers. The issue is the continued professional development of teachers and actual application of technology in the schools.

Introduction

Technology and teacher education in New Zealand are undergoing considerable transformation. Unlike the United States, which remains in the grips of societal debate regarding even the very basic goals of education, teacher education, and the role of technology within each, New Zealand has a established a decided direction for technology in education and teacher education. The history of teacher education in New Zealand is not without controversy and domination by traditional praxis. Specific issues unique to New Zealand teacher education include the role of New Zealand in the world, relations with other nations, Maori and bicultural issues, the recent debate over the curriculum documents, the overarching goals of teacher education for transmission or transformation, and the role of technology in education and teacher education.

The history of teacher education has traditionally been conducted by teacher’s colleges which have been separate from the university system. As a result, one finds most of the faculty with only bachelors or masters degrees; and many who are still teachers in local schools. Students enter colleges of education immediately after finishing secondary schooling. The three year program includes both content specific courses that are directly tied to content the prospective teachers will be teaching. Students are also required to take the pedagogy courses at the same time. School placements occur during each of the three year program. The focus is to provide placement early on and build on length of placement throughout the experience. There is no semester-long student teaching although students have lengthy placements during the last year in the program. Issues with placements seem to be a lack of organization, lack of relevance (context and connections), and saturation of the schools.

Issues

Technology in schools and teacher education in New Zealand is definitely supported by the ministry of education and the universities themselves. Schools receive funding for technology integration and every school in has at least one internet connection. One also finds at least one fairly new computer in every classroom. There are web sites and online support for teachers interested in technology integration in their classrooms. The issues of standards for technology within education and teacher education are again debated here.

Very similar issues exist in New Zealand as in the U. S. regarding integration of technology in education. These issues include access, support, funding, and “training.” Teacher education institutions offer undergraduates one course on computers in education and students can take others as electives. Very little technology integration is included in other face to face teacher education courses. It is generally left to the individual faculty member to decide for themselves. Recent literature reinforce the issue that in general
future teachers are not receiving the experience needed to effectively integrate technology in teaching and learning both in the U.S. and in New Zealand (Moursund and Bielefeldt, 1999; Hunt, 2000).

New Zealand is grappling with the issues of technology and standards and many provide a critical response to the technology “by in” by schools, education, and teacher education. A critical understanding of ideology and the social practice of technology leading to an equitable distribution of resources and power should be discussed (Hilty and Gitlin, 1996; Snook, 2000). Brown (2000) suggests that without critical knowledge of pedagogy and a philosophical framework for application in one’s own teaching and learning, critical reflection in teacher education, educational technology, and schools is highly problematic.

Perhaps because of the rural nature of the country, New Zealand has made great strides in online course development for teacher education. New Zealand rivals the U.S. in per capita internet usage, thus meeting the needs of students via distance education is a particular directive from the Ministry of Education and colleges of education. As a result, many courses are offered as online alternatives with Webct as the chosen software. In fact, only this year the first totally online cohort in teacher education graduated from Massey University (they did engage in traditional school placements however).

It does seem that recent efforts in technology and teacher education have gone toward online course development rather than integrating technology in teaching and learning in the schools. Massey University has excellent support for online courses. Faculty receive extensive opportunities for professional development and technology support. The university has also established Webct templates to make it easier to get up and running with online courses. The online course office establishes accounts for faculty and students, manages the sites, coordinates all mailing, and even has established general discussion forums and online help sites for addressing issues and concerns. The university web site has all kinds of links to assist faculty, staff, and students with online courses and technology integration.

There is a concerted effort throughout the country to improve information and communication technology (ICT) for prospective teachers. Massey University for example, has established a “knowledge net” metaphor outlining principles of preservice teacher education and technology knowledge and skills for classroom application. The idea is that teaching learning and technology include linking to innovative teaching, be understood as social practice, be located in meaningful contexts, be infused throughout the curriculum, and be integral to lifelong teacher professional development (Brown, 2000).

Perhaps New Zealand is at a crossroads and what really is accomplished regarding schooling, education, and technology integration depends on teacher education, professional development, and eventual application of ideas in the classroom. There is no doubt that there have been efforts made by the ministry in improving education, teacher education, and technology integration within each, but it remains to be seen whether the curriculum documents and teacher education changes will make a difference for the future in New Zealand.

Conclusions

In summary, many similarities exist regarding schooling, education, and teacher education in New Zealand and the U.S. In both nations schooling, education, and teacher education have suffered from inconsistencies dealing with definition, purpose and rationale, and approaches. Curriculum, instruction, and assessment issues are also prevalent in both societies. Perhaps the most important issue has been the continued focus on traditional rather than transformation praxis in teacher education. These issues make for problems as New Zealand attempts to improve teacher education in the new millennium.

Skelton (1997) suggests that there is a desperate need to transform education and teacher education so that the goal is to encourage respect for different perspectives, uncertainty, and provisionality as preparation for living in a increasingly pluralistic, fragmented, and rapidly changing world. Powerful approaches including meaningful, integrative, value-based, challenging, and active teaching and learning are needed to transform both schools and teacher education (Hope, 1996). Likewise, the potential for technology as a tool for transforming schools, education, and teacher education can not be denied (White, 2000).

The real future of schooling, education, teacher education, and technology integration in New Zealand has yet to really be determined. Despite the mandated curriculum documents, there remain entrenched educators, administrators, teacher educators, and others in society bent on ensuring the maintenance of the status quo and traditional teaching and learning, even with the use of technology. As is its history, schooling, education, and teacher education internationally will always be the center of educational debate. New Zealand is no different on this account. But the potential for a transformative
schooling, education, teacher education, and technology integration has at least experienced positive hope in New Zealand.

References

It is always exciting to examine each year's mathematics section papers as they come in for the SITE Annual and this year proved to be no exception. Not only do we see a broader representation of mathematical themes and teaching approaches, but we also see an increasing number of international papers. This points to the growing influence of SITE within the national and international community and bodes well for the future of our organization. When we add to this picture the large number of P1'3 presentations it is clear to see that SITE is rapidly becoming the place to be for technology in teacher education and has made great strides in fulfilling some of the vision of the original founders.

We are also beginning to see some fruits resulting from the maturation of technologies used within the field as a whole. This growing maturity, together with the stabilizing influence of Web based applications, has gone far to providing a more consistent platform within which to explore mathematics in the classroom and teacher education. To a very real extent it is at last possible to seriously examine the impact of technology upon teaching and learning within mathematics without spending two-thirds of the paper dealing with machine specific idiosyncrasies. It's quite exciting to think about what the years ahead might bring when we are able to focus upon substantive issues without having to spend huge efforts in maintaining a stable workplace within which to perform our research.

We thoroughly anticipate that such papers from the future will look markedly different from those of the last 12 years. As we try to imagine what these future papers might look like, it's possible to anticipate changes in at least three areas. The first area would concern itself with the nature of the content to be taught. Mathematics in a technology-enhanced world looks substantially different than it does when the sole tools to think lived are calculator, paper and pencil. Clearly, content issues will need to be addressed in a markedly different fashion in teacher preparation. Secondly, the role of teacher and the interaction between teacher, technology and student will need to be carefully addressed. One might expect to see a growing number of papers dealing with these interactions. The third area of potential change lies in that of the student as they use this new technology enhanced environment to explore mathematics.

The Papers

Putting the crystal ball away for another year, we decided to use these three frameworks -Content, Teacher, and Student - to organize and discuss this year's papers. So let us begin by taking a closer look at this sorting rubric. As we organized the papers around these three major themes, we recognized the false distinctions that occasionally arose. For example, one cannot teach without having content or students. However, in nearly every case we are able to reach a consensus regarding which category might serve to best represent the intent of each paper.

Papers that were classified in the Content area tended to provide meaningful insight into what the actual mathematics in a technology enhanced environment might look like. And what a fascinating view this set of papers provided! Running the gamut from pre-numeracy through calculus and beyond they provide a fascinating series of insights into the future status of mathematics, as well as the tools with which we will enable our teacher candidates to come to understand and teach it.

Papers that were placed in the second major organization area, Teacher, tended to deal more with issues of pedagogy, teacher preparation, and professional development. We also included in this section does papers dealing with the inner life of the teacher and descriptions of general technology tools which might be used across a broad variety of contents and with a broad range of students.

The final theme, students, in many ways is the most important of all. After all, the student is the final consumer in the educational enterprise and should be the center of much of our thinking and planning. As we
examine the role of student as it emerges from the papers presented this year we see a near requirement for more active, critical, and interactive participation on the part of the student. It is interesting to note that the type of student involvement pointed to in these papers nearly mirrors those outlined by the National Council of Teacher’s of Mathematics (NCTM). Relying on the data provided in these papers one can easily build a case that technology can not only be aligned with the NCTM goals, but can easily become a central tool to enable their achievement.

Content. Perhaps appropriately, we begin our discussion of the papers in the content section with Autrey and Myers’ paper describing their experiences with designing and using competency exams in college mathematics. With today’s national trends placing an increasing burden upon teachers to possess high levels of content mastery, such exams are likely to play an increasingly important role in the future. In this paper we see a report on their progress thus far and suggestions for competency exams across the mathematics curriculum. This paper serves to remind us that pedagogical content knowledge, as important as it is, must be thoroughly supplemented with content knowledge of the teacher is to teach with power and authority.

Of course, assessment is of limited value unless we use the results of that assessment to improve student understanding. In Grandgenett, Zygelbaum, Ostler, Hamersky, and Pawloski’s paper we see some preliminary findings regarding an online learning program developed in cooperation with the National Science Foundation. Designed to address the specific content requirements of elementary education majors, this program utilizes a unique database structure and should be examined carefully by those planning to implement a similar approach. We look forward to seeing in future presentations the end result of this work.

In examining those papers dealing with a more traditional view of mathematics content, we find numerous technology-enhanced approaches ranging from beginning mathematical concepts to highly advanced mathematics. Beginning with basic numeracy we have Zelenski’s discussion of a new program dealing with whole number concepts as well as fractions. It would be well worth examining the .pdf versions of the annual to see the colorful illustrations that were presented with this paper. This program places mathematics learning within a jungle exploration context and should provide both incentive and interest for the young child.

Continuing in the tradition of placing learning within the context of personally interesting and motivating experiences, Beal, Woolf, Beck and Arroyo’s paper describing to AnimalWatch: An intelligent computer tutor for elementary school mathematics promises to provide a wonderful existence proof of this effective instructional approach. It should be noted that thanks to the support of the National Science Foundation AnimalWatch will be available at SITE 2001 on a CD-ROM for teacher educators and teachers. We plan on picking up a copy and would recommend that you do also.

Reporting on a project, which includes both CD-ROM and Web based resources; Thomson and van der Kuyl describe the development of their multimedia combined with the Web and CD package geared specifically for the needs of students in the early years of elementary school. This paper truly blended our three categories, as care was taken not only to ensure that the developmental needs of the students were adequately addressed, but also that the materials themselves enabled effective pedagogy on the part of the teachers. The decision to place this paper within the content area was made based upon the perceived focus upon the actual curriculum that was created.

Continuing in this transition from stand-alone CD-ROM to more Web based activities, Lenze’s paper provides a fascinating description of some of the design decisions made by museums to meet the interactive learning needs of their Web based patrons. In addition to his careful and insightful commentary on the design process, we found the resources listed within this paper to be extremely worthwhile as they provided many high quality sites in an easy to locate fashion. Although this paper is not listed in the abstracts, we feel that it is definitely worth the time it takes to find it and would hope that his session will be well attended.

The next presentation suffers from the exact opposite problem. Although it is listed in the abstracts it is not present as a paper. This is to be expected given the nature of the interactive session that Miller proposed. Within this session attendees will have the opportunity to examine two inexpensive software products and use them to script out a series of materials designed to teach linear equations. This certainly sets sounds like an interesting session and we likewise would hope that it to be well attended.

An absolutely fascinating vision of how transformational geometry and matrix algebra might be taught in a technology enhanced setting is offered by Norton and Abramovich. This paper is highly significant on a number of points. First, the software utilized is off-the-shelf - by this we mean a spreadsheet, in this case Microsoft Excel - was used to generate the workspace within which the mathematics is generated. Secondly, the mathematics itself is quite interesting and would certainly catch student interest. And not least among these considerations the nature of the workspace itself lends itself toward student exploration. The authors have kindly included the Web address for the Excel file comprising the tool kit. We feel that this is a must download for teacher educators regardless of the level of their students. A careful exploration of the approach taken by Norton and Abramovich would be
beneficial for anyone interested in using Microsoft Excel, or indeed any spreadsheet, to create such an advanced learning environment.

Finally, Bounaiev provides an insightful discussion regarding the potential for use of databases in teaching calculus and other advanced courses. There is much in this paper of interest not only to the mathematics educator, but the educational theorist as well. It has been fascinating to observe over the past several years the careful theoretical grounding and progress he has made in expanding SSDMA Theory and its applications - not only in terms of information technology, but also within mathematics education.

**Teacher.** At the risk of contributing to the proliferation of yet another buzzword we have chosen to begin our discussion of this section on teaching with Drier’s excellent paper on factors affecting the development of Techno-Mathematical Knowledge. Few would argue that the teacher candidate comes into the methods courses equipped with many believes and misconceptions regarding content, their role in teaching the content, and the role which technology might play in this effort. In this paper we see a careful examination of shifts in belief occurring during a technology intensive mathematics methods course (additional details concerning this course are available via the Web). The included vignettes illustrate how technology can enable subtle shifts in thinking and attitude regarding not only the use of technology, but also the teaching of mathematics.

Continuing this investigation into teacher beliefs, we have Beaudine’s discussion of perspective K-6 educators attitudes towards technology. Although not listed in the abstracts, this presentation promises to say much about the K-6 teacher attitudes toward technology. As the author correctly notes, the use of technology should not began high school classroom. Yet, in examining the beliefs and attitudes of many elementary classroom teachers we find that many of them come to the technology front sadly lacking in desire to use technology. Referring to the author once more, he presents a poignant observation that although students agree the technology is important to say that they like computers would be an overstatement.

Also on the pre-service front, Amarasingshe’s paper describes a technology infusion effort that made use of a set of highly structured technology units in the secondary mathematics course. It is worth reading this paper to see the nature of the design that went behind their creation. We would encourage interested readers to make a point to attend this session.

Moving from pre-service to in-service teachers, in Barber-Freeman, Snead-Greene and McFrazier’s paper on computer-aided personality assessment we are shown some of the personality attributes of secondary and middle school mathematics teachers. Furthermore, we are provided tantalizing evidence which indicates that teacher self awareness of their own teaching and learning styles can prove to be an effective tool for their use in improving instruction.

Making a slight shift in focus, we now examine a series of papers examining various aspects of the teacher preparation process. The first paper in this series from Cavey and Barnes describes a program, *Girls On Track*, requiring active participate part of the student. This summer-based program provided not only opportunities for student growth but also a tremendous experiential base for use by in-service and pre-service teachers. By simultaneously providing a built-in support system as well as immediately relevant and meaningful tasks, this program truly utilizes a variety of approaches towards training teachers. It is an ambitious program, and one well worth watching in the years ahead.

Of course, it is difficult for pre-service teachers to gain appreciation for the role of technology in instruction when the methods professor themselves are unsure of technology’s role. In Jensen’s paper we are promised some insight into the mind of the methods professor’s reflections upon how technology should integrated into the curriculum. Those people who are still on the fence regarding technology use in the mathematics methods course might wish to attend this session at SITE where this paper is discussed for further information.

Some potential technology roles mathematics teacher education are offered in Hovermill and Meloth’s careful analysis of how information technology has been integrated into the teacher education program at the University of Colorado-Boulder. In this paper we see a careful reflections upon the NCTM’s goals, together with a very practical series of recommendations into reforming the teacher education program. Their student findings are likewise of interest. First, the students agree the technology offers unique opportunities and enables connections within mathematics and other disciplines. They also came to realize the technology-enhanced investigations lend themselves to authentic collaboration. These are clearly laudable goals in the authors should be well pleased with their attainment.

We would now like to direct your attention away from the development and support of teachers per se and toward some rather unique tools and resources for teacher use. As we began its helpful to remember that not everything works the first time it’s plugged in. Quite often in generating new technologies there is substantial time spent thrashing about while we wait for either a stable platform or the correct authoring tools to bring our projects forward. The first paper in this section, by Shibata, offers a case in point. Here we see the beginnings of a description of the creation of not only a dynamic curriculum control module but also a full-blown algebraic editor and authoring system. As is often the case in program development there
are significant startup costs and unforeseen problem are common. Those of you planning entering a substantial phase of program creation might do well to attend this session to listen and learn from their experience.

One solution to the dilemma of developing a stand-alone series of applications lies in utilizing the interactive potential of web-based resources. Although not appropriate for every task, it is amazing how often we can accomplish with Java and HTML what is next to impossible to accomplish with C++. We see this approach utilize to great benefit by Zhang who outlines a set of web-based resources designed to teach fractions. Based upon a very careful semantic analysis of the word actions forming the underlying basis for fraction operations over 100 problems were developed and divided into four basic operations and 11 categories. Although not listed in the paper we would love to see the URL for this particular program as it appears to offer great potential forced widespread teacher reference.

Another interesting paper not indexed in the abstracts is Campos, Gomes, and Neto's work using Tele-ambiente in Brazil. TELE itself is a learning environment composed of the TELE interface and a group of activities utilized by this tool. Based in part upon Microsoft's NetMeeting product this interface has been modified to support mathematics. Although still in its beginning stages, this program offers great potential in providing a meaningful and worthwhile environment for student construction of knowledge as well as enabling teachers to have some unique resources available to them.

Another "not in the abstracts" paper by Diez and Moriyón describes another tool designed for teaching mathematics, that of Math Trainer. Drying heavily upon the programming by example methods math trainer appears to be a powerful visualization tool. Of particular interest lies in the importance of the step-by-step actions being delineated by the teacher. This fits in well the SSDMA notions presented by Bouniaev in this section together with other action on objects models (See Connell, 2000). We look forward to seeing the second-generation of this potentially powerful teaching tool and resource.

In the last in this series of interesting papers that are "not in the abstracts" Varvel and Harnisch describe how wireless computer networks are revamping not only what we think of as a network, but also what we think of as a classroom environment. In addition to describing the logistics is setting up such a wireless network, we also see a well thought out and articulated model describing how such a resource might be utilized. Based upon the student responses to the survey conducted for this paper this technology appears to have arrived just in time to meet some very definite student needs.

Finally from the teacher's perspective we have the opportunity of attending a roundtable session by Williams, where we will be able to gain insight into one teacher's efforts on integrating technology into math education. This looks to be a very lively session and I would encourage those of you with an elementary interest to attend.

Student. Given the increasing reliance upon Web based resources in mathematics teaching, it is clearly of utmost importance to consider our students perceptions about such methods of instruction. In the paper presented by Chao and Chiu we are offered a careful look at the impact of putting a large number of mathematics courses online at Golden Gate University. The convenience and flexibility of such online delivery appear to have more then offset the disadvantages of not having face-to-face interaction. It should be noted, however, that these students are predominantly composed of part-time students working full-time. At least for this population the online delivery of mathematics courses make sense.

As has often been suggested, spreadsheets can provide a wonderful environment for the exploration and generation of mathematical concepts. In Brzycki and Hechtman's paper we see how a fifth-grade class was able to successfully use both Excel and PowerPoint to create a very dynamic classroom environment. The authors report that these students not only learned basic financial and mathematical concepts but gained confidence in both creating in sharing their own discoveries.

Recognizing that research, in order to be valuable, must have impact for the population at hand Wang, Swanson and Lam have proposed a replication of some foundational CAI research for the island of Guam. This study as outlined has great potential and we look forward to seeing its successful conclusion and report. Perhaps a day to the preliminary nature of this proposal, it is not currently listed in the abstracts. Hopefully some preliminary data will be made available during the session itself.

In Zhang and Patzer's research on technology and basic math skills over 104 students in 6th, 7th and 8th grades participated in a remedial math lab held over a fourteen-week period. An interesting note to this research was that although it was difficult in the eyes of the authors to see differences between the two groups in terms of math improvement, there were obvious attitudinal changes among the students who had access to the computers. The students reported that they enjoyed working on the computers with their problem solving strategies. An equally important lesson was that simply putting a student in front of a computer does not necessarily mean integration of technology into math curriculum. This is a message which needs to be sent quite often even to those of us who should know better.

On occasion at SITE we often lose track of the fact that for the case of mathematics education the appropriate technology is often the handheld graphing calculator. In Ostler and Grandgenett's study we see how a short
A brainstorming session was able to encourage pre-service math teachers to adopt graphing calculator usage. The session for this paper promises to have insight both in terms of calculator adoption as well as field based aspects of teacher education. We encourage those of you with interest in these areas to attend this session.

**Concluding Remarks**

Mathematics and Mathematics Education have each had long and distinguished histories, which like many other aspects of our world are becoming deeply and profoundly impacted by technology. The papers in this year’s section serve to remind us that whatever the organizing screen we use - Content, Teacher, or Student - or that of our own devising, it is impossible to use old labels to predict the new and emerging trends. As a group, these papers serve to remind us not only of the changes which technology has brought about in foundational issues of mathematical content, but also that our interactions with one another, with our students, and with this changed content will forever be enhanced by these new tools of technology.

We hope that the stability of the modern technology platform will enable us to concentrate more on researching questions of substance rather then on maintaining a meta-stable platform in the midst of logistical and hardware difficulties. Research of this type will prove invaluable in advancing our field of understanding so we might take better advantage not only of the new tools we have to think with, but also the new understandings which they might enable.

Secondary Mathematics Methods Course With Technology Units: Encouraging Pre-service Teachers to Use Technology

Rajee Amarasinghe
Department of Mathematics
California State University, Fresno
USA
ramarasi@csufresno.edu

ABSTRACT: Although technological tools that can be used in the mathematics classroom were introduced to prospective teachers at various stages in their undergraduate curriculum, novice teachers seldom use them in their actual teaching. This paper describes the efforts taken to encourage secondary mathematics teachers to use technology in their teaching by introducing five highly structured technology units into the secondary methods class. The five units are designed to use Internet, Graphing Calculators, Geometer's Sketchpad, Computer Based Laboratories (CBL), and Spreadsheets. The intent of these units is to make students aware of the existing resources, provide hands on experience, look at the resources critically, and collectively develop effective ways to integrate these resources to mathematics teaching.

Background

Methods and Materials in Secondary Teaching is a required upper division course for prospective secondary school mathematics teachers at California State University, Fresno. Students are expected to learn various teaching methods and materials/resources that help them to become effective mathematics teachers in this class. Although technological tools that can be used in the mathematics classroom were introduced to them at various stages in their undergraduate curriculum, students seldom use them in their actual teaching. Various researchers have tried to identify the reasons for their reluctance to use available technological tools in their classrooms (Flake, 1990; Fine & Fleener, 1994; Brooks, D., & Kopp, T.W., 1990). The research findings promote the change of students' beliefs, hands-on experience, group/collaborative work, reflective thinking, and oral communication in mathematics education classrooms. Studies revealed that just learning about technology is not enough to unlock the minds of the preservice teachers to the possibility of those resources as instructional tools. For example, Fine & Fleener, (1994) concluded their study saying "the mention of pros and cons of calculator use and the brief demonstration lesson plan given in the math methods courses left these preservice teachers with at best a superficial understanding of this form of technology. However they appear inadequately prepared to employ calculators in classrooms of their own."

In order to encourage secondary mathematics teachers to use technology in their teaching by infusing technology units into the secondary mathematics methods course, five technology units were introduced to the secondary methods class. The five units are 1) Internet; 2) Graphing calculators; 3) Geometer's Sketchpad; 4) Computer Based Laboratories (CBL); and 5) spreadsheets.

Nature of the Efforts Taken

The intent of these units is to make students aware of the existing resources, provide hands on experience, look at the resources critically, and collectively develop ways to integrate these resources to mathematics teaching effectively. To accomplish these goals, each unit was designed with six components: 1) demonstration; 2) classroom discussion of the resource; 3) students' group projects; 4) student-designed mathematics lessons; 5) sample teaching of the lesson; and 6) peer evaluation and critique of the lessons. The demonstration is designed to introduce the components of the resource to students. In this part students were given a brief introduction followed by a sample use of the resource in teaching a lesson in mathematics. The classroom discussion is designed to discuss the pros and cons of using the resource in a
mathematics classroom by reviewing various research studies and position papers. The goal was to challenge students' existing beliefs about the use of the resource. Researchers suggested that unless students' beliefs about the usefulness of the technology is changed they are not going to use these in their own teaching (Flake, 1990). The projects are designed to familiarize students with the resources via group projects where students inquire about these resources in collaborative groups. The student-developed lesson plans and sample teaching units are the major portion of this effort. In these two parts students are supposed to incorporate the resource they are learning to enhance a mathematical topic they are interested in teaching. For example, students used Geometer's Sketchpad to enhance a lesson on graphing linear equations or used graphing calculators to enhance a lesson on teaching quadratic equations. The last part, the evaluation and critique, is a classroom discussion designed to promote reflection on students' own teaching experiences, oral communication and discussion of teaching methodologies. During these discussions students are expected to receive a constructive feedback from the classmates and explain the reasons behind selecting the mathematical topic, and the activities incorporated into their lesson.

The ongoing study will include details of the student experience in the class, and the results of the survey at the end of the semester will be used to measure the effectiveness of the units. Students' feedback related to the usefulness of the units in their actual student teaching experiences will be also collected along with student-developed sample lesson plans.

Abstract: The idea of competency exams as an integral part of a college mathematics course started at Northwestern State University because of the move to reform based calculus. Further changes in our curriculum have led to a more widespread use of competency exams. While implementation of these exams has been successful in our calculus courses and a course for elementary education majors, we wish to expand our competency exams into developmental mathematics and College Algebra. These exams will ensure that our students have basic analytical skills, while allowing us to maintain reform based courses. We hope to use computer and internet based exams in order to manage a competency exam program throughout the department. We are currently testing a computer based, self-paced program in one developmental math class. We will report on the process we use for these exams and the results we have seen from competency exams across the mathematics curriculum.

Our History

The idea of competency exams as an integral part of a college mathematics course started at Northwestern State University because of the move to reform based calculus. Further changes in our curriculum have led to a more widespread use of competency exams. As a part of the reform based calculus, we place a greater emphasis on numerical and graphical ideas, with less emphasis on the analytical skills that previously dominated the courses. While we believe that a reform based approach leads to a greater understanding of the concepts studied in mathematics, our students were naturally less experienced (and less competent) with algebraic manipulations and other analytical skills. In order to ensure that our students have the ability to perform basic analytical operations and the ability to teach the analytical processes, we have implemented competency exams that students must pass as a requirement of the courses.

In recent years, we have developed two new mathematics courses specifically for elementary education majors. The first of these courses, designed to be taken after a student completes College Algebra and Finite Mathematics, focuses on the concepts and applications of mathematics needed in elementary and middle school grades. We were surprised to notice a deficiency in the basic mathematical competence of students in this course (soon to be elementary school teachers). In order to address this problem, we developed a competency exam as a requirement for this course as well. The exam focuses on problems involving computations with fractions, percents, and basic equations. Students are not allowed to pass this course and become teachers without passing the competency exam.

Having noticed this deficiency within the elementary education majors, we believed that the same would be true for other students. Furthermore, we felt that the deficiencies needed to be addressed at an early stage in the students' preparation. At that point, the decision was made to consider the introduction of competency testing in our college algebra course as well as the developmental math courses.
fluency in mathematics requires students to be proficient with computations as well as concepts. As stressed in NCTM standards, understanding without the necessary computational proficiency inhibits the ability to become efficient problem solvers; the competency tests we are currently using and those we plan to use emphasize that computational ability.

Over half of the students entering the university are in need of some form of remediation; generally, the majority require remediation in mathematics. At Northwestern, students are placed into college algebra on the basis of either their ACT math scores or their scores on the math placement exam. About 900 students enroll in developmental math courses offered on the main campus in the fall semester and about 600 enroll in the spring semester. Many of these students lack basic arithmetic skills as well as elementary algebra concepts. They not only lack computational skills but also the conceptual understanding required for efficient problem solving.

In an effort to better utilize existing resources, the decision was made to offer the beginning developmental course as a self-paced course rather than the traditional lecture course. A pilot section was offered in the fall of 2000 using the existing technology for our online college algebra course to create a hybrid type course. Students still attend class but work in an online classroom setting. This allowed faculty to incorporate competency testing as a component of the course requirements.

Implementation

The competency exams given in calculus courses have been a successful addition to the requirements of the courses. The exams are composed of about 15 problems involving basic differentiation and integration techniques. Students may retake the exams as needed to achieve a minimum competency standard (currently 85%). Since we are a small department, offering only one section of each calculus course per year, the instructor easily manages these tests and re-tests. There are typically 15-25 students in each course. On average, each student requires two attempts to pass the test. Students can schedule times to take the tests, and instructors can find time to grade them within normal office hours.

The competency exam in the course for elementary education majors is a valuable tool to ensure that our students do not graduate without the mathematical abilities they will need in the classroom. Many of the students have been successful in college mathematics, even without a solid background in some of the mathematical concepts that are typically overlooked at this level. There are two sections of the course each semester, with a total of about 60 students. These students require about five attempts to pass the test, making the exams time consuming for the students as well as the instructor, since the tests are scheduled outside the normal class time. Students are not allowed to pass this course and become teachers without passing the competency exam.

Topics covered in the developmental mathematics course include: arithmetic operations with whole numbers, fractions, and decimals; problems involving ratios, proportions, and percents; fundamental operations with sign numbers. To ensure students have obtained at least minimum competency in these areas before moving to the next level of developmental math, four competency tests were created. Students must pass each of these with a minimum score of 80%; failure to do so means that the student will fail the course. Using the technology available through Blackboard (the platform we are currently using for our online course offerings), students may take the tests as many times as necessary in order to achieve the minimum competency. Each test is randomly generated from a test pool and is password protected. Test proctors enter the appropriate password for each test that the student wishes to take. Preliminary results indicate students require, on average, 3 attempts per test to achieve at least the minimum level of competency and those who have passed the competency exams are performing at higher levels on regular exams given during the semester than those who have not passed the tests.

The Future

The college algebra course (Math 1020) taught at Northwestern is also a reform-based course. Since nearly every student takes this course, competency testing is an important element. In talking with faculty members across campus (College of Education, College of Business, Industrial Technology, Biology, etc.), the
most common complaint was the lack of basic algebraic skills by many of the students who have completed their math sequence. What we have seen repeatedly is some understanding of basic concepts involved in solving a problem but a lack of fundamental algebraic and other analytical skills necessary for reaching a solution. In an effort to address this deficiency, faculty at Northwestern have proposed the addition of basic competency testing as an additional course requirement. By doing so, we believe that those students entering the teaching profession will be better prepared to teach mathematics at all levels.

The main issue currently under consideration is the implementation of such testing. Our college algebra classes generally have enrollments of 50 to 60 students per section (about 20 sections are offered each semester). Paper and pencil testing with unlimited retakes would make the task almost totally unmanageable. Use of technology, such as that currently being used in the developmental class, would provide not only a more manageable means of test administration but also a method for generating multiple versions of the test. Use of passwords for the test would address security concerns; however, there are still issues to be resolved in this area.

Conclusions

Overall, faculty believe that the use of competency testing as an additional course requirement will provide some measure of assurance that students have the basic mathematical skills needed for success in the future. For many of the students, their level of motivation and self-efficacy has improved with the addition of these competency tests. They are now able to see the link between conceptual material and computational proficiency. In the developmental math class in particular, students have commented that the tests forced them to study the material and finally master it. We believe that the addition of these tests to the college algebra course will have a similar effect.

ABSTRACT
Mathematics teachers from the state of Mississippi were invited to participate in a training seminar, Technology, Reading, Riting, Arithmetic (TR3), during the month of July 2000. The overall purpose of TR3 was to provide mathematics teachers with effective teaching strategies for improving achievement of Mississippi students. In addition, teachers were provided intensive training with a "hands-on" curriculum, based on the belief that the learner must be an active participant in the learning process and must construct his/her own ideas through reflective thought. This objective was met through the utilization of personality assessments. Research suggests that optimal learning is impacted by understanding personality preference (Alcock, 1998). Thus, the purpose of this research was to examine personality tests that assessed personality, teaching, and learning styles of middle school and secondary mathematics teachers.

Background
Mathematics has been identified as the critical filter for careers in science, technology, engineering and mathematics; thus, it is crucial that all students gain proficiency in mathematics so they can successfully participate in these careers. According to a National Science Foundation (NSF, 1993) report, "Shaping the Future," too many students do not enroll in mathematics courses because they find them "dull and unwelcoming." This report also found teachers lacking the excitement of discovery and the confidence and ability to help students engage in mathematical knowledge. Thus, as part of the overall educational reform initiative, there must be a concerted effort to improve mathematics education in the United States by emphasizing various mathematical concepts that have been educationally, financially, and politically neglected. Also, teachers of mathematics must find innovative and effective ways for encouraging students to have an appreciation for and to achieve at higher levels in mathematics. With these overarching themes in mind, TR3 will be a tool for improving professional skills and providing secondary mathematics teachers the opportunity to acquire knowledge needed to empower all students in the areas of mathematics and technology education.

TR3 was designed to improve the skills of mathematics teachers of grades 7-12 through intensive professional development in methods empirically proven to promote and sustain high student achievement in mathematics. The project objectives are to 1) strengthen teachers' instruction in seventh and eighth grade math, pre-algebra, algebra I & II, geometry, probability and statistics, 2) provide technology training for teaching mathematics in grades 7-12; 3) provide strategies for integrating language arts (reading and writing) instruction into the
teaching of mathematics, 4) address the equity/diversity/multicultural perspectives necessary for teaching math in a diverse classroom and 5) demonstrate how to assess the impact of teachers' instruction on students. Research has shown that a large number of teachers need further training in content areas that have been identified by the NCTM Standards. Thus, TR focused on increasing teachers' awareness, and also provided training and application of mathematics in specific content areas. In many cases, content areas were not included in particular courses taken by the in-service teachers. Therefore, it is necessary to bridge the gap between the prior training of in-service teachers and the expectations of the NCTM Standards (NCTM 1999).

Teachers were provided intensive training with a hands-on curriculum, based on the belief that the learner must take an active role in the learning process and must construct his/her own ideas through reflective thought. The curriculum for the mathematical institute was guided by the National Council of Teachers of Mathematics Curriculum and Evaluation Standards and the Mississippi Curriculum Structure for Mathematics. In addition, in-service teachers were introduced to new mathematical concepts and content, current strategies in teaching the diverse learner, as well as methods of teaching and assessment. All topics were built on the Questioning Approach to teaching. Throughout the project, activities performed were hands-on (manipulatives), based on inquiry, stressing critical thinking skills, and utilizing cooperative learning strategies. The project goals were chosen because of their direct impact on the learning of students.

Technology

Just as students should be provided a problem-solving environment (NCTM, 1989), it is essential to provide in-service teachers with a problem-solving training environment for learning how to identify, explore, and solve problems using manipulatives and technology. It is equally important to be aware of how the integration of technology can affect students' opportunities to learn important mathematics concepts. Technology can effectively transform teaching and learning by:

a) Moving the focus of instruction from whole class to small groups; changing the primary mode of instruction from lecture and recitation to coaching;

b) Requiring students to be explorers, investigators, thinkers and workers rather than passive recipients of pre-digested information;

c) Allowing individual learners to pursue areas of interest in depth rather than requiring all of them to learn the same material on the same day in the same way; providing teachers with more time to work with students who are most in need while those who are most capable advance at a pace appropriate for them;

d) Creating opportunities for assessment based upon products and real tasks rather than solely upon traditional tests;

e) Promoting cooperation and collaboration rather than competition; and

f) Making it possible for teachers to address diversity more effectively rather than teaching primarily to the mean. (United States Department of Education, 1996, p. 2)

In addition to electronic technology, participants had opportunities to use other math manipulatives. Sufficient repetition of events through the use of hands-on materials should occur in order for ethnically diverse students and females to obtain an internal locus of control with regard to mathematics (Freeman, 1995). Further support for use of hands-on manipulatives involved cognitive theory. Piaget believed that cognitive growth occurs best when there is repetitive use of concrete materials in the learning process (Piaget and Inhelder, 1975). Consequently, teachers participated in the computer aides personality test rather than the traditional method of assessment.

Equity/Diversity/Gender

Culturally and ethnically diverse populations within public schools are increasing to the point that minorities now comprise the majority population in 25 of the largest city school systems in America. This growing phenomenon suggests that educational strategies must adequately address how to prepare all United States students so they can successfully compete in an ever-growing technologically dependent world. Our science, engineering, technology and mathematics work force will be in jeopardy of not meeting the needs of the nation, unless there is an increase in higher order thinking proficiencies in both mathematics and technology for the culturally and ethnically diverse students at the middle and high school levels. Instruction must be taught to promote participation in and understanding of mathematics for diverse students.

Eighth and tenth grades have been identified as the pivotal points for encouraging females and ethnically diverse students to pursue higher mathematics courses (Freeman, 1995). An additional aspect of the TR training ensured that teachers were aware of the varying learning styles and personality preferences which
should help lead to an increase in the number of females and ethnically diverse students enrolling in higher mathematics courses.

In order for in-service teachers, students, and administrators to reach their educational, professional and personal potential, they must be actively involved in developing and implementing instructional models. The primary outcome sought through this research was to promote what Franke, Carpenter, Fennema, Ansell, and Behrend (1998) call "self-sustaining, generative change." Self-sustaining, generative change is when teachers make changes to improve their methods of instruction to ensure continued growth and problem solving. To ensure that self-sustaining, generative change is on-going, a teacher personality assessment was conducted. One's personality is without question the most important driver influencing career choice, relationships, health and sense of well-being (Shaughnessy, 1998). To understand the full potential of one's personality, it is critical to first measure and then gain insight into your strengths and developmental needs through examining the results of personality assessment.

What is Personality Assessment?

Personality assessment, as a scientific endeavor, seeks to determine those characteristics that constitute important individual differences in personality, to develop accurate measures of such attributes, and to explore fully the consequential meanings of these identified and measured characteristics (Ozer & Reise, 1994). Simply stated, personality assessment measures such traits as motives, intentions, beliefs, and styles (Wiggins & Pincus, 1992). This measurement can be used to gain supplementary insight into an individual's temperament or character (Keirsey, 1998).

There are a multitude of personality type inventories available for use in the educational setting. These days, taking the Myers-Briggs Type Indicator (MBTI) or the Keirsey Character Sorter and using the results to determine the teaching styles of educators, the leadership styles of administrators, or the learning styles of students is not unusual. For all intent and purposes, we chose to utilize the Keirsey Character Sorter to measure specific personality styles of mathematics teachers.

The Keirsey Character Sorter attempts to help individual's understand both their temperament and character through an investigation of personality differences. In his recent book, Please Understand Me II, Keirsey (1998) introduces the definition of temperament by asking the following insightful question, "What, we might ask, is this thing called "temperament," and what relation does it have to character and personality?" This is an important question to consider when attempting to measure and define one's personality. Keirsey observes that there are two sides to personality: One is temperament and the other is character. Temperament is a set of inclinations we are born with, while character is a set of habits we acquire as we grow and mature. Character is disposition, developed over a lifetime; temperament is predisposition, hardwired in from birth. And, as temperament plays an important mediating role in efforts to assess and understand differences and to facilitate human development (Tice, 1994), an understanding of how a combination of the two creates one's unique personal style is very important when we seek to examine or assess learning styles and teaching styles as related to personality.

**Personality Assessment: A Measurement of Learning Styles and of Teaching Styles**

Self-assessment is an in-depth look at who you are. It is the process of discovering and learning your personality type; becoming aware of what's important to you; and understanding yourself (i.e., your values, interests, aptitudes, abilities, strengths and weaknesses). It is also a way to gain knowledge of what is a good fit or match for your personality (Ellis, 1999). As one begins to explore his or her learning style or teaching style, they will first need to understand themselves.

Learning styles have been defined as physiological, cognitive, and affective behaviors that serve as relatively stable indicators of how learners perceive, interact with, and respond to learning environments (Keefe, 1987). It is the way a person concentrates on, processes, internalizes, and remembers new and difficult academic information or skills. Styles often vary with age, achievement level, culture, global versus analytic processing preference, and gender (Shaughnessy, 1998). Likewise, teaching styles have been defined as either progressive or traditional. The *progressive* style is characteristic of the following: (1) integrated subject matter; (2) teacher as guide to educational experiences; (3) active pupil role; (4) pupils participate in curriculum planning; (5) learning predominantly by discovery techniques; (6) intrinsic motivation, where external rewards and punishments are not necessary; (7) not too concerned with conventional academic standards; (8) little testing; (9) accent on co-operative group work; (10) teaching not confined to classroom base; (11) accent on creative expression; while the *traditional* style is characteristic of the following: (1) separate subject matter; (2)
teacher as distributor of knowledge; (3) passive pupil role; (4) pupils have no say in curriculum planning; (5) accent on memory, practice and rote; (6) extrinsic motivation, where external rewards are used; (7) concerned with academic standards; (8) regular testing; (9) accent on competition; (10) teaching confined to classroom base; (11) little emphasis on creative expression (Francis & Grindle, 1998). Although the above information indicates that unlike learning styles, teaching styles may be characterized more so by preference then aptitude, both learning styles and teaching styles are thought to be stable and enduring personal qualities and not easily acquired (Derry & Murphy, 1986; Apple, 1999).

**Methodology**

Schools are a wonderful and vast mix of unique teachers and students with individual educational styles and perspectives. Hence, it is imperative that teachers be knowledgeable of the impact that personality style has upon optimal learning. In order for teachers participating in Technology, Reading, Riting, Rithmetic (TR3) Seminar, to develop a better understanding of the importance of personality, teaching and learning styles, they were required to complete a personality assessment via Internet. According to Wenzlaff (1998), teachers of today and tomorrow must first know themselves and how those intangibles will guide them in their classroom before that can effectively empower their students.

Research has shown that a large number of teachers need further training in content areas that have been identified by the NCTM Standards. Thus, TR3 not only increased teachers' awareness, but also provided training and application of mathematics in specific content areas through the integration of technology. Teachers were provided intensive training with a "hands-on" curriculum, based on the belief that the student must take an active role in the learning process and must construct his/her own ideas through reflective thought. In meeting this objective, personality assessment was vital in enlightening teachers as to how their own teaching and learning styles, beliefs and values will impact learning within their classroom. Because teachers should be aware of the impetus of personality style/preference on optimal learning (Alcock, 1998), participants were given the opportunity to complete on-line personality assessments. Following the completion of the survey, counselors assisted with the explanation and interpretation of survey results.

Twenty middle school and high school teachers from the state of Mississippi participated in a Mathematics Summer Institute sponsored by the Institutions of Higher Learning in the state of Mississippi during the summer of 2000. Eighteen of the 20 teachers completed the on-line personality assessment. Nine of the participants were middle school teachers and nine were high school mathematics teachers. Figure 1 identifies the breakdown of the mathematics teachers' temperament according to grade levels. According to Keirsey (1998), those individuals with an Artisan portrait are concrete in communicating while utilitarian in instituting goals. Where as, the Idealist is an abstract communicator and cooperative in goal implementation while the Guardian is concrete in communicating and cooperating in the implementation of goals. The individual with the Rational portrait is abstract in communication and utilitarian in the implementation of goals, however, they are highly skilled with strategic analysis.

Figure 1 suggests that of the nine middle school teachers the majority of their portraits were Idealist. According to Keirsey (1998), the Idealist is usually found teaching, counseling, mentoring or tutoring. In addition, Idealist comprises approximately eight to ten percent of the population. The greatest temperament found among the high school teachers was Guardian. The teachers portraits that reflected Guardian are identified as supervisors, inspectors or protectors. Individuals that projected the Rational portrait are planners, inventors or engineers. In Figure 2, the character style of the majority of middle school teachers were "Teachers," while the majority of the high school teachers character style was the Protector.

![Figure 1](image-url)
Conclusion

The Keirsey Character Sorter as a Personality Assessment Tool

Temperament, which helps us to understand why we process and respond to situations as we do and why others may process and respond differently in terms of the same phenomena, can operationally be defined through four dichotomous traits: 1) extraversion -E and introversion – I, 2) sensing -S, and intuition-N, 3) thinking -T, and feeling -F, and 4) judging -J and perceiving (Myers & Kirby, 1994). Keirsey and Bates (1984) describe four basic temperaments that can be derived from the interaction of these types of traits, each temperament having its own primary or core value. Keirsey (1998) utilizes the previously stated traits to explain temperament, character and personality as either Artisan, Idealist, Guardian or Rational.

Personality factors, teaching philosophy, and preferred learning styles can play an important role in effective teaching and effective learning in the classroom. According to recent research, the blending of personalities and teaching styles is likely to have a great impact on course success, course continuance, and teacher and student satisfaction. A satisfying (or not so satisfying) teaching situation will affect how the teacher relates to the student; that in turn, affects how the student views the success of the academic course their interest in continuing in such a curriculum (Bruneau-Balderrama, 1997). Fairhurst and Fairhurst in their 1996 studies on how temperament and personality type theories can affect teaching and learning call this type of classroom satisfaction the “personality connection.”

In conclusion, personality assessment as used during the TR3 Mathematics Summer Institute received favorable responses from the participants. Some responses from the completion included: “Now, I understand why I teach like I do...” “...I feel this will really help me within the classroom...” and several teachers were anxious to have their students to complete personality assessment via e-mail. Finally, this research concurs with Wenzlaff (1998) findings that teachers of today and tomorrow must first know themselves and how those intangibles will guide them in their classroom before that can effectively empower their students.

Abstract. AnimalWatch is a computer based tutor for mathematics instruction, designed for use by 10-12 year olds. AnimalWatch integrates mathematics problem solving with adventure narratives about endangered species (Atlantic Right Whale; Giant Panda; Przewalski Wild Horse). Whole number operations, and like and unlike fractions are included. AnimalWatch uses artificial intelligence algorithms to model individual student performance and continually adjusts its problem selection, instruction, and hints so that each student is challenged without becoming overly discouraged. AnimalWatch is available on CD-ROM (both Macintosh & Windows platforms) for teachers and teacher educators and will be distributed at SITE 2001. A web site provides a forum for comments, updates, support, and authoring tools for teachers to create their own mathematics problems and endangered species adventures.

Project Goals
There are many concerns about the poor level of mathematics achievement by students in the United States, as well as the lack of interest in studying mathematics that can be apparent at the transition from elementary to junior high school. This dislike and avoidance of mathematics has been particularly noted among female students, and among members of traditionally underrepresented groups. Much research has sought to identify the factors that contribute to math avoidance, including gender role stereotypes, peer pressure, gender-biased instruction and expectations on the part of parents and teachers, poor preparation for mathematics teaching on the part of classroom teachers, among others. Although the role of teachers may well have been somewhat overemphasized in the popular press in recent years, it is still the case that many new teachers at the elementary level report feeling ill-prepared to teach mathematics and that they prefer to focus on reading. To address these concerns, teacher educators need well designed, easy to use resource materials that can support effective and engaging classroom instruction in math.

One way to address concerns about the quality and effectiveness of math instruction is to use well designed, multimedia materials to enhance learning. The goal of the AnimalWatch project is to use the power of an artificially intelligent, multimedia computer tutor to provide high quality mathematics instruction that will engage both male and female students, increase their math self confidence, and encourage them to continue to study math. With the support of the National Science Foundation, AnimalWatch will be available at SITE 2001 on CD-ROM for teacher educators and teachers to use in their programs and classrooms.

Program Description
AnimalWatch is a computer program that is easily installed via CD-ROM. It will support roughly 10-14 hours of use by students in the 4th, 5th or 6th grades. AnimalWatch runs under both Windows and Macintosh operating systems. The program is self contained, meaning that it can be launched by the student and used without full time, direct teacher supervision or input.

Mathematics in Context. When the student starts the AnimalWatch program, he or she first selects an endangered species: Atlantic Right Whale, Giant Panda, or Przewalski Wild Horse (Figure 1). Then, the student begins a narrative in which math problem solving is integrated with information about the chosen species. For each animal, the narrative includes four distinct contexts. For example, in the case of the
Prezewalski Wild Horse (also known as the Takhi Horse), the first context includes problems about the unique characteristics of the Takhi along with background on how it became extinct in the wild. The second context provides information about how the Takhi species was preserved in zoos around the world and on efforts to save the animals. The third context focuses on the history, geography and culture of Mongolia, the original home of the wild Takhi. In the final context, the student plans and raises funds for a trip back to Mongolia with zoo-raised horses that are being released back into the wild at the Hustain Nuruu Nature Preserve.

**Figure 1: Endangered species selection in AnimalWatch**

Math Problem Template Bank. Each of the four contexts provide dozens of problem templates that are based on factual information about the endangered species and their habitats (see example in Figure 2). For example, in the case of the Giant Panda, math problems involve research at the library about the Panda and its habitat, reading about the birth of a new Panda in captivity at the San Diego Zoo, the reviewing of maps of the Panda's habitat, estimates of the expenses associated with a trip to China, and analyses of the rate of decline of the Panda population over time, etc. Each math problem includes an image or graphic that is tailored to the problem, e.g., a map of Cape Cod bay showing the migration route of the Right Whale for a problem in which students must calculate the fractional progress of a whale pod over the course of a week's travel.

**Figure 2: Example of word problem about the Right Whale**
To date, the problems in AnimalWatch include whole number operations (addition, subtraction, multiplication, and division of numbers up to 3 digits), introduction to fractions, and addition and subtraction of like and unlike fractions (up to 2 digit denominators). In most cases, the specific math problems are custom created "on the fly" by AnimalWatch. The system uses about 1200 unique problem templates that are instantiated with specific numbers and operations that are tailored for individual users. For each animal and each context, problem templates are available for all mathematical operations included in AnimalWatch. This allows students to work at different levels of math problem solving while also making progress through the narrative at roughly the same pace. (This avoids the potentially demoralizing situation in which one student has finished the story whereas the student at the adjacent computer is still on the first context.) After reaching the end of one narrative, students can also change to a different endangered species and continue working at the same level of mathematics; for example, if a student was working on addition of single digit like fractions at the end of the Panda narrative, he or she would start with like fractions when moving on to the Right Whale narrative. AnimalWatch continually generates new problems from templates, rather than drawing on a fixed, stored set of pre-prepared problems, students who are strong in math can work for longer periods on the most difficult problems, while their less skilled classmates can progress at the easier levels.

Help, Hints and Instruction. AnimalWatch has been designed as a supplement to classroom instruction in math, and was developed with master teachers to incorporate the vocabulary and materials (e.g., Cuisenaire rods) that students would encounter in the classroom. Although it is not designed to offer primary instruction, it does include many hints and instructions screens that will guide the student through the problem to the solution (see example in Figure 3). The particular hint or help screen provided is selected by the system based on its estimate of what the student understands and where there might be a misconception. For example, AnimalWatch might reason that a student who has made several errors in adding unlike fractions might need a hint about how to find the least common multiple, whereas a classmate who has solved such problems successfully in the past might simply need a reminder to check the denominators.

The Student Model. The heart of the AnimalWatch system is its “student model” function: a feature that allows the system to estimate what an individual student user understands about the mathematics domain, compare the student knowledge to its expert knowledge of the curriculum, identify appropriate areas of challenge, and construct a specific math problem that is tailored to the student user. The estimate, or “student model”, is continually updated based on the student’s performance, which is assessed by number and type of errors, response to instruction and hints presented by the system, and latency to reach the correct solution. As the student progresses, hints typically become less concrete and procedural, which encourages the student to generalize past solution strategies and move to a more abstract level of reasoning. The combination of intelligent problem selection and instruction, along with the ability of the system to redirect its teaching focus very quickly in response to student performance, is analogous to having an expert teacher provide individualized tutoring for each student in the class at the same time.
Evaluation Studies

AnimalWatch has been field tested in three school districts in Western Massachusetts, including both affluent and resource-limited schools in rural and urban settings. The primary dependent measure has been students' math self concept, which includes measures of confidence in one’s ability to do math; liking of math; and interest in learning math and the belief that math is valuable to learn (Eccles, Wigfield, Harold, & Blumenfeld, 1993). In pre-post test designs, we have found that 3-6 sessions with AnimalWatch leads to significant increases in math self concept, particularly for girls (Beal, Woolf, & Beck, 1998; Beck, Arroyo, Woolf, & Beal, 1999). The provision of math problems that are appropriately challenging along with the availability of help when errors are made is particularly effective with female students, who are less confident and less interested in math to begin with. In one study, we compared a version of AnimalWatch with the full student model to a drill-and-practice version that simply presented problems in order through the narrative and did not provide the range of hints and help available in the full version (Beck et al., 1999). The results indicated that the “intelligent” version of AnimalWatch fostered more rapid student progress through the curriculum, and that this effect was greater for girls than boys. Consistent with the findings of others, it appears that girls’ interest in studying math is more fragile than that of their male classmates; however, responsive and supportive instruction can significantly enhance girls’ math self concept.

Student perceptions of AnimalWatch. Student responses to post-test surveys indicate that they generally rated the experience of using AnimalWatch highly: Means range from 3.78 to 4.85 (on a 5 point scale) for questions such as “Would you like to use AnimalWatch again?”, “When you made errors, did AnimalWatch give you enough help?”, “Do you think the computer is a good way to learn math?”. On the question, “Did you like working with AnimalWatch?”, girls gave significantly higher ratings than boys (mean 4.50 for girls, 4.05 for boys).

Although both boys and girls give high marks to AnimalWatch, they prefer different types of instruction provided by the system, and they respond to different types of instruction. In an experimental study, the system was “tuned” to provide either detailed procedural hints that walked the student through to the correct solution, or more conceptual hints. Girls reported that they liked the procedural hints better, and procedural hints were also more effective for girls (i.e., procedural hints were followed by fewer errors in subsequent problems), whereas there was no relation for boys. The distribution version of AnimalWatch is designed to select procedural or conceptual hints on the basis of the student model’s estimate of the student’s current comprehension; hints that are highly effective will increase the probability that similar types of hints will be used with subsequent problems.

Teacher perceptions of AnimalWatch. During the development of the program, teachers were invited to the UMass campus to try out AnimalWatch and provide feedback. During the workshops, we made an initial presentation about gender equity in SEM education, and outlined the goals of the AnimalWatch project. The participating teachers then worked with AnimalWatch, made notes and suggestions, completed a survey about the system, and participated in a group discussion about its strengths and weaknesses. AnimalWatch received high marks from the teachers, who rated it very highly on such issues as appropriateness of math topics, sufficiency of help, ease of use, fit to their curriculum. They also felt that working with AnimalWatch would help prepare weaker students for high stakes achievement tests such as the PSAT or the MCAS (a new state assessment in Massachusetts). Teachers responded very positively to AnimalWatch’s ease of use and resilience (i.e., there is little that a student can do to “mess up” the computer and thus require teacher intervention). They were also very pleased that it will run on any platform. About 75% use Macintosh machines at their schools, but many have PC machines in their homes, and a number reported that the computer labs at their schools included both platforms.

Educator Support

AnimalWatch has been designed in collaboration with a team of master teachers of 5th and 6th grade students, and includes several features that facilitate its use in the classroom. First, a student progress report function is provided so that instructors can see at a glance the various curriculum areas that are being worked on by individual students. Second, a companion web site provides background information about the project, support information, updates, and a discussion board. There is also a facility for downloading
the AnimalWatch program "shell", along with the three adventures. (Due to the large number of images, the entire system is at this point best distributed via CD-ROM unless the user has an extremely fast connection.) Third, the web site offers numerous authoring tools so that teachers can create their own word problems and submit them for inclusion on the AnimalWatch adventures (see Figure 4). Teachers can also create new adventures with their own endangered species.

![Figure 4: Word problem authoring tool for teachers](image)

**Conclusions**

Declines in math interest, as well as gender differences in math self concept, are already apparent by the end of elementary school. Unfortunately, many new teachers at the elementary level, most of whom are female, report that their own mathematics education was weak, that they feel better prepared to teach reading than math, and that they prefer to focus on reading instruction. Thus, there is an urgent need for high quality resources to support mathematics instruction, to encourage all students to feel confident in their ability to learn math, and to maintain student interest in pursuing mathematics training. Many commercial mathematics CD-ROMs for students are simply “drill and practice” packages that do not provide individualized instruction and tutoring; many are also inappropriate for classroom use due to commercial content (e.g., TV cartoon characters), or are targeted primarily to male users (e.g., successful problem solving earns the opportunity to "blast" a target; heavy emphasis on competition).

In contrast, AnimalWatch has been designed to mesh with the classroom curriculum. It uses the same vocabulary and materials that students will see their teachers use during lessons. It links mathematics with an area of the curriculum that both male and female students like: environmental biology. It employs sophisticated artificial intelligence algorithms to provide individualized tutoring to students that is both challenging and supportive. AnimalWatch has been shown to engage student interest and to boost students’ math self concept. It is easy to use and is self contained; teachers can allow the system to pace student work. At the same time, it offers teachers the chance to review student progress, and to create new materials when they are ready to do so. Our goal is to reach teacher educators who will be in a position to introduce AnimalWatch to prospective teacher users, and to help us integrate effective technology-based math instruction into as many elementary classrooms as possible.

Acknowledgements

The AnimalWatch project has been supported by a grant from the Program in Gender Equity at the National Science Foundation, awarded to Carole R. Beal and Beverly P. Woolf. We are most grateful to Charlene Galenski, Diana Campbell, Douglas Tierney, Jillayne Flanders, Amy Ryan, and Mario Cirillo, as well as the other members of the Deerfield Elementary, Hadley Elementary and Chestnut Street Accelerated Middle Schools in Western Massachusetts for their generous support and help with the project. We would also like to thank David Marshall for his excellent assistance with programming and technical support, and Mary Anne Ramirez, Jennifer Berry, Rachel Wing, and Alisha Crawley for their help with the field studies.
Prospective K-6 Educators Attitudes about Technology

Dr. Brian Beaudrie
Department of Mathematics and Statistics
Northern Arizona University
United States
Brian.Beaudrie@nau.edu

Since the late 1970's, the use of technology in the classroom has been increasing at an almost exponential rate. The use of computers and calculators is so prevalent in the modern classroom that it is rarely challenged today, whereas twenty years ago the very idea was practically unthinkable. In that short time frame, most educators and parents have gone from asking themselves whether calculators and computers should be in the classrooms at all to how they may be best used to maximize the learning potential of students.

In the publication "Curriculum and Evaluation Standards for School Mathematics," the National Council of Teachers of Mathematics (1989) stressed the increased use of technology in the classroom at all grade levels. The NCTM also emphasized that students should have access to a computer at all times in their classroom, and that each school should have some type of computer laboratory facility to allow whole groups or classes to work on computers at the same time. In the publication of "Principles and Standards for School Mathematics", the NCTM (2000) asserts that technology has become an essential part of teaching, learning and doing mathematics.

However, the NCTM (2000) also states that technology in and of itself is not a panacea. Calculators and computers are tools, much like pencil, paper and manipulatives. As with any tool, calculators and computers can effectively enhance the student's mathematical learning experience or detract from it. Those experiences depend largely upon how the mathematics teacher uses technology in the classroom. Thus the preparation of mathematics teachers in the proper use of technology is of utmost importance.

The use of technology should not begin in the high school mathematics classroom. Rather, computers and calculators should be used throughout the K-12 learning experience. Many colleges and universities have incorporated courses and programs that include the use of technology as part of the pre-service secondary mathematics teacher's preparation. In many situations, elementary teachers are not given the same preparation or background, which may lead to future elementary teachers concluding that using computers or calculators will not be an important part of their teaching experience.

This paper will present the findings of a work-in-progress study concerning the experiences with technology and attitudes towards technology of pre-service elementary school teachers. In addition, it will focus on what this unique group believes should be the role of technology in the classroom, and how they personally will use technology in the classroom. This information was gathered through the use of surveys during the Fall Semester of 2000. The surveys were given to students at Northern Arizona University, a mid-sized university in the southwest United States. Note: Since the data is still being analyzed, many of the results are still pending; they should be ready by the time this paper is presented during the conference. However, there are some preliminary descriptive results of data analysis of one survey, which will be described and presented below.

Computer attitudes were measured by the Computer Attitude Scale, a forty-item questionnaire developed by Loyd and Gressard first in 1984, and later modified. The Computer Attitude Scale is an instrument that measures attitudes towards learning about and using computers. It is perhaps the most extensively used and tested scale of its type in use (Woodrow, 1991). The developers claim that this scale is "a convenient, reliable, and valid measure of computer attitudes, and that it can be confidently and effectively utilized in research and program evaluation contexts." (Woodrow, 1991) The instrument provides scores on four different scales: Computer Anxiety, Computer Confidence, Computer Liking and Computer Usefulness. Positively and negatively worded statements are included in each of the four areas. Alpha reliability coefficients calculated by the creators of the instrument for each of the four subgroups range from .86-.88, .87-.91, .88-.91, and .82 for each subscale, respectively with the total score having an alpha reliability of .95. An independent researcher found similar reliability coefficients (Woodrow, 1991). Each subscale consists of ten items. Students responded to each item by selecting one of four possible responses; strongly agree, slightly agree, slightly disagree, and strongly disagree. Some sample items from
the CAS are statements such as "Computers make me feel nervous and uncomfortable" or "Computers do not scare me at all". The correlation between the subscales range from .69 to .84. Scores can range from a low of 10 to a high of 40 on each of the subscales. In general, the higher the score, the more positive the attitude about computers. Any composite score above 90-95 indicates a neutral to positive attitude towards computers. In previous studies, it was found that gender played no significant role in computer attitudes (Loyd and Gressard, 1987), and that computer attitudes were significantly affected by computer experience (Loyd and Gressard, 1984).

The Computer Attitude Scale was administered to four sections of Principles of Mathematics I, the first of two one-semester courses that are required of all elementary education majors at Northern Arizona University. Students in these sections were asked to fill out the survey, but it was not required; a total of 100 students responded to the survey. Of those students, 91 were female and 9 were male; most (56) were freshman, and almost all students (87) were under the age of 22, which is the lowest age category on the Computer Attitude Scale. Surprisingly, a large number (70) indicated having more than one year of experience with or learning about computers; only 25 had less than six months experience. Some of the more common experiences listed by students were using the computer for word processing, for e-mail, and for surfing the World Wide Web.

Results showed that only five of the 100 students had a composite score below a 90, which would indicate that most (95) students indicated a neutral to positive attitude towards computers. Of those five, four had six months or less experience working with and learning about computers, which may have attributed to their negative attitude.

The results from the individual subscales are shown in Table 1.

Table 1: subscale results of the Computer Attitude Scale

All means indicate that students show a neutral to positive attitude among these four subscales. However, there does exist some variety among the subscales. Students exhibit a relatively strong positive attitude towards the usefulness of computers, yet were not so positive when it came to liking computers. Computer anxiety, unlike mathematics anxiety, does not seem to be a major problem among these students. Also, students overall indicate a fairly positive attitude in their own computer confidence.

The individual numbers in each subscale present some interesting findings as well. The fact that so few students scored above a 30 in the Computer Liking subscale when compared to the Computer Usefulness subscale is of particular interest. This seems to indicate that while many students believe computers are useful, to say that they like computers might be stretching the truth a bit. The fact that almost one in five students scored less than 20 in the Computer Liking subscale (which would indicate a negative attitude) is particularly alarming. However, almost half of the students in that category have less than six months experience working with and learning about computers. This could mean that the more these students experience using the computer, the more positive their attitude would become towards computers. As for those students with negative attitudes that have significant experience with computers, more study is necessary to determine why these students may feel this way.

A quick glance at the individual statement results provides more insight. On the statement "Learning about computers is a waste of time", 97 students either strongly disagreed or slightly disagreed. While this is an excellent result, one must wonder about the three who agreed with the statement. Another finding of particular interest concerned the statement "I'll need a firm mastery of computers for my future work". The results were mixed; fourteen students strongly agreed with the statement and seven strongly disagreed, but the majority either agreed or disagreed only slightly. Of the 10 statements that dealt with Computer Usefulness, this question had the most negative response. Given that these students will be often, as teachers, the first to introduce primary grade children to the educational value of the computer, this result more than any could indicate that they might need more preparation in the use of technology in elementary school. More study into the results of why students responded as they did and the implications of those responses will be undertaken with the results presented during the conference.

Using Databases in Teaching Advanced Mathematics Courses

Mikhail Bouniaev

Southern Utah University
United States
bouniaev@suu.edu

Abstract: This paper is a follow up of the papers that discussed how information technologies could be used in teaching Advanced Mathematics (Bouniaev, 1995) and in developing general logic actions (Bouniaev, 1999). Here we discuss the possibility of using databases in teaching Advanced Calculus. The psychological foundations of our considerations are Stage-by-Stage Development of Mental Actions Theory and Constructivism.

Introduction

This paper is a follow-up of research contained in the paper “Some Psychological Aspects of Developing Computer Based Instruction in Undergraduate Advanced Mathematics” (Bouniaev, 1995) as well as in “Computer Based Instruction and General Logic Action Development In Teaching Mathematics” (Bouniaev, 1999). In these papers, we mainly discussed the methodology of using Information Technology (IT) in studying such disciplines as Calculus and Foundations of Algebra and Analysis. They focused on the development of elementary general logic actions such as classification and attributing to a concept. The psychological foundation of the above-mentioned papers was Stage by Stage Development of Mental Actions Theory (SSDMA theory).

Since the first paper in the series was published, long discussions and collaborations with M. Connell led us to the conclusion that SSDMA prescripts for organizing a learning process practically coincide with those of the constructivism (Connell & Bouniaev, 1996).

Thus we would like to emphasize that although we still explicitly proceed from the concepts and recommendations of the SSDMA theory, implicitly there are no contradictions with the theory and practice of constructivism. Proceeding from the above-mentioned psychological theories as a fundamental basis for using information technologies (IT) in this paper we discuss the possibilities of using databases in organizing instruction process of such an abstract discipline as Advanced Calculus. This discipline is a part of most math teacher training curricula and can substantially impact the efficiency of teaching Calculus in high schools.

In the first part of the paper we give a brief summary of the SSDMA theory, which is essential for understanding the paper. Here we repeat most of what we said about it in (Bouniaev, 1995). In the second part we analyze some particular aspects of using IT in studying more advanced math courses as compared with lower level courses and their significance for math teachers training. And finally, proceeding from the SSDMA's five stages of development of mental actions we describe the possibilities of using such databases as Access at the initial stages of action development.

Basic concepts of the SSDMA theory

This paragraph is based on the monograph of Talysyna (Talysyna, 1975). According to this theory the major goal of instruction is developing mental actions with objects of the studied field. Instruction is viewed as controlling students' activities and hence controlling the process of development. Thus, instruction efficiency is determined to a great extent by a well-developed system of control.

All actions can be referred to two categories: general logic actions and specific actions. General logic actions are inherent in every subject field and are different only in objects at which they are directed.
Examples of such type of actions are qualification; break up into classes, comparison, contributing to a concept, action of proof. For example, qualification as a type of action exists in mathematics (qualification of the conics and differential equations) as well as in other disciplines. Specific actions are basically inherent to a given subject field. For example, in mathematics they are arithmetic operations, differentiation, etc.

The SSDMA theory specifies four independent characteristics of any action used to judge the level of development of an action:

**Form of action.** An action can be in a materialized (material), speech or mental form. A materialized form of action is connected with manual activities (manipulation, hand-on activities, etc.); objects of action (or their models) are presented in a material form; results of action should be real transformations of these objects or of their models. There is no need to discuss the speech form of action. However, it should be noted that according to the SSDMA theory, writing belongs to the same speech form. Mental form of action is the highest form of action development. An action in this form is imperceptible for one's associates and its results are also recorded in an imperceptible for others form. For example, in considering a specific problem a task of qualifying conics may arise, which is a subsidiary problem with respect to the main one. If a number of conics presented for qualification is not excessive then any mathematician can perform this action in his/her head and record its results in memory. As experiments show, for students studying the theory of Conic Sections it is difficult to perform this action in their heads (even if the number of conics at the beginning of study is 3 or 4). The mental form of action also means that its objects are representations, notions, concepts and all operations are performed in the mental form. The ability to perform a whole action in the mental form indicates that it has gone through all the stages of development and interiorization.

- Each of the described forms of actions has another three independent characteristics: (a) degree of generalization; (b) degree of completeness; (c) degree of assimilation.

  (a) Generalization of an action means ability to apply it to objects of a different nature. If the degree of generalization is high enough a person can easily apply this action to different objects, or example, if the action of qualification of conics is developed with a high degree of generalization then it can be applied to a similar problem in three-dimensional space. In this case a person has developed some general ideas how to perform a qualification action.

  (b) The degree of completeness indicates if all the operations that were to be performed in the process of performing an action have been actually completed. For example, in teaching the action of qualification of animals an operation to be performed is obtaining enough specific characteristics to be able to refer an object to a particular class. It is evident that sometimes all the answers can be correct but based on superficial characteristics which indicates that in the process of performing an action either wrong operations were made, or the order of operations was wrong, or not all of the necessary operations were performed. The common method of establishing the degree of completeness of an action is restoration of all the operations necessary to perform it.

  The degree of assimilation, as a rule is connected with such indicators as the speed of performing an action, technical errors and mistakes, the level of automatism, etc. It should be noted that drill-and-practice software first of all is aimed at developing certain actions with a high degree of assimilation.

The SSDMA theory singles out five stages in the process of instruction. Detailed analysis of each of the stages in organizing a computer oriented learning environment is given in "Development of multifunctional dialogue CAT programs" (Bouniaev, 1991), therefore here we will provide just a brief outline of these stages.

The first stage deals with the presentation of the material to students and description of an action to be developed. Note that passive reception of knowledge by students is not performing an action. The second stage consists of developing actions in the materialized form. The third stage deals with developing an action in the speech form (both oral and written). The fourth stage is beginning interiorization. Each of us probably noticed that before performing an action to make it easier we tend to speak it out to ourselves. Speaking out to ourselves is the fourth stage of development. At the fifth, final stage, the action is developed in a mental form. Note that at each of the last four stages the action is developed at a certain given level of generalization, completeness and assimilation.
Construction of materialized objects in studying advanced mathematics

As it follows from most modern psychological theories, for example, constructivism or SSDMA theory, at the initial stage of instruction the object of action should be presented in a material or materialized form of action (Bouniaev & Connell, 1996). Moreover, this action should be developed at a high enough level of generalization, completeness and assimilation. As a rule it is not hard to do when we deal with development of arithmetic or algebraic actions. But the more abstract the material, the more difficult it is to present the object of action in a material or materialized form. Thus in organizing the instruction of more advanced math courses it is common practice to start right from developing the action in the mental form. This negatively affects the level of student's knowledge in abstract math disciplines.

The math teacher curriculum traditionally includes such disciplines as College Algebra, Calculus, Linear Algebra, Foundations of Algebra and Analysis, Abstract Algebra and Advanced Calculus. In training a math teacher each of the above-mentioned courses plays its particular role. A change of this role in studying more advanced courses significantly affects the character of didactic goals to be achieved in the process of instruction. This change can be easily observed in changes in wording of the exercises of the above-mentioned courses.

Thus in College Algebra and Calculus I the majority of exercises deal with finding a new object. For example, find a sum of two algebraic fractions, find a derivative or an integral, etc. At the final stage of instruction of Calculus and in teaching Linear Algebra the number of problems dealing with finding new objects is balanced by the number of classification or attributing to the concept problems. For example, to prove that the given series converges (in Calculus), or to prove that the given system of vectors forms a basis (in Linear Algebra). So we see a new type of problems, however, as we already mentioned they deal with development of elementary logic actions.

As a rule, the object of action of this type of problems can be easily presented in the material or materialized form. For example, it is easy to represent the terms of converging series as a sequence of dots on the plane. However, it should be noted that a model presentation of an abstract notion that looks superficially good is not always helpful in doing a specific problem.

Development of logic actions such as classification is connected with construction of materialized models that physically may not look like the respective actions but present in the materialized form the structure of such actions. For instance, tables can be used that students fill in while doing specific problems. It is also expedient to use electronic text fragments, which can be moved to different places on the screen. The details of using IT in solving this type of problem can be found in (Bouniaev, 1999). Therefore we are not going to elaborate it here.

At the next stage in teaching such courses as Advanced Calculus and Abstract Algebra besides simplest logical actions such as classification and attributing to the concept we have to develop more complicated logic actions such as the action of proof. Bearing in mind that in studying Calculus students have mastered the simplest "transformation problems" like finding a derivative or an integral, then in Advanced Calculus development of the action of proof becomes the major goal of instruction. And not only development of the action of proof, but proof of statements applicable to the whole class or classes of objects. In this case the object of action is a theoretical abstract concept, which makes it significantly different from the situation when the object of action is a particular function even if the action itself is an action of proof.

Thus for example the task to prove that function six x is continuous is significantly different from the one to prove that any continuous on the closed interval function is bounded. In the first case the object of action has materialized representation both in the form of a formula connected with numerous trigonometric identities and in the form of a graphic using which all the actions performed in the course of proof can be "materialized". In the second case the object of action is a math abstract notion for which it is difficult to find a materialized representation. Any continuous function viewed as an illustration is just an example of an object coming under this notion and thus cannot claim to be a materialized representation of a math abstract notion.

Besides that, math abstract notion itself significantly depends on the level of development of an individual in whose mind it exists. For example, the notion of continuity exists both in the mind of a freshman before studying Calculus I and in the mind of a senior ready to study Advanced Calculus. At the same time in the framework of the studied course (Calculus or Advanced Calculus) further development of
abstract notions determines different actions that are objects of these abstract concepts.

For example, in Calculus I to develop the notion of continuous function it is enough to use the action of classification of pictures illustrating graphics of continuous and discontinuous functions. We can also effectively use pictures in a formal proof of continuity. However, in the proof of theorems in which continuity is a premise or a result, an illustration may help but it cannot serve as a materialized model of proof. A model should reflect not a particular case of the proof of continuity but general characteristics of any proof. In the framework of the model needed for instruction, "proof" and "proof of continuity" are related as general and particular. As the conducted experiments showed databases or bases of knowledge can serve as materialized models in teaching proofs.

Databases in the Study of Advanced Calculus

A natural information model of any subject field including mathematical theories is a database or a base of knowledge. We consider databases a named complex of data reflecting a stage of an object or a number of objects, their properties and relationships. In fact a database can be viewed as an information model of a given object, and effectiveness of the control system of the object depends on its preciseness and authenticity.

Using databases or bases of knowledge in the process of instruction is not something new. Already ten years ago reference and information systems built within the framework of prevalent databases constituted about one third of all the databases used in teaching math. However, we offer much more than just using databases for reference and information purposes although we do not exclude it either. Let us consider the possibilities of using databases at every of the five recommended by SSDMA theory stages of developing mental actions based on the organized process of instruction of Advanced Calculus.

According to the SSDMA theory at the first stage of instruction a student gets necessary information about a goal of action and its objects. The instructor in familiar from previous courses terms explains a system of reference points (prompts that help the student to master the studied material.) He/she also discusses the content of the studied material. It should be mentioned that even at this early stage of instruction, certain difficulties arise first of all because it is hard to explain to a student what the goal and object of instruction are. The thing is that students have been studying Calculus for three semesters but they still have a very vague idea of theoretical math fundamentals thus making it very difficult for them to understand what kind of proof they are going to deal with in this course. For the majority of students at this level, math is associated first of all with such words as find, calculate, etc. Problems of existence and therefore of proof are still completely alien for them. It becomes even more confusing since in most traditional advanced calculus textbooks the problems (especially in the beginning) are worded in the same way as they are formulated in their Calculus textbooks.

Questionnaires to monitor the students response that we have been distributing and analyzing during the last ten years of teaching Advanced Calculus invariably indicate that even after two or three weeks of instruction students were confused about what is required from them to succeed. At the same time most Advanced Calculus students already took courses incorporating databases. Thus terms associated with them such as table, record, form, report, query, relationship, etc., are familiar to them and do not provoke psychological rejection.

Using this previous experience with databases as an advantage we determine the goals of instruction as structuring the material contained in the textbook and explained in class. By structuring we mean constructing databases using the studied material of the course. Naturally the structure of any database significantly depends on what kind of information this database is used for. Therefore as points of reference for constructing databases we offer students typical questions that will be part of the test. Naturally, the most important points of reference are the examples of proofs discussed in class. By no means we imply by this that this is enough to teach students the action of proof. At the same time we include into the system of prompts questions like: "how to build a database so that using it one could reproduce the proof presented in class?" We also linked questions that students had to answer using their own constructed databases to the points of references. It was mentioned that the tests would include the following questions.

1. Formulate the theorem. 2. What is the theorem's premise? 3. What is its conclusion? 4. What notions are used in the theorem's formulation and what is their meaning? 5. What theorems were used in the proof of the given theorem? 6. Give examples of problems, which are based on solving this theorem. 7. What
the records (or their parts) that have the same conclusion; like "sequences converge". It is also useful to create queries to make decisions what queries to create independently. It looks expedient to create queries that provide access to all theorems, fields: "Name of the theorem" (for example "Intermediate value theorem"); "Object of the theorem" (for example "A function f"); "Premise 1" (for example "Domain is an interval <a, b>"); "Premise 2" (for example "Continuous on the interval"); "Premise 3" (for example "Domain is a closed set"); "Premise 4" (for example "f(a)<C<f(b)"); "Premise N"; Conclusion 1" (for example "There is a point "c" between "a" and "b" such that f(c)=C");...; Conclusion N"; "Concept N used in the theorem statement" (for example "Continuity on a set");...;"Concept N used in the theorem statement"; "Model Problem 1";...;"Model Problem N".

The next set of requirements deals with the possibility of using databases during tests. First, students should act quite fast since the number of problems presupposed certain operational speed. Second, to speed up the process, the students could print out certain forms from databases but only those that closely followed the question in the premise of the problem and contained no additional information. That demonstrates how at the second stage of developing the action of proof we used the materialized form to enhance the instruction process. Students worked with texts and databases. The texts were given but they constructed the databases independently. We also focused on all the characteristics of developing the action of proof in the materialized form to ensure its success - generalization, completeness, and assimilation.

Theorems need to be used to do this problem? 8. Is the conclusion true in absence of any of the premises? 9. Are all the premises necessary for the conclusion to be true? 10. If you answered, "yes" in 9, demonstrate it. 11. Give an example of an object that can be attributed to this concept. 12. Give an example of an object that cannot be attributed to this concept. 13. Prove this theorem. 14. Solve a proof problem.

It should be noted that at this stage of instruction students are not yet involved in performing the action or they perform it in a perceptive form, i.e. students just observe how it is performed. Besides, in the process of demonstration/observation points of reference (prompts) are determined that help to develop the action at the next stages. At this stage the instructor can also use his/her own prepared database as an information system to get illustrations of examples, links with respective sites in the Internet, etc. Certain fields in such a database can be "objects" representing different program packages. At the second stage proofs are developed in the materialized form. In the course of experiment the entire group (about 30 students) was divided into subgroups of three. Students took decisions concerning the structure and elements of databases independently. It was assumed that any member of the group could use this database during the test.

At the same time there were certain limitations to the base itself and ways of its use. First, none of the fields could contain more than 50 symbols; second, none of the fields should contain a statement that could be divided into two conjunctive statements. For example, none of the fields could contain the statement "continuous on the closed interval function". Such field should be broken up into three: a) function domain is interval; b) function is continuous; c) interval is closed. This way the students could not record the whole theorem in one field. This requirement also makes students seriously contemplate the possibilities of structuring any material.

The next set of requirements deals with the possibility of using databases during tests. First, students should act quite fast since the number of problems presupposed certain operational speed. Second, to speed up the process, the students could print out certain forms from databases but only those that closely followed the question in the premise of the problem and contained no additional information. That demonstrates how at the second stage of developing the action of proof we used the materialized form to enhance the instruction process. Students worked with texts and databases. The texts were given but they constructed the databases independently. We also focused on all the characteristics of developing the action of proof in the materialized form to ensure its success - generalization, completeness, and assimilation.

A high enough degree of generalization was achieved by involving students in the action of determining for themselves fields of records in a universal way so that they accommodate analysis of all other theorems as well. If the fields of record determined for one group didn't accommodate a new theorem then the whole group had to be reviewed. A high degree of completeness was provided by the process when all the activities were broken up into two classes - determining the structure of databases and creation of new records, queries, filters and relationships. The first part implied breaking up an action into all the included operations and the second enabled its performance in the automatic regime. And finally, a high degree of assimilation was provided by the necessity to structure quite a lot of instructional information. Besides, one of the factors of successful use of databases was the speed of acquiring and utilizing necessary information.

As we already noted, the students themselves determined the structure of databases, fields, records, etc. However, at the beginning of this experiment we had a certain database structure in mind. First of all since we deal with development of the action of proof, it seems expedient to have a table of theorems, with the following fields: "Name of the theorem" (for example "Intermediate value theorem"); "Object of the theorem" (for example "A function f"); "Premise 1" (for example "Domain is an interval <a, b>"); "Premise 2" (for example "Continuous on the interval"); "Premise 3" (for example "Domain is a closed set"); "Premise 4" (for example "f(a)<C<f(b)"); "Premise N"; Conclusion 1" (for example "There is a point "c" between "a" and "b" such that f(c)=C");...; Conclusion N"; "Concept 1 used in the theorem statement" (for example "Continuity on a set");...;"Concept N used in the theorem statement"; "Model Problem 1";...;"Model Problem N".

It also seems useful to have a table "Theorem Proofs" including the following fields: "Name of the Theorem"; "Object of the Theorem"; "Definition of Concept 1 used in the proof"; "Definition of Concept N used in the proof"; "Theorem 1 used in the proof";...; "Theorem N used in the proof"; Transformation 1 of the proof";...; "Transformation N of the proof"; "Proof structure".

We also believe it would be helpful to create such tables as "Concepts and their definitions", "Model Problems", etc. Creating queries plays an important role in the instruction process. As with tables the students make decisions what queries to create independently. It looks expedient to create queries that provide access to all the records (or their parts) that have the same conclusion; like "sequences converge" It is also useful to create queries...
enabling to find a model problem solution proceeding from the problem being solved.

The third and fourth stages of action devolvement are designed to develop an action in external and internal speech forms. As we already noted, results of students activity at this stage should be either articulated out loud or written down. If at the previous stages in organizing the instruction process we focused on determining the structure of databases and building them then at this stage it already played a secondary role. At the same time, naturally, in the course of study new records were created and added. As a task, the students were required more and more often to write a standard proof using information from the student databases. If in the first test questions 1-12 were prevalent, then in the second test we included questions immediately related to proofs (13-14) and the third test consisted mostly of proofs with access to databases.

At the last stage the action should be developed in the mental form. At this stage students continued to replenish their databases, however, their use as an information system was limited to an emergency. Using databases during the test was penalized, though insignificantly.

Conclusions

Recommendations proceeding from the theory of constructivism and SSDMA theory in studying abstract math disciplines can be formalized using databases. The database approach is hard to overestimate in forming actions in the materialized form. At the same time using databases proved extremely effective at all the five stages prescribed by the SSDMA theory.

Abstract. The fifth grade mathematics curriculum at the University School of Indiana University of PA contained a long-term project on the real-world concept of budgeting. Students were to develop a budget to spend $1 million on a specific interest. Learning to track project expenditures in a spreadsheet was a natural next step. Using PowerPoint to communicate the results added another technological dimension and integrated language arts. Along the way, students learned financial concepts and reviewed mathematical concepts in a real-world context and in a way that supports NCTM standards. As they gained confidence with Excel, students shared their own discoveries. The instructors gained valuable reflections about what works in infusing technology into the curriculum, and the project proved the efficacy of Donald Schoen’s model of the reflective practitioner.

Introduction

The fifth grade mathematics curriculum at the University School of Indiana University of PA contained a long-term project to enable students to experience the real world concept of budgeting. Students developed a budget to spend $1 million on a specific project or interest. Learning to track project expenditures on a spreadsheet was a natural next step. The use of PowerPoint to communicate the results to classmates added yet another technological and curricular dimension. The University School is the campus laboratory school, where curricular ideas like these can be developed, field tested and disseminated. This project came about in Spring 2000 when two faculty members became involved in a professional development model created in a PT3 Grant. The objectives of the million-dollar Excel project addressed both content and technology. Students were to see how mathematics is used in their daily lives and learn the fundamentals of budgeting. They were also to learn the basics of the MS Excel program and refine their skill in using PowerPoint as a communications tool. Finally, the project addressed Pennsylvania Standard 3.7.7, Grade 7 D—apply computer software to solve specific problems: i) identify software designed to meet specific needs; ii) Identify basic multimedia applications; iii) Demonstrate basic knowledge of desktop publishing applications.

Methodology and Results

After looking at examples, the class was able to develop an operational definition of a spreadsheet: a table created with computer software; contains information, especially numbers; does calculations for you; often used for spending plans; can answer “what if” questions — e.g., what could I buy if my allowance went up, if the cost of a computer game went down, or if taxes went up. Among the examples were small budgets such as an allowance, as well as a more elaborate million-dollar budget. They also saw three ‘what-if’ scenarios, demonstrating the impact of price changes on one’s allowance.

Students then got to work on a “Puppy Budget,” where their task was to plan what they would need to acquire and keep a pet for a year, using MS Excel. The simple initial budget contained only a purchase column, a cost column and a total. With little urging, students soon forged ahead in adding formatting. Their first function was AutoSum, which they pronounced “awesome.” Next we added columns for unit price, total cost...
per item, "must have" items, and a "what's left" column or balance. It was now time to learn formulas for multiplication, subtraction and adding. Requiring more work, formulas were not quite as awesome as AutoSum, but the ability to copy rather than type them saved the day.

Our class was now ready to apply their Excel skills to the Million-Dollar Budget. They brainstormed with partners what to buy, entered a list of planned purchases into Excel, looked for prices on the Internet and entered them into their spreadsheets, and calculated costs and a running balance in the spreadsheet. A large spreadsheet requires more formatting to be understandable, and students returned enthusiastically to beautifying theirs. They began to discern the difference between "cool" and "understandable" or "legible," however.

At the next class, students reviewed percentages. Students added columns to show the effect of price hikes and to calculate sales tax. Now that the data were in, we could turn our attention to charts to provide a graphic illustration of where their money was going and the percentage spent on various categories. With many ways to customize, charts proved to be another fertile ground for student creativity. But they learned again that what looked glorious on screen was not always readable in print or when displayed on a projector.

Finally, the students reviewed PowerPoint and created a short presentation summarizing what they would buy and why, incorporating copies of their spreadsheets and charts as well as illustrations from clipart and the Internet. They then delivered these presentations to their peers.

Along the way, students learned financial concepts such as budget and unit price. They reviewed percentages, means, and other mathematical concepts in a way that supports NCTM standards and applied them in the real-world context of budgeting. As they gained confidence, students made their own discoveries and even began to demonstrate them to the whole class. Some things they learned the hard way. The students found it tedious to rearrange their spreadsheets in broad categories and calculate subtotals. When they inserted detailed spreadsheets and charts into PowerPoint, however, they realized their beautiful creations were too large to display effectively on screen. Now they understood that broad categories and subtotals would have been useful. Students often get caught up in the bells and whistles of computer programs. This experience was a first step in learning to use computers effectively—i.e., as a tool that aids understanding and communication.

Dr. Brzycki and Dr. Hechtman also shared some interesting reflections while they planned. Students need a project they can relate to in order to buy into using the Excel program as a learning tool. Models are helpful. Student partnering is not a good method in a project that requires skills acquisition. It is easier to have students hone estimation skills than to determine costs to the penny. This, too, is a real-world lesson in that it encapsulates the difference between accounting and budgeting. It was clear that there were many possibilities for extending the project, and some are already under way—recording and analyzing weather data, Olympic medals, election polls, and states data; and importing data from the web. Spreadsheets are a versatile tool that can serve as a mindtool in many disciplines (Jonassen 2000).

The model of technology diffusion and training used here was a success. A technology expert and a content expert collaborate to design the units. The technology expert leads the first round of classes while the teacher assists; then the teacher leads the class while the technology expert assists; and lastly the teacher can solo. Here Dr. Hechtman gained experience and became enthusiastic about teaching the unit herself. This model was based on the work of Donald Schoen (1988) and is also being used in the university setting in the teacher preparation curriculum at IUP and Clarion University of PA. A PT3 grant (Preparing Tomorrow’s Teachers to use Technology) funds an instructor and/or graduate assistant as technology expert. The model permits both teacher and students to gain or consolidate skills without creating dependence on the expert and encourages colleagues to engage in collaboration and mentoring.

Abstract: It is a challenge for teachers at all levels to bring mathematical concepts alive for their students, and to engender excitement about the technology tools used to facilitate data representation and communication. We introduce a teacher training process in which participants actively engage in investigations that integrate information technologies into the teaching and learning of mathematics. These investigations can be used in both teacher training and in the classroom. Our approach has several advantages: Mathematical concepts are introduced through relevant technology-enhanced problem investigations, engaging participants in defining and solving problems. Group interactions promote creativity and variety in ideas and approaches. Participants learn to present ideas in computer-based, multi-media formats. In addition, the training process is a model for the active, small-group learning process that students will experience, and is thus an experience in modeling for teachers. The process also prepares participants to formulate similar instructional techniques of their own.

Introduction

Today's students are facing a world that is becoming increasingly information-driven in both work and the home, creating a more urgent need for all students to develop a clear understanding of mathematical principles and the ability to use technology in communication and problem-solving. In the workplace, students will also be expected to work in teams to solve problems (Felder & Brent 1996), which may not already have known solutions, a very different situation than the traditional math-class problem. And yet, researchers increasingly agree that this type of engaged, active learning, which occurs when students actively participate to learn concepts in a meaningful context, is important in building student comprehension, retention, and internalization (Jones, et al. 1994; Felder & Brent 1996). Girls on Track aims to design and disseminate technology-enhanced, student-centered investigations of urban and social problems to join the strengths of engaged, meaningful learning, with the tools of technology, to help students develop strong, creative skills in problem-solving, mathematics, and data gathering, representation, interpretation, and presentation.

Girls on Track is a multi-institutional program that was developed to encourage middle school girls to continue taking advanced math and computer science classes through high school by introducing girls, educators, and counselors to new ways of approaching mathematics and technology. This program could not be implemented without the foresight of the principal investigators and the help of a dedicated staff, whom you will find listed in our program report (Berenson, et al. 2000). In this paper, we describe the teacher training and investigation aspects of the Girls on Track program, which we believe will be beneficial to educators in all math and science related areas. Our findings are preliminary, but we believe that our methods are supported by educational research theory. In the first section, we describe the summer program in brief. We then discuss the details of our investigation method, how it is introduced to teachers, and how teachers may use the method in their own investigations. In the final section, we reiterate our findings and discuss future plans for the program.

The Program
During the summers of 1999 and 2000, Girls on Track, our 3 weeks of professional development workshops and summer camp introduced two groups of middle school teachers, guidance counselors, pre-service teachers, graduate students, and middle school girls to mathematics and computing in an integrated, small-group learning process centered on primarily math and computer-based investigations of local and national urban and social issues. We designed several investigations for Algebra I that integrate group learning techniques, and information search, gathering, and presentation, all facilitated by the use of our website. We began each investigation with a group brainstorming exercise on a central question like, "What will life be like in our county in the year 2020?" Each team generated their own predictions, and moved to the computer labs where our website reiterated the brainstorm question, provided links to web sites containing relevant data and provided a direct link to a blank PowerPoint template, which each group down-loaded and modified to create their own presentation. Every presentation was loaded onto our website, which was then accessed to downloaded the slides for presentations to the whole group.

The summer program began with a full week of professional development for middle school math teachers, guidance counselors, pre-service teachers, and graduate students, all of whom we will refer to as camp counselors or simply counselors. Camp counselors were broken into groups of 3-5 professionals, and were presented with our math investigations in the same manner that girls would experience the investigations in the following two weeks. Each group created their own interpretations of each problem we investigated, including topics such as population growth, solid waste disposal and reduction, traffic congestion, and the relationship of math skills to job salaries. Counselors experienced first-hand the excitement and difficulties which the students would later face. Rising to the challenge, each group formulated a problem statement, collected and interpreted data, and presented their findings.

In the course of learning this new investigation technique, counselors also were introduced to new technologies, including Internet browsers (Netscape) and searching (via www.google.com), Excel spreadsheets and graphs, PowerPoint presentation software, and FTP. Each of these technologies was introduced on an as-needed basis during the investigation process, with scaffolding to facilitate their use (see Soloway, et al. 1996). Computers were initially set up with browsers ready and on the appropriate page on our program website, ontrack.ncsu.edu. This page reiterated the investigation questions, gave links to relevant data on the Internet, and also linked to Excel and PowerPoint templates and help sheets. Each progressive investigation web page linked to fewer templates and offered less guidance in technology use, to promote participants to develop their skills in using these tools. This scaffolding prevents the need for educators to become experts in all the technology they use, instead providing the tools to get started, like "handles" for both professionals and students, leaving the door open for more exploration when creativity drives participants to look for new ways to use the tools.

After the first week of professional development, the summer camp began, with sessions in the morning where professionals would act as counselors for middle school girls, joining them in their own investigations of the same problems. As group facilitators for the students, professionals had the chance to apply what they’d just learned about this new pedagogy. This is a crucial aspect of Girls on Track – without this immediate application of new concepts, many professionals would feel under-qualified to bring these same techniques to the classroom. Fear of technology, and the fear of not being an expert in every problem the students face are very strong deterrents to trying new classroom methods. As leaders in the math camp, professionals became aware that this method encouraged both students and leaders to become adventurous explorers in problem solving, working together. This is a sharp contrast with the traditional, unrealistic model of the all-knowing teacher, which makes both students and teachers uncomfortable. Instead, leaders become participants and guides in investigations, and students become peers in problem solving.

Investigations

Experts agree that using multiple representations and problem solving approaches increases mathematical problem solving ability (Jiang & McClintock, 2000; NCTM, 2000). We believe that the creation of such multiple representations and approaches can be greatly enhanced by the use of technology. During the summer professional development program, investigations are conducted in an atmosphere of collaborative learning where multiple pathways to solutions via technology are encouraged. The methodology of the investigations involves four main phases: an exploration phase, where small groups of problem solvers define their specific investigation question and make their data collection plans; a data collection phase, where the problem solvers collect data via the worldwide web or other methods; an analysis phase, where the problem
solvers use Excel to represent and analyze their data; and an interpretive phase, where the problem solvers design and share a presentation using PowerPoint and other dynamic presentation techniques, some of which have included skits, video segments, and audience quizzes. In line with other technology teacher preparation programs, the use of technology for the mathematical investigations was not for the purpose of teaching technology, “but for the purpose of enhancing mathematics teaching and learning with technology” (Garafalo, Drier, Harper, Timmerman & Shockey, 2000, p. 68).

By design, the Girls on Track investigations follow the same format, and also connect via a common thread. Participants first brainstorm about what problems our local community will face 20 years in the future. Groups quickly realize that population growth is a central determinant of social problems of the future, from overpopulation, to traffic congestion, to waste generation and disposal. These are the very topics of three of our investigations. As an example, our population investigation is illustrated in the following section.

### Population Investigation

The investigation is introduced by initiating a discussion about community problems of the future. After problem solvers have shared their ideas with the whole group and realized that understanding population growth is a major factor in solving other community problems, they are ready to work in their small groups to determine how they want to tackle the population growth problem. They must decide how they will collect and organize their data and are provided with several web sites that contain information about population to aid in their data collection. Once they have data in hand, problem solvers used Excel to represent the data in a table and as a graph. We asked that each group come up with some type of mathematical model for their data that they could use to project future populations. Requiring the creation of a model forced problem solvers to think about issues concerning rate of change and inexactness of solutions to real world problems.

### Teacher Preparation

Preparing teachers to use technology to enhance mathematical teaching and learning has been considered a major challenge for teacher educators (Mergendoller, 1994). One of the goals of the professional development program is to encourage this use of technology in the classroom and make the implementation as simple as possible. The approach taken during Girls on Track is to offer teachers one week of professional development before the students arrive and then ongoing professional development during the afternoons of the two-week camp for students. Teachers experience the investigations during the first week of professional development exactly how the students are intended to experience the investigations during the summer camp. They come out of the first week of professional development ready to challenge the students and prepared for technical and mathematical issues that may arise. Some may feel a little uncomfortable due to the alternative approach to professional development that we take, but by the end of the first week of professional development, most are very pleased with the results, as indicated by one teacher’s statement:

> I really appreciate the opportunity I have been given to stretch myself professionally. Although my anxiety level has see-sawed since Monday morning, I still feel much better about next week than I thought I would by this time.

This confidence comes for the teachers not only through their experiences working through the investigations, but also by knowing that there is a support system available to them at all times during the camp. In essence, teachers get an opportunity to merge theory with practice, actively building new knowledge as they try out new ways of teaching and motivating students to learn mathematics within a “safe” environment.

Teacher preparation is also greatly enhanced through their collaboration with other educators. Educators experience first hand the joys and challenges of group work, and are better prepared to guide students as they face their own challenges in working together. In addition, as they work together to solve investigation and group interaction problems, the varied skills of each professional provide new insights for all into classroom strategies. Teachers can share different approaches they have used before; what works and what doesn’t, and also have the opportunity to share their greatest teaching triumphs with their peers. This interaction truly enriches the professional development experience, creating collaboration among professionals that can enhance their career development for many years to come.
I have really enjoyed getting to know the people on my team and have appreciated their areas of expertise as well as their empathy for my anxiety at times. For the most part, we were very open about our levels of anxiety, learned to depend on each other, and take risks at learning something new.

After experiencing the investigations themselves, teachers are well prepared to create new investigations. The process that we have used to create investigations is quite simple. First, determine a social problem or issue that will be of interest to the problem solvers. (We've used population growth, trash accumulation, traffic congestion, and job salaries, thus far.) The next step is finding resources on the World Wide Web that can provide you with appropriate data, but keep in mind that it is perfectly reasonable to supplement these resources with other data collection techniques. (Our problem solvers were out counting cars near a busy highway for the traffic investigation.) Once data is obtained, the investigation designer should experiment with multiple representations and solutions that are appropriate for the target audience. This experimentation prepares the instructor for possible problems that may arise during the investigation process, ensures that it can lead to appropriate mathematical thinking, and aids in the development of useful scaffolding techniques that may be required in assisting problem solvers throughout the investigation process. One teacher’s summer camp 2000 reflections includes the following plans for her own investigation:

I really like being able to use PowerPoint to have students present any of the skills we are learning in class. … I also have an activity that requires the kids to take a conventional cereal box and redesign it as a cubical cereal box with the same volume. (It shows that volume can remain constant and the surface area changes) Next year I hope to take them to the lab and input the original dimensions of their cereal box into a spreadsheet, put in the formulas to compute surface area, volume, the edge of a cube with the same volume, [and] the surface area of the cube. I would then have different pairs of kids graph different variables to see if there was any relationship. They would then go to a word processing page, explain the relationships they noticed, and paste the graph into that page.

Conclusions

We believe that Girls on Track has developed a strong, multi-faceted approach to training teachers in technology-enhanced student-centered instructional techniques. Our investigation design garners the benefits of meaningful, engaged collaborative learning, enhancing teacher and student motivation and excitement. Our design also incorporates the use of technology in appropriate ways that encourage creativity and individual exploration. Our training method uses the same instructional techniques we are promoting to engage educators in learning a new pedagogy for their classrooms. As professionals, educators build skills in collaborating with their peers, facilitating student investigations, and designing their own investigations. Our program fosters both independence and interdependence in professionals, offering tools to create new classroom activities, and bringing a network of professionals together to share their knowledge. In addition, Girls on Track enhanced teacher confidence in using technology and in exploring new ideas.

Computers and the Internet are vitally important aspects of this program. Daily schedules online kept everyone up-to-date with last-minute changes, and linked to each activity during the day. Handouts for information technology help were online and available at all times. Investigation guidance, data links, and starting templates smoothed the data gathering and representation. Training in information technologies centered around student tasks, and the creation and expression of ideas, instead of on the applications themselves. Girls and educators were given the opportunity for individual expression and exploration in an open, accepting atmosphere, where ideas were created and shared at impressive rates, and with outstanding results.

This program is evidence that the worldwide web can become a vital part of any education process, enabling creativity and facilitating information gathering and sharing. Both girls and camp counselors created web pages of their own, linking to their own presentations, which could all be accessed through a central location for easy sharing. Our investigations remain on our website (ontrack.ncsu.edu), providing resources for teachers everywhere, and serving as a template for the development of other investigations which integrate curriculum material and the use of information technologies.

In a short time, both teachers and girls became adept in communication through the website. Computers complemented the learning process, giving teachers and girls the confidence they need to continue using computer technologies in the future.
We believe we have successfully met our end goals: to boost confidence and motivation of girls, counselors, and teachers in math, teamwork, sharing ideas, and in using technology to achieve these goals. In program evaluations, both teachers and girls expressed increased confidence in using technology. Educators expressed excitement in the program and in using similar investigations in their classrooms.

Girls on Track has built similar enthusiasm in all its participants, encouraging some to try new software, and new classroom presentation styles and methods. Our investigations have given participants firsthand experience in using any available tools to creatively solve problems and communicate their results. When computers and the Internet are not available, any tools on hand can be used, substituting data collection for web searching, and creating poster or slide presentations instead of using PowerPoint. The result is still the same: investigating relevant issues, using problem solving and analysis techniques, and communicating findings builds confidence and motivation in students and educators alike. In the words of one Girls on Track 2000 preservice teacher:

When my friends and family asked me, “What is Girls on Track?” I told them that it is a math and technology camp for middle school girls. After the one week of staff development, my description has changed. I would still say that GoT is a math and technology program for middle school girls, but also a confidence-builder for young women, a community awareness builder, an environmental awareness builder, a computer technology and math camp for counselors, and a wonderful social experience for all. My computer competencies have grown this week as well as my friendships among fellow educators. I only hope that the girls get as much out of this experience as I have.

Abstract

Convenience is the most important benefit perceived by online students of the asynchronous online delivery format. Students appreciate the flexibility of course access at any time and in the comfort of their homes or at the office. That online courses are well received by Golden Gate University students is not surprising, as our student body is predominately composed of part time students who work full time.

Three years ago the math faculty was asked to put a number of courses online. Anticipating difficulties, the math faculty worked extremely hard to design courses that somehow transcend these problems. In the initial stages of development we feared that the online popularity would not extend to graphics-based courses such as those typically taught in the Math department. How would the student draw a graph or write a formula over the Internet without first learning sophisticated software packages? How would they communicate with faculty and classmates other without this capability?

In this paper we will present enrollment trends of online math classes verses traditionally delivered classes in relationship to enrollment trends university-wide. In addition, we will present an overview of the characteristics of our online courses and present findings from recent research on online instruction.

Online course delivery has been warmly embraced by many of today's students. This phenomenon, as indicated by numerous recent studies, is not unique to Golden Gate University, but evident at a number of other universities.

Convenience is the most important benefit perceived by online students of the asynchronous online delivery format. Students appreciate the flexibility of course access at any time and in the comfort of their homes or at the office. That online courses are well received by Golden Gate University students is not surprising, as our student body is predominately composed of part time students who work full time.

Three years ago the math faculty was asked to put a number of courses online. Anticipating difficulties, the math faculty worked extremely hard to design courses that somehow transcend these problems. In the initial stages of development we feared that the online popularity would not extend to graphics-based courses such as those typically taught in the Math department. How would the student draw a graph or write a formula over the Internet without first learning sophisticated software packages? How would they communicate with faculty and classmates other without this capability?
In this paper we will present enrollment trends of online math classes verses traditionally delivered classes in relationship to enrollment trends university-wide. In addition, we will present an overview of the characteristics of our online courses and present findings from recent research on online instruction.

Aside from the convenience factor, a number of other facets have contributed to the online success of our math courses.

- Serious attention and effort was paid to the design and utilization of effective online pedagogy. Our content delivery, which can be considered "online lectures", consists of multi-faceted activities. For example, in our Introductory Statistics course, we include PowerPoint slides, worked out examples, Excel projects, "micro lectures" disguised as learning objectives, online quizzes, extra credit essay assignments, etc. We partition the content of courses into weekly modules that contains the same structure week after week so that students know exactly what to expect. We encourage discussions by suggesting interesting topics and provide frequent and positive feedback, where possible.

- The online format is basically a learner-centered format as the student sits alone in front of the computer. The instructor must communicate with the student in both static and dynamic ways. All the above mentioned conference postings, except the quizzes can be considered as static communication from the instructor to the student. Our primary dynamic communication is via asynchronous conferencing and email. As many researcher have found, the student is less intimidated and more willing to "talk" online than in the FTF classroom.

- As many of our students have jobs that require computer and Internet skills, their conferencing and working with each other online is perceived as developing good online working skills.

- The emphasizes our statistic course places on the use of Excel is seen as an advantage by the students as most of them perceive that being facile in Excel is an added advantage at work.

Our online students may feel some awkwardness about the inability to readily use symbols or draw graphs over the Internet. They have found ways to get around this and were able to achieve a deeper understanding of the concepts by trying to express themselves verbally.

Analysis of enrollment trends in multi-section key courses throughout the university reveals that students are replacing the face to face (FTF) traditional course with online instruction. Furthermore, this trend is the most clear and evident for math course. In fact, while total enrollments have decrease throughout the university, the math enrollments have stayed about the same. The decrease in FTF enrollment of math courses has been offset by online course enrollment increase.
Teaching Mathematics by Means of MathTrainer

Abstract: This paper describes MathTrainer, a system that guides the student while learning mathematical concepts that involve symbolic manipulation, like the resolution of Ordinary Differential Equations. MathTrainer shows students the steps that are required to solve exercises with symbolic calculations. The exercises are posed by the system. The student can also modify some of the formulae that appear in a statement and ask MathTrainer how to solve it. MathTrainer identifies the type of exercise by means of a pattern matching mechanism and then it shows successively the tasks that have to be accomplished in order to solve the exercise. MathTrainer has been integrated in the MathEdu teaching environment which includes an authoring tool for the design and interactive resolution of exercises of mathematics. Thanks to this integration, MathEdu allows the student to learn first how to solve problems of different types; after this, s/he can practice and get feedback about his/her actions.

Introduction

During the last years new tools have been developed that simplify the design of generic user interfaces using Programming by example techniques (Myers, 2000; Cypher, 1993). In principle, these techniques can be used in an authoring tool in order to make the work of the teacher who designs the contents of a course more intuitive and simpler to accomplish. This kind of environment facilitates the discovery by the teacher of the difficulties the student can have when working by himself, as well as the enhancements that can be incorporated to the course under development. Moreover, the mechanism of generalization allows the teacher to work just on a specific example or problem and later on to extend his work to a whole set of situations that include the original one as a special case. The development of a module with this feature for an authoring tool is very complex, but it is a task that has to be accomplished just once. Once this work is done, it is reused constantly by the different course designers in each course they develop. Moreover, in this way the course designers do not need a deep knowledge of the language or technology that is used behind the scenery, so most teachers can use the tool without any special training.

In this paper we describe how we have enhanced a tool based on Programming by example for the interactive resolution of problems of Mathematics, MathEdu (Diez 1999). A new module, MathTrainer, that guides students through the steps that are required to solve exercises that can be specified dynamically, has been added to it. The exercises solved by MathTrainer are posed by the system. The student can also modify some of the formulae that appear in a statement and ask MathTrainer how to solve it. MathTrainer identifies the type of exercise by means of a pattern matching mechanism and then it shows successively the tasks that have to be accomplished in order to solve the exercise. Thanks to the integration of MathTrainer, MathEdu allows the student to learn first how to solve problems of different types; after this, s/he can practice and get feedback about his/her actions. In case the student repeatedly makes some mistake while s/he is practicing, MathTrainer takes control of the session and shows him/her how to finish the resolution of the problem s/he is trying to solve. MathCAL (Mei-Chuen, 1999) does something similar for problems that involve trigonometric calculations. The enhanced MathEdu system can be used to develop complete interactive courses about mathematical subjects that
involve symbolic manipulation, like the resolution of Ordinary Differential Equations. Both MathEdu and MathTrainer are developed over Mathematica® (Wolfram 1999).

**Brief description of MathTrainer**

From the point of view of the student, MathTrainer is just a program that allows him/her to visualize sequentially a presentation of an example. At the beginning of an explanation the student can choose the type of problem to be explained, and he can also modify the formulae that appear in its statement. For example, when seeing how to solve a linear differential equation, and after having seen a simple example like the resolution of the equation \( y' + y = 1 \), the system will explain that any function of \( x \) and \( y \) that is linear in \( y \) can appear instead of \( y \), and any function of \( x \) can also appear instead of \( 1 \). The student can then ask the system to show him how the solutions of equations like \( y' + y/x = x^2 \) can be computed, and MathTrainer will then give him/her a step by step explanation of the resolution of this problem. In case the example proposed by the student is not appropriate, the system will tell him/her that, and it will also let him/her know whether his/her example can be already solved using some other method s/he has already studied with MathEdu or even if s/he is expected to study problems like the one s/he has posed later on during the course.

Another way in which MathTrainer is integrated with the previous MathEdu module for interactive problem resolution by the student is by giving him/her explanations about how to go on in case of a repeated mistake while solving a problem, or in case he/she just asks for this help. In the original version of MathEdu, this kind of help could be provided only in case the designer of the course had foreseen its necessity, and in this case, the designer had to specify the whole explanation by hand. This limitation of MathEdu was especially important, since the same situation appeared at every step of the student’s work, so the amount of work involved if the designer wanted to give support for the student getting additional explanations at any moment of his work was tremendous.

**About the design process**

The design process can be seen as the designer doing *by hand* the actions that both the system and the student are supposed to do at resolution time, and the design engine recording these actions. When MathTrainer is showing the student how to solve a problem, either generated by MathTrainer itself or posed by the student, it just reproduces the actions specified by the designer and makes by itself the computations that are involved. On the other hand, when the student is solving a problem, MathEdu just executes the actions specified by the designer that correspond to the system, and it checks that the expressions introduced by the student through the dialogs are all right according to the corresponding formulae.

MathEdu also uses the power of symbolic computation of Mathematica to allow the designer to define strategies and cases for each type of problem depending on the specific data associated to the problem. Different strategies for the same type of problem differ by the actions that have to be accomplished in each case, while different cases for the same strategy differ by the pattern that characterizes the values of the initial metavariables that are present in the statement. For example, linear ordinary differential equations correspond to the pattern

\[
\text{a}_\text{var}' + \text{f}_{\text{function}}[\text{b}_\text{var}] \text{a}_\text{var} = \text{g}_{\text{function}}[\text{b}_\text{var}],
\]

that is specified by the designer.

Both when showing the student how to solve a problem and when checking how s/he solves it, the first thing MathEdu does once the precise statement has been specified is to determine the possible strategies and cases that correspond to the problem among those specified by the designer. This is done by means of a pattern matching process between the formulae that appear in the statement and the patterns that correspond to each strategy. For example, if the problem consists of solving the differential equation

\[
y' + y/x = x^2,
\]

then the metavariables \( a \) and \( b \) are associated to the variables \( y \) and \( x \) respectively, and the functions \( f \) and \( g \) are associated to \( 1/x \) and \( x^2 \) respectively, hence the strategy for resolution of linear differential equations is accepted, which has only one case.
Conclusions

In this paper we have shown the main features of a highly interactive system to train students in solving problems of Mathematics. The specification of the way the system has to show the student how to solve each type of problem and how it has to check the resolution of each problem by the student is done through the use of a variant of the Programming by Example paradigm.

MathTrainer incorporates new functionality that was not available in previous tools. This functionality simplifies the definition of courses on subjects that involve symbolic computation. Moreover, these courses allow the student to learn faster how to solve the different types of exercises that they include. The main goal is to make the student feel the system as a collaborator in his learning process.

At this point there is a first prototype of MathTrainer. The first version of the enhanced MathEdu environment will be ready in some months, and the validation of the system will be done through the development of a course on Ordinary Differential Equations.

Finally, among the future work we have plans to develop mechanisms that allow the system to detect automatically the existence of priorities between different parts of the course, so that in case a student wants to learn some special subject, an optimal path is created automatically that will show him all the necessary prerequisites before teaching him the desired subject.

Beliefs, Experiences, and Reflections that Affect the Development of Techno-Mathematical Knowledge

Hollylynne Stohl Drier
Department of Mathematics, Science, and Technology Education
North Carolina State University
Hollylynne_drier@ncsu.edu

Abstract: The purpose of this paper is twofold. First, the author discusses her views on teachers' development of techno-mathematical knowledge. Second, the author presents key elements from a course and key course activities and experiences that appear to impact preservice teachers' beliefs about teaching and learning with technology, including those activities that allowed preservice teachers to gain a deeper understanding of mathematics by using technology tools.

Introduction

Preservice teachers "have little experience with how technology can change the nature and emphasis of the mathematics curriculum" (Gay, 1994, p. 172). They often have varied experiences with using technology, as both personal productivity tools, and as a learning tool in their own mathematics experiences. These varied experiences affect preservice teachers' beliefs about using technology as a teaching and learning tool. The author has designed a course to provide many opportunities for preservice teachers to engage in mathematical explorations with technology and discussions of subsequent pedagogical implications. The preservice teachers reflect on their course experiences, compare these with prior learning experiences, and critically evaluate their own beliefs.

As a teacher/researcher, the author is interested in identifying key course experiences that appear to affect preservice teachers' beliefs about appropriate use of technology as a teaching and learning tool. The teacher/researcher analyzed all written work by the preservice teachers to help answer the following questions:

1. What are preservice teachers' beliefs about using technology for teaching and learning mathematics?
2. How do course experiences affect preservice teachers' beliefs?
3. What course experiences seem to be critical in the development of preservice teachers' techno-mathematical knowledge?

This paper will trace the beliefs, course experiences, and reflections of several preservice teachers throughout the author's course. The analysis will be used to inform future development of the course.

What is Techno-Mathematical Knowledge?

According to the National Council of Teachers of Mathematics, "technology is essential in teaching and learning mathematics; it influences the mathematics that is taught and enhances students' learning" (NCTM, 2000, p.11). The use of the word essential in this statement has many implications for school mathematics, as well as preservice and inservice mathematics teacher education. Not only are teachers charged with a vision of transforming their teaching and students' learning of mathematics, but teacher educators are challenged with the task of preparing teachers who can utilize technology as an essential tool in developing a deep understanding of mathematics, for themselves and for their students. I claim that such teachers must develop techno-mathematical knowledge. Such knowledge consists of several intertwined elements:

- Solving mathematics problems and constructing mathematical ideas utilizing technological tools
- Using technological tools to justify mathematical ideas and engage others in meaningful mathematics
- Designing experiences with technology that will allow others to develop techno-mathematical knowledge. This includes designing lessons with appropriate tasks and questions, as well as
interactive technology templates using tools such as dynamic geometry environments, spreadsheets, and web-based technologies (e.g., java, Shockwave).

- Critically analyzing the value and role of technology to make decisions as to the appropriate use of technological tools in teaching and learning mathematics.

### Course Development

A traditional approach to mathematics teacher education assumes that skills needed in mathematics, pedagogy, and technology are distinct entities. In many mathematics teacher education programs, preservice teachers learn their mathematics content separate from their pedagogy content and separate from basic technological skills. These preservice teachers are then expected to combine these separate skills in a classroom as a mathematics teacher. Some teacher education programs do combine content with pedagogy courses, but still have separate technology courses that are often taken jointly by preservice teachers from a variety of disciplines and grade level concentrations. The message behind this type of teacher preparation is that technology is an add-on “subject” rather than a subject-specific learning tool. Garofalo, Drier, Harper, Timmerman, and Shockey (2000) set forth guidelines advocating integrated and appropriate uses of technology in mathematics teacher preparation.

Teaching and learning mathematics effectively in a technological classroom requires multifaceted knowledge that extends beyond what is typically learned in mathematics methods courses. The work of Garofalo et al (2000) can help teacher educators weave appropriate technology experiences into mathematics methods courses. However, several mathematics teacher education programs (e.g., University of Georgia, North Carolina State University, Pennsylvania State University) have taken another approach -- making a separate course in technology and mathematics education a required part of a secondary program, in addition to existing methods courses. Such courses provide opportunities for preservice teachers to learn how to use technology to better understand mathematics themselves and promote students' learning of mathematical concepts. Thus, these courses are a blend of mathematics content, pedagogy, and technology.

"Teaching Mathematics with Technology" is purposefully designed to put an emphasis on teaching and learning a variety of school mathematics topics (e.g., Pythagorean theorem, sequence and series, correlation and linear regression, rational numbers). A primary goal in the course is for teachers to deepen their understanding of fundamental topics in secondary mathematics through using technology such as dynamic geometry tools, spreadsheets, interactive websites (e.g., www.exploremath.com), graphing calculators, and probability simulators. The teachers are engaged in solving rich mathematics tasks with technology, discussing pedagogical implications of using technology in mathematics, reading the NCTM Principles and Standards (2000) and various articles describing classroom practices, and reflecting on course experiences and reading.

### Data Collection and Analysis

The one semester course met once a week for 2 hours 45 minutes and included 6-9 hours of assignments each week. During the semester studied, there were 9 students enrolled: 3 Master's level teachers, 4 undergraduate preservice teachers, and 2 lateral entry teachers who were currently teaching without a license and taking courses towards certification. The targeted students for this paper are the 4 preservice teachers.

As teacher/researcher, I gathered data from a variety of sources for the purposes of assessment as well as research analysis. Each teacher completed a pre- and post-survey to assess their beliefs and attitudes and to document their own comfort level and past experiences with using technology tools. Throughout the course, they completed many assignments in which they used technology to investigate a variety of mathematics tasks. As part of these assignments, the teachers reflected on how the technology helped or hindered their own understanding of the mathematics, as well as how such use could help or hinder their students' understanding. The assignments were submitted and graded electronically. Thus, there is a chronological electronic trail of all written work, including word processed documents and The Geometer's Sketchpad and Microsoft Excel files.

I coded the electronic documents and files based on the preservice teachers' mathematical beliefs, technology beliefs, pedagogy beliefs, developing mathematical understanding, critical analysis of role of technology in developing understanding, and experiences that seem to affect 1-5 above. The evidence supporting each category was further analyzed chronologically to establish patterns of beliefs and how
experiences and reflections may have affected an apparent shift in belief. (I purposefully used apparent since there is no evidence of how these preservice teachers put their beliefs into action in a classroom. Such evidence may be gathered as part of a longitudinal study of teachers' development of techno-mathematical knowledge.)

**Shifts in Beliefs During Course**

Two students (Nick and Gary) had used graphing calculators extensively since high school and had many experiences using computer software in mathematics and statistics as well as for advanced personal productivity (e.g., web development, programming). The other two students (Nancy and Trina) had limited experience with graphing calculators in math courses and only used computers minimally for personal use (e.g., word processing, email, internet). Overall, the initial beliefs of the 4 preservice teachers indicated they believed technology should be used as a complement to "regular instruction" and feared students' dependency on technology to do math "for them." All of them expressed that technology should be used after paper and pencil skills were mastered. They emphasized the quick computational and graphing features (e.g., "plugging and chugging", saving time) of technology and appeared to have little or no experience with how technology could be used to develop a deeper understanding of a mathematics concept.

During the course, each of the preservice teachers experienced several "a-ha" moments while using technology to explore a mathematical idea. Nick and Gary often made advanced connections between school mathematics concepts and their college level mathematics. They also proved to be very good at posing questions or tasks to their classmates during group work to allow others to use technology tools to further their understanding. Nancy and Trina were not as comfortable with the technology and often struggled with the mathematical ideas. However, both of them were tenacious and expressed their enthusiasm and pride when they felt they understood a mathematical idea or were successful in solving an advanced task. All of them gradually showed more evidence of careful thought about how and when technology should and could be used. They still advocated the use of technology as a "time saver" to alleviate computational constraints; however, their focus shifted from skill-driven mathematics towards understanding mathematics concepts and solving real world and higher level problems than they remembered solving themselves in high school.

At the end of the course, Nick, Gary, and Nancy had made evident shifts in their beliefs about how students learn mathematics and the appropriate role of technology in that process, especially in engaging students in developing understanding and making connections with various representations. Trina still held strongly to the belief that that technology was best used after students had learned mathematics in a more traditional manner. Although she often reflected that she felt technology helped her understand mathematics better, those experiences did not appear to affect her core beliefs.

**Tracing Development: A Glimpse at Nick and Nancy**

To further illustrate shifts in beliefs, I have included a brief synopsis of Nick’s and Nancy’s work throughout the semester. Recall that Nick was an advanced user of technology before the semester began, while Nancy only had minimal experience with technology. Nick was also a high achieving student in mathematics while Nancy was an average mathematics student. Nick was a senior taking this course concurrently with a 5-week mathematics methods course (6 credits) and 10 weeks of student teaching (8 credits). Nancy was a junior and had only taken a sophomore level course that was an introduction to mathematics teaching and learning.

**The Development of Nick**

On the pre-survey, Nick expressed his belief that calculators should be disallowed below 5th grade, minimally used through Algebra I, and compliment classroom instruction in Geometry – Calculus III. In the second week of the semester, he further noted "I believe in not letting students use technology until they have first demonstrated the ability to reason critically and to think mathematically." Nick appeared to believe that technology could impede a student’s ability to think mathematically. I conjecture that this stemmed from his prior experiences with technology being used as a time-saving computational or graphing device, and little experience with teachers asking high level questions and posing challenging tasks with technology tools. However, during the 5th week of the course, Nick did some advanced work in an assignment to use dynamic
Nick further shared his thoughts in a class discussion. He emphasized that technology tools could help students. This experience was also a critical step in his development of techno-mathematical knowledge. Not only did Nick use technology to explore a concept that he had never dealt with before, but he extended his importance of using technology appropriately to help students understand concepts and “think

Nick experienced using technology to gain a deeper understanding of a mathematics concept. I believe this was a critical moment in his development of techno-mathematical knowledge.

During the 6th week (Nick’s first week of student teaching), we did an investigation of sequence and series using multiple representations. Nick was enthralled during the investigation and continually used the technology (spreadsheet and dynamic geometry) to conjecture, test, and make connections on his own. In reflection of the investigation and subsequent assignment, he wrote:

“ I liked especially the sequence generator that we used in Excel … Excel makes it much easier for students to focus entirely on pattern recognition. In this way, I feel that using the spreadsheet can definitely enhance teacher instruction and/or the learning of sequences and series. I also liked the idea of using the geometric spiral to represent the infinite series. Clearly, this representation helps students to ‘organize their thinking.’ You can use GSP [The Geometer’s Sketchpad] to draw the other three spirals [he did this on his own] … The geometric spiral will also appeal to so-called visual learners.”

In the following week, Nick reported that he had used a geometric spiral to model infinite series in a precalculus course. Although he did not have access to technology in the classroom, he had students construct a spiral on paper and make connections with the numerical and symbolic representations of an infinite series. I feel our investigation with sequence and series helped Nick understand the value of multiple representations and affected his pedagogical approach to teaching infinite series. Not only did he incorporate multiple representations, he claimed students were engaged in building connections while he asked guiding questions.

Concurrently in the 7th week, Nick was engaged in an assignment for creating an interactive spreadsheet to explore “nearly golden ratios” (Bradley, 2000) from a generalized form of the Fibonacci sequence. Instead of using the recursive formula \( w_{n+1} = w_n + w_{n-1} \) to generate the sequence, one uses the formula \( w_{n+1} = k \cdot w_n + w_{n-1} \) where \( k \) is any integer. The nearly golden ratios emerge from the limit of the sequence of successive ratios. Nick wrote the following about his work on this assignment:

I think it takes much less effort with the spreadsheet to see that the sequences [of successive ratios] always converge to some real limit. The graph also helps to motivate this idea – regardless of what values the students chooses for \( w(0) \), \( w(1) \), and \( k \), the sequence [of successive ratios] and the graph will always converge to a real number. I was especially intrigued by negative values of \( k \): I experimented by looking at the relationship between the sequences when \( w(0) \) and \( w(1) \) were unchanged and \( k \) was changed to \(-k\). I think this could be a good question to ask students – have them explain what happens and why it happens when the first two variables are left constant and \( k \) is changed to its additive inverse.

Not only did Nick use technology to explore a concept that he had never dealt with before, but he extended his experience to imagining high level tasks that would engage students in mathematical thinking with technology tools. This experience was also a critical step in his development of techno-mathematical knowledge.

Another critical shift occurred in the 9th week of the semester. After reading an article about third grade students using a spreadsheet environment to investigate rational number relationships (Drier, 2000), Nick wrote:

Prior to reading the article, I had always felt that technology didn’t really belong in elementary schools. The gist of my argument was that technology (calculators) might impede the progress of beginning students by no longer forcing them to think. But what I read in the article was quite the contrary – the technology was the motivating factor for the students’ to think mathematically.

Nick further shared his thoughts in a class discussion. He emphasized that technology tools could help students develop mathematical understanding but that “it really depends on how the teacher decides to use the tools.” It seems that reading the article and using the same spreadsheet environment to explore several mathematics tasks affected Nick’s perception of the usefulness of technology to engage young students in mathematical thinking.

Throughout the remaining part of the course, Nick continued to share his ideas and emphasize the importance of using technology appropriately to help students understand concepts and “think like
The Development of Nancy

Although she had little experience with technology and was a product of traditional mathematics education, Nancy had a very open mind and was interested in learning about how to teach mathematics. Nancy had some difficulty in her college level mathematics courses – difficulty she attributed to her own lack of understanding. During the first week she noted, “so many times I remember learning how to do a problem, but having no idea of what it meant to do that problem.” She further wrote the following reflection after reading the six Principles from NCTM (2000):

When students can learn and see for themselves, they have a much greater chance of remembering and understanding concepts ... it is hard for students to focus on a lecture for a good length of time and using technological visual aids can help redirect student thought processes back into the right direction. Students are also able to learn and draw conclusions for themselves ... Teachers are lucky to have the resources in technology they have now ...

As a pre-service teacher I am very nervous about going into education with the knowledge that I will have to use technology ... I am just not very good with computers.

Nancy is openly honest about her feelings. Although she seems to think students should learn and see for themselves, her notion of “technological visual aids” indicates that she may have envisioned students using technology as a display rather than a dynamic interactive tool.

Several weeks later, after an assignment on creating a tessellation, Nancy noted that “by using the geometer’s sketchpad, students will have a chance to come out of their everyday habit of taking notes and watching their teacher teach. Technology is always good for giving the kids a break.” It is evident that although Nancy may think dynamic geometry tools can help students understand better, she believes that a primary benefit is to give students a “break” from “watching” the teacher. Even though she had several “a-ha” moments while solving mathematical tasks with technology during this course, she appears to be strongly influenced by her own educational experiences, and imagines a classroom where students passively take notes while a teacher provides all the “knowledge.”

During the 6th week, a critical shift occurred when Nancy reviewed a videotape lesson of students using graphing calculators to examine patterns and quadratic functions. Reflecting on her analysis, she wrote:

I saw so much interaction between the students and I could really see their brains working. I thought back to my own high school experiences and honestly did not remember ever putting so much thought into any kind of mathematical topic because my teachers never challenged me in quite this way. The material I learned was basically straightforward and here, I saw students learning and discovering ideas for themselves.

Nancy needed to see real students engaged in mathematical thinking with technology. Following this assignment, there was a shift in Nancy’s beliefs and attitude towards using technology as a thinking tool and posing tasks that actively engage students in mathematical thought. During the next week, after successfully solving a challenging task with the generalized Fibonacci sequence and discussing ways to engage students in such a task, Nancy commented “I need to break away from my own experiences and branch out my mathematical knowledge.”

Further, in the 9th week, Nancy also seemed intrigued by students’ thinking with technology in the Drier (2000) article. She noted “more often than not, teachers ask their students the ‘obvious’ questions, questions that do not require much thought. But, I tend to wonder exactly how beneficial these questions really are. If deeper thought is not called for, then I do not believe that minds are developed to their fullest potential.”

Again, Nancy appears to be shifting her belief about mathematics teaching and learning. She seems to understand the value of appropriate questions and tasks. In addition, she continued to develop her mathematical understanding with technology and continually proposed ways to use the tasks and technology from her assignments with students.
Nancy's culminating course project was a well-planned investigation using dynamic geometry and graphing calculators to engage students in developing theorems related to parallel lines. In reflecting on her course project, Nancy's words, although lengthy, tell an amazing story of her recognition of her shift in beliefs.

When I first heard about this project, I was anything but thrilled. I honestly thought that this would be the most tedious thing that I have ever attempted to do. However, I have actually had fun doing this project and through my efforts to produce a meaningful lesson, I really learned just how valuable technology can be in mathematics ... I have always been a little skeptical of this whole "discovery learning" stuff. I do not remember "discovering" anything in high school and therefore wondered why it was necessary for students to figure out ideas for themselves ... I even felt like "discovery learning" was just some sort of new math fad ... This semester has changed my mindset about this idea and this investigation finalized my new attitude. It just makes so much more sense for the kids to learn things themselves because it requires them to think. There is no doubt in my mind that when students actually have to put thought into figuring something out, then their retention rate is much longer and their comprehension is deeper. The technology definitely adds to the discovery process and in the future I plan to look for opportunities where students will benefit from activities in which conjectures are formed. I know that my own recollection of many mathematical ideas is very vague and I believe that this is because I was told everything rather than being forced to think about ideas for myself ... I do not want my students to have this same problem.

Obviously, Nancy's openness and willingness to learn and her experiences, both prior to and during this course, affected her development of techno-mathematical knowledge.

Summary

The evidence from this first semester of the course indicates that several of the investigations, readings, and assignments impacted the development of these preservice teachers' techno-mathematical knowledge. The reflections required as a part of most assignments also seem to be critical components for the teachers to critically think about their experiences and communicate with me. What was not revealed in this paper were the comments and questions that I wrote back to each student as I read and graded each assignment. I believe these personal communications established a mutually respectful and caring environment that allowed the teachers to take risks in their own learning.

I will continue to develop the course and analyze my subsequent students' beliefs. However, I believe that much more than a single course is needed to develop teachers with techno-mathematical knowledge who can enable students to use technology as an essential tool in learning mathematics. Meaningful experiences need to be woven throughout a mathematics education program, and continue throughout a teacher's career.

Author's Note: The details of the author's course can be found at http://courses.ncsu.edu/ems480.

Making geometry on a virtual environment: a proposal of continuous distance education for teachers

Márcia Campos, Alex Sandro Gomes and Hermino Borges Neto

Tele-ambiente is an environment composed of a virtual site linked to applications that favor the cooperative work, in which the interaction among participants is mediated by tele-conference resources (image, sound, text and mail) plus an efficient protocol of real-time file and software sharing among the working group participants (for instance student-student and teacher-student).

The final goal is to develop a distance learning tool for middle-school mathematics teachers in-service professional development in the state of Ceará, Brazil. The course focus on selected topics on geometry, using software as resources for teaching geometry and emphasize problem solving instead of algorithms and proofs. The aim is to develop teachers' conceptual understanding about geometrical topics and at the same time to provide them with tools for planning their classes using internet and educational software.

The present work discusses a pilot experience for implementing this environment. We are currently developing materials for the course. In a previous study conducted in classroom, we observed how teacher interventions could be reduced. In this work we report on findings with a group of pre-service elementary school teachers at the Universidade Federal do Ceará. We first describe the virtual environment called Tele-ambiente.

The Tele-ambiente's Structure

Tele-ambiente is a learning environment composed of a tool, called TELE, and a group of activities that can be used by this tool in real time. We assumed two premises for initially implementing TELE. The first was to adopt patterns established by organisms such as ITU (International Telecommunications Union) and IETF (Internet Engineering Task Forces); the second was to adopt the Internet as the basic infrastructural environment.

TELE was implemented using the ActiveX controls, a Microsoft™ NetMeeting product. The interface was developed using a group of parameters to control the interface objects presented to users. The features of NetMeeting are supported by industry patterns designated by the International Telecommunications Union (ITU), the Internet Engineering Task Forces (IETF) and other normatization agencies. NetMeeting allows ITU H 232 for audio and video-conference, ITU T.12o for the multi-point conference, and IETF LDAP for directory services.

1 Tele-ambiente (Developing collaborative and adaptive applications for distance instruction) is a research project approved by ProTeM-CC (it Programs Thematic Multi-institutional in Science of the Computation) of CNPq, Brazil
Pedagogical structure of the courses

Tele-Cabri is a distance course conducted in Grénoire by IMAG, of the Joseph Fourier university, for hospitalized children. We choose to adapt it for a group of in-service public schools teachers in Fortaleza, Ceará, Brazil. The teachers usually have insufficient content knowledge in mathematics and geometry.

Initially, we have students' machines linked to an internet server which has already properly learning situations stored and scheduled, an virtual tutor agent, interventional objects and historical of the sessions. These items are integrated in the Tele-ambiente environment allowing sharing of Cabri-geometre software, and oral, visual and written communication.

To explain them, begin why commenting the term tutor it is used. Pavel (1997) says that Balacheff prefers to use this term because it differentiates the teaching through TeleCabri from a simple tutorial program tutorial containing all the answers rigidally structured. In a certain way, TeleCabri works as a program tutorial because it possesses an virtual tutor agent that generates problem-solving situations, intervening in students' difficulties through an analysis of didactic engineering accomplished a priori in possible ways to solve the subject, taking in consideration, still, possible mistakes and the student's difficulties.

When identifying the students' difficulty, the virtual tutor has two roads to proceed: it makes an automatic intervention, running over the intervention objects, or it falls back upon the human tutor. The human tutor's importance resides in the fact that not all the students' difficulties can be solved in an automatic way. In the Tele-ambiente database, we set up the virtual tutor, the interventional objects with the situations problems and texts and images with explanatory and illustrative routes.

To structure the course, we will select part of the official curriculum for the geometry teaching demanded for 5a and 8a grades of the Brazilian middle school teaching. We will create the activities with Cabri-géomètre to allow active construction of the geometrical concepts. We also intend to use other available resources in the Internet for not limiting ourselves to one only application. We intend to use with teachers a methodology that stimulates thinking, so that they can learn how to propose problem solving situations that contribute in an active way to constructing students' knowledge. It is also our objective to prepare the teacher to accomplish the analysis of children's answers.
Helping Elementary Education Majors Brush Up on Mathematical Modeling: Insights from a Field Test of a New Online Learning Prototype

Abstract: This paper describes insights related to the potential use of on-line training modules with elementary education pre-service teachers for enhancing their experience and background in mathematical modeling. These insights resulted from a field test of a new online learning prototype developed within a National Science Foundation Proof-of-Concept project. The insights listed in the paper are further supported by two URL addresses that link to detailed notes, background documents, and various demonstration pieces.

Various studies and national reports have suggested that elementary education majors are often weak within academic content areas, and particularly mathematics and science (see web-site for references). Such studies and reports often suggest the need for remedial content instruction within teacher preparation programs. However, these future teachers may have a difficult time receiving the remedial help they need within a traditional university setting, since as a elementary education major they are often already taking a full load of courses representing numerous disciplines. Thus, the potential of other approaches, such as the use of on-line learning modules, need to be examined for filling this remedial content need of pre-service elementary teachers.

Related to this potential assistance, several online learning strategies are being examined at the University of Nebraska at Omaha with pre-service elementary teachers, including the use of a new online learning module, developed within a National Science Foundation Proof-of-Concept project related to mathematical modeling. The module and other simulations used represent several innovations in online...
instruction, such as a node-based database structure for the instructional pieces. The assessment questions and answers, sequence of nodes visited by the student, and duration of time a student visits an instructional node are all recorded. A detailed map of a student’s path through the instructional process is also generated to help in the overall analysis of an individual student’s learning process. For more information see the extensive URLs at http://ois.unomaha.edu/aflearn/index.html and http://ois.unomaha.edu.

The investigation of these online learning strategies is just beginning, but some initial insights are already apparent from the results of some initial field tests. These include the following:

1) Response patterns reflect that elementary teachers indeed have a wide range of background and experience in mathematics and mathematical modeling.

2) The pre-service elementary teachers sampled recognized that online learning might be a useful strategy for their own remedial work in mathematics.

3) The pre-service elementary teachers were at first uncomfortable and impatient with the “discovery learning” approaches used within the modules and simulations.

4) The pre-service elementary teachers eventually preferred to work in groups of two or three, rather than to work on the on-line activities individually.

5) A periodic discussion component (that accessed a real teacher) was seen as essential by the pre-service elementary teachers when using on-line learning activities.

6) After some initial resistance with the on-line instruction, the elementary pre-service teachers eventually embraced on-line training that contained some periodic discussion components.

The overall vision for the use of such technology based learning environments is one that is consistent with many national visions and documents. For the pre-service elementary teacher, the use of such learning environments within methods classes may not only help them extend their own backgrounds, but also allow them to experience a potentially powerful new learning environment that will become increasingly available to both themselves and their elementary students.
The Modern Classroom: 
Using Portable Wireless Computer Networking in the Classroom

Virgil Varvel - Illinois Online Network, 
University of Illinois at Urbana-Champaign, USA 
vvarvel@uillinois.edu

Dr. Delwyn Harnisch – Dept. of Educational Psychology, 
University of Nebraska at Lincoln, USA 
harnisch@unl.edu

Abstract: In the Spring semester of 2000, the College of Education at the University of Illinois sought to alleviate the lack of available class-time in a standard computer lab by implementing a laptop computer lab that could be transported throughout the building and connected to the World Wide Web via a wireless network connection. This paper reports on the usefulness of such a system in a higher education classroom and on the support aspects necessary to implement such a system and control for user needs. Views by our learners from a one-semester course in advanced statistics reveal that a wireless computer lab is effective in providing students with motivation, mobility, and learning while providing the instructor with increased pedagogical choices.

Introduction

Technology continues to be at the forefront of the modern educational system. The latest technology to inundate classrooms around the world is wireless networking. The recent affordability and speed of wireless networks combined with the power and affordability of current laptop computers have allowed portable wireless computer labs to become a reality in many schools. The College of Education at the University of Illinois serves as no exception to this rule. In order to alleviate the overcrowding of a desktop computer lab, a portable solution was implemented that would also take advantage of recent advances in wireless networking. This paper describes this wireless computing environment and the views by our learners from a one-semester course in advanced statistics. Summaries from the survey are shared along with anecdotal comments from our participants. Finally, conclusions are drawn concerning the effectiveness of the system during our trial.

Advantages of Portable Wireless Computer Networks

Wireless computer networks offer schools a big advantage (mobility) over hardwired network technology. Using a wireless network with laptop computers allows students to use computers as they move around a classroom without having to be connected with a network or power cable. With the use of the wireless network on a portable computer comes greater flexibility and mobility for students and classroom activities.
As the wireless network technology continues to improve and the costs decline we will see more and more schools turning to wireless solutions for their local area networks (LANs). Wireless LAN computers (connected to a server through PCMCIA cards that send and receive) provides classroom instructors with greater flexibility in gaining access to the Internet at anytime from anywhere within reasonable distance. It is also a benefit in school communities that are experiencing rapid student population growth where the installation of a wireless LAN is common place in portable classroom settings. Having a wireless LAN allows students and teacher to communicate with each other without cables, sending and receiving data, accessing the Internet and printers.

Recent support systems (LearningStation.com) are beginning to provide enabling, real-time instructional tools through wireless web-based solutions. With these support systems schools are able to gain valuable information in setting up real-time wireless network access and networked computers while providing a more enhanced learning experience. Schools that are using these wireless computing environments are reporting results that are linked to improved performances on statewide achievement tests (math & writing), improved attendance, improved performance on a writing proficiency test, improvement in students’ and teachers’ research skills, an increase in student motivation and parental involvement (Greaves, 2000).

Overview of a Wireless Networked, Portable Computer Lab (iLab)

The functioning of our iLab is relatively simple. Apple iBook computers with upgrades to give 96 MB of RAM and Apple AirPort wireless networking cards provide the core component. The networking is achieved via radio signals, thus no line of site contact is required for the system to function. The iLab is contained on a cart that provides mobility throughout the College, security of system components, and a custom built recharging system. Once the iLab is in the classroom, students retrieve their assigned laptops. Within a few minutes, the class can be exploring the Internet or performing other computer facilitated activities.

Our iLab implementation took a student centered approach. Enough computers were supplied to provide a one-to-one student to computer ratio when applicable. Furthermore, the wireless aspect is primarily from the student’s perspective. The instructor computer was an Apple G3 laptop. This provided an external monitor/projector connection, but the computer was not included on the wireless network for security reasons. Therefore, the instructor’s computer still required a network cable. Furthermore, to insure optimal signal strength, the Apple AirPort network hubs were built into the cart that goes into the classroom with the computers. These hubs also have to be hard wired to the College’s network and plugged into a power outlet. To allow connection of all devices to a single network jack and power outlet within all classrooms in our College, a switched Ethernet hub and a power strip were also built into the cart. A single network cable and power cable that extend from the back of our transport cart are then connected within the classroom to activate the system. These additional wires are transparent to the students who need only to pick up their laptop to begin working.

New Roles For Classroom Teachers and Students

With the use of wireless technology a new role emerges for the classroom teacher. Greaves (Greaves, 2000) report that with the use of wireless networks one sees an improvement in collaborative learning and support for more individual, small group and whole class projects. For teachers that use wireless systems, Greaves reports that teachers are using technology for more effective instructional strategies that allow students to discover knowledge and to develop their own personal learning and growth. Many others have concurred. Bradshaw and Massey explain, with laptops, the students learn advanced communication skills and computing techniques in a laptop-enhanced classroom. Also, the PLAFT project (Gardner, 1994), the Copernicus Project (Fouts, 1997), and Project Pulse (McMillan, 2000) among others have all demonstrated the utility of laptops in education. A common theme among the studies is enhanced student centered learning with increased pedagogical choices for the instructor in a laptop-enhanced classroom.

Few projects, however, have examined the impact that wireless networking in conjunction with portable computing can have on the instructor and students. Stetten and Guthrie (Stetten, 1995) report how diffuse infrared wireless networking lends itself well to collaborative, computer-enhanced classroom experiences. They enumerate a number of useful teaching techniques or modes of instruction. Two of their...
four modes utilized collaboration while all four modes were enhanced by the laptop presence. The wireless computing provided flexibility that they argue could "serve well for any subject in which human-computer interactions capture the intellectual or creative process."

Such positive classroom environments do not create themselves. Our studies have shown that the positive application of technical components is more than a simple show and tell. Beyond network and computer presence, the instructor needs to have instructionally sensitive programs and activities for use in an iLab environment. Some idea of activities using the technology needs to exist and the instructor needs to have the ability to transform those ideas into functional lessons. When necessary, the instructor must be willing to forgo ingrained power systems within the classroom so that the students can be empowered to carry on their own learning at their own pace within limits that the instructor can still set. In all, the system must provide added value to the educational experience of instructor and students alike.

Model for Supporting an Instructor’s Use of a Mobile Computer Lab

Fundamental to the use of a wireless computing environment is the organization of educational materials that can be shared and implemented with a portable classroom environment. To achieve added educational value, some form of support model is necessary to provide the instructor with the tools and knowledge to make use of such materials. In this section we address the support structure that is needed to facilitate a professional learning environment for both the students and the professor. This system must insure computer and networking functionality while providing instructional support for instructors and students so that the computing environment is best utilized to benefit all.

Any use of equipment, independent of its technological nature, requires a support system. An expensive, high-tech piece of equipment quickly becomes an expensive paperweight if the appropriate steps are not taken to ensure the continued functioning of the system as well as instructor support and training. It is only through a continuous stream of communication between the support staff and instructors that viable and effective technology use can be achieved.

Numerous approaches can be executed to maintain a constant connection between the instructors using the iLab and the support staff. To begin with, a communication channel must be opened before the technology is introduced. In our system, all instructors planning to use the iLab must attend an orientation meeting prior to iLab use. Several reasons exist for establishing early communication lines. For one, independent of the desire to implement a system, such action should not be taken if it is against the best interest of the students. It is possible that an alternative method could meet the student’s needs better. For example, a video resource may be available that could serve the students as well as World Wide Web access. Secondly, the earlier that communication lines are opened, the more time they have to develop into a functional state. Only once the instructor is comfortable communicating with the support staff can a free flow of information occur to the instructor’s benefit. Finally, the support staff must know the needs of the instructor in advance. Early warning is required for the support staff to install required programs, research program effectiveness, test and correct any program conflicts that may exist in the computer systems once new software is installed, and to schedule maintenance of the systems around the class schedule of the instructor.

Once the computer components are in use, the communication between staff and instructor must continue. An instructor needs to feel comfortable with reporting a problem and confident that such problems will be corrected in a timely manner. This comfort leads to greater instructor satisfaction, which can translate into a more diverse and more regular usage of the computer lab in the classroom to the students’ benefit. Furthermore, every time that the system is deployed, the support staff should be aware of any changes in instructor needs so that concurrent changes can be made in the computer system to best meet the new needs. Interaction with the instructor was maintained in our system through email, phone, and in-person contact every time that the system was used. The support staff maintains a willingness to communicate and to help the instructor as needs arise.

Helping the instructor is a key concept in creating effective programs. Effective technology use requires more than a simple understanding of how a piece of equipment is turned on, and more too than an understanding of how to start and run a computer program. Instructors should also be given support in the area of ideas. While the instructor is a content expert, the instructor may not be a computer assisted instruction
specialist. Therefore, it becomes an important function of the support staff to complement an instructor’s existing strategies with ideas concerning how to integrate technology to best meet the course’s needs.

A final step in communication between instructor and staff is evaluation of the systems usage. Post-use meetings were established to evaluate the effectiveness of the system and to search for solutions to any problems that may have arisen. Not all problems may have been reported during a semester, since some may have been small or have slipped the instructor’s mind. Also, while some problems may have been small on a single occasion, a continued occurrence of a small problem can become a big problem over time. Therefore, the support staff needs to identify these problems and make corrections prior to future system usage.

Not all requirements to system’s needs can be gained directly through communication. Support staff should understand that while an instructor knows the needs of the students, these needs might not be reported if the instructor is unaware that these needs can be met with technology. In other words, the instructor does not always know what is possible. Hence, a support staff needs to be proactive and anticipate student needs. Through anticipation, lessons can be envisioned that make more effective use of the system than first envisioned by the instructor, which can lead to greater satisfaction for the instructor, the students, and the support staff from a job well done.

Results & Discussion

In addition to analyzing feedback from the instructor and knowledge of support personnel as outlined in discussions above, pre and post surveys were administered to the 26 students attending a graduate statistical methods course in a Midwestern university setting. The pre survey asked seven background questions and nine Likert scaled (Responses ranged from 1 to 5 where a 1 represented Agree and a 5 represented Disagree) items regarding the use of computers and wireless networks. The post survey consisted of 10 Likert scaled (Similar response scale as the pre survey) items and two open ended items focusing on wireless networking. Copies of the survey are available from the website [http://eval1.crc.uiuc.edu/site2001.html]. The respondents were represented by 11 males and 15 females with an average of 8.6 years of computer experience, 4.3 years of Internet experience, predominantly owning PCs (85%, with only 1 student not owning a personal computer), and typically spending 1.7 hours a day on Internet. No significant differences existed in average computer experience or knowledge based on student status or gender in our study.

The responses to the open ended items revealed the student’s perspective on the use of wireless networks in classroom settings. Overwhelmingly, the responses were positive in nature. Figure 1 highlights some of the responses.

"If you are familiar with the computer it can be of great advantage..."

"Nice to have ability to use Internet in a normal class. Able to use websites to enhance learning."

"Everyone should have the knowledge to access computers."

"With portable computing in an educational setting people will easily access the Internet."

"Nice to relate to book learning... nice to be able to work on the same thing as other classmates."

"Convenient," "enhanced learning...without having to leave the classroom."

"Easy to use software... easy to get info from a variety of sources."

Figure 1: Student Responses to Use of a Wireless Computer Lab

The results from survey items reveal a strong positive level of agreement with the questions concerning the effectiveness of wireless computing. The mean level of agreement to the question on excited about the use of wireless networking" was a mean of 1.62 where 1 represents a high level of agreement.
Similarly we see a high level of agreement (M = 1.54) with their response to the question of “using wireless networks in the future.” The majority of the students reported not understanding the security issues involved with wireless networking (M = 2.85). From the Post survey we see the students reported high level of agreement (M = 1.6) with the “enjoyment” of using iBooks in this class. The use of the iBooks created a greater sense of the security issues as end of course the students rated the question of understanding the security issues involved with wireless networking with a significantly higher level of agreement (M = 2.1). Finally, the majority (85%) of the students viewed the use of wireless networking as enhancing their learning experience (M = 2.2).

Several enhancements to learning became evident from our study (Figure 2 provides a model for our learning environment that includes student outcomes). First, an iLab enhances student mobility. The computer now goes with the student to where learning is taking place instead of the student going to a computer environment that may inhibit typical classroom learning. This mobility provides increased usability of computer-based and Internet-based learning. A second enhancement is motivation. The iLab places the students in control of their learning as they pace themselves through a choice of computer-based activities. This control, along with a general enthusiasm over computer use, can be a motivating factor for many students.

This control requires that proper planning occur to develop and find appropriate materials prior to lessons. In our class, value was added through simulations of statistical concepts that provided visualization of abstract concepts that the students could manipulate to yield better representations of themes. The computers provided real-time representations of data in a visual format. Student participation seemed increased and students mentioned when questioned that the visualizations provided them with a better understanding of statistical concepts.

Appropriate materials can also merge with student assessment. Through the use of online quizzing, assessment choices for the instructor increased while overall meaningful learning was increased. Online quizzing provides instant feedback to students, thus correcting misconceptions while the thought processes that led to them are still fresh in the student’s mind. In addition, students can complete multiple non-identical quizzes over the same material through “quiz banking” on the computer, thus providing multiple opportunities for reinforcing concepts. Finally, placing the quizzes in an online format provides the student with control over quiz speed, since the quizzes can be taken when the student wants at their own pace.

![Figure 2 - Simplified Model of iLab Use](image)

**Summary**

Through dynamic interaction among computers, support systems, instructor, and students, a wireless networked portable computer lab can provide student motivation, mobility, and learning while providing the instructor with increased pedagogical and assessment choices in a standard classroom context. Use of iBooks
facilitated small group interactions among students pairing up to solve problems, alternating between acting as the problem solver and listener. The iBooks provided natural small group opportunities to clarify and test student’s own ideas and perceptions as well as build teamwork and communication skills. Through this process the students gained insights into their own thinking processes and those of others. Furthermore, active engagement of the students via the iBooks in discussions, practicing what they were learning, and applying concepts and ideas to complex performance tasks can yield added value to the educational experience from the instructor and the students’ viewpoints.

Integrating Mathematics Education Technologies into Teacher Education at the University of Colorado-Boulder

Jeff Hovermill and Michael Meloth
School of Education
University of Colorado-Boulder
United States
hovelmill@colorado.edu
Michael.Meloth@colorado.edu

Abstract: Technology is transforming the face of mathematics education. The National Council of Teachers of Mathematics' Principles and Standards for School Mathematics (Standards) states “the existence, versatility, and power of technology make it possible and necessary to reexamine what mathematics students should learn as well as how they can best learn it” (NCTM, 2000). Furthermore, NCTM describes that “the effective use of technology in the mathematics classroom depends on the teacher. Technology is not a panacea. As with any teaching tool, it can be used well or poorly” (NCTM, 2000).

Evidence suggests that teachers frequently have difficulty aligning their practice with these Standards and that they need financial, cognitive and technical support in order to do so (OTA, 1995). This paper describes ways that the University of Colorado-Boulder has infused technology into their teacher education program in general, and their mathematics education program, in particular, in order to “prepare tomorrow’s teachers today” to effectively teach with mathematics education technology.

Teacher Education Technology Framework

The teacher education experience embodied at the University of Colorado-Boulder (CU) is designed to instill in preservice teachers an informed and critical perspective on the uses of new media so that these teachers are provided with the skills and confidence necessary to implement their professional objectives and decisions. The teacher education program at the School of Education at CU has long been committed to training exceptionally well-prepared teachers so that they think critically about education and theories of learning, and establish inclusive classroom environments that foster learning opportunities for all students. Our program is imbued from the ground up with philosophies of teaching toward democratic ideals, and the goals of providing students with constructive, learner-centered classrooms founded on scientific research on education. As we enhance our own capabilities to use – and teach about – educational technology in K-12 education, we are similarly committed to an integrative and systematic approach to teacher education reform. Thus graduates from this new program aimed at preparing teachers to effectively use technology will learn to operate with an inquiring disposition that considers the When?, Why?, and How? of using technology to foster basic skills, knowledge, and conceptual understanding in all students. Because we as teacher educators are obligated to provide our students (preservice teachers) with the best and most up-to-date professional program, we believe that future teachers should be learning to use, teach with, and teach students to think with modern technologies as an integrated component to their teaching practices. Toward this end, educational technology use needs to be infused into the curriculum by education faculty who are modeling technology-proficient instruction, particularly in those courses where preservice teachers develop the subject area expertise they will use in the classroom. In this way, our teacher preparation programs can be sure that future teachers master new instructional strategies, multiple learning styles, and content applications that enable them to make full use of modern technologies for improved learning and achievement.

Secondary Mathematics Methods Technology Framework
Secondary Mathematics Methods (Methods) is taken by preservice teachers the final semester of their teacher education program, just before they begin their student teaching experience. By this time in their teacher education program students have learned much about the discipline of mathematics, taken education courses examining theories of schooling, teaching, and learning; and have observed and participated in various educational settings. An explicit goal of Methods is to help preservice teachers develop their mathematics teaching philosophies and practice (Peressini et. al., 1998). This course strives to help preservice teachers develop the skill of being able to make connections between the discipline of mathematics and effective ways to help students understand mathematics; the ability to help students to learn their way around the discipline while attending to conceptual barriers along the way (NRC, 1999).

During this course, preservice teachers engage in authentic mathematical tasks. The preservice teacher's participation in these mathematical activities is done in a two-fold manner. First, these aspiring teachers participate as learners in order to experience the reform-based mathematics they will be asked to teach, and then reflect as pedagogues on the instruction and curriculum they have just experienced. Much of the reform-based mathematics that occurs in Secondary Mathematics Methods includes technology rich instruction and curriculum. This technology is integrated through a see once, try once, do once model. In this way, preservice teachers can observe, participate, and reflect upon the Why, When, and How of technology use in mathematics education. Examples follow in the next section.

Utilized Mathematics Education Technologies

“In mathematics-instruction programs, technology should be used widely and responsibly, with the goal of enriching students' learning of mathematics (NCTM, 2000).” The first author of this paper has identified, and worked extensively with four mathematics education technologies, which have demonstrated particular promise towards enhancing student learning. These technologies fit well with multiple teaching and learning styles, especially reform-based pedagogy, and help to foster connections between students’ mathematical understandings and other parts of their in-school and out-of-school experiences. These technologies are Geometer’s Sketchpad (KCP, 1997), Graphing Calculator’s including Calculator-Based Laboratories, Fathom (KCP, 1999), and The Jasper Woodbury Adventure Series (CTGV, 1992). These mathematics education learning tools can be used dynamically, and when utilized effectively, help to meet NCTM’s recommendation of using technology to “blur some of the artificial separations among topics in algebra, geometry, and data analysis by allowing students to use ideas from one area of mathematics to better understand another area of mathematics” (NCTM, 2000).

These technologies afford opportunities to link mathematics curriculum and instruction across subjects and to students’ lives (Hovermill, J. & Anderson, K., in progress). Calculator-based laboratories allow students to collect data about real-world phenomena via the use of tools such as motion detectors, pH probes, light sensors, and temperature probes. Students can investigate the world around them by using this equipment and then use graphing calculators or Fathom software to analyze the data they have collected. Fathom is a particularly powerful mathematical exploratory tool since students can simultaneously investigate multiple representations of the data they have collected. While students try to understand interesting data sets they are motivated to learn and apply many mathematical concepts (Finzer, 1999).

The Jasper Woodbury Adventure Series is a video-based learning environment that fosters student problem posing and solving. Fifteen to twenty minute videos are presented to students in Jasper Adventures. Embedded in these videos are critical ideas that are necessary towards solving the multi-step problems presented to the students at the end of the adventures. The developers of the Jasper Woodbury Series comment how their design “anchors” students’ subsequent project-based learning (CGTV, 1992). Multiple classrooms investigating Jasper problems are often networked together with other schools and learning communities or “collaboratories” are thus created. Learning communities increase student motivation, provide opportunities for formative feedback and assist towards promoting learning with understanding (NRC, 1999).

Geometer’s Sketchpad is another dynamic learning environment, which can be used to help connect aspects of the subject of mathematics, within or outside the discipline. Specifically, students can quickly produce dynamic sketches that can lead to conjectures, investigation, and communication (Schattschneider & King, 1997.)
Results

Preservice teachers have responded favorably to opportunities to experience technology-based mathematics as learners and as teachers. They have reflected upon these experiences in regards to student motivation and understanding as well as instructional and curricular issues. They have engaged in meaningful dialogue inside of class and outside, via electronic discussions. These preservice have themselves integrated technology into their student teaching fieldwork experiences. Three themes have repeatedly surfaced as aspects of technology-based mathematics. First, these preservice teachers have concluded that technology affords opportunities for rich mathematical investigation. Second, these investigations involving technology can help to make connections within the discipline of mathematics and between mathematics and other disciplines. Third, technology-based investigations can drive instruction and curriculum in authentic, collaborative ways that help to foster learning for understanding. Examples of these preservice teachers' conclusions are below.

Responding to technology-based activity learning in general, one student responded:

I think technology-based activity learning offers a richer way (for students) to understand academic subjects. I think that it provides a contextual framework for mathematics so that students understand connections between mathematics and other disciplines.

Another student responding specifically to a light sensor Calculator Based Laboratory activity, which investigated the fluctuations of fluorescent lights and modeled this fluctuation on the graphing calculator with an absolute value sine function, said:

It is pretty obvious that activities such as the light activity can be interesting, fun, and educational as well. The activity made good connections, it involved thinking about scientific concepts, and also required that mathematical concepts and computations be involved. Activities like this make the learning more fun, simple as that.

Yet another student added:

I think technology-based activity learning helps students ask why formulas are the way they are. They can see algorithms they have learned in class put to practical uses. If they don't have all the content knowledge while working on the lesson, it will force them to ask more questions about the lesson. When we were working on the lesson, because we didn't all know everything, the lesson was more of a discovery lesson. It integrates technology, content knowledge, and group work and allows students to discover answers instead of just being told them.

Another student concluded:

students are able to see how ideas and concepts are interrelated across disciplines. This inter-relatedness makes for a stronger foundation of knowledge for students. I believe it lets them see that content areas do not exist solely by themselves.

Conclusions

"Technology is essential in teaching and learning mathematics; it influences the mathematics that is taught and enhances students' learning" (NCTM, 2000). Although NCTM and other educational organizations recommend integrating technology into mathematics curriculum and instruction, this is still
not often accomplished in many classrooms (NRC, 1999). At the University of Colorado-Boulder, we have infused technology throughout our teacher education program and provide students with many opportunities to experiences and discuss the Why?, When?, and How? of technology integration. These multiple learning situations allow preservice mathematics teachers to critically examine issues of teaching and learning and to integrate technology into their personal educational ideologies. Teacher education at CU provides a framework that helps to "prepare tomorrow's teachers today" to teach effectively teach with technology. We utilize a model of observe once, practice once, lead once in supporting preservice teachers towards discovering the affordances for student learning that technology offers and integrating meaningful technology based investigations into their own mathematics curriculum and instruction.

Students in this program have articulated three findings about technology-based activity learning. First, these preservice teachers have concluded that technology affords opportunities for rich mathematical investigation. Second, these investigations involving technology can help to make connections within the discipline of mathematics and between mathematics and other disciplines. Third, technology-based investigations can drive instruction and curriculum in authentic, collaborative ways that help to foster learning for understanding. With continued practice and support these beginning teachers will become the leaders for change in their new schools and help to integrate mathematics education technologies into school mathematics.

Teaching Technology With Technology: A Case Study.  
How One Faculty Member is Integrating Technology Into His Pre-Service Mathematics Methods Classes

Ken Jensen  
Instructional Design Center  
University of Nebraska  
Lincoln, NE 68588-0351  
United States  
kjensen1@unl.edu

Abstract: This case study tracks a secondary mathematics pre-service class. The professor's thoughts give insight into why he is incorporating technology into his curriculum. The pre-service mathematics class is also participating in a pilot project in which wireless Macintosh® iBook computers are put to use. Classroom observations, interviews and documentation of student feedback were used for analysis. This professor's philosophy is that technology should be an instructional tool, a contribution to productivity. This faculty member is pleased with the results of technologies utilized in the course. Students reveal they benefits of technologies used in this methods course. The interesting concern of students was not the use of technology, but "which brand" would offer the best results.

Introduction

We are all familiar with the critical cries that teachers need better preparation in using instructional technology. Accordingly, we hear that university faculty themselves need a better understanding of technology. When a faculty person does have a high level of technological understanding, is there necessarily a gain in that person's productivity?

This study is motivated in part by economist Robert Solow's often quoted remark "we see computers everywhere but in the productivity statistics," This has often been used to describe the phenomenon called the "productivity paradox." The paradox questions the true benefit of computing technology in the workplace; in simple terms, do we get less done using computers than we used to? Until recently, evidence suggested that the productivity paradox did, in fact, exist. The latest results from the business world suggest that computers are contributing to productivity, at least in sectors of the economy that are themselves highly focused on technology.

Is it possible, that a technology paradox may exist in the process of teacher preparation? To explore this possibility, the author has undertaken a case study of a professor of mathematics education who is highly skilled in the use of computing technology. In this paper, the author presents background information on the subject, and describes the methodological approach in process.

The Study

For this on-going case study, classroom observations, instructor interviews, and student written feedback were analyzed. Several students were also interviewed to gain their perception of technology, the use of technology in the classroom, and how effectively technology was being used in this particular class. Data from student journals and observations from other faculty augment the study. The themes, which emerge, were examined in the light of the "productivity paradox" and the increasing mandate for educational colleges to produce technologically literate teachers.

Students in this course were also included in a college pilot project, which allowed students access to a Macintosh® iBook computer during this class period. The iBooks computers were equipped with wireless technology, which allowed the instructor and each student access to the Internet anywhere in the classroom. Mathematica®, Geometer's Sketch Pad®, access to e-mail, and Internet browser tools were installed on each computer. Advanced calculators and other technology tools were utilized during some portion of this course.
A portion of this pre-service methods course involves students going out into the schools. The purpose of these school experiences is to observe, help teach classes, and practice many skills, which have been learned during their pre-service instruction. This study did not track the students into the schools during these practicum exercises.

It should also be noted that this professor has a mathematics and a technology background. Prior to his current tenure as a mathematics professor, he was a faculty member in the technology division of this college.

Findings

The instructor is pleased with the way technology is being integrated into his pre-service mathematics course. Observations and interviews reveal this professor has prepared the coursework and incorporated technology to augment elements being presented. Students have reacted to this form of instruction in a favorable manner. One male student gave the following written feedback. "I thought Wednesday would be a bore ... after all I am an experienced user. Boy was I wrong ... I learned lots of neat features that would work beautifully in my Calc reci as well as the prealgebra we will be teaching." A female student observed, "I enjoy a ... teacher who is trying innovative things in the classroom." Perhaps one male student best summarized the issue of technology in the classroom. "It is amazing what technology will allow you to do in a classroom. It was also amusing ... to see some of the difficulties technology presents and the troubleshooting that is sometimes required."

The use of Macintosh® iBooks created new experiences for both the instructor and the students. Most students found this pilot study very useful and were excited to be part of this project. Students liked being able to work Mathematica® problems in class, so information could be shared and solutions discussed. Students appreciated the fact they could explore web sites as information was being communicated.

The Macintosh® iBook project also presented the instructor and students with several shortcomings. The instructor discussed missed class time when students were checking out machines and returning them to the designated carts. Several students commented that having a laptop in front of them the entire class period lead to distractions, such as reading your e-mail, "surfing" the net, or using other software. Others said, if you are going to be distracted, don’t blame it on the computer. Yet, the overall perspective of the iBook project is viewed as a valid and positive experience. Surprisingly, one of the most controversial points of this project arose when class discussion focused on whether Macintosh or Windows computers should be used.

Discussion

Faculties are divided about "how" and "to what extent" technology should be used in today’s curriculums. This Secondary Mathematics professor, at a large midwestern university, considers technology an integral part of his curriculum. Students tend to agree with this perspective. A valuable follow-up to this study would be to track these students into future classrooms and ascertain if technology is being infused into their curriculums. The size of a school and a school district’s perception of technology have been factors that can alter a teacher’s use of technology.

Museums Meeting Schools: Online and Right On the Mark

James S. Lenze
College of Education and Educational Technology
Indiana University of Pennsylvania
United States
jlenze@grove.iup.edu

Abstract: Schools, individual teachers, and students are entering museums through the World Wide Web instead of the entrance off Main Street. Museum directors are faced with the challenge of designing and using Internet based technologies to enhance the bond between students, schools and museums. This article discusses some of the technologies that museums are using based on an analysis of the Detroit Institute of Arts Education Department's Internet site and like efforts around the world. Each discussion is followed by an example of a museum that is using a particular technology and information directing the reader to a web site with more information. Design considerations for museum based educational web sites are also briefly discussed.

Introduction

Schools, individual teachers, and students are entering museums through the World Wide Web (WWW) instead of the entrance off Main Street. Museum directors are faced with the challenge of designing and using Internet based technologies to enhance the bond between students, schools and museums. This article discusses some of the technologies that museums are using based on an analysis of the Detroit Institute of Arts Education Department's Internet site and like efforts around the world. Each discussion is followed by an example of a museum that is using a particular technology and information directing the reader to a web site with more information. Design considerations for museum based educational web sites are also briefly discussed.

The following is a description of technologies subsumed under the Internet and examples of their educational use by museums.

On-line Design Considerations

Designing online educational outreach is not difficult. A few design considerations can greatly enhance the value of a museum's educational web site. The following design tips address some of the technologies more commonly used by museums today.

When designing an educational component of a museum web site, the museum's home page should have a hyperlink that is clearly labeled Education. From there, categories like lesson plans, e-mail, chat, video files, and sound files should be clearly visible.

Web sites should be easy to navigate. A visitor should be able to move between major parts of the web site with no more than two clicks of a mouse. Museums should avoid navigation features that frustrate web surfers like automatic pop-up windows and restricted access to going back. E-mail links should include the name of the institution or individual receiving the mail as well as the address.

Teachers and students should be encouraged to download pictures, graphics, sounds, and video. The site should clearly encourage the downloading of these elements and ensure that they are copyright free and identified as such. Cooperating teachers, students, and museum staff should create many, if not all, of the downloadable elements to avoid the unintentional use of protected materials.
If uploading documents is encouraged, simple procedures for doing so should be clearly visible and easy to find. Uploaded materials should be sent to the museum's web master for review and placement on the site. Since any materials on the site will reflect on the museum, careful screening is important.

Chat events should be clearly announced weeks in advance. Rules for participation should also be easy to find. Use the speaker's previous speaking engagements as a guide for estimating the number of people who would be interested in participating in a live discussion. Make sure that the software and hardware can handle the expected number of chat participants.

Video is a powerful tool on the Internet but usually requires more than a standard system to be received. Plug-ins or special programs for running video should be available through links to vendors who are willing to supply free versions of their software. Avoid video formats that are uncommon.

Directors need to remember that the Internet is not a static environment. Materials, listings, and links must be constantly updated and maintained. The Internet offers museums and other academic communities the most dynamic opportunity available today for collaboration.

It is also important to promote the educational component of a museum's web site. Search engines like Yahoo and Excite make it relatively easy to list a web site in their database. Key words should include terms like lesson plans, teacher resources, and educational activities. Content specific terms like Egypt, mummies, and pyramids should also be included.

Examples of Technologies used by Major Museums

Web pages are the most commonly recognized component of the Internet. Created using Hypertext Markup Language (HTML) and a variety of other programming languages, the vast number of web pages linked together through phone lines and satellite make up the WWW. Most museums already use web pages to post schedules and promote exhibits. They can also be used to post educational materials related to exhibits and events at the Museum. The Detroit Institute of the Arts has created a site off of their home page entitled "Ancient Egypt: Lesson Plans for Teachers (Ancient Egypt: Lesson Plans for Teachers, 2000, November 28)." This site includes a selection of cross-curricular lesson plans created by teachers in the Detroit Metro area.

This site is an excellent example of the most desirable relationship between museums and schools. The site was not created simply for teachers but with teachers. This integration helps the museum to offer instructionally sound courseware while giving teachers access to the Museum's extensive collection of artifacts and knowledge. The lesson plans in the site are tied to the Michigan's Content Standards and Draft Benchmarks (Content Standards and Working Draft Benchmarks, 2000, November 28). These standards are not a state mandated curriculum but they are widely used throughout Michigan as a curriculum guide by school districts. This enhances their value to other teachers who are also teaching a curriculum based on the standards. The site includes lesson plans for Art, Science, Math, Social Studies, and Language Arts. The lesson plans at the DIA site include activities, assessments, goals & objectives, pictures of students and projects, preparations & resources, and comments from the teacher who wrote the lesson plan (Ancient Egypt: Lesson Plans for Teachers, 2000, November 28). In fact, more and more museums are providing lesson plans as part of their educational outreach (Classroom Ready Lessons and Activities, 2000, November 28; Kids Project, 2000, November 28; Online Museum Educators, 2000, November 28; Teacher Resources, November 28a; Teacher Resources, November 28b; Teacher Resource Center, 2000, November 28).

The art of writing a letter is making something of a comeback with the popularity of e-mail. This technology gives students a chance to compose thoughtful questions that go beyond what their teacher, their textbook, and even the WWW can answer. Museums, with their in-house collection of experts can provide many of those answers.

The Milwaukee Art Museum has an e-mail link that allows students to pose questions to some of the artists whose work make up the institution's collection (Ask the Artist, 2000, November 28). Even minor celebrities seem remote and impossible to contact. Teachers dream of giving their students the opportunity to meet and interview the author of a children's story, the successful explorer, and the commander of the latest shuttle mission. Museums can host such interviews through the use of chat technology.

Chat refers to asynchronous conversations over the Internet. Typically, a chat room looks like a small box with a list of names. In the case of a museum interview, the names of the children and the name of the
An expert would appear. Students type in their questions or comments, which then appear on the screen in the order a central server receives them. The expert then replies in similar fashion. The National Air and Space Museum in Washington, DC maintains a link to NASA’s Space Team Online Project (Chats, 2000, November 28). This link provides schools with an access to live interactions with various NASA personnel including astronauts. Schools must register to take part in live chats.

Museums frequently sponsor events and lectures. These can be video taped and then converted to streaming video. Most people are aware that video files take up a substantial amount of room on a computer’s hard drive. It also can take many hours to download even a small amount of video through a standard modem connection. Streaming video is a technology that sends only a small amount of video through the line at a time while the video is being viewed. The result is substantially quicker access to video on the web and elimination of disk space problems.

Museums like the Tech Museum of Innovation at have begun offering some of their education-related content in the form of streaming video (Online Events, 2000, November 28). Teachers and students can watch lectures and interviews at any time.

Web based video works by connecting a small camera to a web page. The result is live video available on the WWW. Museums with dynamic or active exhibits can display all of the motion using this technology. Bishop Museum and The State Museum of Natural and Cultural History in Honolulu, Hawaii now offer live video feeds of some of their exhibits (Bishop Museum-Quickcam, 1997).

Interactive video is a similar technology. It doesn’t display its video images on the WWW but sends them through phone lines in a similar manner. Interactive video using ISDN lines currently offers better quality sound and picture than web-based video. Unlike web based video, which may be available 24 hours a day, interactive video is used for events like lectures and presentations. The Philadelphia Museum of Art offers a program called ArtLine (The ArtLine Distance Learning Program, 2000). Artline is a distance learning initiative used to offer virtual tours of the Museum or interactive events with speakers.

Summary

Museums can enhance educational outreach through the use of on-line resources for schools, teachers, and students. But to be effective museum directors must understand fundamental design considerations. More importantly, they must reach out to schools, teachers, and students to partner in the creation of educational materials and on-line interactive environments that make the most of museum resources and are relevant to learning situations. Many museums are experimenting with new technologies for educational outreach. With cooperation from other academic communities, museums can find new ways to serve their local communities and the world.

Bridging Transformational Geometry and Matrix Algebra with a Spreadsheet-Based Tool Kit

Anderson Norton
Mathematics Education Department
University of Georgia
anorton@coe.uga.edu

Sergei Abramovich
Department of Teacher Education
State University of New York at Potsdam
abramovs@potsdam.edu

Abstract: This report presents technology-enhanced activities designed for secondary mathematics teachers within the context of matrix algebra, transformational geometry, and fractals. It concerns the ways in which a spreadsheet can be used as a tool kit that enables one, through encoding and manipulating matrices, to create fractals with reliance upon the Chaos Game. The authors argue that such use of a spreadsheet can help prospective teachers link properties of matrices and concepts of transformational geometry in a meaningful and representational manner.

One of the central tenets of the current reform movement in mathematics teacher education is the appropriate use of the tools of technology in teaching and learning mathematics at all grade levels. The recently published document Principles and Standards for School Mathematics, by the National Council of Teachers of Mathematics (NCTM), included technology as one of its six Principles. The technology principle is based, in part, on the notion that computer-enabled pedagogy extends the range of problems that students can access and provides, with relative ease, more representational forms than a pencil-and-paper environment (NCTM 2000).

Indeed, a variety of representational forms relevant to secondary school mathematics instruction can be created through the use of computer graphics, electronic tables, symbolic manipulators, and dynamic geometry. All these types of software have proven to be useful cognitive tools in technology-rich classrooms and have become an important cultural component of the modern educational system. The various technology tools should not be considered in isolation; rather they should be viewed as a tool kit conducive to mediate mathematical action.

Any technology tool kit is a product of social evolution and cultural development. Thus, it may be helpful to structure the discussion on the mediation (through use of technology tools) of students' mathematical action in contemporary classrooms from the socio-cultural perspective (Wertsch 1991). This theoretical perspective distinguishes three major positions associated with a tool kit approach to mediated action: heterogeneity as genetic hierarchy, heterogeneity despite genetic hierarchy, and non-genetic heterogeneity. The first two positions admit an inherent ranking of available notation systems (electronic tables, graphing tools, etc.) within a learning environment. The third position does not admit the existence of the hierarchy of a cognitive effectiveness among the elements of a tool kit. In this report, we adopt the third position.

More specifically, non-genetic heterogeneity of a mediational tool kit implies that there is no inherent ranking within the manifold of representational formats in human mental functioning. As far as a representation of complex ideas in a computer environment is concerned, this position is in agreement with Kaput's (1992) claim that each notation system in a technology-rich tool kit reveals more clearly than another some aspects of a mathematical concept and hides some other aspects of the concept. From this position, a tool kit approach to mediated action brings about the abundant property of a representational variety in which the whole exceeds the sum of its parts. This paper will show how a variety of representational formats in the context of transformational geometry and matrix algebra can be examined from the third position.

The metaphor of a tool kit in the context of technology-enabled mathematics instruction means an array of representational formats that mediate students' mathematical thinking in a technology-rich environment. The major claim of a tool kit approach to teaching and learning mathematics in a computer
environment is that the variety of qualitatively different representational formats (notation systems) provided by
the environment affects students' acquisition of new concepts in different ways. While there is basically no
inherent ranking among different types of software used in secondary mathematics classroom, the
appropriateness of a particular type for a specific classroom depends on the topic being studied. Therefore, the
metaphor of a tool kit in the context of a technology-rich mathematics classroom may be associated with the
non-genetic heterogeneity position.
Variety in representational format may seem to require diversity in software, whereas many classrooms lack
diverse software tools. However, the non-genetic heterogeneity position appears to be particularly helpful in
supporting an alternative idea of using a single computer application - an electronic spreadsheet - as a tool kit
(Abramovich & Brantlinger 1998). Indeed, this single computer application is comprised of many tools that
have properties of their physically separate analogues. Sliders (manipulative parameters), electronic tables,
random numbers generators, graphical and geometric charts, and other tools available in a spreadsheet
environment comprise a non-genetically heterogeneous tool kit. As this paper demonstrates, such a tool kit can
bridge two traditionally advanced topics - transformational geometry and matrix algebra - using a variety of
tools that reveal a uniform cognitive effectiveness over the whole kit.

In what follows, a spreadsheet-enabled approach to understanding matrices as geometric
transformations is suggested. This particular approach is motivated by students' interest in learning about
fractals and self-similarity. Peitgen, Jürgens, and Saupe (1992) rely upon the metaphor of a Multiple Reduction
Copy Machine (MRCM) and the use of lenses in describing the encoding of fractal images. Here, the focus is
upon the matrix representations of lenses and the linear transformations that the lenses, in turn, represent. The
authors argue that linear transformations in the Cartesian plane can be easily represented via their effect on a
unit square, and, in turn, these resulting lenses are most efficiently represented as matrices. As such, the lenses
used in MRCM constitute a fundamental link between two-by-two matrices and linear transformations of the
plane. Using a spreadsheet-based tool kit of numerical, analytical, graphical and geometrical notations, one can
develop the conceptual links between transformational geometry and matrix algebra that are needed to fully
understand both topics.
In order to frame the mathematical ideas of this report, we will first establish the formal relationship
between the two topics, and then demonstrate how the tool kit described above can aid students in bridging
them conceptually.

Formal Approach

To formally build the link between matrix algebra and transformational geometry, we can construct a
two-by-two matrix to represent each linear transformation of the plane. This construction relies upon the
treatment of points in the plane as two-dimensional vectors on which the usual addition and scalar
multiplication are defined. First, consider that a line is defined by two distinct points \((x_b,y_b)\) and \((x_d,y_d)\) - the
first point indicates a base point and the second indicates a direction relative to the base point. Every other point
\((x,y)\) on the line is given by the point \((x_b,y_b)\) plus some scalar multiple \(t\) of the point \((x_d,y_d)\):

\[
(x,y) = (x_b,y_b) + t \cdot (x_d,y_d)
\]  

(1)

A linear transformation must take lines to lines. Thus, if the respective images of the points, \((x_b,y_b)\) and \((x_d,y_d)\),
under linear transformation \(M\), are known to be \(M[(x_b,y_b)]\) and \(M[(x_d,y_d)]\), then

\[
M[(x,y)] = M[(x_b,y_b)] + t \cdot M[(x_d,y_d)]
\]  

(2)

For now, let us put one more restriction on \(M\) by insisting that it fixes the origin:

\[
M[(0,0)] = (0,0)
\]

Note that removing this restriction yields an affine transformation - a linear transformation followed by a
translation. Thus, throughout this report, we will refer to linear transformations with translations as affine
transformations. By using equations (1) and (2), we get the following results:

1569
Thus, the image of every point \((x,y)\) in the plane is determined by the images of the points \((1,0)\) and \((0,1)\). To illustrate, let \(M((1,0))=(a,c)\), and let \(M((0,1))=(b,d)\). Then

\[
M((x,y)) = x \cdot (a,c) + y \cdot (b,d) = (ax + by, cx + dy)
\]

In other terms, \(M((x,y))\) can be defined in a matrix form using four parameters: \(a, b, c\) and \(d\):

\[
\begin{pmatrix}
a & b \\
c & d
\end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} ax + by \\ cx + dy \end{pmatrix}
\]

If we want to allow for translations, we can augment the above matrix by translations \(e\) and \(f\), in the \(x\) and the \(y\) directions, respectively. Finally, we have the following matrix representation of an affine transformation \(M\):

\[
\begin{pmatrix}
a & b & e \\
c & d & f
\end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} ax + by + e \\ cx + dy + f \end{pmatrix}
\]

We can also represent affine transformation \(M\) geometrically by considering the image of the unit square in the plane. Linearity of \(M\) will force this image to be a parallelogram, which exemplifies the combination of rotations, reflections, dilations, shearings and translations that \(M\) performs on the plane. Figure 1 illustrates an example of an affine transformation that includes a dilation, rotation and translation. The figure also includes labels with the notation mentioned above for matrix representations. While this figure is not part of the tool kit, it indicates a formal relation, through use of notation, between the two representations. An informal (activity-based) approach to this relation is the focus of the first part of the tool kit.

![Figure 1: Geometric representation of an affine transformation.](image-url)
Activity-Based Approach Using the Tool Kit

As an activity, we suggest that (prospective) high school teachers use the spreadsheet-based tool kit in the following manner. Sheet 1 enables the user to change the six parameters (a, b, c, d, e, f) of the three augmented matrices, each representing an affine transformation of the plane. We can make changes to each real-valued entry in a seemingly continuous manner (in increments of .01) using spreadsheet sliders. Also, the dynamics of such changes is interactively illustrated with spreadsheet graphics, which make it possible to generate a graph of the image of the unit square associated with each matrix (Fig. 2).

![Figure 2: Algebraic and geometric representation of dilation.](image)

The matrix in Figure 2 has entries a, b, c, d, e and f arranged in the conventional manner. We can immediately see the effect of these parameters in the graph of the unit square: the points (1,0) and (0,1) are scaled down to (a,b)=(0.5,0) and (c,d)=(0,0.5), respectively, and the origin is kept fixed at (e,f)=(0,0). Thus, the image of the transformation is the unit square dilated about the origin by one half. This image square illustrates that each point in the plane is scaled by one-half, which we can verify by performing multiplication of the matrix M by an arbitrary vector (x,y). We can use a similar examination to understand the transformation illustrated in Figure 3, except, this time, the origin is not fixed. Note that, according to Figure 3, the points (1,0) and (0,1) are mapped to (a+e,b+f)=(0.5+0.35,0+0.2)=(0.85,0.2) and (c+e,d+f)=(-0.3+0.35,0.5+0.2)=(0.05,0.7), respectively.

![Figure 3: Representations of a combination of dilation, shearing and translation.](image)

Next, students can analyze the values of coordinates of points (recall that these are being treated as two-dimensional vectors) under the transformation of matrix M1, M2 or M3 selected randomly at each iteration from the three defined in Sheet 1. The iterations are performed in Sheet 2 by "teaching" the computer to perform matrix multiplication. The formula used to do this is shown in the formula bar of Sheet 2 (Fig. 4). Teachers may find pedagogical value in having students examine this formula. Note, however, that the matrix entries are now listed as rows (rows 4, 5 and 6). The matrix to be used at each iteration is selected randomly as
indicated by the numbers in column C, beginning at C10. By tracking the images of the initial point \((x_0, y_0)\) after each iteration, we can observe that points are, in general, not revisited. In fact, the pattern as a whole appears very chaotic, as we may expect from a random process. However, the subsequent iteration of a few thousand points yields a nice set, which is due to the Chaos Game. The graph of the resulting set is displayed in Sheet 3 (Fig. 5), and it represents a very popular fractal known as Sierpinski's triangle.

Figure 4: The iteration of points by randomly selected matrices.

Sierpinski's triangle is the result of iterating among three matrices, all similar to the one displayed in Figure 2, except \(e_2=0.5, f_2=0\) for the second matrix, and \(e_3=0.25, f_3=0.5\) for the third matrix. The fractal can be constructed geometrically by repeating the following simple algorithm (Fig. 6): start with a triangle with base and height of length 1 and construct the midpoint segments creating four new triangles; delete the inner triangle and iterate on the outer three triangles. Note that the sketch in figure 6 is used to illustrate the algorithm, but is not part of the tool kit itself. To understand more about the results of the geometric process and our point-wise iteration by randomly selected matrices, we should consider the matrices themselves.

Figure 5: Point-wise generation of Sierpinski's triangle.

Each of the three matrices used for Sierpinski's triangle dilates points about the origin by a factor of one-half. In effect, given a point \(p\) in triangle A (created at an \(n^{th}\) iteration), matrices \(M_1, M_2\) and \(M_3\) without translation map \(p\) to a point in triangle \(B_1\) (created at the \(n+1^{th}\) iteration). Now, the \(e\) and \(f\) values of \(M_i\) translate this point to \(B_i\). As this process continues, points get deeper and deeper into the triangles created by the geometric process and ultimately approach points on Sierpinski's triangle.
Arguments like the one described above provide opportunity for insight into the workings of the Chaos Game. This phenomenon explains the dense distribution of points in Sierpinski's triangle that we have only begun to demonstrate. A more analytical argument might involve us giving addresses to points (see Peitgen et al) based on the various combinations of randomly chosen matrices. Indeed, the tool kit element displayed in Figure 4 could be modified to aid this analysis as well, but this is left to motivated readers. As further motivation, we can try to generate other interesting fractals by altering the given matrices, thus altering the transformations of iteration.

![Figure 6: Geometric algorithm for Sierpinski's triangle.](image)

**Closing Remarks**

This report illustrates how non-genetically heterogeneous tool kit mediates the unfolding of a fundamental relationship between matrix algebra and transformational geometry. The spreadsheet environment described here provides a meaningful and representational manner in which to explore and discuss these topics jointly, rather than separately. In such a way, it boosts the idea that the appropriate use of technology "blurs some of the artificial separations among topics in algebra, geometry, and data analysis" (NCTM 2000, p. 26). In fact, such artificial separation may lead mathematics educators to question the meaning of matrices outside the context of algebra. On the contrary, we propose a bridge, made possible by appropriate use of spreadsheets that would enhance meanings for both topics. Indeed, we can now view matrices as a useful notation and computation device in describing linear (affine) transformations, and can better see connections between transformational geometry and vectors. Moreover, the computation device can be motivated by and used for the generation of fractals in the plane. It can even be extended to perform in-depth analysis of point addresses in the fractals. The Excel file comprising the tool kit described here can be found under "Papers" at http://jwilson.coe.uga.edu/EMT668/EMT668.Folders.F97/Norton/Anderson.html.

Examining Pedagogical Trends within a Graphing Calculator Environment: An Analysis of Pre-service Teacher Perceptions

Dr. Elliott Ostler, Associate Professor of Mathematics Education
University of Nebraska at Omaha
United States
Elliott_Ostler@unomail.unomah.edu

Dr. Neal Grandgenett, Professor of Mathematics Education
University of Nebraska at Omaha
United States
Neal_Grandgenett@unomaha.edu

Abstract: This paper summarizes the findings of a research study designed to collect pre-service teacher perceptions on factors relating to the use of graphing calculators in the secondary math classroom. The study was designed as a way to help improve instruction in university mathematics methods courses. Data collected as part of the study addresses questions of how to overcome barriers of infusing graphing calculator technology in secondary math instruction, and how to create modeling and problem solving oriented activities that use graphing calculators, but still support a traditional textbook based curriculum. Results from the study suggest that greater emphasis on fostering creativity should be considered in mathematics methods courses. The target audience for this research paper include pre-service teacher educators in mathematics and science.

Introduction

Despite the current popularity of the new Process and Content Standards from the National Council of Teachers of Mathematics (2000), many teachers of mathematics tend to remain relatively passive in the implementation of new “Standards” based ideas. Although many traditional factors such as time and training constraints contribute to this phenomenon, it appears that the dynamics of classroom instruction emerges even more from a belief system related to the perceived demands of the traditional curriculum. New teachers in particular are highly impressionable when it comes to incorporating innovative ideas. Most appear to desire to try new ideas, but in many cases they feel bound to the lecture/seatwork model that is still so pervasive. Experienced teachers of mathematics are even slow to try new ideas because they believe that they must abandon necessary topics in order to include these new ideas as enrichment. In addition, instruction tends to be inefficient during the initial attempts at enrichment activities, which adds the threat of more lost time.

The question then becomes how to encourage teachers to incorporate new ideas and methodology while supporting the traditional curriculum. During a short brainstorming session with a group of pre-service math teachers, mathematical modeling and graphing calculator use quickly emerged as potential avenues for enhancing traditional instruction in very meaningful ways. Mathematical modeling and problem solving activities using graphing calculator technology have allowed for traditional curriculum topics to remain the focus while encouraging new ways of thinking about mathematics, as well as providing better contexts and reasons for learning it. However, neither mathematical modeling instruction nor graphing calculator instruction has been largely emphasized in the secondary classroom.

The Research Study

As a result of these observations, a research study was conducted in which pre-service mathematics teacher perceptions were collected related to the value of infusing graphing calculators into secondary level
This paper provides a summary of research data gathered from twelve pre-service teachers for the purpose of identifying instructional factors that would lead to conditions in which graphing calculator technology would be used more appropriately and to a much greater extent in the secondary classroom. The research focused on the perceptions of secondary level, pre-service mathematics teachers for several reasons. First, these students had very recently completed collegiate study in mathematics, which does not necessarily emphasize technology based learning environments; consequently, they were likely not to have preconceived notions concerning the use of graphing calculators. Second, all of the students had completed a field placement in secondary school classrooms where they were able to gather the opinions and perceptions of their field mentors. Finally, the views of these pre-service teachers were considered valuable because they were all enrolled in a university mathematics methods course. Information obtained from the research allowed the university to adapt course content and instruction in some very productive ways.

The primary focus of this research was to identify factors that make the calculators and other technology easily adaptable to the classroom, as well as determining the best ways to build mathematical modeling lessons that support existing curriculums. Three research questions were used as guides for the study: 1) what type of graphing calculator technology do pre-service teachers perceive as most conducive to current secondary mathematics curriculum and why, 2) What are pre-service teachers’ perceptions of current secondary mathematics curriculum in which graphing calculator technology would be most appropriate for inclusion in the instructional process, and 3) What are pre-service teachers’ perceptions of why graphing calculator technology is not commonly incorporated into the instructional process in a mathematical modeling or problem solving format in secondary classrooms.

Results

Results from the study indicated popular trends for all three questions; moreover, open-ended portions of the questionnaires focused on some very useful suggestions and strategies for how technology might be better infused into the curriculum, even for teachers who prefer a traditional format. Each of the research questions was addressed using an open-ended survey instrument and open dialogue from individual interviews.

Question 1: The TI-83+ emerged as the unanimous choice for most “user-friendly” graphing calculator based on several factors (top three listed): 1) Effective manual descriptions and examples, 2) most logical key sequencing and built-in menus, and 3) only a reasonably short learning time was necessary.

Question 2: The most appropriate course topics that emerged were at the intermediate algebra and pre-calculus levels and encompassed factors related to translations, reflections, and asymptotes for the base functions containing linear, quadratic, absolute value, trigonometric, logarithmic, and exponential components. Additional enrichment topics were mentioned for combining modeling with optimization as a central focus. These most commonly supported existing curriculum but focused on mathematical interpretation.

Question 3: The teachers felt (based on a variety of factors) that the primary reasons their field mentors did not use graphing calculators did not have to do with availability but rather a lack of time to learn the calculator functions. When asked what would influence them to use graphing calculator technology to a greater extent, the following responses emerged: 1) empirical evidence suggesting that higher student test scores would result from implementation, 2) all students in the class having access to the same model of calculator, 3) curriculum ready activities designed specifically to support textbook based curriculum.

Summary

Although these results are in no way exhaustive, they do provide some initial insights into factors that may help graphing calculator technology become more commonplace in the secondary mathematics classroom. Particularly valuable will be the leadership that these teachers provide once they have become established in their own classrooms. In addition, they themselves have gained special insights into the potential value of effective, focused uses of appropriate technology.
System Development and Fundamental Design of Interactive Mathematical CAI System “MEIKAI”

Masanori K. Shibata
Department of Information & Network
College Circle, Takanawa Campus
Tokai University
Japan
shibata@ttc.u-tokai.ac.jp

Abstract: Computers provide opportunities for users including both teachers and students to make knowledge, to gain access to knowledge, and to share knowledge with one another that are not possible before. Our projects consider system environments and minimum requirements for interactive Math CAI systems that must support to assist building students' preparation for the college-level mathematics, and set three basics for Math CAI system such as to keep track of study processes, have the exact interpretation for math symbols, and construct the dynamic curriculum organization. This paper shows brief description of Dynamic Curriculum Control, Algebraic Editor Ma and Easy-To-Use Authoring System.

This work was supported in part by the Ministry of Education, Science and Culture under Grant-in-Aid for Scientific Research No.06452383 and No.08458031.

Introduction

Private technical colleges and universities have to secure a certain number of students from the management point of view in Japan. Therefore those incoming students' mathematics backgrounds are varied. The Second Subcommittee of the Tokai University Consistency Educational Committee had questionnaires to ask university teachers and students what were in mind for basics and mathematical disciplines from secondary schools to tertiary schools. The analysis focuses on establishment of fundamentals and mathematical disciplines for incoming students. We discussed which mathematical concepts are important for various universities and colleges (Shibata '98). Reforming mathematics curriculum need to be concerned and personal computers provide opportunities for users including both teachers and students to make knowledge, to gain access to knowledge, and to share knowledge with one another that are not possible before. In recent years, awareness of the importance of Mathematical CAI system has increased in the school education. We have observed and tried to resolve the difficulties on Math CAI systems. The establishments of new educational perspectives give guidance to CAI systems' Development (Clements '89). The characteristics are WYSIWYW, WYSIWYG and WYWIWYG. Our interactive MATH CAI System, MACAI, proposed three basics such as Dynamic Curriculum Control, Algebraic Editor Ma and Easy-To-Use Authoring System.

Characteristics of MACAI

Our project, the development of MACAI system called “MEIKAI” in Japanese, considers system environments and minimum requirements for interactive math CAI systems that support to assist building of students preparation for college-level mathematics. Our major distinguishing feature among CAI designs is that MACAI should be able to keep track of learning processes, have the exact interpretation of math symbols, and give the individual curriculum organization. The Easy-To-Use authoring system has Text Editor that consists of Algebraic Editor Ma, Simulation Editor, Exercise Editor, Help Editor, and Scientific Language for Geometry, SLanG, based on regular expressions. In the user system, Text Reader that students are able to study based on Dynamic Curriculum Control also has these editors. As the other functions there are preparation windows for students' making and submitting reports under LAN environments. We observe their learning processes and accumulated points by three tables of Students-Points, Time-Points, and Time-Progress. For the authoring and user systems as a new user interface design we introduce MCA, Model and Control Agent, which is enhanced
MVC model from Goldberg (Goldberg '83). Hutchins classifies user interfaces from two axes, Distance-Engagement (Hutchins '86). We introduce Distance-Concurrence as a new user interface classification and furthermore Compatibility-Flexibility evaluation design for CAI contents.

Dynamic Curriculum Control controls the direction of each learner on the CMI Hub Flows that we have established are called the Adaptive Search based on the Genetic Algorithms. The original curriculum DB contains four different levels of contents on the same subject in the MACAI system. The individual curriculum for each student can be chosen from the DB, and set parameters for the allotment of points. The accumulated points determined the course among these contents on Hub Flows. The Algebraic Editor Ma, which provides the consistency of mathematical symbols and formulae, keeps the mathematical meanings of symbols and best human interpretation for the algebraic system Mathematica through the Math Link and the Tex System. In Easy-To-Use Authoring System, SLanG is the two-dimensional turtle graphics language on the WINDOWS system by using the regular expressions for the simple geometric figures such as regular polygons. The SLanG, which we have developed, is able to choose from two coordinate systems such as xy-coordinate system and non-coordinate system, change the turtle moving speed, paint the designated territory, and draw regular polygons and ellipses which could not be drawn by conventional graphical applications. This is our purpose to provide a strong support for mathematical CAI systems. Simulation Editor can draw figures in the first year university mathematics, and also numerical solutions of linear systems of equations, numerical integration, evaluation of matrices and determinants, linear regression, Lagrange interpolation, and statistics. Therefore we can change the three tools such as Mathematica, Simulation Editor and SLanG of drawing figures to suit the occasion. As a result of that, we were able to apply for patents on December in 1996 and as CAI software with the indispensable CMI and the MCA new interface Control Agent Model on October in 1998. Furthermore SLanG presented on our Internet home page for your convenience. The Handwritten Recognition was also considered especially for mathematical symbols and formulae (Sugamoto & Shibata '98). The research result were released and explained in detail at the Science News in Japan.

Looking to the Future

To make the interactive electronics book is so expensive. For instance we still need more than several hundreds thousands dollars to complete our project and need to build up a network of supporting groups or organizations. Also the Microsoft upgrade versions were inferior goods such as some upgrade versions did not cover old versions. Therefore every time we have to reconstruct our system programming and pay more money. To get rid of these difficulties we need a new OS and a free language not depending upon Microsoft to construct shell systems and agents for CAI systems. Web version using Java would be the one, and the effective use of programmable calculators could be an alternative.

Making Sense of Number: A Resource for Pre-service and In-service Education

David K. Thomson
Faculty of Education, The University of Edinburgh, Scotland
david.thomson@ed.ac.uk

Tony van der Kuyl
Faculty of Education, The University of Edinburgh, Scotland
Tonyv@ed.ac.uk

Abstract: This paper reports on the development of a multi-media/web/cd package which provides users with opportunities to consider issues in the teaching and learning of numeracy in the early years of elementary school. By viewing exemplifications of classroom activities and listening to commentaries from teachers, children, school managers and parents, users are invited to reflect on and critically evaluate their own practices and contexts. The package also provides a basis for the establishment of an on-line learning community where ideas and resources can be shared and issues discussed.

Background

The latter half of the 1990s saw a fundamental re-examination of the psychological and philosophical bases of elementary mathematics teaching in the UK. During the previous 25 years the influence of the developmental model of learning, principally associated with Piaget, was all-encompassing. Teachers were encouraged to construe their role as that of facilitator or enabler in contrast to their traditional role as instructor. Mathematics lessons virtually ceased and were replaced by small group and individualised work, often based on the completion of fill-in worksheets, supported by the use of manipulatives (reflecting Piaget’s contention that children under the age of 7 are typically incapable of logical thought and therefore require concrete models to make a bridge to the abstract processes inherent in number operations (Piaget 1952). For some years, however, there had been an increasing body of research illustrating young children’s possession of many and complex abilities (Donaldson 1978) (Hughes 1986).

The arguments of those who favoured an earlier and more interventionist approach to the teaching of rational counting at the expense of Piagetian pre-number activities such as sorting and matching, (Merrins 1996) (Thompson 1997) were given credence by the increasing evidence from a number of sources, of declining standards of achievement in basic numerical processes by children in Scotland and England.

In England, a reaction to this has been the establishment of the National Numeracy Strategy which has published a detailed (some would say prescriptive) Framework document (DFEE 1999) which promotes the teaching of mental strategies and advocates a delay in the introduction of standard written methods of calculation. The Framework also provides exhaustive lists of learning targets for students in each year of schooling.

In Scotland, it is recognised that the national curriculum guidelines in mathematics (SOED 1991) are somewhat obsolete in terms of their content and expectations of students. The Scottish Executive, however, sensitive to teachers’ oft expressed feelings that they have been subject to a surfeit of innovation, has decided not to review the guidelines immediately and has instead provided only a series of worthy but general suggestions about changing practice. This is the educational vacuum that Making Sense of Number seeks to fill.

Making Sense of Number
The goal of *Making Sense of Number* is to inform and enhance the teaching of numeracy in kindergartens, elementary schools and pre-service teacher education programmes. This action research-based multimedia/web/cd package is designed to illustrate effective learning, teaching and assessment and to provide information about specific activities and resources. It is intended to provide a framework for discussion and development rather than to be used as a manual for teaching.

The national publication, *Improving Mathematics Education 5-14* (SOEID 1997), based on evidence obtained from HM Inspectors reports, the Assessment of Achievement Programme Survey (SOEID 1996) and TIMSS international comparative studies (SOEID 1997), summarised the Scottish situation concerning standards of student achievement and teaching practice in mathematics. The report focused attention on several areas of concern and recommended the following:

- relatively more time to be devoted to teaching number within the overall mathematics curriculum particularly at the early stages
- greater emphasis to be given to mental calculation and particularly the teaching of appropriate and flexible strategies
- teaching to be more interactive/participative, with fewer groups,
- schools to raise expectations for student achievement including, where appropriate, increasing the pace of progression through mathematical topics specified in national curriculum guidelines
- schools to further acknowledge the potential role of home learning and to encourage the active participation of parents.

*Making Sense of Number* deals with these issues in a variety of ways, it provides both a structure to help teachers think about and plan the teaching of number and a supporting resource for staff development in this area. It has been designed to enable school and pre-school managers, teachers, student teachers and possibly auxiliary staff and parents to view the types of resources and approaches used in schools actively developing numeracy programmes.

'Making Sense of Number' gives practical help to teachers in identifying useful activities and resources and in assessing learners' progress. By observing the real teachers and children featured in the package, users are encouraged to reflect on their own practice and to relate what they see to their particular classroom or school context. Schools across Scotland were used as sources of the extracts. The package contains some pointers raised from schools who have implemented numeracy programmes over a longer period and who have addressed the implications for later primary years of early intervention (e.g. the impact of an emphasis on the development of mental strategies on the teaching of written methods and the role standard algorithms).

The package also anticipates and facilitates the establishment of an on-line numeracy learning community (via a dedicated website) where 'experts' can be consulted, ideas and resources can be shared, common issues discussed and action research projects and evaluative/qualitative studies developed. It also provides the basis for national training programmes in numeracy as it delivers a consistent message regarding the key principles underlying successful numeracy teaching. While its main anticipated audience is teachers and student teachers, it could also be used under teacher guidance to inform and train support staff such as nursery nurses and classroom assistants and to help parents understand what schools are seeking to achieve.

Abstract: Integrating CAI into the math curriculum is a challenging process. Computers change the way teachers teach and the way students learn. The learning process is affected by a combination of factors; for example, learners' attitudes toward math and computers, learners' computer skills, quality and the suitability of the computer learning system, and the way the instructor conducts the course and interacts with the student. This study is designed to explore factors affecting the Guam Community College students' math learning experiences via CAI interactive learning system. The primary instrument for this study was a modified survey questionnaire. In order to gain a fuller insight into the students learning process, the data for this study were also drawn from other sources: (1) student interview; (2) faculty interview; (3) classroom observation; (4) documentation such as student drop-out rate and grades.

Background of the Study

The island of Guam is the U.S. unincorporated territory in the Western Pacific Rim. It is located between Hawaii and the Philippines. Guam is the largest and most heavily inhabited of the Marianas Islands with a population of 146,000. In addition to the native Chamorro people and "mainland" Americans, Guam hosts many diverse ethnic groups including Filipinos, Chinese, Koreans, Japanese, Pacific islanders from Saipan, Palau, the Marshall Islands, and the Federated States of Micronesia including Pohnpei, Chuuk, Yap, and Kosrae.

With 85% to 90% of college students forced to take remedial math, clearly, students in this region are mathematically challenged. To counter this problem, the Guam Community College introduced interactive multimedia computer-based instructional software into their math courses.

Perspective

The application of CAI in the area of math has nearly as a long history as CAI itself. The earliest attempt to use CAI to teach math was initiated in mid 1960s. Recent years have seen an increasing use of CAI in mathematics instruction, impacted significantly by rapid advances in computer technology. Research indicates that CAI is most effective when it is targeted to disadvantaged groups such as low achievers and at risk students.

Integrating CAI into the math curriculum is a challenging process. Computers change the way teachers teach and the way students learn. The learning process is affected by a combination of factors; for example, learners' attitudes toward math and computers, learners' computer skills, learners' confidence level in learning math and computers, learners' learning styles, the quality and the suitability of the computer learning system, and the way the instructor conducts the course and interacts with the student. This study is designed to explore factors affecting the Guam students' math learning experiences via a CAI interactive learning system.
Significance of the Study

This study was inspired by several major concerns related to CAI research.

(1) Although a substantial CAI research in math is available in the literature, most CAI research was conducted in the 1980s. There is a need to renew CAI research, taking into consideration that CAI learning systems have made tremendous progress qualitatively in recent years, equipped with sophisticated features not even conceivable a decade ago. "This need is emphasized and reinforced by the increasing use of technological devices in mathematics instruction" (Galbraith & Haines, 2000).

(2) Major CAI work has been concentrated in the four countries: the United States, the United Kingdom, Canada, and Japan. There is no CAI research conducted in this region, targeting this particular ethnic group. The subjects for this study are Pacific islanders on Guam with the majority of them being local indigenous Chamorro students.

(3) Most CAI research was conducted in elementary or secondary schools. "There are still many unanswered questions about the effectiveness of CAI for post-secondary students" (Owens & Waxman, 1994, p. 328). This study was conducted on the campus of a community college. As the result, this study will contribute to the literature in the area of post-secondary students' experiences learning math in a computer environment.

(4) This review of the literature reveals that CAI research in math is limited in utilizing multiple research methodologies. Most research involved one research methodology, either a qualitative method or quantitative method. The present study employs a combination of research methods to gain an insight of the post-secondary students' math learning experiences in a computer environment. The research methodologies in this study include a survey questionnaire, classroom observation, student-researcher e-mail communications, face-to-face interviews with students and the instructor.

(5) Last, but not the least. The previous studies tended to study learners' attitudes towards CAI as an isolated phenomenon. Factors that impact learners' attitudes towards CAI remain largely unexplored. This study investigates the determinant factors that impact the learners' attitudes towards CAI and introduces a new conceptual framework to explore the complicated interaction of computers, math, and learners.

The Design of the Study

The primary instrument for this study was a survey questionnaire. A portion of the questionnaire was adapted from the Mathematics-Computing Attitude Scales developed by Peter Galbraith and Christopher Haines (2000).

The survey questionnaire contains nine sections; (1) demographic information (e.g. ethnicity); (2) math confidence (e.g. Math is always a difficult subject for me.); (3) math motivation (e.g. I'd rather spend my time and efforts learning subjects other than math); (4) computer confidence (e.g. I expect to do well if I take a computer course.); (5) computer motivation (e.g. Once I start to work with the computer, I find it difficult to stop.); (6) math learning styles (e.g. When learning new mathematical material I make notes to help me understand and remember.); (7) math-computer interaction (e.g. Visualizations on the computer help demonstrate math concepts.); (8) computer math learning environment (e.g. The computer reduces the necessary interaction between the student and the math instructor.); (9) evaluation of the CAI math learning system (e.g. This software explains and presents math content logically and clearly.). Except for section 1, all the other sections contain 10 items on a Likert scale (1-5).

Mean for each item (except for section 1) will be calculated and the group mean for each section (except for section 1) will be calculated. Factor analysis will be conducted to identify to what extent each factor correlates with math-computer interaction and computer math learning environment.

In order to gain a fuller insight into students learning experiences, the data for this study were also drawn from other sources: (1) student interviews (e-mail interviews and face-to-face interviews); (2) faculty interviews; (3) classroom observation; (4) documentation such as student drop-out rate and grades.

Data collection will span over a period of three semesters. Final report of the study will be completed in the fall of 2001.
Abstract: The purpose of this project is to develop a CDROM to address the numeracy problems faced by many adult learners. The CDs will help adults improve their numeracy skills in whole numbers and in fractions. By using multimedia, users will be able to overcome a number of barriers facing adults with low numeracy skills. Most of the learners returning to the classroom feel they simply cannot do math. The traditional style of education did not work for them in the past and by presenting the material in an innovative, interactive environment with audio and visual presentations, we offer these learners a new beginning and added incentive. The programs are interactive and use a step-by-step approach to math, simple language, and specific learning guides.

Acknowledgments

The development of the Numeracy CD was supported by a grant from the National Literacy Secretariat of Canada, and funds from SIAST Education Equity. The development of the Numeracy II CD was supported by the Department of Post-Secondary Education and Skills Training, Government of Saskatchewan.

Introduction

Our CDs are being developed in response to requests by educators for material to help teach basic math skills. Literacy levels for many adult learners exceed numeracy levels. Lack of understanding of basic number concepts and the inability to do math computations leave adults in a very difficult situation. Improved numeracy skills are vital to achieving independence and economic goals. Mathematics is a subject that builds on itself and if the basic skills are not there for the foundation, success is difficult to achieve. Our CD programs prepare learners for work-based training opportunities. They are seen as a companion to existing education programs and a bridge to further studies in math.

Learners need a great deal of rehearsal and repetition. CDROM delivery facilitates this well. It directs students who have mastered the concepts to move on quickly and reroutes those having difficulties to a review of the material. The self-instructing and self-paced style of the CDs provides increased flexibility for students and instructors. The programs teach basic math skills, so the content will not change, making it a cost-effective tool.

The scope of this project is broad, both in prospective clients and in areas of use. These programs can be utilized in the areas of literacy, corrections, equity, and remote schooling programs. These CDs are a valuable resource for people with learning disabilities, ESL students, slow learners, youth at risk, remedial learners, and corrections inmates. They can be used by learners in Basic Education, and students in Competency Based Education programs needing to upgrade their math skills in courses such as carpentry, cooking, welding, and mechanics. The universal content and nature of the storylines make the CDs appealing to children and young adults, furthering the field of applicability. The multimedia approach accommodates the diverse needs of learners on campus and in alternate settings, such as home, communities, and the workplace.
Numeracy CD

Objectives

- Create an interactive CD program, focused on whole numbers, which uses a step-by-step approach, simple language, and appealing graphics.
- Develop a CD that helps students understand ten basic concepts in whole numbers, concepts vital to understanding and working with numbers.
- Develop a CD that helps students understand how to add, subtract, multiply, and divide whole numbers and apply this knowledge to word problems.
- Provide students and instructors with an additional learning resource that can be easily accessed and allows flexibility with its self-instructing and self-paced style.
- Develop tutorials, drills, practice, tests, and learning aids to achieve the desired outcomes.
- Teach the use of a calculator as part of the process.
- Make learning basic numeracy skills enjoyable.

Outcomes

- Students will have an understanding of ten concepts in whole numbers.
- Students will be able to apply these concepts to real life situations and be able to use the operations in everyday problem solving.
- Students will be able to use a calculator and will acquire basic computer skills, skills necessary in the majority of employment opportunities.
- Students will have increased their self-esteem through the development of math skills that have eluded them in the past.

Description of Numeracy CD

The program teaches whole numbers and consists of two parts. The first part explains ten concepts that are important to understanding whole numbers. They are: place values, standard and expanded, rounding, averages, odd and even, greater than - less than - equal to, exponents, prime and composites, order of operations, and Roman numerals.

The second part of the program focuses on the four operations of addition, subtraction, multiplication, and division and includes a unit on word problems to help students learn to choose the correct operation and to solve problems, relating to everyday situations.

The student accompanies George on a journey through the jungle to help save a village facing grave peril. To complete his journey and overcome the obstacles along the way, George must understand whole number concepts. There is a pretest at the beginning of each unit to assess prior knowledge and if understanding of the concept is verified, the student continues to the next unit. If not, the student works through the unit with instruction being provided by a wise parrot named Pinkerton. Numbers, his monkey, provides assistance and comic relief. Practices are included after each idea is covered. If the student demonstrates competence on the practices, he goes to the unit test. If mastery is not evident after a practice or after the test, the student is returned to the instruction section. As George and the student progress through the instruction for each unit, hint charts are established. These charts give an outline of the concept being learned or the steps to follow in order to complete an operation. The student can access each chart by clicking on a toggle switch. A calculator and timestable are built into the program and available to the student by a click of a button. Each unit follows a similar pattern to make the program easy to follow and the instruction is clear and concise. The text on screen is kept to a minimum, with only very important information appearing for clarification. Audio is used extensively to keep the student progressing at a good pace. The program is interesting and entertaining, keeping the attention of the student.

Numeracy II

Objectives

- Create an interactive teaching CD program, focused on fractions that uses a step-by-step approach, simple language, and appealing graphics.
- Develop a CD that helps students understand fractions and use this knowledge to perform the four operations of addition, subtraction, multiplication, and division and then to apply their knowledge to ratio, proportion, scale, probability, and metric measurement.
- Provide students and instructors with an additional learning resource that can be easily accessed and allows flexibility with its self-instructing and self-paced style.
- Develop tutorials, drills, practice, tests, and learning aids to achieve the desired outcomes.
- Teach the use of a calculator as part of the process.
- Make learning basic numeracy skills enjoyable.

Outcomes

- Students will have an understanding of fractions and be able to add, subtract, multiply, and divide fractions.
- Students will have an understanding of ratio, proportion, scale, and probability.
- Students will be able to use both standard and metric measurement.
- Students will be able to apply these concepts to real life situations and be able to use the operations in everyday problem solving.
- Students will be able to use a calculator and will acquire basic computer skills, skills necessary in the majority of employment opportunities.
- Students will have increased their self-esteem through the development of math skills that have eluded them in the past.

Description of Numeracy II CD

The program teaches fractions and has three parts. The first part focuses on understanding fractions. The introduction helps the student to understand fractions, read and write fractions, name the parts of a fraction, and identify the different kinds of fractions. The student learns the concept of equivalent fractions and how to establish equivalency. To manipulate fractions, the student learns how to raise and reduce fractions, compare fractions with like and unlike denominators, and change fractions from one form to another.

The second part of the program then focuses on the four operations of addition, subtraction, multiplication, and division and includes word problems to help the student learn when to use each operation. Each section includes the basic skills necessary to work with fractions in all different forms. The word problems relate directly to everyday practical issues.

The third part of the program utilizes fractions to teach ratio, proportion, scale, probability, and measurement. As part of ratios, the student deals with measurement, time, and money. In the proportion section, the student uses ratio and cross products to find unknowns and to use this knowledge in comparisons. Scale is taught using proportion, and map scale is part of the application. Ratio is used to explain the concept of probability. Measurement includes understanding and using both standard and metric units and applying this knowledge to drawing plans and construction.

In Numeracy II, the learner accompanies a young Aboriginal woman on a journey of discovery through the North where she experiences the beauty of the country, learns about the native plants and animals, and discovers ways to overcome obstacles she faces along the way. In the same way that she learns the ways of nature, she comes to understand fractions, learns how to work with them, and applies her knowledge to solve problems involving fractions. The girl's grandmother accompanies the girl on her journey and provides the instruction.

The Reasons

I have instructed in a literacy classroom for ten years. Although the makeup of each class was different, I faced certain similar challenges each year. There was always the challenge of teaching a group of adults from very different backgrounds and with very different skill levels, without holding some back and leaving others behind. Then came the challenge of teaching math to unwilling learners. Most students entering my class felt they simply couldn’t do math. Math was a mystery, a subject with a million rules that they didn’t have a hope of learning. They hated math and the barriers were up. The reading level in most books was too high, and the problems contained words and ideas that were unfamiliar and irrelevant to the students. The traditional style of teaching had not worked for them in the past. How could I subject them to more of the same?

I needed to find a way to teach math so that it became part of the student’s lives, it had relevance, and the stigma was removed. Math skills are essential for everyday living, and most of my students lacked even the basic math skills. I needed to find a way of making math fun for the students. I became an entertainer. I made up stories, I drew pictures, and I created situations that put the students in the problem that needed solving. I tried to show the relevance of math in their lives and the need for an understanding of basic math concepts. The students enjoyed the learning and began to lose their fear of math. They began to make slow, steady progress and their self-esteem grew.

A second teaching method that worked well in class was the use of computers as a teaching tool. Introducing my students to a computer opened a whole new world for them, giving them freedom to explore and confidence in their ability to learn new things. They took great pride in any work they produced and worked diligently to get it done. However, it was difficult to find material at a basic level. Either the programs overwhelmed them with text, or were geared toward children. The most glaring error in most math programs, was the assumption of prior knowledge. Most of the students couldn’t work through the programs because they lacked certain skills that the program assumed they had.

The Results

Armed with a love of math and an understanding of what is required to have students succeed in the basic skills area, I began the task of creating the material for the development of CDs to teach basic math skills to adults. I tried to follow the methods that had worked in the classroom. The CDs entertain. Each CD tells a story, using characters with which the students can associate, and situations that put students in a problem that needs solving. There are wonderful graphics that are a fundamental part of the CDs, adding clarity and visual reinforcement to the instruction. The instruction is clear and concise, using small steps and many examples with relevance to the students. The programs demonstrate patterns for learning and outlines steps needed to work with each concept.

To overcome the reading barrier, text is kept to a minimum and is accompanied by audio. The audio component reduces difficulties created by reading deficiencies, reinforces the instruction, and appeals to auditory learners. The voices interact on the CDs rather than simply reading the text, adding to the students’ enjoyment.

The programs have a calculator built into the programs. The student can use the calculator to perform basic math operations by using the mouse to click on the keypad on screen. There is a timetable for those students who cannot memorize math facts, accessed by a click of a button. There are hint charts in each unit, built as the instruction proceeds and accessible for the remainder of the program. These charts allow the students to review steps and procedures at any time. Rather than memorization, the focus is on understanding concepts and operations.

These programs provide one-on-one interaction and allow students to proceed at their own speed. The interactive aspect encourages student participation and gives students a feeling of ownership of their learning. Integrating technology and math instruction, with stories and graphics, can be a powerful way to teach and reinforce basic skills.
Technology and Basic Math Skills

Abstract: This paper intends to report on a variety of innovative ways to utilize technology in teaching basic math skills and to motivate students in mastering the basic skills. Teachers will be able to turn so-called boring practice routines into interactive enjoyable learning experience for students to learn the basic concepts necessary for further exploration in the depth of mathematics, therefore to lay a solid foundation. Our experience also showed us that using technology in teaching does not mean simply putting students in front of the computer. The instructional materials have to be carefully designed which will provide opportunities for authentic learning, hence to achieve the outcomes that are expected.

As science and technology have come to influence all aspects of life, mathematics has come to be of vital importance to the educational agenda of our nation. Mathematics is the foundation of science and technology. However, there is a cry for reform in math education because of the poor performance of our students at all levels. It is time for all educators to examine what we are teaching and how we are teaching.

Traditional mathematics teaching is still the norm in our nation's schools. For most students learning mathematics is an endless sequence of memorizing and forgetting facts and procedures that make little sense to them. More and more students go into remedial programs that may assist them to obtain their basic math skills. However, the results have not been so impressive. Teachers are facing serious problems and concerned about the poor math skills that may directly impact students' future career and even the quality of their life.

Math anxiety is a widely spread and accepted reality. While many people won't openly admit that they cannot read, they readily admit that they are not good at math. As a result our children have an excuse for poor performance.

Many studies have showed that computer technology has positive impact on learning mathematics among k – 12th students. The dynamic and interactive capability of various computer software packages can improve the somewhat static environment that had traditionally existed in classrooms using paper-and-pencil procedures and routines. Technology assisted mathematics activities provide students with an opportunity to explore an even wider range of mathematics problems that ever imagined, and it allows students to visualize the connections among various mathematics topics. Computer technology makes it possible to create a situation in which a graphing utility can be used to enrich the investigative environment for learning mathematics.

The National Council of Teachers of Mathematics (NCTM, 1991) promotes student use of technology to model real-world phenomena that possess a variety of interpretations. Implementation of technology in the classroom can help shift the focus of mathematical ideas from computations and manipulation to modeling and representation of functions or other phenomena in the real world. Mary C. Enderson (1997) in her paper of “Old Problem, New Questions” discusses her experience of teaching students mathematics using computer technology. She believes, “A computer can help eliminate obstacles in doing mathematics – particularly problems involving formulas and calculations.” (p32).

More evidence shows that computer assisted instructions (CAI) hold a great deal of promise for providing mathematics instruction to all students, especially to those who suffer from mathematics anxiety which may well be caused by their poor performance in learning mathematics. In addition of offering individualization and flexibility, CAI is impartial, reinforcing, appeals to students' interests, and also offers a sense of privacy for students who are concerned about their performance (Wittman et al. 1998).

Computer technology can positively impact students' learning of basic math skills because it can provide visual effects which can assist learning of better understanding the SEQUENTIAL OPERATIONS.
math concepts, therefore they may better apply these math skills learned at school in their real life. Technology used as an effective teaching tool in mathematics education will provide students with opportunities to practice basic skills in an interesting and enriched way, to solve complex and challenging problems, to combine reading, writing skills and communication skills in exploring, discussing and formulating the validity of personally constructed mathematical ideas so that students can draw their own conclusions. Students can use visual aids, drawing, graphics and real-life objects to convince themselves and their peers of the validity of their solutions.

Approximately 104 students in sixth, seventh and eighth grades who have been assigned to participate in the remedial math lab participated in a fourteen-week study. Their selection is based on three criteria: their teacher’s recommendation, their last year declining performance and their MAT (Metropolitan Achievement Test) scores (below 21 percentile). These students were not qualified for any special education programs. They were placed in the remedial math lab in an addition to their regular math class to assist them in mastering the basic skills within a semester. Besides attending regular math class everyday, all participants were in the math lab daily for 45 minutes. The students were randomly assigned into one of the two groups. Both groups used a software application on Apple II GS computers for drill and practice to raise the competency level in the areas of addition, subtraction, multiplication and division. The control group used the traditional method, textbooks, paper and pencil exercises and worksheets, while the experimental group used Internet as a practice tool and a multimedia application Astound 2.0 on Macintosh computers. The concepts involved were Surface Area of a Cylinder, basic math facts, subtraction and division problems of 3 or 4 digit numbers.

A Criterion-Referenced test was used to evaluate the growth of students’ basic math skills. This set of tests was designed to be used in the district to measure student achievement on the goals set by the district. The evaluation instrument was established by a committee of math teachers within the district, which was comparable to other established instruments to ensure that bias was neutralized and content was sufficient. The test results from this study showed that among the sixth and seventh grade students, the experimental group average criteria-referenced pretest score was 18.75 and the posttest score was 41.63 with an increase of 22.88%. The control group average pretest score was 16.93 and posttest score was 38.22 with an increase of 21.29%. There was some improvement in the MAT test scores in both groups but there was very little difference between the two groups. The average pretest score for the eighth grade experimental group was 37.77 and the posttest average score was 51.05 with an increase of 13.28%, while the pre- and posttest averages in the control group were 40.57 and 45.48 with an increase of 4.91% respectively, which shows significant difference between the experimental group and control group.

It would be difficult to say that there were significant differences in the improvement of basic math skills between the two groups of the 6th and 7th graders even though the growth in each group was noticeably significant. There was, however, an obvious attitude change among the students in the experimental group according to the teacher’s observations. The students enjoyed working on the computers to present the problem-solving strategies and to share their experiences with their classmates. They showed more enthusiasm in learning math skills. The one important lesson we learned as teacher educator and classroom teacher is that simply putting a student in front of a computer does not equate with integrating technology in a math curriculum. Desirable learning outcomes from technology-based learning cannot be realized in the absence of meticulous planning, identification of appropriate resources and materials, and carefully organized presentations dedicated to leading the students through the entire problem-solving process.

An On-Line Math Problem Solving Program That Stimulates Mathematical Thinking

Jiannan Y. Zhang, Hollywood Elementary, MD, jyzhang@mail.ameritel.net
Leping Liu, Towson University, lliu@towson.edu

Abstract. This paper presents a case study in which the authors developed a Web-based instruction (WBI) unit—an on-line interactive math problem-solving program, and explored the means of using this WBI program to stimulate young children’s mathematical thinking and develop their skills of and interests in solving mathematics problems.

Problem solving is a primary objective for math effective learning, and a required proficiency in real life. Instead of spending a high proportion of instructional time in practicing basic algorithms for the four operations, teachers need to use problem-solving to address computational needs (Peterson et al., 1989); not only teaching how to start from a middle point to computer with an equation, but also how to proceed from a beginning line to write an equation using the given data. Problem solving process becomes more and more imperative, especially when technology assists students in computation fluency and accuracy. A calculator does not solve a problem; a human with a calculator does.

Word problems bring various real life situations to a math class, and encourage the students analyze and interpret information as the basis for a solution. Poor reading and comprehension of word problems, and lack of good strategy use are two main causes of the students’ inability in problem solving. (Benko et al., 1999) To lead students to deeper understanding and to avoid depending on cues words, researchers suggest using indirect language (Pawmar, Cawley & Frazita, 1996), i.e. word problems without direct cue words.

A schema is involved when students attempt to understand semantic relationship in a problem (Riley, Greeno, & Heller, 1983). Seven types of word problems are found under the four operations (Vandewalle, 1998). In this program, they are simplified into four types, and further developed into 11 categories.

Table: Semantic Structures of Word Problems

100 math problems were developed without direct cue words, divided into the four basic operations, and further sorted into 11 categories at three difficulty levels. Studying the semantic structure and recognized characteristics of the known and unknown information helps students understand the relationship among the numbers involved in word problems, and discriminate between operations required to solve word problems.

The KWHL format is used to organize the data. Students analyze the given information—I know, find the goal—I want to find, choose an appropriate operation—how I can find, and write an equation—I have learned. The above process follows the five-step word problem attack strategy, i.e. to recognize the problem, analyze and organize the data, devise a plan, do the computation and check the answer (Howell & Barnhart, 1992). Additionally, using the KWHL format encourages multiple reading of the problems and prolongs mental attention to their semantic structures (Benko et al., 1999). Research shows that US students tended to favor verbal statements over mathematical expression, and less sophisticated methods of solution, e.g. using addition instead of multiplication (Silver et al., 1992). Adopting semantic structures can also promote students’ mathematical expression and encourage them to choose more effective operations.
Next was to set an active learning environment and choose an appropriate way to deliver these problems to students. The authors determined to create a drill program on the Web for students to construct math problem solving skills. First, Web is the multimedia portion of the Internet that delivers information interactively from different media—text, sounds, graphics/animations, pictures/movies or information from other Web sites. As suggested by previous research, such learning environment enables young learners to be more motivated and active in their learning. Second, the authors hoped that larger population of students could access this program. There were many multimedia authoring tools, such as ToolBook, Director, or HyperStudio, that could be used to develop this program. The problem is, however, most classrooms did not have the expensive multimedia software. In today's schools, the most convenient and least expensive tool is the Web—a Web browser and Internet access. Therefore, the on-line drill program was designed as a WBI unit, and delivered as a Web site. Microsoft FrontPage was used to create all the pages.

The program was structured into the 11 categories and three difficulty levels. Basically, this math problem-solving program gives one problem in one page, with text, graphics, and colors. The “thinking processes” of solving each problem were provided in a list of “fill-in-blank” sentences, and a list of answer options. The answer/solution of the problem can be multiple choices or text-input. The feedbacks to the answers were provided and the learner has the option to try several times until he/she reaches the correct answer. The program was designed in a non-linear approach, navigating by categories and difficulty levels. Learners/teachers can select appropriate problems for their learning/teaching purposes.

The math problem-solving program has been used with elementary students. The children started to use this program with specific learning goal, that is, the students would be able to write correct equations to solve different word problems, involving addition, subtraction, multiplication and division. The authors have been observing the eight children's performances focusing on how they (1) organize data using KWHL format, (2) choose correct operation, (3) write correct equations, (4) compute correctly, and (5) answer the question in a complete sentence. Their interaction with the program was another observation focus. The screen design, use of objects, orientation and navigation of the program, to certain extent, attracted children's attention, and influenced the speed of their problem solving. Since the set of problems was designed reflecting the process of mathematical thinking, it is assumed that the on-line program could stimulate this mathematical thinking process. Their performances showed a clearer path of thinking during the process of solving these problems. Also, informal interviews were conducted before, during and after their performances. Children's interests in mathematics problem solving were increasing with the use of the on-line program.

The current case study was the preliminary part of an on-going project, which is extending to a larger population. An experimental design is suggested for further study. The implementation of the program is suggested to include the use of an authoring tool such as Hyperstudio, which could be converted into a HTML version and delivered through the Web.

References

As an educator in the field of instructional technology, I am often challenged by deciding what technology skills and software should be added to the courses in our graduate program. I’ve found that the papers in the New Media section of the SITE Annual are good predictors of future trends in technology. This year is no exception! I’ve organized the papers in this section around four themes involving several aspects of multimedia: Digital Audio and Video; Research in Specific Multimedia Technologies; Multimedia Portfolio Development; Innovative Multimedia Projects, Tools, and Software; Technology Collaboration of Students and Teachers; and Course and Instructional Model Design and Development.

**Digital Audio and Video**

This year, the New Media section contains five papers that describe and document different methods of creating and integrating audio and video into teaching. As the technology for capturing and editing audio and video becomes simpler, the growth of these enhancements in teaching and learning environments will flourish. Many of these authors include product descriptions as well as practical guides for creating and using audio and video in educational settings.

Bauer and Bauer present a brief overview of the advantages of audio as an instructional medium. The authors also discuss information about basic audio capturing and editing, and include recommendations for processing audio for both Web and CD-ROM development. Specific information about software tools and program is also detailed.

Yao discusses the differences between traditional video and digital video and examines the current technology. Yao also includes a step-by-step guide on how to create digital video and provides educators with practical suggestions of how to create digital video economically and effectively.

Handler, Benavides, Morgan and Houghton, a group of Apple Distinguished Educators, describe an interactive session at SITE that will allow participants to develop hands-on practice with digital video cameras, PowerBooks, and iBooks. Imovie software will be demonstrated and examples of how iMovie may be integrated into both K-12 settings as well as higher education will be shown. The organization of workshops for new users will also be discussed.

Borzov examines ways to integrate digital video into a language classroom. This paper describes the process of shooting, editing, and formatting videos for students who are learning English as second language. Borzov also compares VCR/camcorders with digital cameras for shooting video and CD-ROM, DVD, and Web technology for disseminating the projects.

Pan presents the results of a study that examined the perceptions of teachers as well as other people in non-education related fields toward the use of text-to-speech technology. Synthetic speech, produced by a computer, has matured considerably over the past few years, and this study indicated that few people are aware of or use this technology. Participants were given a pre-test, and then introduced to the synthetic speech functions and activities; finally a post-test was given. The results of the study showed a statistically significant difference between pre-test and post-test scores, and most participants became engaged in developing ways of integrating text-to-speech technology into their teaching activities. Pan suggests that teachers are more likely to adopt the synthetic speech technology and integrate it into instruction if properly introduced.

**Research in Specific Multimedia Technologies**

Four papers highlight research conducted about specific multimedia products. Albion discusses the initial evaluation of an interactive multimedia CD-ROM called Integrating Information Technology into Teaching with pre-service teachers. The evaluation of the materials based on a problem-based learning framework indicates positive changes in these students’ beliefs. A variety of data was...
gathered through a teaching efficacy instrument, questionnaires, and journals. This data indicated that the interactive materials using a problem-based learning framework assisted students in increasing their knowledge of the work of teaching as it relates to the use of computers and also increased their self-efficacy in teaching with computers.

Unfried and Crooks also report on a pilot study that measures learners' self-efficacy, as well as attitudes and access/utilization patterns. The study was initiated to discover areas that could impact an expanded study on factors influencing the use of electronic textbooks. Participants were given a self-efficacy questionnaire, assigned readings in an electronic textbook on CD-ROM, and participated in open-ended questions about the advantages and disadvantages of electronic textbooks. Preliminary results showed that students overwhelmingly preferred print-based textbooks to electronic textbooks, but acknowledged the fact that electronic textbooks provided advantages in color, animation, and hyperlinks.

Stuckey, Hedberg, and Lockyer describe the first phase of a research study to examine the role played by Internet-based teacher professional development in the implementation of an innovation. The innovation in this study is the software application, StageStruck, a educational multimedia CD-ROM designed for the performing arts. StageStruck has won many awards since it was launched in 1999, and the authors describe the development of an online community to support K-12 teachers in their classroom use of the software. The Web site offers professional development, support and resources for teachers as well as activities and projects for students. The authors will demonstrate the CD-ROM and online community in an interactive session at SITE.

Santos and Dias describe a study focused on the use of hypertext in the design of a Web-based learning environment designed to support the understanding of poetry for high school ESL students. Preliminary results show that students had a deeper involvement in suggested reading activities and a higher level of interactions with poetry when supported by a Web-based learning environment. Positive attitudes about poetry and greater feelings of participation were also noted.

**Multimedia Portfolio Development**

Two papers in this section focus on the development of technology tools that assists pre-service teachers in portfolio development. Holt presents a description and evaluation of a multimedia CD-ROM project, *Developing Your Professional Portfolio for Internship and Beyond*. It includes feedback from pre-service teachers who used the CD-ROM to help prepare their professional portfolios during internship, supervising professors, and educational personnel at teacher education institutions both nationally and internationally. Holt also provides an overview of professional portfolio literature.

Mullen, Bauer, and Newbold describe a collaborative process used in conceptualizing a digital portfolio requirement for all teacher education majors. The authors describe the development of a digital portfolio model by a team of university faculty with input from community and business representatives. The overall goal of the portfolio is to meet the learning and competency objectives of the teacher education program; the emphasis of the process is on reflection and to highlight the developmental process of portfolio construction. The authors also discuss portfolio structure, development process, and assessment.

**Innovative Multimedia Projects, Tools, and Software**

Eight papers in the New Media section report specifically on the design and development of innovative multimedia projects, tools, and software. These examples are certainly imaginative and provide exciting examples of multimedia product development.

MacKinnon and Bellefontaine describe a CD-ROM resource for a Middle School Teacher Education Course. Since the university setting for this course requires all students have a laptop computer, the use of this technology is a logical and innovative way to effectively use available resources. The authors provide an overview of CD-ROM technology and discuss the categories of educational applications and examples for each type. The approach to using the CD-ROM in one teacher education course is described and ways to integrate it are proposed.

Laufer, Blois and Choren report on an application tool for the development of case-based Web environments. This tool is described as a reusable, component-based application that can be specialized to produce custom applications. The authors provide a brief overview of the case-based learning model which is closely aligned with social constructivism and problem-based learning. The tool, called *Case-based Training Environment*, has a student area and an administrative area. It also has a stand-alone application for module authoring. Because it is primarily Web-based, students only need a browser to use the tool's functionalities. A specialist environment will be developed next where content specialists can share training modules.

O'Brien and Van Der Kuyl describe the development of a CD-ROM, *Dealing with Disruption*, for teacher professional development in dealing with disruptive students. The authors provide a brief description of the problems and challenges of dealing with students with disruptive behaviors and emotional problems in the context of the Scottish education system. The CD-ROM contains effective methods for dealing with classroom disruption and aggressive behavior with a wide range of scenarios available from a menu. The authors describe the methodology for the project and relevant development phases.
Pivec and Mauer describe the theoretical framework and development of "Situation Learning" modules. The authors give an overview of situation learning and explain the characteristics of the environment in which the learning takes place. Educational aspects of situation learning and examples of applications are also described. Pivec and Mauer also illustrate the authoring of situation learning modules and point out the levels of authoring supports.

Gutl and Lackner describe the design and development of WebSave, a Java-based tool that supports the research process by managing relevant information by importing bookmark files from common browser clients. The authors provide an overview of archiving and discuss the process of archiving Web resources for later retrieval. They also note problems involved with archiving and organizations involved with archiving Internet resources. Gutl and Lackner conclude by describing future implementation plans.

Yacine reports on the architecture of the system SACA (systeme d'Apprentissage Cooperatif base sur le modele d'Agent), a multi-agent system to support cooperative learning. He describes the different sets of agents, both human and artificial, which offer the possibilities for the learner to cooperate and collaborate with peers.

Hart and Cafolla present an overview of Macromedia Flash, a software program used to create multimedia Web presentations. The authors provide an overview of Flash, and describe advantages and disadvantages of developing interactive, multimedia Web sites with the software. Hart and Cafolla also discuss ways to use Flash to create presentations and animations for online delivery.

Musgrove, Knee, Rodney, and Musgrove discuss how a course authoring program, WebCT, can be used to make Web-based learning appealing and effective for a variety of individual learning styles. The authors provide an overview of learning theories as it pertains to Web-based learning and argue that professors need to adapt their course materials utilizing the same foundational learning theory concepts that are effective in live classrooms. A description of three types of WebCT tools, communication tools, content tools, and assessment tools, is also provided.

**Technology Collaborations of Students and Teachers**

Two papers explore the technology collaborations between students and their teachers. Zdravkovic discusses the relationship of higher education students and their instructors. He proposes different approaches and techniques to encourage better student-teacher relationships and foster learning.

Pierson, Booth, McNeil, and Robin describe the development of a school-university partnership composed of three groups: student "consultants," teacher "clients," and university "experts." The authors describe the yearlong project that is designed to develop a cadre of technologically and pedagogically skilled middle-school students who can assist the technology development of their teachers. Activities, challenges, and achievements of the two-year project were also included.

**Course and Instructional Model Design and Development**

Five papers discuss the design and development of courses in new media or instructional models that facilitate construction of knowledge in a less formal sense. Drazdowski describes the evolution of a media design course into a multimedia design course over the past five years. He compares the physical changes in computers, presentation hardware, and peripherals available for the course, and he includes ideas and recommendations for other teacher educators seeking such changes in the preservice curriculum.

Zdravkovic discusses teaching environments for computer visualization, especially in the areas of 3-D modeling, animation and special effects. He proposes that a different learning paradigm is needed with a more flexible approach that incorporates project-based learning techniques. The task of combining theoretical knowledge with production capabilities is difficult, and Zdravkovic describes several strategies for developing the required competencies and assessing student progress.

Putnik proposes a learning model that allows teachers to actively communicate with others electronically, participate in online discussions, use Web-based resources, and contribute to a shared body of knowledge. He proposes an outline for the course that includes characteristic elements about interactions, collaboration, and skills. Putnik notes that it is important for interactivity to move beyond short moments between student and teacher and to invoke a feeling of togetherness between students, teachers, and the instructional materials.

Pelton and Pelton describe the Enhanced Instructional Presentation (EIP) model for the development of educational hybrid linear/hypermedia presentations. The EIP model is a hybrid, combining a linear presentation with playback control and a synchronized, hyperlinked network of supplementary linear and hypermedia segments. The authors provide an overview of the EIP model and describe future activities for developing a tool to support construction of modules.

Zdravkovic describes the design of a graduate course in visual learning based on constructivist teaching principles. The conceptual framework is described, and guidelines and examples of each project are presented. Innovative strategies that contribute to a constructivist teaching and learning environment are discussed. Student and instructor comments are also shared.

Sara McNeil is an Assistant Professor in the Department of Curriculum and Instruction at the University of Houston, 4800 Calhoun, Houston, TX 77204. Phone: 713-743-4975 Email: smcneil@uh.edu
Interactive Multimedia Problem-Based Learning: Evaluating its Use in Pre-Service Teacher Education

Peter Albion
Faculty of Education, University of Southern Queensland, Australia
albion@usq.edu.au

Abstract: Interactive multimedia using problem-based learning as a design framework (IMM-PBL) has been proposed as a method for influencing teachers' beliefs about integrating computers in their teaching. Initial evaluation of IMM-PBL materials with pre-service teachers found evidence of changes in beliefs, including a statistically significant increase in self-efficacy for teaching with computers among participants who recorded initially low values on the same measure.

In a previous paper (Albion 1999b) it was argued that teachers' self-efficacy beliefs about teaching with computers are an important influence upon their tendency to integrate computers into their teaching. Based on a consideration of self-efficacy theory, it has been proposed that interactive multimedia using problem-based learning as a design framework (IMM-PBL) might be effective for increasing teachers' self-efficacy beliefs about using computers in their teaching through exposure to examples of appropriate practice (Albion 2000; Albion & Gibson 1998). The underlying theory of IMM-PBL (Albion & Gibson 1998) and aspects of the development (Albion 1999a) of a CD-ROM using the design framework have been described elsewhere. This paper reports the results of initial evaluation of the completed multimedia package, Integrating Information Technology into Teaching (Gibson & Albion 1999), in use with a class of pre-service teacher education students.

Evaluation Methods

A pretest-posttest design was used. The experimental group (N = 22) comprised students who had self-selected into a class in which the IMM-PBL materials were used as the basis of two-hour sessions attended over a five week period. The control group (N = 27) comprised an equivalent group of students studying alternative electives. The key research question sought to determine the effects of IMM-PBL materials on pre-service teachers' self-efficacy beliefs in respect of teaching with computers. This variable was measured using the Microcomputer Utilization in Teaching Efficacy Beliefs Instrument (MUTEBI) (Enochs, Riggs, & Ellis 1993). Both the experimental and control groups completed the MUTEBI as part of a battery of instruments prior to and immediately following the five-week period in which the experimental group used the IMM-PBL materials.

Additional research questions sought to describe users' reactions to the content and presentation of the materials and to determine the effect of the materials on users' perceptions of their knowledge and understanding of using computers in teaching. Data relevant to these questions were gathered from the experimental group using a questionnaire which included both Likert scale and open-ended, journals maintained while working with the materials and interviews with a small sample of participants (Albion 2000).

Results

Users responded positively to both the content and presentation of the IMM-PBL materials. They agreed that the four problems framed in the materials were relevant to their future work as teachers and cited new insights about various aspects of teaching obtained as a result of working with the materials. The element which attracted most favorable comment was the digitized video, especially that which presented interviews with teachers. Although all participants used the materials under equivalent conditions in a computer laboratory, patterns of use varied. Some worked systematically through the four problems, while others preferred to browse the resources, especially the video segments. This variation in patterns of use resulted in different outcomes for different users.
Increases in self-efficacy for teaching with computers (SE) were observed for some participants. Participants were partitioned according to their initial levels of SE (high or low) and the changes for each group were examined (Fig. 1). A statistically significant increase in SE ($t = 2.71$, df = 23, $p = .013$) was recorded for participants who had recorded initially low values of SE.

Statements made in open-ended responses, journals and interviews indicated that some students had experienced significant conceptual change as a result of working with the IMM-PBL materials. These data supported the conclusion that the materials were effective in changing the beliefs of participants.

Conclusions

There is evidence that the use of the IMM-PBL materials assisted students to increase their knowledge of the work of teaching especially as it relates to the use of computers. There were increases in self-efficacy for the use of computer technologies and for teaching with computers. Technical difficulties experienced in the trial and the variations in patterns of use may have restricted the effect of the materials but the available evidence suggests that the presentation and content were appropriate and that further investigation of IMM-PBL and its use in teacher education would be worthwhile.

Platteville Elementary School
Weld County School District RE-1
USA
mb4@aol.com

Abstract: Examine most web-based courses and you will find that very few of them make use of audio support for instruction. Quality audio on the web once meant large files and clogged bandwidth. However, new data reduction formats such as MP3 make it possible to include quality audio support for instructional materials. Most computers come equipped with the necessary hardware and software for web developers to use their existing equipment to produce good quality audio programming. This paper presents a brief overview of the advantages of audio as an instructional medium. Information regarding basic audio capturing and editing on a typical PC is presented, followed by recommendations for processing audio for web and CD-ROM development. Samples of the author's work can be found at www.mp3.com/jeffreybauer.

Research in the Effects of Audio on Learning

Audio is an important instructional medium that can significantly enhance web and multimedia based learning. Research in this area reveals several benefits. Allen (1973) has shown that audio can be skillfully included to direct learner attention to particular elements of an instructional message. Just as animation can be used on the web to gain attention, audio can also be included to help the learner focus attention on particular elements such as the starting point, or help links of a web site. Severin (1967) has also shown that multi-channel communications enhance learning because of the impact of the summation of cues between channels. Audio also provides an opportunity for the learner to "relate" to the narrator (Hoban & van Ormer, 1950). Verbal simplification in media commentaries has been shown to increase teaching effectiveness (Travers, 1967).

In the area of music, Seidman (1981) concluded that musical accompaniment enhances the emotional impact of a media production. He found that music could also provide continuity by tying together scenes in a script. Thus, a case can be made supporting of the use of music as well as narration in web based training environments.

Basic Audio Capturing on a Typical PC

Audio Inputs and Microphones

Most current computer systems, both desktop and laptop varieties come standard with nearly everything needed to capture and edit good quality audio files for web and multimedia instructional purposes. Many computers even come equipped with built in microphones or external microphones that plug into the audio in port on the back of the computer. How do you know whether you have such an option? Simply examine the back of your computer and see if there is an audio in receptacle or an input receptacle with a picture of a microphone associated with it. If there is, you have the basic hardware necessary to capture audio.

You may need to purchase an external microphone in order to capture sound on your computer. A medium quality dynamic microphone ($30-$100) by a reputable manufacturer such as Shure, AKG, Audio Technica, or Realistic should be adequate for producing good quality instructional audio. Radio Shack carries the adaptors.
necessary to convert the cable on the microphone to the proper format for your audio card on your computer. Usually, computers accept 1/8" stereo mini plugs. Computers with more sophisticated A/V capabilities, such as PowerMac G3s and G4s, accept a pair of RCA cables. Again, consult with someone who is familiar with audio adaptors in order to get the proper connectors.

Audio Capturing Software

The only other ingredient necessary for digital audio production is a program that will allow you to capture the signal from the microphone to your hard disk. Again, many computers come standard with a utility that allows you to do this. For example, the current Macintosh Operating Systems 8.6, 9.0, 9.04, and X, include a program called Simple Sound which allows you to capture audio either from the built in microphone or the sound input receptacle.

Figure 1. SimpleSound recording interface for the Macintosh.

![SimpleSound recording interface](image1)

Figure 2. Quality level choices on SimpleSound. Higher quality such "CD" and "Music" will create larger, better sounding files.

![Quality level choices](image2)

Figure 3. SimpleSound Dialog box providing technical details about the recorded sound clip.

Programs such as Adobe Premiere, Digidesign ProTools, CakeWalk Home Studio 8, Steinberg Cubase and many others have more sophisticated audio capturing and editing capabilities. While these programs are intended for more advanced applications, all are reasonably priced and most have both Mac and PC versions. It is beyond the scope of this article to explain the intricacies of these programs; suffice it to say that all of them offer more exacting editing capabilities. They also allow the user to add special effects such as echo, chorusing, audio compression (not to be confused with file compression), and hundreds of other options. All of the programs listed above allow multitrack recording and editing, meaning that you can add multiple layers of audio. For example, using ProTools, you might want to start by recording an instructional narration using a microphone hooked into the computer. Later, you might want to disconnect the mic and hook a cassette tape player to the audio input and capture some background music. This music can be put on its own separate track so that it can be edited separately from the narration track. Gain levels and stereo panning (left/right soundfield placement) are additional typical features. High end programs such as ProTools and Cubase offer different ways...
to view files such as an edit view which graphically displays the audio file, and mix view which looks like a typical analog mixer that audio engineers are sure to recognize. A free version of ProTools for either the PC or the Mac can be found at www.digidesign.com.

Figure 4. ProTools Edit View offers many professional editing features. A free version is available at www.digidesign.com.

Figure 5. ProTools Mix Window allows real time editing of sound levels and special effects.

Selecting a Quality Level
When capturing and editing audio that will eventually end up on the web or on a multimedia CD-ROM, it is best to start with the best quality possible. This means that the initial file sizes will be quite large. Later the audio file will be converted to a more compact format such as .wav or .mp3. Data reduction and compression works best when the raw product is of the best possible quality. It is a good idea to optimize hard drive space using Norton Speed Disk or another similar defragmenting program before you begin capturing audio. Your computer will run much more smoothly, and the chance of a glitch will be greatly reduced. Set the audio capture preferences to CD Quality which is a capture rate of 16 bits at 44100 kHz. To save hard disk space, you can select mono instead of stereo if it is available. This is the raw file. Typically this file occupies about 10 MB of hard drive space per minute. A five minute piece of instructional audio will occupy about 50 MB on your hard drive, but remember that this file will be compressed later.

**Processing the Captured Audio Files**

**Helpful Tools**

Two tools that can help improve the quality of your audio recordings are audio compressors (not to be confused with data compression), and audio mastering software. Audio compressors smooth out the dynamic range of the sound that you are recording. Basically, compression boosts the quiet parts of the audio program and cuts or limits the loud parts of the audio program. Inexpensive compressors such as the Alesis Nanocompressor (about $100) are fully adjustable so that you can determine how much the signal is squashed. A simple setup would be to plug the microphone directly into the input on the compressor, and then run a line from the output of the compressor to the audio input of the computer. Compressors are the single most useful tool to improving the sound of a recorded program. Their effects are deceptively subtle, but when the audio material is converted to a format that will work well on the web or in multimedia, it is essential that the audio be without overly soft and loud extremes.

![Alesis NanoCompressor](image)

**Figure 6.** Alesis NanoCompressor. An essential tool for improving audio quality.

Another helpful tool is mastering software such as Berkley Integrated Audio Systems PEAK (about $40 for the LE version). Mastering software is useful if you have several audio clips that are going to be used on your instructional website or multimedia program. This software allows you to normalize the various individual files so that they are all of approximately the same loudness. It also allows you to cut and paste pieces of audio or fade in or out on a track. Mastering is the second to the last step in preparing audio for the web.
Converting the Audio File for the Web or Multimedia Applications

The final step in the production process is to convert the edited and mastered files to a format that will work well on the web or in multimedia software. The format that offers the best compromise between file size and quality level is MP3. The raw audio files that you captured and edited which occupy about 10 MB of hard drive space per minute of audio can easily be reduced by a factor of 10 without significant deterioration of quality. Data reduction of up to 20:1 can yield very usable results in an MP3 format, and the audio can be formatted on your website for either streaming or downloading. Your users will need to download a free MP3 player (www.mp3.com) in order to playback your audio files. The original uncompressed 10 MB per minute file is reduced to 1 MB per minute for good quality or 500 KB per minute for fair quality—good enough for narration. Using an MP3 program such as SoundJam, converting audio files to the MP3 format is as easy as dragging and dropping to a conversion window. The user then chooses the quality (bit rate, stereo/mono, sampling rate) that will work for the instructional program. I usually make several conversions of the same file and test them to see which settings give me acceptable quality while trying to keep the file size manageable. You can check my results at www.mp3.com/.

Real Audio streaming formats are also very good for the web. Various file formats (.wav files, Quicktime, and others) can be processed as Real streaming audio during the mastering stage. It is simply a matter of performing a "Save as..." and selecting the desired format. You should experiment with different file types and compression settings to see what works best for you.

Final Thoughts

Using your PC to produce good quality audio support for your web based courses or multimedia CDs is not a difficult endeavor. Research supports the use of multimodal teaching materials, and audio can bring life and personality to an otherwise bland web course. Three major steps were discussed: (a) capturing the audio, (b) processing and editing, and (c) converting the audio to the appropriate file format. Data reduction technology has advanced to the point where high quality audio takes up very little hard drive space and bandwidth.
Figure 8. The author prepares audio tracks on his Mac G3 using Digidesign's ProTools. You can hear a sample of his work at www.mp3.com/jeffreybauer.

Teacher-Developed Video for Classroom Use: 
The Transition from VCR to Digital Format

Eugene Borzov
Center for Technology in Learning and Teaching
College of Education
Iowa State University
United States
borzov@iastate.edu

Abstract: This presentation will examine the ways to integrate digital video technology into a language classroom. The process of shooting, editing and formatting educational video films for students learning English as a second language will be discussed. The focus will be on a comparative analysis of traditional VCR/Camcorder technology versus digital cameras and modern CD-ROM/DVD/Web technology for disseminating the resulting video. The examples of effective techniques and original QuickTime movie clips will be included in the presentation.

Introduction

Educational video has become an essential part of instructional technologies, but its integration into curriculum is often limited by utilizing commercial films, rather than self-made productions. Digitized video is often considered too raw for effective use in more than a very short clip, while the picture is quite small (only by 2 in. by 2 in. or 4 in. by 4 in.) and may be jerky and unclear, especially if blown up to a large size (Healey, 1999,p.131). Still, digitized video holds promise for the future. Students, who will make presentations in the scientific, business or academic realm need to know how to look as well as sound good in a presentation, and video offers them a full picture of what they do well and what they need to improve (Healey, 1999,p.132).

Teachers, developing educational films for classroom usages may take advantage of analog and digital video technologies, depending on the resources and tools available. The video I produced for English as a Second Language classes may represent both a traditional approach, focused on camcorder/VCR technology, and a more progressive one, utilizing advanced computer-assisted technologies, based on digital audio and video processing.

Analog Video Production.

The equipment necessary to produce an analog video film may consist of a camcorder, a VCR with editing functions, a tape-recorder or a CD-player, a microphone and a TV. Once all the original footages are specified and chosen for a film, a long and time-consuming process of editing begins. All selected fragments are exported step-by-step from the source tape to the target one. This manual way of putting pieces together may not guarantee a seamless video picture. Some unfortunate noise bars and unexpected frames may show up at transition areas, making a producer start a new round of attempts to eliminate these flaws.

Setting a precise duration of a footage may also be a hard thing to do, because a synchronous manipulation of a "start" button on a camcorder and a "record" button on a VCR may appear quite problematic in the beginning, but the teacher is sure to improve after some practice.

Audio dubbing is the next challenge for a producer after the video is done. The most complicated task is to strike a balance between a background voice/music track and a foreground narration. My experience proved to be successful after I managed to acquire some accuracy in handling a CD-player and a microphone switch at the same time. Some special care should be taken about a distance between a microphone and a background sound source. This may be crucial for the narration to dominate over musical tracks.

Any video production without titles or script messages cannot be considered complete. Some analog camcorders (JVC RG-AX48) have a character generator, which is able to store up to 18 letters and superimpose it over the scene being shot. The teacher may actually use a different and a very simple way to entitle the film by making a close-up picture of a text printed on a sheet of paper.
This approach in constructing analog video films may challenge teacher's skills and demand a lot of industry and patience, but it is quite good and practical particularly for those circumstances, when the facilities are limited and the resources are scarce. Teachers with absolutely no computer literacy may practice this type of movie-making, since no software is meant to be used in this process.

Digital Video Production.

Most digital semi-professional camcorders on the market today use MiniDV format, which meet the demands of extremely high-quality audio and video production. DV differs from analog in that it stores all sound and image information in digital form and enables to copy video between a DV camcorder and a computer with no loss of quality. So every time when video is captured, edited and exported back to tape, the quality of the original footage is retained. This is not so with analog video, where electronic signal is likely to lose strength, when the video is copied from one medium to another.

Digital audio sound is also a perfect match to digital quality images. Most MiniDV camcorders offer two recording modes: two-channel (16-bit linear, 48 kHz sampling) for optimum quality and four-channel (12-bit non-linear, 32 kHz sampling) for stereo dubbing.

The process of digital editing is entirely computer-based and the teacher has a number of options to choose between quite easy and friendly software, like iMovie or Avid Cinema and more professional, like Ulead Video Studio and Adobe Premiere. Some manufacturers of digital camcorders (JVC) may include editing software (JLIP Video Capture, JLIP Video Producer) into a purchase package and provide a lot of useful instructions online (www.jvc-victor.co.jp/english/cyber/us/software/index.html).

All the problems and challenges, related to analog video production, can be easily solved by digital technologies. Elaborate applications and tools may ensure perfect selecting, cutting, pasting, random assemble editing, adding scene transitions, audio dubbing, importing and exporting sound and images, creating still-images, renaming video clips.

But perhaps the most dramatic advantage of a digital format lies in the ways to disseminate the resulting video. The iMovie tools I used to produce my educational video, made it possible to convert the footages into a QuickTime format movie, ready for different compression strategies and delivery mediums, including videotape, CD-ROM, DVD and the Internet.

The Web dissemination is an exciting opportunity to include personal video into global distant learning schemes. A movie can be posed to a home page site to have people download it. In this case the film should be short enough, otherwise the downloads may be too lengthy for a waiting viewer to enjoy. A compression used for publishing my Quick Time movie in the Internet gave me a 1/8-screen image (240 x 180 pixels), 12 frames per second and a stereo sound 22 kHz. JPEG compression with Avid Cinema may allow exporting a Quick Time movie to a compositing program, such as Adobe Premiere After Effects with even more dynamic resolution:

- 1/8 screen (320 x 240 pixels NTSC or 397 x 288 pixels PAL)
- CD-quality stereo sound (44 kHz, 16-bit)
- 29.97 frames per second NTSC or 25 frames per second PAL (same as Television)
- 55 MB disk space per minute of video

Quick Time movie may be streamed online, so that people can see the resulting media play right away on the screens of their computers, using Quick Time Player. One more advantage of direct streaming is that the video files are not limited to reasonable sizes, as opposed to HTTP downloads. Long feature films, that would make multi-gigabyte files, can stream easily and rapidly.

It is also important to know, that streaming makes it possible to gain control over the distribution and copyright issues. When somebody tries to save the incoming media, the actual data is never copied, but is simply displayed as it arrives by the Quick Time plug-in and in Quick Time player. So the audience may have access to the Quick Time movie's URL, rather than have a chance to copy it on a hard disk.

Tales, Trials, Triumphs, and Trends: The Evolution of a Preservice Multimedia Course

Thomas A. Drazdowski, Ph.D.
Director, Teacher Technology Center
King's College
United States
 tadrazdo@kings.edu

Abstract: With the introduction of our new multimedia computer lab in the Spring of 1996 (Drazdowski, 1997), our preservice teacher education program at King's College began the transition of its traditional "Media Design" course to one in "Multimedia Design." This paper will discuss the evolution of this course over the past five years, including ideas and recommendations for other teacher educators seeking such changes in their preservice curriculum.

Tales

First, some tales. Probably one of the most dramatic developments in the evolution of our multimedia course over the past five years is in the rapid advancements in hardware, software, and Internet resources. Where our initial multimedia lab consisted of Power Mac 5200/75 LC's, our upgraded machines are Apple G3 computers with 450 megahertz processors, 12 gb hard drives and 256 mb of memory connected to Pioneer laser disc players with their own separate Sony color video monitors. The built in Zip drives in the new towers have provided tremendous flexibility for storing and sharing large files, projects, and QuickTime movies. The current data projection system is three times as bright as the old LCD panel, eliminating the need to totally darken the room. The HyperStudio program is now version 4.0, which offers many improvements, especially in the areas of animation, special effects, enhanced transitions, and printables. The new scanner is USB compatible, has higher resolution dpi and 42-bit color, and has trays to scan slides, pictures, and transparencies. A Sony Mavica digital camera has replaced the old Apple QuickTake 150, and its built in disk drive has eliminated the need to download pictures through a serial port and then use cumbersome software. Our video camera for making QuickTime movies is now digital instead of analog, and can be connected and controlled by the computer through FireWire technology. Third party vendors have developed a large variety of texts (see Drazdowski, 1996) and resources (see Drazdowski, 1998) such as Month by Month for HyperStudio and HyperStudio Project Resource Kit, and other vendors have designed complimentary software packages, such as Sound Companion for HyperStudio, Morph Pro 2.5, and Apple's iMovie 2 that can enhance student projects. And the Internet has exploded over the past five years with sites that serve as resources for text, pictures (see Picts4Learning at http://pics.tech4learning.com), clip art, video clips, sound effects, and music tracks. Students today are literally overwhelmed with available multimedia components. Finally, the teacher station now has a recordable/rewritable CD-ROM, so that all projects can be easily copied, saved, and distributed to students for use in their student teaching assignments. The course continues to model constructivist and cooperative learning theories, and serves to anchor our "Professional Semester" requirements. Education department faculty members are making an earnest effort to model effective technology use in their own teaching, and I encourage them, as Brown (2000) has pointed out, to go first for the "low-hanging fruit," and then decide if it's worth the effort to climb higher in the tree. Faculty also continue to take advantage of professional development opportunities to enhance their own technology skills. We have made significant progress, and hopefully our department will continue to receive the administrative and financial support needed to accomplish and sustain all of our technology infusion plans (Drazdowski, Holodick, & Scappaticci, 1998).
Trials

The literature is replete with examples of the barriers educators are confronted with when attempting to integrate instructional technology into the curriculum: lack of training, insufficient time to develop instructional innovations, enlarged class sizes, lack of equipment and technical support, resistance from faculty and technology anxiety, the need to revitalize faculty attitudes toward teaching, underfunding and lack of sustained administrative support, little system-wide planning and vision for technology use, and other simultaneous innovations in pedagogy, curriculum, assessment, and school organization not being coupled to the use of instructional technology (Albright, 1996; Dede, 1998; Lee & Johnson, 1998; Middleton, Flores, & Knaupp, 1997; Pink, 1989; Selwyn, 1999; Tapscot, 1999). Our program continues to face all of these challenges in various degrees which often impedes the pace of the progress that we desire. Like all educators who wear a variety of hats, I occasionally suffer from what Fullan (1996) has identified as “overload and fragmentation,” which can combine to reduce educators’ motivation for working on reform. But one of our biggest barriers, which the OTA Report (U. S. Congress, 1995) also cited, continues to be the lack of technology rich field settings for our students’ practicum experiences. As I read my students’ journal entries that are required as part of the multimedia course, many write that they are disheartened when they visit their school sites to find that little technology will be available for their use in student teaching, and much of what is available is old and obsolete. Some local districts have made a few technology strides over the past five years, but many continue to struggle with weak property tax bases that are their foundation for funding and are also facing major financial concerns with the burden of structurally upgrading or replacing their old school buildings. Our student teachers write that their students often do not even have access to their own textbooks, never mind advanced technologies. Without a major infusion of money from the state and the federal level to address these serious concerns, many of our school districts will continue to limp along the road to the information super highway.

Triumphs

Various authors in the educational technology field have noted that computer use in schools is framed by the beliefs of users about computers and schooling (Bigum, 1998), that computer use often requires changes in a teacher’s educational ideologies (Robinson, 1995), and that teacher computer use often hinges on their computer experiences (Hadley & Sheingold, 1993). As Michael Dertouzos, a columnist for Technology Review, writes:

Learning may critically depend on what humans, not computers, do best: Lighting a fire in the student’s heart, role modeling, and nurturing may contribute more to learning than the neatest hyper-linked courseware. (1998, p.20)

Therefore I feel that one of most beneficial aspects of providing preservice teachers with a required course in multimedia design is to provide teacher educators with the opportunity to model what Jonassen, Peck, and Wilson (1999) refer to as “meaningful learning,” that is using technologies “to engage students in active, constructive, intentional, authentic, and cooperative learning” (p.7), and to show students how to use technologies as “mindtools” (Jonassen, 1996) or as an intellectual toolbox that can be used to engage them in critical thinking about what they are studying. Instructor modeling of these concepts is critical, for we are all aware of the old but true adage that “teachers teach as they have been taught.”

As I have read the students’ journals over the past five years, I am struck by a continuing pattern of student thought: usually initial anxiety as they enter the course, followed by growing confidence as they master the authoring program and become more comfortable with the various pieces of technology equipment, to finally a great sense of accomplishment as they complete their projects and an endless list of possibilities for technology integration into their own teaching curriculum. We now have available on CD-ROM some 250 educational stacks prepared for a variety of grade levels, topics, and content areas that
students can utilize in their own teaching assignments, and our department continues to provide two laptops and portable video projectors for student use in their field settings if necessary. Graduates continue to contact me with exciting stories of their technology use with their own students and their inservice work with veteran teachers, and several have become technology teachers and computer coordinators for their districts, all doing their best to act as “change agents" (Strudler, 1991) for their learning organizations. As for me as instructor, I couldn’t agree more with the CEO Forum School Technology and Readiness Report (1999) that stated, “technology, applied well, can enhance and reinvigorate education, making schools richer and more exciting interactive communities of learning for students and teachers alike (p.6).”

Trends

The introduction to the report entitled Technology and the New Professional Teacher – Preparing for the 21st Century Classroom (NCATE, 1997) clearly states the technology challenge facing teacher education programs:

The nation’s teacher education institutions must bridge the teaching and learning technology gap between where we are and where we need to be. Although progress has been made and exemplary practices exist, recent research indicates most teacher education programs have a long way to go. Teacher education institutions must prepare their students to teach in tomorrow’s classrooms. Rather than wait to see what tomorrow’s classroom will be like, they must experiment with the effective application of computer technology for teaching and learning in their own campus practice. Today’s teacher candidates will teach tomorrow as they are taught today (pp.2-3).

Some other recent reports support the concept that teacher education programs have a long way to go in technology preparation. For example, the National Center for Education Statistics (U. S. Department of Education, 1999) found that only 20 percent of teachers reported feeling well prepared to integrate educational technology into classroom instruction. The Milken Exchange on Education Technology (1999) and the CEO Forum School Technology and Readiness Report (1999) both conclude that, in general, teacher-training programs do not provide future teachers with the kinds of experiences necessary to prepare them to use technology effectively in their classroom. Recently the International Society for Technology in Education (ISTA, 2000) and NCATE have specified the technology skills that teachers are expected to have as they enter the teaching profession. The state of Pennsylvania, where my college resides, is currently reviewing new Academic Standards for Science and Technology (Pennsylvania Department of Education, 2000), which will also affect what preservice teachers need to know and demonstrated before receiving initial teacher certification. Hopefully these technology standards will serve as a catalyst as well as a blueprint for change in preservice technology instruction. Schools of education must integrate technology into the entire preservice teacher curriculum, faculty must effectively model technology integration and new pedagogic methods in their own courses, and education programs must provide preservice teachers with meaningful field experiences in technology rich settings if we are to meet these new standards. To paraphrase the poet, we in teacher education “have promises to keep, and miles to go before we sleep, and miles to go before we sleep.”

Abstract: The WWW provides a variety of scholar information, like theses, studies, etc, which may be valuable basics for further and new scholarly work. Referred information of the WWW has to be archived (at the time of writing) for further usage because Internet resources could be changed. The working prototype WebSave - described in this paper - support users in their research process. The advanced and novel system manages relevant information of the WWW by importing bookmark files from common browser clients. The system allows adding a wide range of local metadata, storing the referred resources and generates a literature list. Furthermore, it is capable of interacting with other services like preparation for building a background library on CD ROM, building a document archive using Hyperwave, building a scholar dynamic Web library by quality metadata exchange to xFIND.

Introduction

More and more information, citations and conclusions in scholar works refer to information on the World Wide Web (WWW). This statement may be confirmed e.g. by observations of scholar works and theses at the Institute for Information processing and Computer supported new Media (IICM) at Graz University of Technology. This applies also to publications and reports of conferences and journals. As a matter of fact the WWW is a large - most likely the largest - information repository. However, there is also the serious problem of changing and moving documents on the Internet. It is well documented that the WWW is a highly dynamic Information repository and a perfect media for a fast publishing process. To get revisable Internet references it is necessary to archive and provide the referred information of the WWW for further usage. This may be backed by different basic studies (archiving information from the Internet) by organisations like National Libraries and further institutions. The consideration results in specific requirements within the archiving process of Internet resources for scientific papers and scholarly works. Therefore, the authors of this paper emphasise that it is necessary to suggest possibilities on assistance for users and institutions within their scholar work to archive cited information from the WWW.

The structure of the remaining chapters is given as follows. The first part of the paper, a survey, discusses in brief the archiving process in a historic view as well as the archiving process of electronic documents in general. The second part describes the prototype implementation of the advanced and novel WebSave tool to archive and administrate Internet resources within the process of scholar works, which is based on the conclusions on the first part of the paper.

The Archiving Process of Web Resources

Basically, the motivation for archiving Web pages is to represent snapshots of society for later retrieval and to preserve knowledge for mankind. Therefore, archiving is a long-term process that never ends. Today, search robots or offline browsing tools are used to collect Web sites and to build local archives. However, such tools do not support the process and the requirements of scholarly work. New interactive systems (e.g. chat facilities) require new efforts to gather such documents. It is quite obvious that the archiving process of objects in history is quite different from the requirements on archiving Web pages today, which is discussed as follows.
Archiving from a Historical Perspective

In history, since about 2500 B.C., archives can be found. Archiving is the process of collecting and managing objects with historical background. In general, these documents are not prepared for publication (e.g., official documents) and are called dead documents (Weiß 2000), because these documents or objects never change. The term archiving describes also the classification of documents by formal methods (e.g., grouping, indexing, etc.). Indexing parameters can be subjects, locations, and authors. Result of classification tends to an index summary in a printed and/or electronic version.

Three different types of the archiving process can be identified: Archives store only important records or documents, which are not publicized but worthwhile to preserve for mankind; Libraries archives published (reviewed) documents; Museums archive artistic and scientific documents, images, objects, etc. The storage media and the process of archiving are basically in the analogue sphere (Alschler 1999).

Today, the motivation for archiving is the same, but new technologies (for objects to be archived and within the archiving process) have to be regarded. It is to be mentioned that e.g., on the Internet nearly everyone can publish without any quality control, but also huge valuable amounts of research work and technical reports can be discovered for further scholarly work. A deeper discussion of electronic archiving and detected problems are discussed in the following sections.

Electronic Archiving of Information

The term electronic archiving (Weiß 2000) is similar to the concept of imaging (the process of digitizing, storage in databases and retrieval). In general, electronic archiving may be the first step to a digital office. Considering the electronic archiving process, it is subdivided into data storage, data retrieval, and data migration. The process of archiving depends on the characteristics of the document (VSA 2000), which can be categorized in different ways: readability - human and/or machine-readable; type of storage media; document type (text, images, videos, music, etc.).

As a special scope, electronic archiving or imaging can also be understood as the preparatory operations to build Web pages and Web archives. That means the Internet can be used to archive valuable information and enables access also by the Internet. On the other hand, information available on the Internet should be archived, which can also be performed by an Internet archive.

It is well documented that the Internet is a huge - maybe the biggest - knowledge repository of mankind. The Internet offers a cheap and simple way to publish documents without nearly any restrictions. Because of this, the Internet is a disordered, decentralized and mostly not censored worldwide library. It is well known that humans have produced more information since 1945 as in the whole history before. The increase of knowledge is estimated to be exponential. Therefore Internet archives also have to process increasing amounts of data.

Following the idea of archiving (process of collecting and managing), different types of already existing Web archiving methods can be identified like: (1) link collections (e.g., annotated link lists), (2) search engines (e.g., full-text index and document cache), (3) data collections (e.g., ftp) and finally (4) Web archives. All these types provide similar viewing techniques and hierarchical data structures. One advantage of Web archiving methods is the ability of systematic access, which can be performed simultaneously and from different places. Considering the development of mobile communication, this will be increasingly important. The storage is cost effective in relation to the quantity of data. The information can be requested in real time. However, one of the main disadvantages is the dynamics and malleability of Internet resources. In addition, information depends on the context, which means that a bit sequence can be interpreted in different ways (digital codes). It is absolutely necessary to use a tool (computer, PDA, etc.) reading and understanding a digital code. Thus, the representation the information depends on the used hardware and software. Because of changing technology over the years, data must be copied to other storage media keeping the information safe (migration). Furthermore, today common transformation rates cause problems related to media objects (video, sound, etc.) performed by remote requests. To sum up, the demands on future archiving systems consist of standardized retrieval interfaces, standardized storage formats and especially standardized document formats. Detected Problems, as followed, has to be considered.
Detected Problems

Some problems related to electronic archiving (focused on Web archives) can be identified as follows:

Information overflow and duplicates: The digitizing of pictures, sound and music data, videos and films produce a huge amount of information. Most of this information should be archived at least for years or even forever. There exist many copies of the same documents at different places.

Information malleability: Information of electronic documents, especially Web resources, could be highly dynamic, and location of documents could be changed or even be deleted. E.g. the average live span of a Web page is about 75 days (Kahle 1996).

Migration and Lifetime of Documents: The capacity of storage media has been increased in the last ten years about hundred times. The transfer rate increases only four times in the same period (Phelps et al. 2000). The result is that the entire set of data cannot be copied in acceptable time. Migration is the process of storing documents permanently. This includes periodical copying into new system environments. Thus, metadata has to be transferred and in general the documents must be converted into a new document format. Parts of information may be lost (VSA 2000).

Access Rights: When people buy a printed journal, they never lose the access right and the content cannot be changed. Online journals can change ownership and therefore the copyright could be changed and the access right will be lost. No one knows how long and who should manage user data concerning access rights.

Related Work and Concluded Requirements

The following paragraphs are focusing especially on archiving Internet resources. Few organizations can be identified, which archive country-specific information. The mentors of these projects are national libraries and governments. They define specific guidelines about registration and documents that have to be archived. Furthermore, single initiatives of public or commercial organizations can also be identified, which effort to archive the entire Internet. A selection of examples is discussed as follows.

EPPP (Electronic Publication Pilot Project) is a project of the National Library of Canada. It has been founded in the time of June 1994 to July 1995. They decided to use the WWW as the primary gateway to access electronic publications. Collection guidelines define that archived documents must be published in Canada, sponsored or produced by a Canadian company (see EPPP 1996).

The PANDORA project of the National Library of Australia (NLA) may provide long term access to significant Australian online publications for national preservation. The usage of metadata based on Dublin Core attributes improves the searching process. The online publications are categorized in monographs, serials, home pages and ephemera. The NLA cooperates with other Australian libraries to ensure that there is no duplication of archive materials (see NLA 1997).

ETEXT: Paul Southworth founded the ETEXT archives in the summer of 1992. The project was started in response to the lack of organized archiving of political documents and discussions disseminated via Usenet on newsgroups. In the last five years three GB of mostly ASCII text are stored (see http://www.etext.org).

PURL: The PURL (Persistent URL) service provides an archive server solution avoiding the "404 page not found" error. A PURL is like an URL and associates the PURL with the actual URL and returns that URL to the client. The client can then complete the URL transaction in the normal way. PURL's are the result of OCLC's URN (Uniform Resource Name) standard and library cataloguing communities (see Shafer et al. 1996).

The Internet Archive (IA) is an association, which collects and stores materials from the public Internet (WWW, Gopher, Newsgroups, FTP). Any Web page that uses CGI requests or needs to authenticate to get access is blocked by the gathering procedure. The archive is not yet publicly available but provides free access to researchers, historians and scholars. The IA archive size is about 14 TB (mostly Web sites) since 1996 to the time of writing this paper (see http://www.archive.org).

Alexa: Alexa is a free Web Navigation Service that gives a public access to the IA and rates Web sites of IA. The navigation tool works with common Web browsers. Information about the page recently visited are available (related links, quality, traffic, actuality, etc.). Alexa provides a "non-dead link" service by offering archived pages of IA (see http://www.alexa.com).

Google: Google is a fast search engine which uses the patented PageRank™ technology. PageRank counts incoming links to a document and assesses also outgoing links. "Google stores many web pages in its cache to retrieve for you as a back-up in case the page's server temporarily fails" (see http://www.google.com).
**Offline browser:** Offline browser tools gather single HTML pages or structures including embedded objects (images, scripts, audio and video files). Such systems follow the idea that reading takes much more time than to replicate the pages. Thus, the reading process can be done offline. Examples of free tools are WebStripper™ (see http://webstripper.net) and WebCopier (see http://www.maximumsoft.com.)

Based on the survey (see above) and the related work (stated so far), the authors of this paper propose a solution in the field of scholarly work. Existing commercial and non-commercial mirroring tools provide only offline browsing on the local file system. Furthermore, online archiving systems cannot guarantee that documents of interest are archived. Therefore, the proposed scholarly solution follows a different idea. Users have to be supported in the process of collecting relevant information from the WWW or Internet by less or even no further effort. In addition, they have to be supported to manage these resources and enabled to enrich these resources with remarks, quality metadata, etc. Because of the human effort within the process for discovering **good** and **relevant** information, such resources and its meta-information should also be provided other users, research teams, scholar organisations and Internet communities for further research. Based on the results stated so far, the *WebSave tool* was designed, which is discussed in the following Chapter.

### The WebSave Tool

On a glance, the *WebSave* tool is a Java based prototype implementation, which supports users at their research process within the scholar sphere. Unlike existing offline browsing tools, the advanced and novel system manages relevant information of the WWW by importing bookmark files from common browser clients. First, the users' view of the WebSave tool is discussed, followed by brief information of the administrators' view and the cooperation with the xFIND system. A more detailed discussion of the archiving of resources in electronic media and a detailed description of the WebSave tool can be found in Lackner (2000).

Simply by using a common Web client, interesting links can easily be collected as bookmarks placed in particular folders. Different folders can be assigned to different projects or chapters of scholarly works. The WebSave tool imports these link collections and supports the user to manage these resources. In addition, any of these projects can be titled and described in an abstract by additional attributes. It should be noted that also incremental updates from the bookmark list could be performed. That means that users can search for relevant information on the WWW, set bookmarks and finally import the bookmark information in the WebSave environment. Within another session, further relevant information can be added to the corresponding bookmark folder and incremental imported. Because of the short life of Web sites, it is recommended to gather the documents of interest within some days (at the time of writing a paper).

WebSave append additional information (WebSave system information and metadata) to the imported bookmarks. System information is e.g. identifier, last visit time, last modification time, etc. Metadata are e.g. notations as well as quality metadata (xQMS), etc. The xQMS (xFIND quality metadata scheme) consists of descriptive (e.g. subject domain, etc.) and evaluative (e.g. authority, target audience, etc.) quality metadata. xQMS is developed by the xFIND group (http://xfind.iicm.edu) and described in detail in Weitzer (2000).

In addition, the WebSave tool provides literature entries of the resources by compiling reference identifiers, the reference descriptions (author, organisation, year of publication, title, version), the time of last visit and finally the time of the saving process (see also below).

Furthermore, the resources can be gathered and locally stored on the file system. That means that a relevant bookmark imported by WebSave refers to a document available as HTML with embedded graphics, scripts, applets, etc. The tool stores the HTML files as well as the embedded objects. The WebSave tool manages several projects for any user and allows the cooperation of users. After finishing a project the literature list can generated automatically by the system. Furthermore, WebSave generates an HTML version of the list of literature and prepares links to the local (cached) Internet resources. WebSave supports the preparation of the Internet resources and its metadata for a CD-ROM production. The HTML reproductions of a project comprise the project abstract, summary, reference list including links to local stored sources as well as links to the original Internet sources. Users who are finishing diploma theses can also provide an electronic version of their work and in addition provide local (saved) versions of referred Internet resources (CD-ROM version of the work).

WebSave allows the usage by more than one user. All data are stored in a subfolder of a predefined network directory. The subfolder contains the entire set of user data (personal data, project data, etc.), which can be managed by the user and administrators. Within any subfolder, Web resources are stored also project dependent and managed in the original hierarchy. Also the embedded objects of HTML files are mirrored within
the same structure if these objects are located on the same origin then the HTML files. It is to be mentioned that duplications of objects are enabled, because in different projects different version of objects can occur.

The WebSave administrator view provides more options. Administrators can admin a group of user (e.g. a. course, a research group, a research institution, etc.) by adding, editing and removing user records. Administrators are enabled to collect user folders or user projects building a scholarly knowledge pool. An HTML reproduction of the knowledge pool can be built to place them at the disposal of an institution library (e.g. CD-ROM, Intranet, etc.). They also allowed to evaluate, edit and add xQMS metadata (Fig. 1). In addition, they can prepare the repository to render them searchable by the xFIND search system (see below).

As already stated above, discovering relevant information causes substantial human effort (a scientist looks up to 100 documents before finding a relevant one). Because of that, good and relevant information as well as additional information (descriptive and evaluative quality metadata) should also be archived and provided for further scholarly works by users, organisations and communities. In addition, these (local) metadata have to be used to improve the retrieval process of the resources. A possible solution meeting this requirement is the novel xFIND (extended Framework for Information Discovery) system (see xFIND 2000), which can build an index of the local Internet resources. Furthermore, the system combines the full-text index of the resources with the quality metadata and allows an improved search process (e.g. looking for a peer reviewed paper containing the phrase “web based training” in the full-text). In addition, the system also allows to index the original sources and to track changes of the resources. In a further version, a notification (e.g. user who referred the Web resource) will be performed. The human-created metadata (provided by the WebSave tool) and the computer-automated information (processed by the xFIND system) of the resources represent a helpful and growing information repository based of references of scholarly works. The idea follows the strategy of causing little effort by any individual within their research process (e.g. working on a paper), and accumulated output (a big background library of distributed Web resources and valuable metadata for the retrieval process) for the scholar communities or mankind. It is worth mentioning that the aim of the xFIND system is to build up a distributed, huge knowledge management system for Web resources enriched with descriptive and evaluative metadata.

**Current and Future Work**

Current work is going on to develop an interface layer for data exchange between the xFIND system and the WebSave tool. As a future work, in addition to local archiving of Web resources, an interface for an online document archiving system will be implemented. The first prototype implementation will be done on a Hyperwave Information Server (see http://www.hyperwave.com), which supports versioning and an advanced rights management. Thus, new relevant information of Web resources provided by the WebSave tool is transmitted to the xFIND system. The later system gathers the new documents and renders the full-text as well as the additional metadata searchable. In addition a document repository is requested to archive the Web resource. If the xFIND system detect any changes of the document, the document archiving system will be informed to archive also the new version.
Conclusion

It is obvious that increasingly Web resources are cited in scholar works. However, the problem of changing and removing of these resources requires solutions to preserve this referred information for further access. The WebSave tool in combination to the xFIND system is a possible solution to counteract the shortcomings stated so far. First experiences by the usage of students have shown that the tool will support their scholarly work preparing studies and diploma theses. The preservation of valuable Web resources and the enrichment of quality metadata allow to build up a growing scholarly knowledge repository, which supports further scholarly work. The xFIND system can be perfectly used to renders such repository searchable and provides an interface to the original sources and tracks changes of them.

Furthermore, we thank Infodelio (http://www.infodelio.com), which has supported us finishing this paper and has financed the conference fee and travel costs. Infodelio is working and researching e.g. in the field of Web resource discovery for research departments and scholar institutes.
iMovie and Educators: the Right Partnership for Making Digital Movies

Marianne Handler, National-Louis Univ., USA; Otto Benavides, California State Univ., Fresno, USA; Kathryn Morgan, Bemidji State Univ., USA; Robert Houghton, Western Carolina Univ., USA

The use of digital video and video desktop applications is spreading. So is the word about the ease of use of iMovie, the Macintosh software, used for creating finished digital video products. IMovie is a digital video editing application to help beginning users create digital movies from existing digital video footage. Beginning moviemakers can transfer clips from their digital camcorders, edit and arrange them into stories, add transitions, animated on-screen titles and publish them to the web.

The main focus of this interactive session, organized by a group of Apple Distinguished Educators (ADE), is to demonstrate the ease of use of this Macintosh application in the creation of digital videos in education. The demonstration would include:

• Transferring video from a dv camera into iMovie on the computer
• Demonstrating the digital video editing process
• Adding transitions and titles
• Adding narration, music and sound to the video track
• Transferring digital video back to tape

Digital video cameras, PowerBook's and iBooks will be available to session participants so that, in small groups, they can try some of the demonstrated techniques with sample video/audio files provided during the presentation. New and experienced users will find value in exploring the software and in seeing the examples of how iMovie is used.

Following this hands-on experience presenters will share examples of how iMovie and digital video are integrated into the educational arena. Examples will include projects created by K12 students and current practitioners as well as examples of efforts to improve technology experiences in pre-service and graduate teacher education. Participants will see examples from teacher credential students and early education teacher iMovies. Creating these clips can serve as a teacher tool as well as an opportunity for student involvement in the process. Presenters discuss the ways in which digital video's importance as an instructional tool can be demonstrated through its use in improving student learning by expanding the skills of emerging teachers. It is one example of a tool that allows faculty to focus on the critical need for teacher preparation reform to effectively use technology. As the ability to 'read' and plan visual communication becomes more and more important in students' lives, these tools help teachers to provide the needed skills in an authentic experience. There will also be opportunity to discuss the organization of workshops for helping new users of iMovie.
Abstract The challenge of developing engaging, interactive websites has spawned a variety of technologies including Java, ActiveX, Shockwave and Flash. Those teaching educational technology courses that include some web design are finding that they need to incorporate some of these technologies in their courses. The purpose of this paper is to present an overview of Macromedia's Flash, one of the most popular tools used in creating multimedia web presentations. Flash is a program that allows users to easily create full-scale interactive multimedia splash pages that can be delivered over the web (DelRossi, 2000) and allows both professional and amateur Web site designers to deliver fast interactive web pages even over slow modem connections.

Introduction

This session will provide an overview of how to use Macromedia's Flash to develop engaging, interactive websites. Flash makes it possible to develop fully animated web pages that allow learners to discover concepts that are not readily accessible on pages in a textbook or on static web pages. Educators can use Flash to create sophisticated presentations for the Web. For example, animation can be used to show water flowing into a beaker or to show shapes dividing to illustrate the concept of halves. With the help of Flash, web sites can contain interactive timelines and maps. Today's teachers need to be trained how to create educational Web sites where users are able to interact with the information. Davitt (2000) states, "the use of Flash and other interactive animation software as a visual thinking tool looks set to take off in schools." The session will provide a discussion of the advantages and disadvantages of Flash and provide participants with specific examples.

Flash makes it possible to develop fully animated web pages that allow learners to discover concepts that are not readily accessible on pages in a textbook or on static web pages. Educators can use Flash to create sophisticated presentations for the Web. Animation can be used to show water flowing into a beaker or to show shapes dividing to illustrate the concept of halves. With the help of Flash, web sites can contain interactive timelines and maps. Today's teachers need to be trained how to create educational Web sites where users are able to interact with the information. Davitt (2000) states, "the use of Flash and other interactive animation software as a visual thinking tool looks set to take off in schools.”

For example, the School Board of Palm Beach County, Florida has adopted Macromedia Dreamweaver as the standard authoring software for all Palm Beach County schools to use for Web page development. A majority of the schools have purchased the software in a bundled educational package that also includes Flash and Fireworks. The teachers have this software at their fingertips, and the county is offering free training that grants in-service points. Other counties are sure to follow in their footsteps.

The basic paradigm used to develop Flash applications is similar to other Macromedia development tools like Director and Premier. Flash applications, called movies, can include animations, buttons, pictures, sound, and text. Flash allows users to create interactive web sites with little or no computer programming. In working with Flash, you create a movie by drawing or importing artwork, arranging it on the stage, and animating it on a timeline. You make the movie interactive by making its objects respond to events and to change in specified ways. When the movie is complete, you can export it as a Flash Player movie, embed it within an HTML page, and transfer it and the HTML page to a Web server. The session will discuss some of the advantages and disadvantages of developing interactive, multimedia web sites with Flash. Topics will include vector versus bitmapped graphics, animation techniques, the Flash interface, and scripting and other features of Flash.
Vector graphics Versus Bitmap Graphics

To optimize graphics for transmission on the Internet, Flash uses vector graphics wherever practical. Because vector graphics represent the images as a series of mathematical formulas rather than storing information on each pixel, they tend to be much smaller files. Smaller files, of course, are essential in any technology delivered over the web.

Animation techniques

The basic animation technique used by Flash is page flipping. Page flipping works by simply placing an object on a background, taking a "snapshot" of the scene, moving the object slightly, and taking another "snapshot." This process continues until the animation is complete. By rapidly "flipping" these pages, the object appears to move across the background. Flash also allows you to designate a starting point and an ending point, and Flash fills in the frames between. This process is called, descriptively enough, tweening. Using tweening, you can even specify a specific path that the graphic object will follow. This section of the paper will give specific details of how Flash implements animation including several screen shots.

Interface

The Flash interface will be familiar to users of other Macromedia's multimedia development products like Premier and Director. The metaphor is "making a movie" and Flash applications have scenes, frames and a stage. Objects are placed on the stage at various points along a timeline. This section will describe the process of developing a simple Flash Movie.

Scripting

While it is possible to develop fairly sophisticated Flash movies without doing any computer programming, Flash does support its own simple programming language called ActionScript. ActionScript is really more of a scripting language that a programming language, so it works more like creating a macro than writing a computer program. Stringing a few basic commands together lets you add more complex interactivity to a web project (Price, 2000). Flash also makes it easy to create a fill-in form on a web site. Flash associates every editable text field with a variable containing the value currently entered in the field. You can pass the variables between Flash movies and CGI scripts (Long, 1999). This allows you to interact with user input.

Advantages of Using Flash

Flash provides a user-friendly environment that allows the user to develop high quality vector graphics. The resulting Flash movie is a compact file that has been optimized for Internet delivery. Flash movies scale to the viewer's screen size without increasing the file size or deteriorating the graphic quality. The smaller files mean less memory requirements and faster download times. Also you can export Flash movies to QuickTime or import QuickTime files (Price, 2000).

The Flash graphical user interface allows the designer to easily include interactive elements, multimedia, and hypertext links. Flash animated vector graphics are superior to any GIF animation - the file sizes are smaller and they can be changed as easily as any vector graphic. Flash makes it easy to create graphics react to the visitor's actions, creating multimedia Web interfaces to add sound, transparencies, and color blends (Teague, 1998).
Conclusion

Macromedia's Flash program is a significant technology for developing interactive, multimedia web sites that can be used to develop educational applications. As leaders in the field of Learning and Instructional Technology, it is important to keep abreast of such new technologies.

Using CD-ROM to Guide the Development of Professional Portfolios

Dennis M. Holt
College of Education and Human Services
University of North Florida
United States
dholt@unf.edu

Abstract: This article presents a description and evaluation of a multimedia CD-ROM project, “Developing Your Professional Portfolio for Internship and Beyond, First Edition”. It includes feedback from pre-service teachers who used the CD-ROM disk to help prepare their professional portfolios during internship. With the help of the CD-ROM, pre-service teachers developed portfolios that displayed their mastery of Florida’s Pre-professional Accomplished Practices, including the use of educational technologies to facilitate student achievement of Florida’s Sunshine State Standards. Contained on the CD-ROM disk are examples of electronic and multimedia portfolios.

Introduction

The College of Education and Human Services at the University of North Florida (UNF) has established a pre-service teacher education program that emphasizes portfolio assessment and clinical experiences in school classrooms. At UNF portfolio assessment is defined as the practice of collecting data to make decisions on the progress of pre-service teachers as they develop their understanding of teaching and acquire skill in facilitating student learning. Clinical education is the organized and supervised program of school-based teaching and learning experiences that serves to gradually induct pre-service teachers into the profession of teaching.

This article presents a description and an evaluation of a CD-ROM project titled “Developing Your Professional Portfolio for Internship and Beyond, First Edition”. During the past year the CD-ROM disk was field-tested. Feedback on its usefulness was received from pre-service teachers, supervising professors, and education personnel at teacher education institutions across the USA and abroad.

Portfolio Assessment and Clinical Experiences at UNF

The teacher education program of the College of Education and Human Services at the University of North Florida (UNF) prepares professional teachers to effectively participate in diverse and evolving learning communities. The program emphasizes structured clinical experiences in school settings. The evaluation of these experiences by UNF personnel is accomplished through a portfolio assessment process carefully designed and supervised by the faculty.

In the freshman year pre-service teachers complete their first portfolio for EDF 1005 - Introduction to Education. Details of the requirements for their portfolios are contained in the course syllabus. The 18-hour clinical education component of the course provides opportunities to link the applications of their learning with actual classroom experiences with students in school settings. In the sophomore year students complete EME 2040 – Introduction to Educational Technology. A portfolio of technology products linked to teaching tasks is required. Details of the course requirements are contained in the course syllabus.

During the completion of 100 hours of clinical experience through two, two semester hour field laboratory courses, pre-service teachers prepare working portfolios through which they document their work with students in classroom settings. These working portfolios contain collections of carefully selected documents used to portray their professional growth. (Boulware and Holt, 1998) Details of the requirements for the courses are contained in the course syllabi.

The culminating experience of the teacher education program is a sixteen-week internship during which pre-service teachers produce their professional portfolios. These portfolios are a selective and streamlined collection of teaching and learning materials that include a documentation of their mastery of Florida’s 12 Pre-professional Accomplished Practices. (Florida Education Standards Commission, 1996) Details of the requirements for internship and the portfolio assessment process are contained the internship handbook.
Professional Portfolio Literature

During the past few years an interest in portfolio development for teacher education has gained considerable momentum. There are several excellent books and articles that provide comprehensive information on the current state-of-the-art of portfolio development.

Campbell, Melenyzer, Nettles and Wyman (2001) provide helpful details to pre-service teachers for developing their portfolios. They state that the creation of portfolios is an authentic and holistic way to illustrate the developing professional competence of pre-service teachers. They found that portfolio development enables pre-service teachers to chart their own professional growth while following step-by-step procedures. In another publication (2000), the authors provide information for teacher educators on the portfolio development process. The critical elements of a well-designed portfolio assessment system are defined and illustrated. The authors provide directions to link performance assessment tasks to adopted state and national standards for success in professional education while making them faithful to real-life teaching. They provide specific help with the design and use of portfolio rubrics to assess the performance of pre-service teachers.

Farr and Tone (1998) provide a multitude of illustrations and helpful information on portfolio and performance assessment for improving teaching and learning in the school classroom. The authors define portfolio assessment as “the practice of saving lots of things that a student creates so that the student and the teacher can look at the collection and see how the student is doing” (p. 11). Portfolios are viewed as collections “organized in such a way as to reflect, promote, and report a considerable amount of thinking that students have applied to the contents in them” (p. 11). They believe that portfolios should “inform the teacher about the student’s progress as a thinker and language user, while indicating how effective the instruction has been and what additional instructional emphases are needed” (p. 11).

Cole, Ryan, Kick and Mathies (2000) provide definitions, strategies and details on the uses of portfolios and electronic portfolios across the teacher education curriculum. They define and describe a variety of useful tools for incorporating educational technology into college teaching and learning. They note, “bringing the learning process alive and using portfolios to document the products of this process requires various technologies” (p. 53). They suggest teacher educators consider the incorporation of the following with their use of computers in education: Local and wide area networks; servers; school networks; on-line databases; global educational networks; optical media; laser discs; Zip and Jaz cartridges; CD-ROM disks; scanners; digital still cameras and camcorders; and multimedia software.

Barrett (2000) defines several categories for the evolution of electronic portfolios and provides a conceptual framework for thinking about their development. She describes two bodies of professional literature that define the process for developing electronic teaching portfolios to support long-term professional growth: The multimedia development process and the portfolio development process. She illustrates levels of technology for developing electronic portfolios that are appropriate at each stage of the professional development of teachers.

Read and Cafolla (1999) provide an extensive review of the portfolio literature. They base their portfolio assessment work on a constructivist theory of learning which “views the learner as actively engaged in the construction of his or her own representations of knowledge” (p. 98). They found that the process of creating professional portfolios requires pre-service teachers to “engage in self-reflection as they select performance items for their portfolios” (p. 99). The authors view the production of portfolios as a means for pre-service teachers to provide evidence that they have met national and state professional education standards. They found that standardized and criterion-referenced tests fail to fully reflect the actual learning that takes place during instruction in teacher education. They describe the computer software and hardware used for the successful production of multimedia portfolios in their pre-service teacher education program.

Hartwell-Young and Mouriss (1999) offer help to teacher educators interested in digital portfolio development. The purpose of their textbook is to help teachers learn how to use multimedia to describe their unique teaching and learning experiences and to reflect on how they grow and develop their professional life. The textbook is designed to help teachers “understand ways in which technology can assist them to record and communicate their professional achievements, and how they can share what they have learned with students to help them unlock the secrets of multimedia” (p. 3).

Holt and McAllister (1999) provide a research-base for their work with electronic portfolios. They describe the implementation and evaluation of a five-year project with electronic portfolios for pre-service
teachers linked to the electronic folders of their students. They provide details on how computer software for language arts, mathematics, and science was successfully employed in school-based professional development classrooms through collaboration between a school district, university teacher education program, and business partners.

**CD-ROM Development**

Read/write compact disk technology, commonly called CD-ROM was selected because of its effectiveness as a means for presenting the multimedia needed to accomplish the teaching and learning outcomes of the project. CD-ROM enabled the author to include computer graphics, digital video, photographs, recorded sound, scanned documents and text as integral parts of the learning product. The media also provided a means to illustrate a large number of examples that included samples of electronic and multimedia portfolios.

The computer hardware and software used in the production of the CD-ROM included a powerful multimedia personal computer with large RAM and hard drive equipped with stereo sound; read/write CD-ROM recorder/player; digital capture card; color scanner; digital still camera; camcorder; video capture card to convert analog video from a video camera or VCR to compressed video for storage; large storage devices for graphics, sound and video, including an Iomega Zip drive (Iomega, 1998); software to accompany the hardware, including Photoshop (Adobe, 1998); and software for pre- and post-production digital design. The student documents were created in Word (Microsoft, 1998) and the CD-ROM was created in Director 7 (Macromedia, 1998).

The author was responsible for planning the project, including the overall design, script and budget. Help was contracted to complete the storyboard, graphics, audio, video and related production work.

**Findings**

During the 1999-2000 academic year pre-service teachers used the CD-ROM disk during their internship semester along with other materials to complete their professional portfolios. They completed a feedback form by answering five questions. The results are summarized below.

**A. What were the key concepts you learned from this CD-ROM?**

How to display mastery of the 12 Florida Pre-Professional Accomplished Practices; The value of educational technology as a means for illustrating the contents of a portfolio; Ways to include educational technology in teaching and learning; The ease of preparing a portfolio; Becoming aware that portfolios help provide prospective employers with a clear view of teaching skills; Ways to provide reasons for the selection of portfolio artifacts; Professional portfolios do not have to look the same.

**B. What did you find most useful/meaningful in this CD-ROM?**

A better understanding of accomplished practices and the criteria for their documentation; Attractive and interesting artifacts, including bulletin boards, unit and lesson plans, photographs and video clips; Being able to print any page contained on the CD-ROM disk; Receiving a personal copy of the CD-ROM disk so that it could be viewed when convenient; Viewing portfolio examples which were direct and to the point, without a lot of extraneous material; Reasons why portfolios are necessary for professional growth and development; Viewing different approaches to portfolio development; How to write a resume and develop a PowerPoint presentation; Sample video segments on various topics, such as a personal teaching philosophy and classroom management plans.

**C. What would make this CD-ROM even more useful/meaningful?**

Add more detail on navigating through individual accomplished practices; Refine the back buttons; Add more video episodes of classroom teaching; Include additional artifacts illustrating the accomplished practices; Make the CD-ROM disk cross-platform for both the PC and Macintosh computers.
D. What ideas or information will you apply?

Incorporate lots of educational technology into the professional portfolio; Use the CD-ROM disk as a reference guide while building the professional portfolio; Include videotaped examples of classroom teaching to document teaching skills and learning outcomes; Incorporate ideas found in the table of contents from the sample portfolios as an organizational structure for the professional portfolio; Include student electronic folders to illustrate knowledge gained from instruction; Develop a personal CD-ROM portfolio from the professional portfolio.

E. What additional comments do you have?

The CD-ROM disk helps with the preparation of a professional portfolio; Learning how to develop a professional portfolio and incorporate good video clips is good preparation for the process of preparing for National Board Certification of teaching. The CD-ROM disk helps relieve anxiety about the task of developing a professional portfolio by providing model examples to clarify the expectations for doing the assignment.

Summary

CD-ROM technology can help pre-service teachers with the production of their professional portfolios. Through the uses of multimedia, pre-service teachers were able to learn that portfolios are a natural way to document their professional growth and development during internship and throughout their teaching careers.

Abstract: Over the last several years there has been significant progress in techniques for creating autonomous agent, i.e. systems that are capable of performing tasks and achieving goals in complex and dynamic environments. In this paper we present the architecture of the system SACA(Système d'Apprentissage Coopératif basé sur le modèle d'Agent). Which is a multi-agent system to support cooperative learning. In this system, the agent is modelled in terms of their capabilities and mental states. This system is composed of a set of agents(human and artificial). We present here its main features.

1. Agent Model:

Shoham proposes an agent architecture in which each agent possesses the concept of mental state(e.g. belief, intention, obligation) as an internal expression(Shoham 1993). Also, the agents in GRACILE have already been designed adopting the framework proposed by Shoham (Ayala & Yano 1995). To design and construct an agent model, we referred to their view of an agent model.

For us, an agent consists of a knowledge base which includes beliefs and commitments to itself and to other agents, a set of function modules that constitute the agent's capabilities, a communication module in order to communicate with other agents and a reasoning module for updating the mental state/commitments of the agent.

2. Architecture of SACA:

SACA is composed of a set of agents (human agent and artificial agent). The human agents are: Learner agent, Author agent and Formative agent. The artificial agents are: Tutor agent, Domain agent and Evaluator agent. Artificial agents are cognitive agents.

1. Domain agent: allows to represent the matter to be taught. This matter is organised on educational objectives related by a « prerequisite » relations(Lafifi & Bensebaa 2000).

2. Tutor agent: orients the learner (propose an educational objective to the learner, this educational objective is adopted to his knowledge level) and provide learner with informations about cooperation opportunities with their peers.

3. Evaluator agent: evaluates a learner in an educational objective.

4. Learner agent: has informations about learner and facilitates the task of learner to communicate with their peers or in the learning task.

5. Author agent: is the responsible of the construction of the matter to be learned. It creates the educational objectives and makes the conditions to present these educational objective, i.e. « prerequisite » objectives.

6. Formative agent: is the responsible of the formation process of learner from the initialisation to the achievement of their formation goals.

3. Conclusion:
We had presented an architecture of a system that offer the possibilities to the learner to cooperate/collaborate with their peers. For doing this, the tutor agent posseses information about the knowledge state of learner(Student Model). This tutor can give advices to learners and can provide them by informations about cooperation opportunities. Our system is a multi-agent system that is composed of a set of agents(human and artificial). Now, we are in the step of implementing this system.

Abstract: Cases and case methods of teaching represent a promising approach in education. This approach has always been best used to teach people about realistic decision-making situations. Case methodology is especially effective if students are required to identify facts and issues, to view events from different perspectives, to apply current professional knowledge and research, and to predict consequences of various courses of action. The purpose of this work is to present an application tool for the development of case-based web environments. This tool is a reusable, component-based application that can be specialized to produce custom applications.

1. Introduction

Cases and case methods of teaching represent a promising approach in education. This approach has always been best used to teach people about realistic decision-making situations. Nevertheless, cases have been used extensively for professional preparation, and are only now beginning to be widely employed in education (Merseth, 1991). Case methodology is especially effective if students are required to identify facts and issues, to view events from different perspectives, to apply current professional knowledge and research, and to predict consequences of various courses of action (McNergney, Herbert, and Ford, 1993).

The use of case methods can help students to forge important connections between knowledge and practice (Cooper and McNergney, 1995). Case-based learning is a flexible model where an lecturer uses leading questions to direct students toward "correct assumptions". Cases are like stories or story lines that students read or explore interactively. They can direct students toward a conclusion, or provide the resources and context to discuss and debate issues dynamically. During a case-based process, the students must be involved in authentic practices.

From the point of view shown above, the case-based learning model is not far removed from direct instruction. However, if the students are allowed to formulate their own opinions of a case by promoting group-coordinated research activities, debate, or simulated decision making, the model is more closely aligned with social constructivism (problem-based learning).

Two primary methods are possible to deliver cases (Jarz, Kainz, and Walpoth 1997). The first is a low-tech option of simply presenting the case to a class, then debriefing and discussing orally. This way is best suited for face-to-face lessons, with both students and lecturers on the same place at the same time. The second is using technology. A system can contain case information and increase the possibilities for student interaction with the data (collecting, sorting, organizing, etc.).

The purpose of this work is to present an application tool for the development of case-based web environments. The tool is a reusable, component-based application that can be specialized to produce custom applications.

2. The Case-based Training Environment

The Case-based Training Environment (CbTE) is intended to aid the acquisition a specific ability, using a series of cases. A case places a practical problem for a student, who needs to choose the action that solves the problem shown in the best way. For example, a company wants to train its management staff in Organizational Leadership. The following case could be created: a very productive employee informs his manager that he is
unhappy because his wage is below the market's average for his position. However, the company cannot afford a wage raise. What is the best way to handle this situation?

A set of cases can be created to develop a specific ability. A case describes a situation and presents a list of possible actions among which the student must choose the best way to handle the situation shown. A set of cases build what is called a training module in the CbTE. Training modules are created with an authoring tool, and they are saved in a format that allows its easy installation into the environment. An author can create a training module in three different modes: Training, Evaluation and Outline.

In the Training mode, each case shows its references and all its action options. When a student selects an action, the best answer and a feedback for the chosen action are shown before the next case is exhibited. In the Evaluation mode, each case presents all its action options, but its references are omitted. When a student selects an action, the next case is exhibited immediately, showing neither the best answer nor the feedback for the chosen action. In the Outline mode, each case shows only its best answer, along with its references and feedback.

Figure 1. A case sample (in Portuguese)

While solving the cases presented in a module, a student leaves his passage track. The CbTE does not require a student to go through all the cases of a module at once, except in an Evaluation module. The student can stop, continue or restart his track.

A student can go through the cases of a training module in three different ways. In the Pre-ordered way, the cases are shown in a pre-defined sequence defined by the author. In the Random way, the cases are shown randomly, in an order sorted by the environment. In the Custom way, the student chooses the sequence he wants to follow the cases.

There is also the Free Access module. Any student can access this type of course, which does not even require enrollment.
3. Administrative Area

The CbTE has an administrative area where it is possible to have a comprehensive control of the learning environment. An administrator is responsible for installing training modules created by instructors in an offline tool (as we shall see later in this work) and registering the students who will participate in each module. As a result of a module closure, the administrator can view a whole set of student performance statistics, such as, case most common mistakes and students tracks. These statistics can serve as reports for the faculty board or for the HR department, for example.

The CbTE's has an open architecture based on components. This component-based architecture allows the integration with other faculty/corporative systems and with other existing training environments. This way, it is possible to create a fully customized training environment using a subset of CbTE's components and an all-new Web GUI.

All the communication exchanged between the CbTE and a corporative system is done using XML (extensible markup language) with predefined DTDs (document type definition) for each type of communication. XML has been designed for ease of implementation and for interoperability (W3C, 1998). So, the tool’s persistence mechanism becomes completely transparent for the corporative system. This feature aids the integration with other systems, simply requiring the development of a “driver” that is able to understand both the corporate system and the tool’s XML interface.

![Diagram of Module DTD](image-url)

**Figure 2.** Module DTD
4. Authoring Tool

There is also a standalone (non-Web) authoring tool that allows the independent creation of training modules. The instructor does not need to be online to develop modules. Since some module cases may have rich multimedia contents, such as videos, animations and so on, the offline aspect of module generation allows for rapid development without the burden of multiple file uploads and downloads to the CbTE server.

The instructor must indicate what module he is creating: Training, Evaluation or Outline. He also needs to indicate how the students will access the module cases and, whenever it applies, how many times a student can go through the module cases.

Currently, cases within CbTE's training modules support the use of images, applets, videos, texts and shockwave animations, i.e., basically all kind of media a browser can display. Thus, the instructor can choose the way he finds best to introduce the case problem, enriching the students learning experience. Besides case introduction, the instructor can insert context-specific references (only for Training mode modules) for each case for student consultation during the case problem solving. These references serve as the support didactical material in the training module.

These modules can be easily installed (imported) to the CbTE by the local administrator. The authoring tool generates a XML representation of the module data. XML representation releases the instructor from having to worry about interface aspects, which is a administrative task. In addition, XML is a step forward learning environments integration. Since the contents of a training module are represented in XML, they do not hold proprietary interface properties. This makes possible for a specialist to develop a training module that can even be commercialized with institutions that use the CbTE as their training solution.

5. Conclusion and Future Work

This article presented an application tool for the development of case-based web environments. The case-based training method is a powerful hands-on/experimental approach for learning process. The tool is a reusable, component-based application that can be specialized to produce custom applications.

The CbTE has an area for students where they are able to go through the training modules and an administrative area where an administrator can install modules, register students, etc. These areas have a Web-based interface, requiring them (students and administrator) only to have a browser to use the tool's functionalities. The CbTE has also a standalone application for module authoring. This application allows the independent creation of modules, serving as a work tool for content generator enterprises.

Cases within training modules are multiple choice-like questions. In next versions of CbTE authoring tool, it is intended to provide other kinds of case representation, such as true or false, matching etc.

Currently, the CbTE is an all self-paced training tool. However, the Web brings a whole set of capabilities for collaboration that can be used to enhance learning experiences. The CbTE will support online learning groups. Doing so, it will be possible for the students to share their experience with others. Student interaction is always helpful, increases the motivation and saves time, leading to a better overall learning process. It may also be used a help desk to allow the communication between students and instructors (and possibly the administration).

The CbTE has a component-based structure to facilitate its integration with other pre-existing corporate systems. The data communication between legacy systems and the CbTE is done through XML documents with specific DTDs for each type of communication required. XML is a tool to help solve data-management problems.

The XML nature of training modules generated by the CbTE's authoring application aids content exchange and commercialization. We seek to create a specialist environment, where specialists (content providers) can exchange and trade training modules.

Abstract: This paper presents a cursory overview of CD ROM applications to instruction. This is followed up by a specific example of how a CD ROM resource was created for use in a Middle School Teacher Education Course. The CD ROM was purposefully designed to allow instructors flexibility in how it may be integrated into the curriculum. In closing, the paper will entertain the notion of designing software with an understanding that the instructor may subvert the intended classroom usage.

The Promise of CD ROM Technology

The advent of recordable and rewritable CD ROMs has revolutionized data storage due to the low cost of the media and associated CD burning hardware/software. As an instructional tool, CD ROM technology has many advantages by comparison to other recordable media. Stibbons, (1997) suggested these include: (1) significant capacity for storage of graphics, (2) rapid and facile access to the storage medium, (3) the potential for information sharing through hypertext linking and (4) the ability to treat the CD ROM as a searchable database.

The CD ROM has enjoyed a plethora of applications in a variety of educational settings. Table 1 outlines but a few of the categories and specific examples where CD ROM has been successfully implemented.

In the Middle School Project described herein we have capitalized on the ability to store documents on CD ROM in the efficient Adobe Acrobat format. The ready availability of Acrobat reader software has made the pdf file format a very useful tool to the educator. The companion Acrobat Writer program allows you to save text and graphics together as a single document using far less memory than either scanned documents (graphic format) or text and graphics separately. The Acrobat software environment allows for a user-friendly interface that includes a simple hyperlink table of contents menuing system and a built-in search engine. In this project the Acrobat Writer software was used to create the Middle School resource which students in turn could access using the Acrobat Reader.

The Infrastructure for The Middle School Project

At Acadia University we offer teacher preparation programs which include a course in middle school education as part of our two-year post-degree teacher certification program. Students completing the program receive a Bachelor of Education and are issued a public school teaching license. Acadia University however is unique in that it is the first laptop university in Canada. The so-called “Acadia Advantage” program was initiated in 1996 in partnership with IBM. In effect this puts a laptop computer in the hands of every student on the fully-wired campus network. This has had profound instructional implications (MacKinnon & Hemming, 1998).
The CD ROM project I am about to describe makes particular use of the fact that all students in our middle school courses have anytime-anywhere use of an A20m IBM ThinkPad®. Student computers are equipped with the latest multimedia capabilities as well as a complimentary software package that includes Adobe Acrobat reader.

Table 1: Some Categories of Educational CD ROM Use

Contents of the CD ROM

The Middle School CD ROM has the following components:
- An essay summarizing the middle school movement, the nature of the adolescent and middle school curriculum.
- Adapted case studies surrounding the challenges of middle school teaching.
- Hyperlinked access to current academic articles on the middle school.
- Videotaped interviews of middle school administrators and teachers around a series of relevant topics.
- Powerpoint slide presentations of actual middle schools, highlighting the teaching environment

The interface for the interactive CD ROM is shown in Figure 1. The CD was formatted in such a way that it auto-loads to present this menu to students. From this page students could hyperlink to the theory behind middle school education (as shown in Figure 2). The menuing system in the left column allows students to access.
printable course notes. The second component of the interactive CD ROM is the database of case studies. The ready access of these studies as compared to sending students to the library has the potential to promote more efficient use of the class time. On-line articles were prepared by scanning them into pdf format and then placing them on the local campus network. The format and content of video interviews is shown in Figure 3.

Design of the Middle School Resource

In teacher education the notion of constructivism (Greening, 1998; Jonassen, 1994) arises frequently. This resource has the potential to be used in a constructivist teaching environment but what about the software itself? In preparing constructivist software the designer faces a dilemma. Clearly knowledge construction has its roots in the experience of the student and as such prior knowledge should have a significant impact on the direction of the instruction. At the same time the software designer no doubt has a vision for how the software might be used in a classroom. Particular structuring of the software may then be counterproductive to true constructivism and more likely to lead to behaviorist responses from students.

Squires (1999) has suggested that despite the software designer’s best intentions, instructors will often subvert the intended use of the software and promote more unique applications in their own classrooms. Could this not be accounted for in the design? The Middle School software is a resource which in its simplicity allows the instructor to integrate the resource into their more traditional modes of instruction. Squires calls this approach “volatile design”. This flexibility can improve the utility of such a resource to a wide range of educators.

Using the CD ROM in a Real Course: One Approach

The CD ROM acts as a central resource for the Middle School Course. The following is an outline of how the CD ROM is used in one teacher education class.

Class notes: The Middle School essay serves as a basis for discussion in the course. Each small group of students is assigned a topic from the essay and presents this topic to their classmates. There discussion of the materials also includes reference to the database of 95 online articles which they also access from their CD ROM.
**Case Studies:** Each group of students is assigned a case study from the CD ROM. The group then leads an electronic discussion of the case with another assigned group in the class. The discussion is peer monitored and evaluated using an electronic discussion group coding system (Aylward & MacKinnon, 1999).

**Issues/Strategies in Middle Schools:** Students review the CD ROM video clips of topical issues in the schools and use it as a basis to visit a local middle school and conduct teacher interviews/classroom observations around a particular issue/strategy. There are also guest speakers (administrators/teachers) invited to the class. This entire exercise culminates in a short review on the focus issue/strategy.

**Online Articles:** In their electronic discussion of case studies, students are expected to support their arguments/contributions via reference to an online library of academic articles. Students leading the discussion groups are expected to submit a paper that summarizes the discussion group exchange and integrates this with synopsis of at least three related academic articles from the database.

**Interdisciplinary Unit:** Students are assigned a theme. Using the CD ROM resource notes on curriculum design, students create concept webs (using Inspiration©) of an interdisciplinary unit on their theme.

In ensuing university semesters education faculty will have the opportunity to use the Middle School CD ROM in their classrooms. It remains to be seen whether the volatile design of the resource will allow instructors to utilise the CD ROM in novel instructional approaches.

Abstract. This paper describes the collaborative process we've utilized in conceptualizing a digital portfolio requirement for all teacher education majors. We entail the philosophical, logistical, and infrastructure considerations that have been part of the process along with the portfolio model adopted. Finally, we discuss the assessment timeline for portfolio evaluation.

Throughout the country, three conditions guide how schools of education approach the integration of technology into teacher education programs. (1) University faculty and students need the tools, environments, and on-going professional development to integrate technology into the teacher education curriculum. (2) New national accreditation standards are requiring schools of education to prepare new teachers and administrators who can integrate technology into their curricula. (3) Licensure and certification are now requiring proficiency in technology integration for new teachers and administrators. These national and local imperatives are the foundation of our institutional reform.

As our institution plans for the implementation of such issues, the digital portfolio has emerged as a tool that we envision enabling us to assess students’ competencies. We also believe that engaging in the electronic portfolio process will help students to develop technology-related knowledge and skills.

Background

By June 2002, our university is mandated to have an institution-wide performance-based Unit Assessment System (UAS) approved by the Indiana Professional Standards Board. The UAS has multiple “Decision Points” that are being discussed. A standards-based approach is being used for licensing. The standards, which serve as a foundation for these licenses, include the INTASC Core Standards as the conceptual framework, Indiana Developmental and Content Standards, and the ISTE Standards.
For two years, a campus-wide group called the Teacher Education Performance Assessment Steering Committee (TEPASC) has worked on creating procedures for reaching this goal. In regard to the knowledge, disposition, and performances for teaching majors, TEPASC has recommended that: (a) licensure areas provide multiple opportunities for each student in the program to demonstrate and to document an understanding of the state P-12 proficiencies, and (b) students demonstrate and document successful experiences in planning and executing lessons directly related to relevant P-12 proficiencies. Our institution has identified student digital portfolios as one performance assessment instrument for demonstration of multiple competencies.

In recent years, a number of portfolio types have been used on our campus by faculty from a variety of disciplines. The medium of these portfolios has included paper, PowerPoint, and the World Wide Web. Likewise, the specific purpose of the portfolios has varied according to the needs of the discipline and the preferences of the faculty member teaching the course. As the university began to discuss a campus wide portfolio model for teacher education, it was recognized that cross-disciplinary expertise should be utilized, and that a consensus needed to emerge as to the type of portfolio best suited for teacher education. The decision to recommend a digital portfolio over a paper-based portfolio emerged in part, as a result of parallel initiatives to infuse computer technologies in the teacher education curriculum. The interactive, non-linear attributes of digital media, which may include audio, video, text, numerical data and graphics, may potentially bring a depth and richness to student work and understanding.

As one initiative of our PT3 grant, a team of university faculty met weekly to develop the portfolio model. In addition, a series of experts from other universities and corporations such as Apple computer were brought to campus to provide their insights regarding conceptual frameworks, technological infrastructure, and portfolio logistics. These sessions, which were open to all of the university community, stimulated discussion about the shape and form of our portfolio system. We sought out and examined other teacher education institutions attempting to implement similar initiatives as well as individual faculty across the country working in this area.

Portfolio Purpose

There is no universal portfolio in terms of purpose and structure. Portfolio types include process portfolios, reading portfolios, showcase portfolios, and exit portfolios (see Katz & Johnson-Kuby, 1996). The portfolio structure we envision responds to a variety of needs – personal, pedagogical, and program related. While the overall goal for the digital portfolio is to meet the learning and competency objectives of the program, our goal is to maintain the emphasis on reflection and to highlight the developmental process of portfolio construction. The primary purpose of the student digital portfolio is a cumulative and on-going reflection of their progress and readiness in learning to teach. The portfolio as a whole must reflect the students' entire certification program. That is, students are expected to draw on as many of their courses and experiences as possible. Klenowski (1998) writes that portfolios provide a structure for documenting and reflecting on teaching and learning practice. The portfolio allows for the collection of a range of tasks and information about teaching over time in different settings. Consequently a richer portrayal of teaching practice is possible. Good (1992) writes that portfolios should enable students to think critically about important identifiable content as well as develop particular dispositions.

Given the longitudinal nature of the student portfolio, we hope that student reflection will become more rich and complex as they continue in the program providing quality information that can be used to examine growth and progress over time. Wolf, Whinery & Hagerty (1995) indicate that by engaging teachers-in-development in the practice of documenting and reflecting on their teaching, and in holding regular and focused conversations with their colleagues about their practice, we are building individual dispositions and a professional culture that values reflective, collaborative practice (p. 37).

The portfolios our students develop will serve many purposes. A primary goal of the digital portfolio will be to provide a vehicle for students to demonstrate they have met the learning and competency objectives of the teacher education program. Another important objective will be to emphasize reflection and to highlight the pre-service teacher's developmental process. Students will be expected to draw on as many of their courses and experiences as possible. Given the longitudinal nature of the student portfolio, we hope that students' reflections will become more rich and complex as they progress in the
program, providing quality information that can be used to examine growth and progress over time. Finally, students will need to continue to document their development as a teacher via a portfolio during the "induction" phase (first two years) of their professional career. The portfolio students develop throughout their undergraduate curriculum will continue to evolve during these initial years as a fulltime teacher.

**Portfolio Structure**

A web-based medium has been chosen for our digital portfolios. The web is advantageous for several reasons. First, it is cross-platform. Therefore persons creating and viewing the portfolio can use the computer of their choice. Second, many media types can be utilized on the web including text, graphics, sound, and video. Multimedia will allow for rich representations of student learning and development. Third, HTML is not a proprietary format. As it is an international standard, with each new version slated to maintain compatibility with previous versions, it will endure. Fourth, web files are easily transportable and can be displayed either online or distributed through other media such as CD-ROMs. Finally, a web-based portfolio can be more easily accessed for asynchronous assessment by all stakeholders (teacher education faculty, content area specialists, and P-12 teachers).

Requirements for documenting student competencies in numerous state and national standards compelled us to frame the structure of the portfolio on a more holistic and broad level. To do this, we returned to our institution's conceptual framework based on the Interstate New Teacher Assessment and Support Consortium (INTASC) Standards. Students will reflect on and document their development as teachers in relation to each of the ten INTASC standards. Appropriate artifacts supporting their development in each standard will be hyperlinked within the portfolio.

The categories of artifacts that can be used for sources of evidence are mandated by the state and may include:

1. Classroom Performance – Video
2. Lesson Artifacts (e.g., lesson/unit planning, handouts, slides, assessment documents)
3. Paper/Pencil Tests of Knowledge
4. On-Demand Tasks (e.g., simulations, case studies, problem-based scenarios)
5. Interviews of Candidates
6. Testimonials (e.g., cooperating teachers, university supervisors, students)
7. Products Reflecting Learning of Candidates’ Students (e.g., student artifacts)
8. Other Assessments (e.g., self-reports, special projects)

**Portfolio Assessment**

We have chosen four main stages for the portfolio development process, within which students build toward "decision points" in their teacher training. Table one illustrates the progression through the program and describes each of the decision points. At each of these decision points, assessment of the portfolio will occur. In addition, selected artifacts of the portfolio will be developed and assessed as part of courses in the students' curriculum. Artifacts are submitted and assessed at different stages of a student’s progress, from admission to graduation. Table one (Tab. 1) demonstrates the progression through the program. Students must successfully complete each stage in order to gain admittance to the subsequent stage.
<table>
<thead>
<tr>
<th>Description of Stage in Decision Points</th>
<th>Resulting Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Stage 1:</strong> The focus of Stage One is the required introductory teacher education course. Course content centers on informing students of the INTASC and IPSB standards, expectations of the program, and the arena for introduction of computing skills related to portfolio production. Students create a self-assessment document or “autobiography that represents them as learners and individuals. This self-assessment focuses on students’ initial reflections about the nature of teaching and education in relation to INTASC standards and the university conceptual framework. The course requirement will include the initial development of a digital portfolio.</td>
<td>Decision Point 1: Builds on successful completion of introductory courses in Teachers College and content areas. Becomes teacher education aspirant.</td>
</tr>
<tr>
<td><strong>Stage 2:</strong> This stage focuses on gathering artifacts to demonstrate acceptable performance with content knowledge and mastery of skills and dispositions, and meeting the ISTE General Preparation Performance Profile in portfolio. Students again submit a self-assessment document. Successful completion of this stage leads to formal acceptance into the Professional Education sequence.</td>
<td>Decision Point 2: Culminates in admission to the Teacher Education Program and may enroll in the Professional Education sequence.</td>
</tr>
<tr>
<td><strong>Stage 3:</strong> During this stage, students select from their body of increasingly extensive artifacts (essays, evaluation, video clips, lesson plans, etc.) examples that demonstrate sufficient mastery of performance and knowledge relative to content and developmental standards, before admitted to student teaching. Students must also perform at the Professional Preparation Performance Profile defined by ISTE. Students again submit a self-assessment document.</td>
<td>Decision Point 3: Culminates in Admission to Student Teaching</td>
</tr>
<tr>
<td><strong>Stage 4:</strong> This final stage adds the student teaching experience. Students will select artifacts generated in classroom performances (lesson plans, video of classroom performance, evaluations, etc.) to add to their prior collection in the portfolio. Students must meet the ISTE Student Teaching/Internship Performance Profile. Students again submit a self-assessment document. The purpose is to demonstrate sufficient mastery of standards for subsequent licensure.</td>
<td>Decision Point 4: Culminates in graduation and possible recommendation for initial licensure.</td>
</tr>
</tbody>
</table>

Figure 1: Decision Points and Outcomes
Infrastructure Considerations

Parallel yet related initiatives involve the development and implementation of large-scale Web-based databases that support longitudinal portfolio construction and distribution as a core service of our licensure program. The portfolio database will be integrated into other Web-based representations of competence. A new critical need is to integrate the portfolio with performance assessment records. This is the systems and infrastructure that will support large-scale, Web-enabled, relational databases that sustain and promote the competency profiling, performance assessment, and digital portfolio initiatives. Teams are building an advanced data engine to support the representation and development of performance and competence. We are building upon established models for examining the NCATE, ISTE and NETS, INTASC, IPBS and P-12 competencies and standards and the ways they interface into the academic cycles of teacher education majors. For the duration of their teacher education experience, students, faculty, and cooperating teachers and administrators will interact with the competency database for the following services:

1. Providing Web-based diagnostics in relation to INTASC, ISTE, NETS, and content area standards and competencies.
2. Evaluating progress towards competence.
4. Maintaining student portfolio and coursework relevant to licensure.

Summary

Other infrastructure considerations under discussion include the need for faculty professional development, staffing for support of portfolio development, and a university-wide plan to support and update technical resources. While the development of a digital portfolio system has presented us with many challenges, it has also provided a glimpse into an exciting future for our teacher education program. At the time of this paper, ultimate decisions about the nature of the portfolio and its place in the unit assessment system have yet to be finalized. For example, while we have decided that the portfolio will be web-based, we have not yet come to consensus on issues such as the extent that individual licensure areas will be allowed to customize the "look and feel" of the portfolio. Many of these decisions will be made early in 2001. In addition, ongoing pilot testing of portfolio structures and processes will continue during the Spring 2001 semester. The current status of our portfolio model will be reported during our presentation.

Abstract: Web-based learning (WBL) is rapidly becoming a staple at all levels of education. Statistics from a national study by the Department of Education in 1997-98 showed almost 44 percent of all higher education institutions offered distance-based courses, an increase of one-third since 1994-95. Estimates are that by the year 2002 there will be more than 2 million students in higher education participating in distance education. In this period of rapid change as education adapts to use the new tools of web-based learning, educators need to consider the foundational concepts of learning theories. Modern learning theories, based on constructivism, emphasize individual differences in learning styles. Focusing on how to use some of the information that learning theory offers can improve WBL just as it has helped with traditional educational environments. This paper discusses how WebCT3.0 can be used to make WBL appealing and effective for a variety of individual learning styles.

Introduction

Web-based learning (WBL) is rapidly becoming a staple at all levels of education. Statistics from a national study by the Department of Education in 1997-98 showed almost 44 percent of all higher education institutions offered distance-based courses, an increase of one-third since 1994-95 (CHEA, 2000). The Council for Higher Education Accreditation found most of the growth in distance education was in higher education institutions that use asynchronous computer-based technology (primarily over the Internet). The Army announced in July of this year that it would spend $600-million over the next six years to enable any interested soldier to take distance-education courses on the Internet at little or no cost (Carr, 2000). Estimates are that by the year 2002 there will be more than 2 million students in higher education participating in distance education.

In this period of rapid change, as education adapts to use the new tools of web-based learning, educators need to consider the foundational concepts of learning theories. Modern learning theories, based on constructivism, emphasize individual differences in learning styles. The most effective learning environments offer content that caters to these individual differences in learning styles. The distance educator must employ a number of strategies focusing on planning, student understanding, interaction, and teaching to ensure a successfully delivered course (Cafolla & Knee, 1999).
Learning theories 101: everything old is new again

The question of how we learn is at the core of all educational theory. Educators and philosophers have been trying to theorize how we learn since ancient times. Theories evolving in more recent times focus on the learner and differences in those learners. Learners are considered to be unique individuals whose learning preferences may significantly vary. Creating content that is learner-friendly for students who prefer a sequential linear content presentation or a more random non-linear preference is important. Older, foundational learning concepts such as Vygotsky's “zone of proximal development” and scaffolding are very applicable to WBL. In computer-mediated learning, scaffolding is more important than in traditional education settings because computer-mediated learning is typically collaborative, and all participants will provide scaffolding to other participants at different times during the learning process (Bull et al., 1999). A second concept is that of dual coding. Memory researchers agree that dual coding is a very effective learning tool (Craik & Tulving, 1975). Dual coding helps in the learning process by using two or more sensory avenues to reinforce memory. Using such dual coding techniques such as relevant visuals and the prominence of imagery use during accretion and retrieval greatly improve learner outcomes (Hodes, 1993). Simonson (2000) uses an Interactive Study Guide (ISG) to help cue visual learners. The ISG is a series of visual cues that link to key lecture concepts to aid memory formation. WBL allows for many different instructional opportunities for dual coding including still images and video elements. Multimedia elements are a critical part of content development on an education website (Knee et al., 2000).

Instructor/designers who consider the information that learning theory offers can improve WBL just as it has helped in traditional educational environments. The focus of this paper is to show how WebCT3.0 can be used to make WBL appealing and effective for a variety of individual learning styles.

WebCT 3.0 as a tool for creating individual learning environments

WebCT is a multifaceted management tool for creating WBL courses. WebCT 3.0 is the newest version of the software and was released in summer of 2000. This is a widely used WBL software application and version 3.0 will be used in many universities beginning in early 2001 as their primary delivery tool. This most recent release of WebCT 3.0 has a greatly improved designer interface that eases the initial course implementation. Distance learning software such as WebCT 3.0 can be used to facilitate the creation of individual, learner-centered environments. WebCT 3.0 offers a rich variety of communication tools, and has the capacity for the inclusion of sophisticated multimedia elements like streaming video. One of the greatest strengths of WebCT 3.0 is that it allows content to be organized along a linear path, or in a more hypertext driven non-linear fashion, or both dependent upon student needs or desires. Some learners are more comfortable with a structured sequential topical organization and others need to reorganize the content in order to make optimum sense of the presented information. WebCT 3.0 has new features such as the Compile tool, which allows the student to reorganize content into their own set of notes. WebCT 3.0 has introduced a new feature called “breadcrumbs.” A breadcrumb is a list at the top of the page that shows the path the student has taken to get to the current page. This breadcrumb tool helps the student build a cognitive map of the web site. The breadcrumbs are especially useful in courses with lots of content where it can be difficult for some learners to navigate down through levels of materials.

WebCT 3.1 Communication Tools

Both synchronous and asynchronous computer mediated communication are key elements in WBL. Communication is a vitally necessary for effective distance learning. Instructors and learners must have the opportunity for frequent and open interaction both between individual students and the instructor and between students themselves. WebCT has a variety of communication tools available for the instructor/designer. These tools include the staples of distance learning communication: email, discussion board, chat rooms, and a whiteboard. The asynchronous WebCT email tool allows every student easy access to every other participant in the class, including the professor. Email in WebCT is server based and not available outside of the WebCT program. Chat rooms are a synchronous communication tool available in WebCT. The instructor can set up
multiple chat rooms devoted to separate subject areas, or interests. The whiteboard tool is another synchronous communication tool, which allows all participants to draw and type on a common screen. The contents of the whiteboard can be saved and reloaded as well as erased by anyone using it. The whiteboard can be useful as a flow chart or concept-mapping tool for visual learners. Synchronous communication is valuable but can be difficult to realize in many WBL situations. Often students chose WBL because their busy schedules do not allow them the opportunity to join in a traditionally scheduled classroom situation, which often means that the email tool gets heavy use (Digilio, 1998).

The discussion tool in WebCT 3.0 can be used to create similar collaborative groups. Collaboration is another key element in learner-centered constructivist theory. Collaborative groups help individual students understand convergent and divergent concepts. In a traditional face-to-face classroom, a teacher may foster collaboration by dividing students into small heterogeneous groups to discuss important topics. There are many creative ways that a teacher can use the discussion tool. The discussion tool in WebCT 3.0 allows you to create topic areas for discussion. Topics can be public or private. Public message discussions can be read and replied to by anyone in the course. Private topics are only available to a set of select students and teaching assistants. The critical feature of such electronic forums is that they tend to put the teacher in the role as first among learning collaborators, rather than as instructor and leader (Doucette, 1996.) The discussion feature can also serve as a scaffolding tool to direct and focus topical discussions. Electronic communication can also serve as the great equalizer, allowing quieter, more reflective learners to participate more in these collaborative learning situations.

Another way of fostering collaborative learning environments with WebCT is by utilizing the student presentation tool. Student presentations are created as HTML based web pages. The instructor can select the members of the presentation groups or WebCT can randomly select the groups of any given size. All members of the class can view the final presentation products.

Because WBL takes place with students physically separated from each other, it is important to try to create a sense of connectedness between them. We use the discussion tool to help create a virtual learning community by encouraging all participants to post an introductory statement and a picture of themselves. We post the names and pictures of our students under an icon on the opening page within the WebCT course structure. Making each student more real with a name and a face makes collaboration more personal and meaningful. This combination of pictures and written introductions also aids the visual learner. Students and professors can refer to these pictures during the duration of the course to help them make personal connections with their fellow participants.

WebCT also has a tool for the creation of student homepages. Encouraging students to create their own homepages helps foster a sense of community. Students can use their homepages to learn more about each and their shared or diverse individual interests. These homepages can also spark other, sometimes-unexpected learning opportunities.

Course Content Tools

The course content tools in WebCT 3.0 include: Content modules, syllabus, glossary, image database, calendar, index, CD-Rom and compile. WebCT3.0 allows for course content to be offered in a linear and non-linear sequence. Course content can be placed outside of the content module tool but it isn't usually advantageous to do so. Certain tools such as the compile tool, the CD-Rom tool, and the glossary tool can only be used with content that is inside the content module tool. Instructor/designers can organize these content modules in any sequential fashion they might choose. Content module materials can include text files, html files, or multimedia files and materials within a content module are set up in a table of contents. The heart of the content module tool is that table of contents. The table of contents is a hierarchical path where individual components can be hyperlinks to the subject materials, or simple organizational files. Students who are most comfortable in a linear learning mode can simply start at the top of the path and progress downward. A student who has a non-linear preference can jump around in a hypertext mode and access the materials in a fashion that makes sense to them. A student can use the Compile tool in WebCT to reorganize and customize course materials into notes. This allows students to use the materials in a way that makes the most sense to their individual learning style. The content compiler tool then allows the student to save the personally reorganized notes and then view the notes on screen, download the notes to their computer, or print them. WebCT also has an index tool which acts like the index in the back of a textbook. Entries are listed alphabetically, with each entry having one or more additional subentries associated with it. The subentry is followed by a link to the page on
which the index entry is located. The index tool is a very effective tool for students trying to locate important concepts in the course content.

Multimedia components are yet another important part of WBL. WebCT can incorporate images, video, and audio into the instructional environment. Simple images used in instruction help visual learners and help with dual coding as well (Burton et al., 1995). Video and audio elements can be streamed which means that the presentation is viewed as it downloads and is much quicker and more time-friendly in terms of download delays for the end-user, the student. Video and audio presentations are both excellent for encouraging dual coding thus increasing learner retention of information. Two of the tools WebCT has to help display multimedia are the Image database tool and CD-Rom tool. The image database defaults to display thumbnail images for quicker screen loads. These Images in the database can be displayed with text descriptions and can be associated with keywords so the students using those keywords can then search the database. The CD-Rom tool allows multimedia elements to be presented via CD-Rom. The student's can either use a CD-Rom provided to them by the instructor for the course, or can view the contents by downloading the content from the server.

Evaluation and Assessment Tools

WebCT contains a variety of evaluation and assessment tools for the student and the instructor/designer. Student evaluation tools include the more traditional types of evaluations such as calculated, multiple choice, matching, short answer, and paragraph style tests. Evaluation has often been a controversial subject in educational theory. Current theorists do often not endorse traditional evaluations and alternative assessment methods are often encouraged. If portfolio assessment is being used as an evaluative tool, then the student presentation tool could be useful. WebCT also has an assignment tool, which lets the instructor place a downloadable file for the student to download, complete, and upload again for evaluation. The assignment could be such items as photographs, a spreadsheet you want the student to modify, or articles that you want students to reflect on and respond. Feedback is useful for any and all learning styles and WebCT has a self-test tool in multiple-choice format that gives students immediate feedback. The self-test can be placed directly with the relevant content.

The elements of good instruction require constant evaluations of content and the organization and presentation of that content. Instruction and course design are often represented by flowcharts, which emphasize feedback loops for adjusting instructional components to improve the overall course product. WebCT has two features called track student, and track page that give the instructor information needed to adjust instruction. Using these tools the teacher can answer questions such as: What pages are the students using? What pages are the students skipping or missing? Instructor/designers can use the information from track student and track page to adjust and reorganize course materials in order to improve instruction.

Conclusion

When teaching in the relatively new environment of the Internet, professors need to adapt their course materials utilizing the same foundational learning theory concepts that are effective in the live classroom. WBL just creates a new set of tools that needs to be exploited in the best way possible for the individual learner. In fact many instructors find that as they create distance learning, the same tools used in WBL such as e-mail, bulletin boards, interactive technology, and graphic designs, can enliven a classroom just as easily as they can liven up a distance student's home computer (Carnevale, 2000). WebCT 3.0 has introduced new features that allow creators if WBL environments to gear their instruction such that the appeal and effectiveness of this instructional medium can be optimized for individuals who have various styles of learning.

MULTI-MEDIA APPROACHES TO
TEACHER CONTINUING PROFESSIONAL DEVELOPMENT:
DEALING WITH DISRUPTIVE PUPILS

Jim o'Brien, Faculty of Education, The University of Edinburgh, United Kingdom
Tony van der Kuyl, Faculty of Education, The University of Edinburgh, United Kingdom

Abstract: Concerns about how teachers deal with disruptive pupils led to the Scottish Executive funding the development of a CD Rom to be used for teacher professional development. The Project involved literature searches, field research and dialogue with teachers in schools to identify a range of scenarios and how they were best dealt with practically. The results and optimum approaches suggested on the CD Rom are treated as problematic with users being presented with a range of interactive situations in video/audio and text. Teachers are encouraged to review and develop their own skills and school policy and are provided with exemplars and additional references for consideration.

Introduction

Despite losing its Parliament in 1707, Scotland remained a constituent part of the United Kingdom, keeping its character and many formal institutions. It has always had a legally and politically distinctive and autonomous education system (Greaves & O'Brien 1996; Clark and Munn 1997). The 1997 referendum determined that the Scots would once again have a Parliament and even more distinctive Scottish education initiatives are now emerging.

Policy Context

The Scottish Executive Education Department (SEED) believes that effective learning and teaching are crucial factors in school effectiveness. Improving the quality of learning and teaching in classrooms is an important strategy to help improve pupils' attainments. Schools and education authorities are being assisted in implementing a range of approaches to raise levels of pupils' attainments as part of the Raising Standards - Setting Targets initiative. Policy initiatives include attempts (Lloyd & Munn (Eds.) 1997; Munn (Ed.) 1999) to cater effectively for pupils with emotional and behavioural difficulties within mainstream settings and special units attached to mainstream schools.

Continuous Professional Development (CPD) of Teachers

Kirk (1995 p.15) suggests that the changes that have occurred in teacher education have to be seen as integral to a wider restructuring of education and of curricular renewal, which have made new and increased demands on teachers. We are under an obligation, therefore, to ensure that teachers are trained to enable them to discharge effectively the new responsibilities expected of them.

The Scottish Office Education Department (SOED 1992) issued a statement of the competences expected of the beginning teacher. These have recently been revised and a series of standards or sets of competences are planned for other career stages as part of a developing Framework for Professional Development. The Scottish Qualification for Headship (SQH) which prepares teachers for principalship is an example of a standards driven qualification (O'Brien and Draper 2001 forthcoming). There is clear official recognition that teacher education is a lifelong enterprise and teachers and higher education have important partnership roles to play (Sutherland 1997). Since 1985 the locus of in-service has become increasingly the school, reflecting what Hargreaves (1994) described as a move from traditional INSET to staff development and
subsequently to the concept of professional development but many teachers have taken award bearing
courses offered by universities (Landon 1995). There is some evidence that for CPD opportunities the
universities are regarded as offering too academic a style of provision (van der Kuyl et al. 1994), and the
trend despite the possibilities of national standards and associated award-bearing courses, is towards an
increased reliance on in-school or school-based staff development.

The learning organisation and school based CPD

Teacher lifelong learning in the form of CPD is increasingly regarded as an important means of
contributing to the creation of more effective schools and as integral to learning organisations. O'Brien and
MacBeath (1999 p71) defined the learning organisation,

... as a place in which there is an infectious desire to learn, to build, to exchange
good practice, to problem solve together, to question the most deeply held
prejudices, to be open to change and new ideas and to experiment and learn
from mistakes. Leadership, culture and planning are important ingredients in the
realisation of such an organisation as is effective staff development which
builds on existing strengths, and individual and organisational needs.

SEED and its predecessors play a strong central role in the provision of national guidelines and centrally
funded support for school-based CPD initiatives including funding a multi-media interactive disk for school
based staff development coordinators (O’Brien and MacBeath 1999) who might promote and encourage
learning organisations. Since the late 1980’s government has supported the development of interactive
technology resources to meet a range of staff development needs in schools (van der Kuyl et al. 1994). This
has involved special funding to provide schools with hardware at advantageous prices and funding the
development of a number of software titles. Cost effective training for staff was attractive as it might allow
greater penetration of training materials, a consistency of approach and meet ‘value for money’ targets.
Early experimentation with the technology in schools centred on the production of curriculum support
materials but it was soon realised that teachers needed to be made more confident in their use of such
technology and to recognise its potential. While curriculum focused materials in interactive format
continued to be important, the targeting of staff development as a focus for interactive resources emerged
as a strategy for extending teaching and learning approaches within schools, this is evident in the range of
disks produced eg Mathematics, Health Education and Differentiation and now also in relation to dealing
with disruptive pupils.

The "Dealing with Disruption" CDRom Project

The promotion of social competence and social inclusion through meeting pupils’ needs in schools and
classrooms and building on alternatives to school exclusion is major SEED policy. However, increasing
concerns about disruptive behaviour by pupils in Scottish schools has led SEED to fund the "Dealing with
Disruption" Project to research and produce an accessible user-friendly dual format [PC/Apple] CD-ROM
for teacher professional development use. This involved inter alia researching in schools, the strategies and
approaches that teachers use to deal with these problems at individual, whole class and whole school levels.
The CDRom provides best practical advice, help and focus for training for teachers on managing behaviour
effectively, concentrating on:

- low-level interruptions in everyday classroom situations
- challenging behaviour by individuals or groups of pupils and by parents and other adults
- whole school and departmental policies.

**Figure 1**: Disruptive Situations Menu

The CD-ROM resource

The CD-ROM exemplifies for primary, secondary and special school teachers effective methods for managing behaviour and dealing with classroom disruption and other forms of aggressive behaviour. In doing so, the exemplars highlight a full range of scenarios, from managing mild but persistent disruptive behaviour to addressing the needs of pupils with major emotional and behavioural difficulties. It also deals with potentially difficult situations involving parents and other adults. A comprehensive range of disruptive situations and behaviours which may be encountered by teachers in mainstream schools are considered. The CD-ROM includes a menu of situations including sequences of classroom incidents and good practice in managing the interruptions (cf Figure 1). It provides advice on avoiding or pre-empting difficult situations. The identified range of potential audiences include classroom teachers, student teachers, senior management of schools, staff development coordinators in schools, EA personnel including advisers and staff tutors, community agencies and school boards; while identified potential uses include:

- staff development for specialist staff
- in-service training for all school staff
- management training
- inter-agency training.

Key issues for the development team included taking account of the diversity of backgrounds of the target audiences including ICT familiarity and expertise; the need for training materials to be interactive, flexible, of the highest quality and using multi-media on CD-ROM; the possibility for written resources, if disk space allowed, to be downloaded by users and the potential migration of the materials to Internet format in the future. The final product is written in 'browser' mode to facilitate such transfer.
Perhaps one of the most difficult situations (and one of the most explosive) for teachers to deal with is challenges to their authority - in the midst of a classroom audience.

This kind of challenge arouses many feelings which can affect the way a teacher responds. We consider what aspects of this challenge are most important for teachers.

We consider what aspects of this challenge are most important for teachers, as well as whether some situations are provoked in part by teachers.

246 Challenges to a teacher's authority

We consider what aspects of this challenge are most important for teachers, as well as whether some situations are provoked in part by teachers.

249 Does the teacher always have to be right?

We consider what aspects of this challenge are most important for teachers and which strategies can be adopted to avert further or escalated disruption.

248 Dealing with an incident and a subsequent challenge to a teacher's authority

247 Resolving challenges to a teacher's authority

Figure 2: A Typical Sub-Menu Illustrating Interactive Activities available

The product developed has a core of exemplification materials in text, audio and video formats (cf Figure 2) to provide advice and strategies relating to:

- whole school approaches
- positive ethos and reward systems
- departmental and individual responsibilities
- classroom approaches.

Project methodology and approach

Drawing on good practice, the disk illustrates

- identified common principles in dealing with disruption
- comprehensive management strategies for dealing with disruption
- a range of teacher skills and behaviours derived from current knowledge about dealing with disruption and identified good practice

and provides suggestions about sources of support which will help individuals and schools deal with presenting issues while recognising the diversity of approaches.

Many recent publications contain case study examples of whole school and whole class approaches in this field. A literature search revealed publications with illustrations of work with individual children/young people with social and emotional behavioural difficulties. In addition to trawling recent advice and publications key individuals and organisations with direct knowledge of school and classroom practice
were engaged. Existing materials and resources, including video, dealing with the management of disruptive behaviour were identified and reviewed. The most useful material was cited in the resource which also built on good practice and experiences from other initiatives which promote positive discipline and the development of social competence.

Project Phases

Complimenting a search and evaluation of existing materials and packages in this field and a literature review, the field research phase involved a team of professional field officers managed by key university researchers who visited primary and secondary schools; these visits were focused and areas of investigation including schedules of inquiry were developed and agreed in advance by the Project team. Discussion with headteachers and teachers identified effective classroom practices. Case studies based on such practices were prioritised and agreement reached with practitioners to video classroom practices and secure copyright clearance.

The concept development phase involved the identification of an appropriate curriculum design for the proposed CD-ROM and included scripting, scenario and interactive materials development. Resources required were identified or confirmed at this stage. Discussions matching screen design and formats to curriculum design and intentions were significant. This phase was iterative, formative and responsive to the quality and richness of video, audio and text assets realised so that the final product was optimised. Several approaches were developed only to be abandoned in favour of simpler more economic designs which encouraged sensible navigation through the resource.

The asset production phase involved co-ordination of professional and technical staff who produced video/audio case study materials and scenarios. Activities, text commentary and feedback were produced which closely matched the collated case studies and exemplified the strategies adopted. The commentary provides background to the situations illustrated and highlights the methods adopted to manage them. Advisory material in the form of text enables visual sequences and activities to be cross-referenced to more detailed information on methodology.

Technical production of the CD-ROM including all programming, engineering, de-bugging and beta-mastering was completed by 31 December 2000. Evaluation in a limited number of schools began in February 2001, this is designed to test the product in the field and provide a final check of curriculum and technical standards before production and dissemination.

The dissemination phase will commence in September 2001 and involve distribution of the completed CD-ROM to all Scottish schools in association with 25 national conferences.

TEACHERS' PERCEPTION ABOUT THE TEXT-TO-SPEECH TECHNOLOGY

Dr. Alex C. Pan
The College of New Jersey
E-mail: pan@tcnj.edu

Abstract:
As the computer technology rapidly advanced, the text-to-speech function, or the synthetic speech, has matured on the Macintosh computers. Most computer users, though aware of the existence of such a technology, did not have real hands-on experiences with it and did not hold positive expectation on it. The current study examined the perceptions of teachers as well as of other people in non-education related field toward the use of such a technology. The results showed teachers' perception changed after they had been exposed to such a technology.

Teachers always look for innovative ways to create activities using available resources. Current computers have come with the text-to-speech function (or the synthetic speech) which may be used to enhance teaching and learning. Many current reading and writing programs and authoring tools, such as Hyperestudio, KidWorks, Storybook Weaver, KidPix, and others, have integrated the text-to-speech function as a part of the essential built-in features. The text-to-speech feature can be easily used in some word processing documents. After text is entered or selected, the sound or speech command from the program can accurately produce authentic speech. Currently the text-to-speech application is also available in Spanish. In addition, the synthetic speech can simulate different voices to represent different personalities. The text-to-speech function may allow various potential uses in the classroom and is worth exploring.

While the synthetic speech has provided a great potential for instruction, it has not been researched for its usefulness to computer users as well as how it may be effectively integrated in education. The purposes of this study aim at the following.
• Investigating how familiar teachers are with the computer text-to-speech function.
• Examining teachers' perceptions and attitudes about the computer text-to-speech function; comparing teachers' perceptions and attitudes towards the computer text-to-speech function before and after they have been exposed to a few teaching and learning activities using the text-to-speech features.
• Comparing teachers' perceptions and attitudes toward the computer text-to-speech function with people from other non-education professions.

Methodology
One hundred thirty seven preservice and inservice teachers who registered in a computer literacy course were surveyed (or pre-tested) for their perceptions about the text-to-speech technology at an early stage of the course. These teachers were then introduced to features of computer synthetic speech and various instructional activities designed specifically for the use of the text-to-speech functions. They were surveyed again (or post-tested) to see if their perception towards such technology had been changed. These teachers were then assigned to interview three non-education related people to find out about how other people perceive the usefulness of the computer text-to-speech function. The written reports of their interview results was collected and analyzed.

Results
There was no significant difference between preservice and inservice teachers. One hundred nine preservice teachers and 28 inservice teachers who registered in the computer application courses participated in this study. The preservice teachers, in general, were younger and more computer-literate than the inservice teachers. Seven inservice teachers reported that they had some prior experiences using the Macintosh computers. Others reported that they had only Windows computer experience. The results of the pre-test showed that there was no significant difference between the preservice and inservice teachers' attitudes and perceptions toward the computer text-to-speech functions.

Most teachers were not familiar with the computer text-to-speech functions. As shown in the pretest survey, all the preservice and inservice teachers had heard of the computer synthetic speech function. However, only four teachers had some prior working knowledge and experiences with it. Most teachers did not have any idea of how to generate speech based on typed text on a computer. Several teachers expressed that current Windows-based computer did not provide an easy text-to-speech function. This is evidenced by the fact that most teachers were Windows users.

Teachers' initial ratings about the usefulness of text-to-speech function were low. In the initial survey, before they were introduced to the synthetic speech functions and activities, neither inservice nor preservice teachers gave a high mark for the text-to-speech function.

There is a significant difference between teachers' pre- and post-test results. Most teachers were amazed by the sophistication of the synthetic speech while they learned about the nearly authentic speech generated by the Macintosh computers. They were also surprised to learn that computer can read sentences like "I love to read and I have read many books", where the word "read" may pronounced differently under different grammatical context. The paired t-test results showed a statistically significant difference between teachers' pre-test and post-test \( t(272) = 3.41, p < .01 \). Most teachers began seriously engaged in developing ways of integrating synthetic speech technology after they had some hands-on experiences.

The attitudes and perceptions of synthetic speech from people in non-education related professions were similar to those of teachers prior to their taking the computer literacy course. After learning ways to integrate synthetic speech into teaching and learning, participating teachers were assigned to interview three people that were not in the teaching profession for their opinions toward the synthetic speech. Altogether, opinions from 411 people were collected and reported. After comparing these opinions, we found that teachers' initial perceptions and attitudes toward the computer text-to-speech technology were very similar to those of people from other professions. Most of these people that teachers interviewed had no experience in using the synthetic speech and 327 (80%) of these people suggested that the synthetic speech was a useless device to them. Also as reported by participating teachers, most of these teachers agreed that their perceptions and attitudes towards computer synthetic speech were similar to those of non-education people. They considered it basically an add-on feature for fun or specifically designed for people with special needs. However, after teachers were exposed to several synthetic speech enhanced learning activities, they became aware of the value and power of such a technology.

Some valued the synthetic speech more than others. The basic information about interviewees' gender, age, and occupation was collected. The results of the analysis showed that there was no significant difference between people of different gender and age. Not everyone would truly value the computer text-to-speech technology. Among all participants in this study, the typical groups that considered the synthetic speech function useful were teachers, people with vision or hearing problems, young children, and ESL students.

**Summary**

New synthetic speech technology has provided a great potential to serve instructional purposes. Such a potential, however, was generally neglected. The results of this study showed that most computer users, including teachers and people in non-education related fields, were aware of the existence of the synthetic speech technology, but were not familiar with it and did not value it for its usefulness. The results also showed that teachers' perceptions toward the synthetic speech changed to become more positive after they had been introduced to the use of such a technology. This study suggests that teachers are likely to adopt the synthetic speech technology and put it to use in effective instruction if they were properly introduced to such a technology.
Abstract: In this document we describe the Enhanced Instructional Presentation (EIP) model for the development of educational hybrid linear/hypermedia presentations. Our proposed EIP model addresses the learners' needs for organized and synthesized content while providing for individual differences in background experience, learning orientation, and cognitive abilities. The EIP model is an instantiation of van Merrienboer's 4C/ID model (1997).

Learning from linear presentations.
Linear presentations (expositions, demonstrations, activity sequences, etc.) are efficient from the perspective of the instructor and the institution. They aim to maximize the overall learning effects for a target audience by identifying the state of understanding and needs of the average learner and building the content to meet those needs. Presentations are often well polished and moderately effective for large portions of their target audiences.

Unfortunately, for some learners, this industrial model does not work well. Because the intended audience is an amalgamation of learners, any given presentation will include varying amounts of content redundancy or delay in progress for some learners and insufficient content or time for other learners. When viewing film or video, learners tend to become passive or adopt a "learned helplessness" (Flanagan, 1996). Even with programmed activity sequences, learners know from experience that they will not be able to process all of the content, reconcile every contradiction or explore all perplexions in the allotted time. If they allow themselves to be distracted by any portion of the content, their inattention to the new content and structures being presented will likely cause them greater confusion. The learners' conditioned response is to become a passive receptor of content whenever the pace of information exceeds their ability to cope.

That linear presentations are often partially effective for the majority of the target population is only a testament to the resiliency and capacity of the human mind. Learners can store up content (information and experiences) for later reflection and learning. Yet we suggest that this is an inefficient process with uneven results depending on the individual learner's capacity for storing and recalling presented content and access to additional resources (supplementary experiences, books, experts, etc).

We are suggesting the EIP model as an alternative model that will allow the learner unlimited real-time opportunities to view, review and process content (accretion), reconcile contradictions (restructure), and reflect and improve their understanding (fine-tuning) (Rumelhart & Norman, 1978).

Questions and Tutoring.
Constructivism tells us that individuals have different backgrounds and understandings, and will have widely varying needs for supplementary explanations and examples (Bruner, 1966). Aristotle suggested that our learning is composed of question answer propositions and Dillon claimed: "No event better portends learning than a question arising to the mind" (Dillon, 1986). Yet student generated questions are typically scarce in the industrial model of education. Factors limiting the use of questions in the classroom include social constraints, limited time and limited background knowledge. Even when questions are asked, they may be different from the students' real questions, or laid aside because they are too marginal or too difficult.

Individualized tutoring has been demonstrated to be a near ideal learning situation yielding two standard deviations of improvement over traditional instruction (Bloom, 1984). Learners lacking sufficient conceptual understanding or verbal confidence to enable them to form or present adequate questions are prompted and led in the direction of the intended learning outcomes. Learners lacking in self-direction, or needing to overcome a learned passive response, are encouraged and prompted with options frequently. Unfortunately, it is not feasible to provide every learner with unlimited live tutoring.

As an alternative to tutoring, the EIP model facilitates the learners' use of their own intelligence to choose paths through a synchronized network of supplementary content in order to meet their individual needs.
The EIP model

If a good educational presentation is like a fine string of pearls, then an Enhanced Instructional Presentation puts that fine string of pearls, along with access to any supplementary information needed, into the hands of the learner in order to ensure full appreciation.

The EIP model has four main components:

1. The traditional linear presentation
2. The playback control which allows the learner to pause the presentation, skip back and review earlier concepts, skip forward over redundant material and control the presentation sequence through a table of contents.
3. The supplementary content is synchronized with the traditional linear presentation to provide a short list of "just-in-time" and "as-needed" material that may be selected by the individual learners. Each piece of supplementary content might be augmented with a further short list of supplementary materials allowing the learners to continue exploring until their questions are satisfied. (thus creating the network of supplementary content)
4. The feedback and interaction mechanism is adjustable to meet the needs of individual instructors, researchers, and/or students. Feedback opportunities could include assessments, surveys, access to the instructor via email, and access to a related web pages and discussion forums.

We are in the process of developing a tool to support the development of EIPs. Once completed, the construction of an EIP will involve three main activities:

1. Collecting and generating original and supplementary content segments in the form of quicktime movies, powerpoint presentations, text files, images, audio clips, simulations etc.
2. Constructing a control matrix, using a spreadsheet, that specifies the names (or URLs) and descriptions of all of the content segments along with arrays of appropriate links between segments and some simple control variables.
3. Constructing a feedback page for the learner to access additional content, communicate with other learners or the instructor, access formative or summative evaluations, etc.

Some examples of how the EIP model might be used:

a. A lecture of a mathematical proof with a supplementary network of prerequisite skills, explanations of "the obvious", potential applications, related theorems, etc.

b. A narrated example of a physical education activity, supplemented with descriptions of the rules as they are applied, basic strategy and alternative strategies, focused training exercises, access to related web sites, etc.

c. A pre-service teacher report on a classroom observation with a supplementary network of their comments related to the activity observed including: discussions on pedagogical issues, management issues, reflections etc.

The EIP model we have described is a hybrid, combining a polished linear presentation with playback control and a synchronized, hyperlinked network of supplementary linear and hypermedia segments. By adding the strengths of these two instructional media modes we hope that Enhanced Instructional Presentations will promote more efficient learning for individuals.

Abstract: Multimedia Masters is unique a school-university partnership of student "consultants," teacher "clients" and university "experts." The year-long project begins with a development day to collaboratively set goals for the year, and four remaining sessions, two on the university campus and two at the district, assist students with meeting these goals. Each session focuses on developing technical, pedagogical, mentoring, and reflective skills. At the end of the project, students present their finished multimedia projects to parents and school administrators. Year 1 achievements include students learning to communicate more effectively, think critically, and reflect upon themselves as learners, in addition to increased technical skills. Teacher clients expressed increased interest in using technology both personally and within their curriculum. Challenges during Year 1 and areas to improve for Year 2 involve student time commitments, more effective teaching of the teacher clients, improved communication with the district technology team, and more effective structuring of session activities.

Professional development remains a pivotal requirement for successful technology diffusion among classroom teachers. Quality professional development opportunities are difficult to design and maintain so that they provide customized training at the level each teacher requires, as well as immediate reward and learning applicability for each teacher's students. To that end, Multimedia Masters is a partnership that was forged between the University of Houston College of Education and Spring Independent School District in Spring, Texas. Recognizing that student technology leaders are in abundant supply and possess ready enthusiasm for multimedia development, the ongoing goal of the project is to develop a cadre of technologically and pedagogically skilled middle-school students who can assist the technology development of their teachers. This brief paper will establish the project design, technical issues, strategies, achievements, and future goals of this model project so that others may consider a similar solution.
Development

Multimedia Masters students are 8th graders who apply for a "special experience" extracurricular opportunity. If selected, student teams invite a teacher whom they have had in the past to be their "client" throughout the year. Students work with their clients, special experience teacher leaders, and university Instructional Technology faculty to learn the necessary technical skills to transform the content material into quality multimedia learning products for the teacher clients to use with their students. A parallel goal of the students is to teach their clients the technology skills as they learn them.

The year-long project begins with a development day at the district with students, teachers, teacher planners, and university faculty to collaboratively set goals for the year, which for Year 1 included proficiency in reflection and planning, mentoring, pedagogy, and technology. Four remaining sessions, two held on the university campus and two held at the district, are planned by faculty members and teacher planners, with regular student input, to assist students to meet these goals.

Activities

Throughout the year, students keep reflective journals of team and teacher relations and personal accomplishments. Students work closely with their teammates, learning together and mentoring each other on technical skills, and all participants brainstorm approaches for students to work with their teacher clients. A portion of each session focuses on developing technical skills, including productivity tools, multimedia formats, and website design and development. Students practice teaching skills by planning and teaching technology skills to university preservice teachers, as research findings have shown that students acting in teacher roles tend to demonstrate accelerated growth in social skills, confidence building, communications skills, and critical thinking. The culmination of the project involves students presenting their finished multimedia projects to parents and school administrators.

Challenges

The project faced several technical challenges in Year 1. There were software incompatibilities between the University and school computer labs. The K-12 labs presented further difficulties with downloading and filtering restrictions. The entire group attempted to move beyond the "coolness factor" of technology to get students to think about how technology can be used to solve problems and communicate new ideas.

Achievements

At the conclusion of Year 1, Multimedia Masters can boast of achievements on a number of levels. Along with using technology tools to create teaching materials for their teacher clients, students learned to communicate more effectively, think critically, and reflect upon themselves as learners. Student participants described increased technical skill, confidence with teaching, and positive experiences working with team members. Teacher clients overwhelmingly expressed an increased interest in using technology both personally and within their curriculum. A vital partnership developed between the district's technology and curriculum departments as a result of facilitating the project, and other classes in the district were able to make use of the multimedia materials for student learning. Finally, university faculty members took advantage of the authentic learning experience for their future teachers.

Goals

As successful as the first year was, we unanimously identified areas to improve for Year 2. Students had a great number of daily extracurricular commitments, making meeting with teachers and team members challenging; we hope to work with them to better organize their time. Students often created learning products and simply gave them to teachers; we will help students better meet the technology learning goals of the teachers. Challenges with technology are expected to continue, but the project team plans to improve communication with the district technology team. The faculty members hope to retain a constructivist, student-driven atmosphere, while at the same time better structuring the session activities to use time efficiently. A final long-term goal is connecting the teachers in this project with real content providers, a concept currently being explored within the graduate IT program.
A New Approach - Situation Learning (SL)

Maja Pivec
Institute for Information processing and Computer supported new Media (IICM), Graz University of Technology, Austria (mpivec@iicm.edu)
University of Maribor, Slovenia (maja.pivec@uni-mb.si)

Hermann Maurer
Institute for Information processing and Computer supported new Media (IICM), Graz University of Technology, Austria, (hmaurer@iicm.edu)

Abstract: The presented solution offers a new approach to knowledge module presentation that is different from the majority of presently used approaches. The interactive component of the SL approach increases students' involvement and motivation for learning. Learners can experiment and investigate within the 'virtual world' of the SL knowledge module. Such experimenting and interacting with different knowledge presentations makes it possible to construct own specific knowledge thus making the factual knowledge more permanent.

Situation Learning - General Description

In the field of Web based learning, numerous attempts have been made to use hypermedia for learning in many different ways. In the first half of the 90s, many scientists have already stated (Maurer92),(Maurer93),(Lennon94),(Elliot95) that hypermedia can be used as a cognitive tool for learning, and have also outlined a number of other potential advantages that hypermedia systems offer. Among the researchers of hypermedia use for education, the following basic questions were proposed: How to design effective learning opportunities? Why is learning by experience very often more efficient than learning by studying? How to provide the learning experiences needed to respond to current challenges?

As reported in (Biljon99), Hague (Hague, Evens & Michael, 1987) emphasised that many students, in spite of possessing the required amount of knowledge, are unable to effectively utilise it and apply it to solve problems. The aim of SL is to facilitate the knowledge presentation and thus to improve the learning process. Using SL for educational purposes two primary aspects of the learning process are supported:
(i) - learners are encouraged to combine knowledge from different areas to chose a solution or to make a decision at a certain point,
(ii) - learners can test how the pathways and outcome of the situation change based on their decisions.

David reported (David97) that there is an increasing demand for greater interactivity to be built into learning materials. SL knowledge modules provide a complex level of interactivity that stimulates users engagement. In SL knowledge modules, different interactivity concepts are (and can be) applied, as object, linear, construct interactivity and hyperlinked interactivity. Also some simplified non-immersive contextual interactivity and immersive virtual interactivity can be applied in the general concept of the SL.

A Situation Learning knowledge module can consist of one or more related situations. The term "Situation" in the context of Situation Learning denotes a specific simulated environment in which the learning objective is embedded. The situation is a collection of different scenes that are related in the sense that they describe a certain event or task. The users are offered some context dependent possibilities or possible courses of action. Based on previously acquired knowledge and described scenes, users make a choice and move on to another scene within a situation. The "scene" consists of several hypermedia and HTML documents (e.g. on request available additional information). The displayed hypermedia document consists
of an image, video / audio, text, meta-instruction and for example four selections. Only a few possibilities
(in general 2-6) are offered to users. Based on users chosen courses of action, they then proceed to the next
scene and eventually to the end of the situation e.g. summary. Each consecutive scene is different and
depends on the previously made choice. By being confronted with the consequences of chosen course of
action, users can stepwise construct the feedback on their choices made. With the help of the "virtual"
world users can explore where a chosen course of action could lead them in the "real" world. In the same
way, users can safely explore possible outcomes when less appropriate choices are made. Using SL
knowledge module, users get the opportunity to learn appropriate responses for different situations / cases.
Such opportunities enable users to improve their ability to discern relevant from irrelevant information and
to combine unrelated (or less obviously related) elements. The interaction provided within each consecutive
step, encourages users to think about the case and to reflect back on their own knowledge base. Based on
this they make a decision. In this way SL effectively facilitates the decision-making process and helps users
to understand and evaluate their choices.

With interactivity and stepwise constructed feedback there is a support to students’ productive thinking and
promoting subconscious or incidental learning. Feedback helps users to build a new picture about how
much they know about a certain topic and if they can use the acquired knowledge within a certain situation.
SL can influence users’ awareness in terms of what the users think they know. Being able to build their own
picture of the knowledge mastered increases users’ motivation for learning. Consider an example: when
reading a book with an interesting topic and good structure, the reader will have a feeling of having
understood everything. But later, when confronted with a specific problem, the reader might want to use the
theory and facts he/she acquired from the book in order to solve a specific problem. At this point at the
latest, the reader will realise that although he/she had a feeling of having understood the content at the time,
he/she did not memorise enough to be able to formulate a solution i.e. to use the acquired knowledge.
Based on such experience it becomes clear that in order to solve a problem conscious learning and a deeper
level of knowledge has to be achieved. Or as the (Queen99) expressed, "Failure is motivation for learning'.

Through the process of applying the knowledge acquired learners can build their own mental concepts e.g.
can check the understanding of the material learned within the concept. Situation learning may bridge the
gap between isolated learning of theory and practical work i.e. applying theoretical based learning to a
practical situation. Situation learning is a way of facilitating the natural learning process, whereby the
successful acquisition of new facts is enhanced by the learners ability to consolidate this information with
their own knowledge base and experience. Such links allow people to master very complex or seemingly
unpredictable situations. Situation learning helps to build and improve learners' mental model.

Theoretical Background of the SL

From the didactical aspect SL knowledge modules can be used also to increase the dynamics of learning
hence SL knowledge modules are less formal and have completely different approach compared to regular
hypermedia used for Web education. SL can be placed in the group of didactical programs. Such programs
are characterised by their interactivity, adaptability, and additional explanation on request and the
possibility to test the acquired knowledge.

SL uses constructivist learning approach where each learner constructs their own individual world and
learns how to manage problems within this world. Using SL knowledge module learners are active
participants in knowledge acquisition. Learners can experiment and investigate within the 'virtual world' of
the SL knowledge module. Such experimenting and interacting with different knowledge presentations
makes it possible to construct own specific knowledge thus making the factual knowledge more permanent.

"Situation Learning" is a similar expression to "situated learning" but should not be mistaken for it. Although both approaches do emphasize that learning should be meaningful to the domain and contextualised, there are also significant differences between these approaches. Situated Learning is a general theory of knowledge acquisition whereas SL focuses on knowledge utilisation. In the SL approach knowledge is primarily acquired by means of individual learning. In SL, in contrast to situated learning, the emphasis is on knowledge utilisation and development of mental models based on acquired knowledge. In
SL users construct their own personal approach to problem and task solving. With the help of the simulated situations learners have the opportunity to create and experiment with so-called different scenarios of behavior within the situation. The behavior reflects the learners' understanding of different theoretical topics, their ability to connect interdisciplinary knowledge and to utilise it in a proper way e.g. to solve a problem or to offer help. Transparency of such systems enable learners to understand sequences of the whole process. Furthermore, learners have to define the problem area, use several different sources of information to justify their decision reasoning and use the support of technology to process their inputs. The aforementioned activities encourage interdisciplinary thought and action that is similar to the situations we get confronted with in real life.

Educational Aspects of SL

In contrast to traditional linearly oriented learning, there are other possibilities for learning for example incidental learning, often called implicit learning (Holzinger99). For the learning process, motivation is a very important factor. Therefore learning programs should be entertaining and challenging to get the learners' attention and give them motivation at the same time.

SL knowledge modules contain both elements, entertainment and challenge. High content interactivity stimulates user's engagement and mental involvement. Higher levels or attention and motivation of learners can facilitate learning. In the SL knowledge module learners use a chosen course of action to directly influence the development of the situation. The principle of constructed feedback in the form of different possible pathways and situation outcomes has some similarity to adventure games and contains other principles of edutainment (Al-Ubaidi00). (Quinn99), (Lepper92) have shown that enhanced learning (which is fun) can be more effective. Using some simple educational tasks, they demonstrated that learning embedded in a motivating setting improved learning outcomes.

In the SL microworld there is a direct relationship between action and feedback. On one hand students can influence the situation development with their decisions. Based on courses of action taken, students proceed from scene to scene. When arriving at the end of the situation at the latest, students obtain feedback in the form of a summary with a thorough explanation of results or behaviors that were expected of them. With the help of information obtained within scenes and partially with the help of information provided in form of a summary which is a concluding scene of a situation, students can construct the whole experience of "actions taken and consequences". Students can get feedback after the session also in form of the computer LOG file, where they can see their pathway and analyze chosen courses of action. This feature gives students, in conjunction with the feedback, the possibility of assessing their own activities to see how they were doing and to be able to more objectively evaluate their decisions / courses of action. Feedback could be provided in different representation forms and could also be used for students overall performance evaluations.

Being able to see students' overall performance and the development of their decision making process the teacher or tutor can effectively test if the learning material was understood. If the content was understood differently, analysis of chosen courses of action and pathway evaluations provide the information required to identify where the problems occurred, e.g. in what context students' performance indicate a misconception. With help of this information the system or tutor can suggest to students a list of additional topics that could be beneficial for acquiring additional knowledge.

Use Cases

In order to present the value of the SL knowledge module in practice, several application examples of the SL knowledge modules for learning are outlined in this chapter. The SL knowledge module approach could be applied to stimulate students' involvement, fight boredom and increase retention. This approach could be applied for different representation of a particular topic or to demonstrate the application of the theory.
Example 1: An SL knowledge module could be created to depict how different parameters influence the ecological balance within the environment. The ecological balance could easily be disrupted by an inconsiderate action. Namely, before wastewater is released back into the waters outside the plant, several parameters have to be checked according to the legal regulations. The temperature, pH, the quantity of biologically decomposable elements, presence of halogen element, should all be controlled and regulated, along with many other factors. When the regulations have not been followed, irreparable damage to the environment could occur. Even if the water is not contaminated but is released back into the water source too hot, micro-organisms, plants and fish could be killed. However, if the water is contaminated, the consequences are much worse as pollution could take place.

Within the SL knowledge module the procedures for chemical engineers when handling the wastewater could be discussed. Students should be confronted with cases of differently contaminated wastewater. Students should have the possibility to choose an industrial sector. Related to the industrial sector defined, specific cases should be created. Based on knowledge of regulations, testing procedures, and prescribed handling in the case of overly polluted wastewater, that has previously been acquired within the course, students can choose one of several offered courses of action. In each scene students are stimulated to think hard and decide which course of action is the most appropriate. Within the next scene students can see the result of their decision. Based on the result, students can see if it was the result they expected or if another decision could be better. If students are not satisfied with the result, they could apply a plausible corrective action and check the outcome with the help of the next scene, and so on. When working through the situation, students can explore different behaviours like what would happen if they were to take actions according to predetermined decisions. In the worst case, they could cause water poisoning and jeopardise the living in the whole area of the "virtual world".

Students can work through the SL knowledge module several times to improve their performance and to encounter different cases offered. Within the described SL knowledge module, students can access numerous theoretical details and explanations available in the course background library. To repeat and acquire additional knowledge students could also 'switch back an forth' between SL knowledge module and the rest of the courseware.

Example 2: Application of SL knowledge module to teach history could bring the possibility to present the life in the past from different perspective. There is a variety of very good movie materials that depict different historical periods from the past. Although the materials are very good and interesting, they do not support active participation of students. When watching a movie, students have the role of observer, whereas SL knowledge module makes it possible to be an active participant. Students could interactive explore different historical periods when they build villages, cities, and infrastructure. Within the knowledge module, a rich collection of pictures and video-clip sequences could be available. Students could have a possibility to build and decorate a typical house of a particular era. Among different domestic and decorative objects offered, that were used in different time periods, students should collect appropriate objects for a specific era.

Active participation of students in activities like collecting objects, building and decorating houses, also provide support for haptic learners that memorise and learn better when they have an opportunity to interact with the learning material.

Example 3: Another possible application of the SL knowledge module for teaching chemistry could be for making experiments with toxic chemicals in the "virtual world". The initial scene of the knowledge module could be in form of a task where an experiment should be executed. Different stages of the experiment could then be presented within several scenes of the knowledge module. Students would have to plan the experiment: resources, chemicals, etc. They would have to check which equipment is needed for the experiment, when the laboratory and the equipment is available, make calculations of chemicals needed, etc. In another situation within this SL knowledge module, students could prepare all of the equipment needed for the experiment and arrange the pieces to put everything together as necessary. When the equipment is arranged properly and everything else is prepared they could proceed with the experiment in the safe - virtual environment. Students should be aware of proper procedures, like not to put water into sulfuric acid because this might cause a turbulent exothermic reaction or how to react in case where part of their skin comes in contact with strong acid.
In the aforementioned knowledge module a variety of interactive paradigms could be applied, like object interactivity, clickable image maps, choosing courses of action, writing calculated parameters and quantities, etc.

The pilot project LIFE, based on the SL knowledge module application, is presented as a part of the medical server in Austria (www.infonied-austria.at). The goal of the project is to educate the population in the areas of fitness, stress regulation and nutrition, in order to increase the common awareness of the importance of these factors on our lives. SL modules were created for knowledge mediation in each of the topic areas.

**Authoring of the SL Knowledge Modules**

It is relatively easy to design and produce the SL knowledge module. It does not require any additional programming skills, apart the basic knowledge of HTML page creation. The course production requires minimal cost and relatively short development time that is justified with the applications benefits and many varied uses within learning. The authoring is divided into the following topics: software engineering approach, importance of the scenario, proposed interface structure, and existing authoring support, including any authoring difficulties that arose.

When developing an SL knowledge module software engineering principles should be considered. Though the SL is different from a conventional program, there are certain parallels that can be drawn. Designing the SL application, in the first step the learning objective is defined e.g. presenting certain facts, comprehension testing, etc. In the second step the situation (story setting) is defined in which the learning experience along with a possible solution will be embedded. In the third step each scene and connections between them is described in a scenario. With the help of a graph and table the knowledge module structure is illustrated. In the implementation phase, the situation author or the programmer makes the hypermedia documents based on the scenario.

A scenario contains a detailed description of the situation, different situation developments i.e. scenes with all screens and multimedia. To enable the production of a learning knowledge module, e.g. situations where a detailed description is needed, the teacher or knowledge module author should write a scenario where each particular scene is described. Based on this description the programmer or media producer is able to make the product without the knowledge of the whole knowledge module or didactical / methodical correlations. The scenario production takes more that one third of the courseware development time.

Each presented scene of the situation can be divided into four main areas as follows.

<table>
<thead>
<tr>
<th>Meta instruction</th>
<th>Situation description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Possible courses of action</td>
<td>Media display</td>
</tr>
</tbody>
</table>

In general the entire left side of the screen is intended for the user interaction. The right screen side gives information about the scene e.g. description, media, links to pages with additional data, ect.

On one hand, authoring is facilitated with the templates for scenario and hypermedia content production, on the other hand, smaller-less complex situations can be re-used and embedded into more complex content. Three levels of SL authoring supports are defined as follows: (i) - authoring supports for facilitating the scenario writing with templates for scene description, (ii) - authoring supports for visualisation of the described situation and connection between scenes, (iii) - authoring supports for facilitating the hypermedia document production with the use of templates (Dreamweaver SL Extensions).

In more complex situations e.g. adaptive situations, the author can find it becoming increasingly more difficult to keep an overview of the situation and possible connections to other scenes or situations. Therefore the present authoring tools should be developed further to support the scene production based on the semantic structure defined by the author or the expert. The possibility should be given either to follow the path along one choice or to describe the key scenes, define levels and then to define the different pathways connecting the levels.
Conclusions

The main purpose of the SL knowledge modules is to offer the opportunity to apply the knowledge acquired thus making it possible to indicate a deficiency in understanding or a misconception. Therefore, a connection to other specific learning programs can be provided to make it possible for students to acquire factual knowledge. SL knowledge modules can also be connected with other programs like Mathematica for learning mathematics, or a program for learning a foreign language, etc. With help of such programs students can explore details or acquire some specific knowledge. For instance in Mathematica students can receive help by calculating integrals, or carrying out other mathematical operations.

It is evident that the major benefit for the learning bring the SL knowledge modules when being offered within an on-line learning environment. Users can profit from the different perspective that knowledge modules are providing, and at the same time from the rich annotation and communication possibilities offered within the learning environment.

Emerging technologies continue to change and improve the landscapes of our classrooms. Computers, Internet, and video have played a large role in changing how students learn. One way to integrate the use of emerging technologies is to enhance older and proven methods of instruction. Schools have created video libraries to augment and improve student retention for years. Now, using a combination of computer software, high speed network access and large screen classroom monitors, teachers can quickly access and control a large cadre of video media, without the past burden of hardware set up and scheduling. ETR, Educational Technology Resources, Inc., provides a software product to assist teachers in using media in the classroom with ease—the product MediaMaster. Whether traditional media or digital media, MediaMaster allows teacher to rapidly deliver video content with ease and confidence.
New Teachers and New Technologies

Abstract: A key moment in emancipating the teacher from the physical limitations of the classroom and encouraging a sense of collaboration, cooperation and collegiality would be introduction of principles and responsibilities of electronic collaboration. Teachers have to be introduced to Internet, electronic mail, newsgroups, list-servers, bulletin boards and other means. By those, they can act jointly and communicate with colleagues near and far. They should be acquainted to online resources and the means of connecting and using them as well as contributing to them. In this paper, I will try to outline a learning model that will succeed in such education of a teacher.

Introduction

The perception of computer assisted learning is shifting from its current position as an optional extra in our fund of course components, to that of a key teaching medium. Learning with computers is a multi-layered, interactive experience. Interactive multimedia is defined as a computer tool that includes a combination of text, graphics, sound, video, and animation sequences packed together (see Lee 1996). With the growth of the World Wide Web, this becomes widely available to more and more people every day, forming a visual/audio presentation of information and knowledge. It can be successfully used to support education and training, to serve as a reference tool and to provide dynamic presentation. Traditional "textbook learning" is one component for learning a subject, laboratory projects provide actual experience, but only multimedia and WWW can synthesize and expand the learning process. With the advent of the WWW, education has a new tool to utilize. It offers the ability to easily distribute educational material around the globe. Also, with a web implementation of educational material, changing the content is trivial, and students need not be made aware of such changes. Facts supporting this, are studies showing that people retain 25% of what they hear, 45% of what they see and hear, and almost 70% when they actively participate in the process (see Myers 1990). Moreover, additional effort that professors may and should incorporate into creation of lessons and courses using WWW and multimedia "offerings", will help in personalization of these lectures. How much this is important, can best be described through findings in (see Goldstein 1997) that: "98% of students receiving individualized instruction, outperform those receiving computer-based training." Even WWW browsers themselves, overcome many of the shortcomings of traditional computer-based learning by affording platform independent, easily updated training materials. Personalization and adaptation to individual student is performed through their profiles and through planning software. As individual lesson components are selected, many of them are adapted to student, based upon constraints attached to the materials, and those "attached" to the students' profile. A student's performance with using materials, in turn, updates his profile.

There's one interesting observation that can be made in connection with the usage of WWW in education. Hypertext organization and interconnection of Internet, confirms to a nonlinear form of presenting information, in which interlinking modules of related information are associated to a central topic. The associative links allow instant access to any of the modules, enabling cross-referencing and browsing. On one hand this confirms to a structure of a World Wide Web, while on the other hand is akin to the manner in which the human mind works to gather facts.

Teachers should be taught not only how to use web, but also how to contribute back to it - how to author for the web, integrate graphics, create links and produce useful content. For some time now, this process - "authoring", has been described as "the design and production of computerized multimedia learning materials", carried out by a single person - the author. This perhaps has never been completely true, although the early authoring systems for computer-based learning did seem to assume that teachers
wanted to and could produce their own teaching material. Besides, there is a view that the wide range and quantity of material now available on the Web, electronically, make possible the notion of “student as an author”, searching the Internet for material to incorporate into a multimedia “story”.

Although both notions contain a lot of truth, there is one specific point in authoring process I would like to emphasize. Despite the decline in costs of equipment, the cost of the time of those involved in production of learning material, remains high. And, not only remains, it goes higher and higher. To “author”, teachers themselves need time to become familiar with the technology, understand the instruments and experiment. Provision of articles for teachers through news-groups or list-servers incorporates and advocates collegiality and stimulates thoughtful and profound discussions. Besides, as teachers are in some extent expected to act as a scientists, it is interesting to suggest a usage of a "collaboratory", or a virtual laboratory created by the means of world wide web (see Cerf 1993): "... center without walls, in which the nation's researchers can perform their research without regard to geographical location - interacting with colleagues, accessing instrumentation, sharing data and computational resource, and accessing information in digital libraries." Educational reform calls for a drastically different kind of teaching - one that asks school to move from lecturing in whole class instruction to the facilitation of learning in small group collaboration and interdisciplinary projects. IF learning takes place in classes that are collaborative, supportive and inclusive, more students can contribute and participate in their own learning.

Another important point is a need for “re-training” of teachers in some areas concerning WWW-based teaching. Most professors come to “multimedia teaching” with traditional teaching experience and find that the theoretical-based assumptions that worked successfully in face-to-face instruction, do not translate well into technologically mediated education. This retraining should initially focus on moving the teacher from the podium to the sideline, from teacher-centered instruction to student-centered. Once this is achieved, the following retraining components can encompass redesign of lessons, continuous and proper usage of technology and integration of interaction in the course content, as few of the first needed changes. During these, a teacher and a student (or students) can have a non-contiguous dialog, exchanging information and ideas, questions, assignments, feedback, etc.

Learning Model

It's been argued (see Winn 1992) that a strength of the free interaction with virtual scenes and Internet is that it gives children - and we add, teachers - the opportunity to explore the same place repeatedly, building their understanding. Besides, as an educational tool, WWW has little in common with the teach-test-correct model of a “traditional” computer assisted learning, providing opportunities for children to construct their individual learning.

A teaching-teachers model should be developed for effective training for lecturers, not only on how to use Internet but, more important, on how to include these technologies into everyday teaching practices. They have to be trained how to be "knowledgeable end-users" AND "creative builders" of learning experiences on the Internet. Yet, with a rather high pace of new developments emerging, training model should drastically reduce the learning curve and enable fast application and retention of skills gained.

More often than not, training concentrates (and emphasizes) on discrete skill development, while in a certain manner "ignores" practices that enable user to increase an understanding of the relation between the training and use of acquired knowledge in the classroom. In contrast to that, (see Kinnaman 1996) advocates one different approach: "Teachers don't need to be "trained". They need activities that engage them with the process of teaching - activities that encourage them to explore, create and reflect upon the benefits and limitations of teaching with technology". In other words, teachers are now being asked to examine thinking and learning process; collect, record, and analyze data; formulate and test hypothesis; reflect on previous understandings; and construct "subjects' own" meaning. Good teachers are constantly making decisions and formulate ideas about goals of education they are "giving". Those ideas must not ever be conclusive - after the initial formulation, those decisions and ideas are subject of careful reconsideration in light of newly acquired knowledge and techniques, in light of information from current theory and practice, from feedback, and from contemplation about social and ethical consequences of their results.
Training is usually given in a form of providing information that may or may not have relevance and importance to the end user. Instead, a good learning model should be made highly meaningful and personalized to the individual teacher, encouraging usage of skills that can be implemented easily and promptly in the classroom. The intention is to enable teachers to think consciously beyond just adopting new skills, automating, simplifying or duplicating current teaching practices. They should be able to reevaluate, reexamine and reconsider teaching in the light of the new skills and produce original learning actions that display these qualities. Still, every step of the way, teachers should be allowed broad opportunities to practice their skills in meaningful activities. This will assist them in accomplishing the greater goal - creation of a project, a teaching plan, a subject curriculum, that shows evidence of the teacher having rethought a lesson in the light of newly adopted skills and technologies. Consecutively, as the skill level increases, authority over one set of skills leads to introduction of the next one. This progress is derived through a proposed learning model, consisting of:

- determining objectives for the training;
- outlining the elements of a training content;
- creating the activities for successful practice;
- inventing a system for evaluation, and
- devising a reward system.

Course Outline

The usage of Internet services becomes an essential part of teacher training. The education profession should realize that this is not some futuristic and frightening development, but merely an extension of the kind of responsibility that schools have long accepted for helping children to be discerning in their use of other media, and to develop skills and judgement in relating to others and caring for themselves.

Given elements of learning model should be adequate to include teachers into a "team" of successful technology users. As always - learners need to approach a subject in more than one way to move from surface knowledge to substantive, in-depth understanding. Here, we will outline elements that should characterize the "course":

- teachers are given the freedom to create their products and give them meaning, while implementing the skills they have learned;
- teachers are clearly informed that the trainer's role is only to provide the training concerning the necessary skills, while their creative implementation, are their own responsibility;
- teachers are introduced to different methods of exploring technology - searching the web, gathering relevant data, collecting information on a given subject and similar;
- the trainer uses prepared materials and live demonstrations to teach data-acquisition, analysis techniques and scientific principles;
- the necessary real-time interactions between trainer and student/teacher go far beyond standard conferencing - they must be able to work collaboratively and interactively;
- some practices require teachers to use data "hidden" somewhere in the web to make calculations and suggest some conclusions based on these calculations;
- course uses an integrated set of communicating tools such as electronic notebooks, (video-)conferencing systems, shared screens, information-access tools and similar, to the extent when they become a regular part of everyday tool for teachers;
- the course should facilitates scientific interaction between teachers by creating a new, artificial environment in which individuals interact;
- a lot of newly adopted information processing skills are used in creative ways to learn new, or re-learn old concepts through interdisciplinary connections;
- while advocating the use of technology takes time, the schools are also obligated to reward teachers initiating those changes within their schools;

While the need to interact with others is an innate tendency, that most teachers possess when they begin working in education process, the introduction of technology that will mediate in this interaction often hinders and delays that tendency. Therefore, it is essential that course includes such kind of
technological instruction, coupled with periodic question and answer sessions, which will assure that the interaction will persist and will include both pedagogical and social attributes.

At the same time, several strategies that will enforce constructivist and inquiry based teaching, include these:

- Accepting and encouraging teacher initiation of ideas and their questions;
- Using open-ended questions and encouraging teachers to elaborate on their ideas;
- Encourage teachers to test their own ideas, answer their own questions, hypothesize causes, and predict consequences; and
- Encouraging self-analysis, collecting data to support ideas, and reforming ideas in light of new experiences and new evidence.

Although new technology addresses shortcomings in current practices, it is obvious that the "higher" the technology is, the more limited is the access and the more knowledge is required for its' usage. Integrating the use of Web into education, however, has more to offer than simply faster and more convenient communication for those who have access. By preparing a study guide that takes advantage of what the Web has to offer, a more interactive experience can be offered to students, stimulating their motivation, curiosity, learning and dialog. Success of those highly depends on teachers' reactions. For example, successful dialog via e-mail, depends on the instructors' rapid response to students' questions and comments. At the same time, teachers might want to suggest taking certain discussions to a more open forum, where more students could participate - from forwarding e-mail messages to conferences.

Conclusions

The fusion of computers and electronic communications has the potential to dramatically change and enhance the quality and "productivity" of schools and faculties. Still, a technology often exists without being used because it is perceived as adding little or no value (see Kouzes 1996). While we claim that the time is right for "collaboratory" solutions helping the scientific and teaching interactions, we still have to make it a necessity for systematic and methodical progress, psychosocially acceptable. Today's modern technology allows for interactivity between student and instructor to take place in many formats - starting with simple e-mail messages, and going all the way "up" to teleconferencing, interactive video, conference calls, or CUSeeMe, being just some of the possibilities. It is important, therefore, for the interactivity to move beyond brief encounters between student and teacher and to invoke a feeling of togetherness between them, between students themselves, and finally between student and the material being studied.

Increased usage of Internet in the classrooms has been reported through the professional publications. Momentarily noticeable advantages of the Internet-based training are the integrated communication capabilities, connecting people, and the use of the huge content already on the Web. Besides, it allows flexibility of the time and place to study, and even enabling flexibility of changing the content and supplying of additional resources, without students being even aware of that. While, in the past, relatively slow adoption of newly introduced technologies into the classroom usage was acceptable, today, all over the world, daily practices of both teaching and learning have been enriched with these in unusual and never seen rate. New technologies, with easy-to-use interfaces, allow both students and teachers to access, develop, make use of, apply and donate to the Internet world of information. They can also add to the world of relevant, applicable and meaningful information, communicate and collaborate with colleagues worldwide and "escape" from formerly separate and disconnected world of isolated classrooms. This chance must not be overlooked and neglected in our schools and our teachers have to be trained to use contemporary resources and technologies and engage the students and pupils in the learning process by making them active partners.

The revolution caused by Internet is providing much needed motive and impulse for large-scale technology implementation into our schools. More importantly, research shows (see Ainge 1997), that interest remains high even after a long time usage, almost without any significant sign of reduction. Even without funds needed for complete computerization of every classroom in each school, we must be able to use wealth of information offered, knowledge and experience "funds" applicable in our environment.

The use of Internet, electronic mail, newsgroups and other elements of electronic communication for supporting classroom instruction is still in its beginnings. However, this innovative method has great potential in enhancing traditional teaching methods. Applied correctly, it can prepare teacher to bring
broadth and depth to subjects being taught, provide efficient use of class time, create flexibility in teaching and enhance student's learning. Examples of Web based teaching (see Hidalgo 1996) show successful implementation of Web-based, multimedia teaching at MIT, used for extending communication beyond the classroom. It allows teacher to post information on the Web both for subject review and for subjects not covered in class. It is also successfully used for easy monitoring of student progress and student interactions in bringing critical discussions on the course.

Internet, WWW and their other services, are here to stay and become inevitable part of childrens' everyday lives. Initial usage of it by teachers and their incorporation of courses should prepare both children and teachers not merely to know something about them, but to think about how best it might be used in classrooms and, generally, in society. If teacher educators do not act soon, or if teachers themselves do not take a challenge, teachers will miss a unique and brief opportunity for having a positive impact on children in this field. Besides, in a few years, teachers will be almost unable to catch up with their students on issues and concerns that they should incorporated in teaching practice some time ago.

It might seem therefore that we, as educationalists, have little choice but to become "Internet surfers", picking up interesting and useful items which can be downloaded and used with our students, or to buy the CD-ROMs we can afford, in the hope that there is within them items which can be helpful in meeting our classroom aims and objectives. But, what guarantees do we have that there will be useful material there? We cannot expect the contributors to WWW to follow goals and objectives, which we see as important. We, as teachers, lecturers, or professors must take that responsibility. We must select and organize, guide ad instruct our pupils and students to use what we can make available, in a way that we find will be educationally profitable. This, in some sense, turns us into authors. As teachers, we play not only “organizing” role, but while creating lessons, we also design and produce original material for them, often making changes as we go along. This material will be directed towards achieving goals used to provide structured learning environments and help improving learning altogether.

Hypertext Flexibility in a Web Learning Environment to Promote Extensive Reading Activities in School Learning

Luísa O. Santos

Abstract: This paper describes a study in progress aimed at secondary school students of English as a Second Language, concerning poetry as a possibility for extensive reading activities, supported by an hypertext approach to the design of the learning environment.

Introduction

Poetry has been a challenge for English as a Second Language (ESL) teachers and students. The former evaded the issue by simply not using poetry in their classes and the latter were quite content in not having to deal with texts that they considered “difficult” (Lazar, 1993; Ur, 1996).

The aim of this in progress study is to understand the importance of the hypertext flexibility in the design of web based learning environment to the literary text and mainly the use of poetry in the second language learning process in every level of teaching as a possibility to be taken into account in the domain of extensive reading activities.

The design of flexible, collaborative and open learning environments directed to building up knowledge in straight relation to the subject’s own pace and the user’s needs has its roots in the educational approaches of social constructivism and situated learning.

The change in the design of new learning environments is shown through the flexibility of the learning processes, the multidimensional exploration of the learning materials, a personal and collaborative commitment in the learning goals and the working out of a individual and collaborative strategy for knowledge construction and experience (Spiro et al., 1995; Jacobson et al., 1996; Romiszowski, 1997; Collis et al., 1997; Dias, 1999, Rogers, 2000).

The Study

The research design is a qualitative based analysis of the student learning interaction and understanding of poetry text through the hypertext and hypermedia support of flexibility and contextual learning. This goal is provided by an hypertext based learning environment, that offers to the student the possibility to explore the dimensions of meaning construction, through associated links to words and images. This associated web of links perform a dynamic view of multiple texts, and suggest a deeper understanding of the internal relationships of the poetic text.

The hypertext based learning design allow students to produce a reconstruction of the poetic text, through the changing and introduction of new words or images to the original poem, composing a personal view that incorporate the choices performed by the student, during the extensive reading activity.

To implement it the research design includes a web based learning workshop in reading poetry and a discussion forum to promote the sharing of personal understandings among students.

The flexibility of hypertext in constructing the representation network is closely related to the construction of meaning in learning. The construction of meaning is a dynamic process, as well as the
arrangement of hypertext nodes; meaning develops through the relationships between nodes (Borsook, 1997:724).

This approach doesn't regard the learning process as an acquisition of knowledge externally organized and separated from its contextual framework. Furthermore, it stresses the importance of contextual building up of knowledge representations in learning, which is supported by the creation of a web of links among the informational materials of the hypertext representation. The educational hypertext is based on non-linear information organization that allows the user to choose his own individual or collaborative paths on a network, configuring it to his learning needs, previous knowledge and learning goals. The hypermedia approach was particularly innovative in terms of training since the hypertext doesn't only display the information but it works out as a dynamic web of representation.

In order to test this possibility, one class of twenty students, aged between fifteen and eighteen, in a large urban secondary school in Porto, Portugal, was selected to have classes on poetry as a part of their extensive reading activity. As in the Portuguese syllabus poetry is not included in the list of options the students have to fulfill this activity, they were given the possibility of working with several poems during the school year, in order to read a poem by e.e.cummings and from it to produce several different readings of the same poem using web based learning environments.

Conclusions

Results from the survey study shown a deeper involvement of students in suggested reading activities, namely: i) the high level of interaction dedicated to the exploration of the poem; ii) the construction of a personal understanding of the suggested poem using the associated links of words and images to produce the individual view; iii) a strong feeling of participation in the activities of reading and developing a personal and collaborative understanding of the poem; and iv) a positive attitude to the challenges of the exploration of the multidimensionality of the meaning in an hypertext based environment.

MINDS - The Learning Environment of the Future, Today

Karl Seiler, DataServ, Inc., USA

Come Join Us for a Lesson in Interactive Learning - Addressing the needs of those seeking knowledge is a timeless call for educators, administrators and all of those involved with the knowledge experience. Exploring resources via multimedia is the way that your learners want to learn. The MINDS Institute, a Learning Portal to Rich Worlds of Information, offers multimedia resources, video conference database, professional development, interactive events calendar, web board/collaboration tools and so much more. We bring you the content and resources that invites you to fully participate in next generation learning.
Abstract: This session will demonstrate the first phase of a research study to examine the role played by Internet-based teacher professional development in the implementation of an innovation. The innovation in this study is the software application (StageStruck) for the performing arts. The professional development web site has been developed to support inservice teachers in best practice use of the software. The StageStruck CD-ROM and web site community (http://www.stagestruck.uow.edu.au) will be demonstrated in this poster session.

In this first phase of development the web site portal has been established to build and support a community of practice in the performing arts areas of learning. The web site development has been an iterative process based on an understanding of best practice in professional development, a review of the literature and exploration of cases available in and about on-line communities, and the contributions and ongoing evaluation of our community members (teachers and students).

StageStruck Professional Development On-line Community

http://www.stagestruck.uow.edu.au
StageStruck - Technologies For The Performing Arts

StageStruck CD-ROM

"The winning choice is a project so all-encompassing in its objectives and execution that it represents a pinnacle of co-operation between art, culture, education and New Media. In addition to impressive content, the technical goal of creating an educational experience for the 12 - 18 year old age group is achieved in a highly relevant and inventive way". This is how the judges of the International Gold Emma Award described StageStruck.

StageStruck, produced by Wollongong University and National Institute for Dramatic Art (NIDA), was launched on 29 January 1999. It is recognised as an innovation in the teaching of performing arts. It is an innovation both as a multimedia technology for performing and creative arts teaching and learning. (StageStruck won BAFTA and EMMA awards in 1998 for educational interactive CD-ROM technology). More importantly it has been recognised as a pedagogical innovation because of its constructivist underpinnings and design realisations as a multimedia knowledge construction tool (Hedberg & Harper 1997).

Students can take on the role of directing a performance through the selection and manipulation of actors, actions, scripts, sound effects and set design elements or become involved in backstage exploration activities learning more about what goes on 'behind the scenes'. This product allows students to interactively create and display the production of scenes from classic plays and or build new performances to share with other users of the package.

StageStruck introduces the learner to the world of performing arts by exploring a performing arts venue (the Sydney Opera House) which showcases contemporary companies, performances, processes and people, and provides theatres and "tools" with which to design, build and direct soundscapes, costumes, sets, scenes and performances. The StageStruck project sought to focus on the construction of multiple meanings in a field that many would argue is highly subjective and open to numerous interpretations. This field of performance enables the student to construct their own ideas about a script and how it might be performed.

By extending the boundaries of interactivity in the context of a virtual setting, learners are provided with opportunities to express their own cultural interpretations and understandings. In this theatrical journey there is the advantage of working with many visual metaphors. The world of theatre, opera, music theatre, dance and contemporary performance styles can be explored through devices such as "The Green Room" where the user can investigate a database of the contemporary world of performing arts. The "Stage" space provides the opportunity to view sample scenes from productions which have been created by professional directors, and, more importantly, to individually direct and design their own scenes with access to the same theatrical elements. In this process individual users explore processes of visual design, sound development, and the concept of direction and motivation. In this project the construction tools have also been extended to enable the user not only to collect from a defined set of resources, but also to construct their own resources based upon combinations of sets, costumes and performers.

Key to the communication of the experience within this application is the facility to save, share files between learners or re-present your constructed performance and interpretation to others located within the same classroom or across the Internet with other learners from different cultural backgrounds. This last act offers the potential to create a range of resources that are not bounded by the storage capacity of a prepackaged CD-ROM but are collected and shared from an ever growing unbounded Internet learning environment. StageStruck like many other technological innovations needs to go through a diffusion process to reach implementation. The on-line community is seen as an effective and cost effective way to realise professional development.

StageStruck Professional Development On-line Community

The StageStruck Community has been designed to support K-12 teachers in their classroom use of StageStruck. The free community offers access to mentors, training, projects, curriculum resources, lesson plans, or the chance to 'buddy-up' with an international school to swap design idea and projects. The site offers professional development, support and resources for teachers as well as activities and projects for students. Subjects such as script writing, set design, costume design, sound effects and stagecraft are explored in an interactive and fun way. Targeted at the busy teacher who wants to use StageStruck in his/her teaching but needs that 'kickstart' - or
to extend the existing user who wants ideas for more sophisticated projects or have student works critiqued by experts in the performing arts field.

The site will grow and develop over time as teachers in the community contribute ideas, resources and develop their own projects. Participants in this interactive session will have the opportunity to discuss aspects of teaching in the performing arts with peers on-line in a number of countries. They will also be able to register their students in the writing and development of an episode of on-line serial to be started in February 2001 or propose and initiate a new International project.

The study will define the role that Internet technologies can play in the change process. Since traditional face to face professional development has been found to be very costly and less than effective in fostering and sustaining change, innovators are looking for new means to both improve the quality of teaching and empower teachers to shape the future of their own learning. One of these new means is Internet-supported communities of practice or networks. The time has never been better for a study of this nature, to show what is possible in an electronically and cognitively networked environment.

Detractors might complain that the technology is just not available or friendly enough yet for teachers to see it as a mainstream tool. This claim will very soon be easily refuted. The access to technology has grown rapidly. Australia is not alone in its efforts to offer schools high speed and effective bandwidth connections to the Internet. Most Australian state's school systems have agendas and priorities for the coming years that firmly position information and communication technologies near the top of the list.

The study's findings will be of significant specific interest to

- Educational multimedia product developers
- Curriculum developers
- Educational leaders
- Teacher training and development officers,

and indeed any educationalist considering the alternative to mainstream professional development.

Session Objectives: The session will involve demonstration and hands-on activity with the StageStruck CD-ROM and On-line Community. An accompanying paper is presented for this conference Professional Development On-line - Doing IT Pedagogically. The paper allows teachers to see the theoretical background to the CD-ROM and the web site. The poster session will allow teachers to further explore both media products and to order or purchase copies of the software.

Through this session participants will be able to:
1. Understand the constructivist nature of the StageStruck program design
2. Make explicit links from StageStruck to classroom activities and curriculum in the middle years of schooling and learning areas related to the performing arts (drama, dance, set design, costume design, stagecraft)
3. Explore hands-on the design and construction capability of StageStruck in a fun collaborative task
4. Join the on-line community to support the use of StageStruck and performing arts teaching
5. Contribute to an International discussion related to an aspect of school based performing arts.
6. Explore collaborative opportunities in International projects as part of the web site community

Proposed Participants: Teachers interested in aspects of the performing arts (dance, drama, stage design, script writing, and costume design) in elementary and secondary schools will find this a unique and valuable product and session. The session itself will be targeted to the middle years of schooling bridging student ages from 9 to 14 years, while the web site and CD-ROM for StageStruck are of value to a wider school education community. The product is a cross-platform development and will be equally valuable to users of MAC and Windows computer platforms.

Experience Level: Participants will require no computer specific experience. You are encouraged to attend the session in pairs to work together through a fun collaborative task.

Learner Self-efficacy, Attitude, and Utilization Patterns for an Electronic Textbook

David Unfred, Steve Crooks
College of Education
Texas Tech University
United States
daveu@lublab.tahc.state.tx.us
scrooks@ttacs.ttu.edu

Abstract: The use of electronic textbooks is increasing. The spectacular growth of the electronic learning space that is accessible through the computer, CD-ROM, DVD, Internet and World Wide Web has impacted a traditional form of mediated instruction, the expository printed textbook. With the digitization of information has come an evolutionary societal change where electronic publishing increasingly supplements (and some would argue eventually supplants) the printed text. A pilot study of learner self-efficacy, attitudes, and access and utilization patterns are addressed using graduate students in instructional technology. This pilot study was initiated to discover areas that could impact an expanded study on factors influencing the use of electronic textbooks.

Introduction

Presentation of societal and cultural values and the evolution of instructional methods have focused on the printed textbook. McClintock (1992) has suggested that Western education has had 500 years of stability which can be attributed in large part to the printed textbook, "The reason for the underlying stability was rather simple: throughout it all, the character and limitations of printed textbooks remained substantially fixed, the keystone of the system." (McClintock, 1992, p.2). Chamblis and Calfee (1998) have noted the importance of printed textbooks in the United States. They identify textbooks as (a) providing 75-90% of instructional content and instructional activities, (b) filling a need where teachers lack comprehensive subject matter or curriculum design expertise, (c) serving as a surrogate for a national curriculum, and (d) serving both as subject matter authority and as an instructional program.

The paradigm of the "book" is changing. The spectacular growth of the electronic learning space that is accessible through the computer, CD-ROM, DVD, Internet and World Wide Web has impacted a traditional form of mediated instruction, the expository printed textbook. With the digitization of information has come an evolutionary societal change where electronic publishing increasingly supplements (and some would argue eventually supplants) the printed text. Electronic textbooks offer several advantages over expository textbooks. Some of these advantages may be derived from comparison with the economics of electronic journals (Odlyzko, 1997). For example, from an author's perspective electronic textbooks provide advantages of scholar-controlled publishing, which implies editorial control of content and presentation. Electronic textbooks publication costs are negligible compared to print media, which makes them easier to revise, thereby improving the currency of the information presented. For the learner using an electronic textbook, advantages are not clearly apparent in the literature.

Pilot Study

In a pilot study nine graduate students in instructional technology were assigned readings in an electronic textbook (Misanchuk, et al, 2000). The electronic textbook met the four criteria suggested by Homey and Anderson-Inman (1999) for defining an electronic book: (1) electronic text must be presented to the reader visually; (2) software must incorporate a "metaphor of a book" to some significant degree; (3) software has an organizing theme or instructional focus; and (4) if other media incorporated in the electronic book, they are secondary to the
text. The electronic textbook use in this study was delivered on CD-ROM. The electronic book is essentially linear allowing navigation from the current page to the “previous” or “next” page. Other navigational aids include a Table of Contents that was maintained to the left of the text. Some pages have sub-menus that allow links to sections providing more “elaboration” of the textual material. The hypertext nature of the textbook was familiar and not a problem for the pilot group. Graphics, some with animation, were used to explain specific concepts within the text.

Although all the students in the pilot study had considerable experience with electronic text, and with various forms of electronic text delivery, none had previously used an electronic textbook. At the beginning of the course students were given a questionnaire to measure self-efficacy beliefs with regard to access, utility, and navigation of an electronic textbook environment. The questionnaire was adapted from an Internet self-efficacy scale developed by Joo, Bong & Choi (2000). Studies have linked learners' attitudes and preconceptions toward media as a positive predictor of learning outcomes. (Al-Khakli, & Al-Jabri, 1998). As might be expected from our group of “expert users,” graduate students in instructional technology, as a group their confidence was high with regard to their ability to access and navigate information in an electronic textbook format, even though they had no prior experience.

Students were given the opportunity to open-ended questions regarding what each user saw as advantages and disadvantages of the electronic textbook. One purpose of the open-ended questions was to help discover differences in user attitudes that could possibly serve as the basis for constructing evaluation instruments for an expanded study. The students were also asked to rank their perceived advantages and disadvantages as minor, major, or critical. By a ratio of 3-to-1 the students preferred a traditional printed textbook to the electronic textbook. The disadvantages most often cited a being major or critical were (1) text on the computer screen is harder to read (eye stress, slower reading, and requires scrolling), and (2) less text on each screen and hyperlinks interrupted the flow of the content. Although disadvantages were identified over advantages 2-to-1, the major advantage was that the electronic textbook’s use of color, animation, and hyperlinks aided understanding of the text. (However, one student commented that the use of hypermedia was under utilized.)

This pilot study posed the following questions to the students in a focus group setting: At the conclusion of the course did the attitudes of students using an electronic textbook change with time and familiarity with the delivery system? What utilization patterns (printing hard copies, transferring electronic textbook material to word processing files, methods of note taking) did the students employ? Would you assign an electronic textbook for a class that you would teach in the future? What changes are needed for electronic textbooks? The results of the focus group are categorized (readability, content navigation, interface design, use of multimedia, etc.) and reported. Experiences with the electronic textbook and user attitudes were surprisingly uniform within the focus group.

Digital Video: What Should Teachers Know?

James E. Yao, Secondary & Higher Education & Media & Technology
Texas A&M University-Commerce
shedey@etsuodt.tamu-commerce.edu
Kennesaw State University

Abstract: Texas State Board for Educator Certification has published new technology application standards for teachers who want to be certified, including teachers of technology. The standards require that teachers should know how to create digital video products for a variety of purposes and audiences and use them in multimedia applications. Other states may follow soon. This paper discusses the difference between traditional video and today's digital video, including streaming video; examine the current technology in digital video; provides a step-by-step guide on how to create digital video; provides teachers with practical suggestions of how to create digital video economically and effectively.

Introduction

In the year of 2000, Texas State Board for Educator Certification published a new set of standards for all schoolteachers in Texas, including teachers of technology - Technology Application Standards (TAS). TAS lists specific standards of digital video knowledge and skill requirements for teachers, especially teachers of video technology. TAS requires that teachers should know how to create digital video products for a variety of purposes and audiences and use them in multimedia applications and presentations (Technology, 2000). Prior to TAS, Texas had already had in place technology application standards called Technology Applications Texas Essential Knowledge and Skills (TEKS). TEKS is the standards for evaluating K-12 students' knowledge and skills in computer-based technology, including digital video. Now with the publication of TAS, the requirement for digital video for teachers has been raised to a new height. Other states may soon have the same requirements, like TAS, for teachers in public schools. Therefore, teachers around the country are facing a challenge for knowing how to create and use digital video technology.

Most public schools today receive certain amount of money from state and/or federal funding. The funds have largely been used in the building of computing infrastructure such as computer lab and computer network (Golden, 1997). However, the ultimate purpose of computing infrastructure is for computing applications. Without application the infrastructure would be a house without residents. Using multimedia has been one of the major applications (Slaughter, 1998). Some teachers and students are using digital camera to capture images and use them in their multimedia presentations and web publications. Nevertheless, digital video is still not a reality for most teachers due to the cost on computer hardware and software, the cost on digital video cameras, and the complicity of capturing and editing video, and the lack of knowledge on equipment involved in digital video creation and the knowledge and skills on how to create digital video. To meet the challenge, a good knowledge on digital video technology, equipment, computing hardware/software, and the skills of capturing and editing video will be a must. The purpose of this paper is to help teachers acquire a fundamental understanding and knowledge of digital video technology.

Why Digital Video?

Video has been around in our life for a few decades. The development of video technology came from the need of television industry to store, edit, and replay broadcasting content, allowing the industry to step ahead from the only "live" broadcasts (Lozano, 1997). Traditionally, individual images consisting analog signals are recorded onto magnetic tapes in sequence. Those individual images are called frames in video jargon. It is by projecting a certain number of frames on a screen, such as TV screen, that we can see motions.
similar to our real life. There are several standards developed by different countries as to how many frames can be projected per second (fps). Professionals call frames per second as frame rate. Video frame rate is between 24fps and 30fps depending on the standard adopted. Also different standards adopt different scan lines on the screen. For example, NTSC (National Television Standard Committee) system uses a frame rate of 30fps (or, more precisely 29.97fps) and 525 horizontal scan lines, whereas PAL (Phase Alternating Line) system has a frame rate of 25fps with 625 lines at a frame. That is the reason why videotape from the United Kingdom, where PAL standard is used, may not be viewed here in the United States with a typical VCR/monitor that uses NTSC standard, unless a multi-system VCR or converter is used.

Editing traditional video is a knowledge demanding, time consuming, and high-cost job. Professionally trained technicians are normally needed to do the job. Due to the linear feature of analog video, dubbing and editing require several people and consume large amount of time. In addition, heavy and expensive equipment is needed to accomplish the task (Yao, Ouyang, & Wang, 2000).

Digital video on the other hand is quite different from analog video. It is more advantageous than analog video (Lozano, 1997, Slaughter, 1998, Vaughan, 1994, Villamil-Casanova & Molina, 1997). Digital video is recorded in digital format if it is shot with a digital camcorder. In this sense, the video footage is universal, e.g., both Macintosh and PC computers can view and capture it. Unlike analog video, digital video equipment with DV terminal or connections lets you edit, copy and transfer data digitally, with virtually no generation loss in image and sound quality. The DV terminal is for both line-in and line-out, since a single DV cable can handle data in both directions. Dubbing with this terminal is much simpler than that in analog video. No heavy and expensive equipment is needed.

The superlative advantage of digital video is its non-linear editing feature. Analog video is recorded on videotape in a linear fashion, which means that there is the time span from the starting point of the video to the end point of the video. Assume that the video is an hour long and we want to view what is on the tape at the point of thirty minutes, the videotape has to be forwarded to the point of thirty minutes in order to view it. If the viewpoint wanted on the tape is five minutes back at the beginning of the tape and at present the video is an hour down into the tape, then the tape has to be rewound fifty-five minutes back to view that point. Let alone the difficulties and time involved to pin point the exact place on the tape, even though some of today’s video editing systems are equipped with digital counters. Adding sound to video can be as difficult and time consuming as the video part of editing. However, digital non-linear video editing has forever changed the rule of the video world (Lozano, 1997). What is non-linear editing? After the video is digitized and transferred to a computer, it is stored on the computer’s hard drive. When editing the video, the editor can find and access any point of the video without winding or rewinding the footage as analog video editing does. Much like word processing on a computer, one can find a time place or frame by simply clicking and/or dragging on the monitor control panel or the timeline to move to the point or frame where you want to be. The newly constructed video can be saved as a new file without destructing the original footage. In digital non-linear editing, trimming, cutting, pasting, adding, inserting, overwriting can never be easier compared with analog video editing. The same is true with sound to video. Almost unlimited video and sound tracks can be used to edit or mix video and sound. All these can be done on a single computer. That is what so-called non-linear editing.

Another advantage of digital video is that video can be compressed, which means that video file size, frames size, and quality can be manipulated. Since digital video file size tends to be very large and takes large amount of computer hard drive space, by reducing its size, one can store more video on the hard drive or on other storage devices. Nevertheless, the quality of the video will be reduced as the file is compressed. The more compression a video file has, the less quality it has. To solve the problem, smaller video frame size and/or lower frame rate are normally the choices.

As World Wide Web is gaining the momentum, digital video is also moved onto the Web. A problem with digital video on the Web is that it takes a long time to download the video file to the computer before it can be viewed if the file size is large. Thus streaming video technology was invented. What is streaming video? Streaming video refers to digital video files can be viewed as they are being downloaded from the Web. “Since viewers watch streaming video on the fly, they don’t have to wait for long downloads” (Davis, 2000a). On the other hand, by compressing video, digital video can be streamed and put onto the Web faster and easier.

**Current Digital Video Technology**

Traditional digital video technology relies greatly on the conversion from analog video to digital video. A video footage is short using an analog video camera and recorded on videotape. A computer with a
video capture board is needed to convert the analog video into digital video and store the captured video on computer hard drive. Of course, one can also capture video footage by connecting video camera directly to a computer that has a video capture board. That is obviously not practical for the cameraman since the computer has to go with the camera all the time. The quality of the digital video capture board determines much of the quality of the digital video footage captured. The CODEC software that comes with the video capture board is the other part that determines the quality of video captured. A digital video capture board can range from a few hundred dollars to several thousand dollars.

Like the advancement of other technologies, digital video technology has also made a leap jump in these few years. The most innovative is the digital video camera. The outlook of a digital video camera is no much different from an analog video camera. But digital video camera captures video in digital format and stores the video on digital videotape. In 1997, Sony Company introduced 3CCD technology, which uses 3 computer chips to calculate the three major colors, elevating digital video camera to a new high-quality level. A good digital video camera is normally equipped with steady shot image stabilizer, which eliminates shaky shots caused by unsteady camera move when long digital zoom is used. Digital video camera also captures sound in digital format. This feature enhances greatly the sound quality in digital video and makes video editing much easier. Some good quality digital video cameras use PCM technology, the same as used in CDs for a breathtaking dynamic range of 96 dB. Since video and audio signals are all recorded digitally, the captured video footage can be copied or edited multiple generations with no loss in quality. Many name brand digital video cameras provides 16:9 aspect ratio recording options, which means widescreen video can be recorded for widescreen movie and future compatibility with HDTV. Another very important feature of most digital video cameras today is that these cameras have built-in high-speed FireWire (IEEE 1394) interface. This interface allows for 2-way direct digital communication between either a digital video camera and a compatible computer or two digital video cameras. When connected to a compatible computer, the interface lets you perform economical, broadcast-quality, non-linear editing easily. When connected to another digital video camera, it lets you to produce duplicate copies of recordings without any loss in picture quality. Each copy is a perfect clone of the original. These advantages definitely overwhelm analog video.

Great improvement for digital video has also been witnessed in computer technology development. Computer is the essential tool in digital video editing. It is the advancement of computer power and capability that promotes the proliferation of digital video. A couple of years after Intel's Pentium chips came into the market, a computer chip technology called MMX was introduced. This technology greatly improved the computer's power to process multimedia, including digital video and sound. Later, MMX technology was integrated into Intel's Pentium II and the chips there after.

Data bus speed was increased from 66Mhz to 100Mhz in most of today's computers. Some have gone up to 133Mhz. 3D video accelerator becomes common for display with 8Mb or 16Mb of memory, or even higher. The most noticeable jump to the public is the computer's clock speed. Within about two years, it jumped from 200Mhz to 1Ghz and over, giving computer a much higher speed to process video. However, the most creative advancement from the point of digital video is the establishment of IEEE 1394 interface (also jargoned as FireWire and iLink) as the standard for digital video communication between digital video camera and the computer. FireWire interface allows transfer rate up to 400Mbps compared to 12Mbps of USB, which is another newly standardized interface for computer peripherals. Such companies as Sony, Compaq, and Dell have integrated this interface with their high-end computers. This advancement has truly made digital video editing available for end users and reduced video rendering time during editing.

Video editing software is getting better and easy-to-use, too. Some, such as MGI Software and Ulead, offer the basics of video editing capabilities. This type of software is called Beginners Editing Software, normally at a low cost. Others, like Trinity and Avid, offer much more editing capabilities, such as more powerful titleer, more transitions, more video and sound tracks, more powerful sound editing and mixing capabilities, more after effects, more encoders, and the like. This kind of software usually requires high powerful computers and is adopted mostly by video editing professionals. In short, software availability, especially for beginners, provides a better opportunity for more people to be able to create and use digital video.

Smart Selection

"What hardware do I need?" "What software do I need?" These might be the foremost questions from teachers who want to start with digital video. The selection of hardware and software does play an important role for the beginners. Advanced digital video and editing systems not only cost more, but also tend to have...
higher learning curve. It would be smart for the beginners to start with a low-end system, including both hardware and software. This can reduce the cost on one hand and make it easier to get started on the other. To select a digital video system, teachers may find the following suggestions useful:

1). Digital video camera or you may call it digital video camcorder. Selecting a digital video camcorder to start with makes it much simpler than starting with capturing video through video capture board. As mentioned above, using a digital video camcorder eliminates the digitizing process. Then how to select digital video camcorder? One concept has to be cleared off first. Some digital camera can also record digital video. However, the digital video that a digital camera records is not the same as what a digital video camera does. What digital camera records is compressed video, usually in MPEG format. Whereas, what a digital video camcorder captures is full-motion uncompressed video. This is the kind of video that needs to be edited by using a digital video editing system. The cost for a digital video camcorder varies greatly as mentioned earlier.

For the beginners, the choice is evident—low-end one. A few tips need to be kept in mind when selecting the digital video camcorder: Video resolution. Video resolution is measured in the number of horizontal lines. Higher number of horizontal lines contributes to higher video resolution. However, higher number of horizontal lines usually cost more. A number around 300 would be a fairly good low-end digital camcorder. FireWire DV interface. Look for this interface while selecting a digital camcorder today. It is a two-way input/output that carries digital audio, video, and control signals from the digital video camcorder to the computer or other compatible devices. A digital video camcorder without this interface may not be an updated product and probably not a good choice. Image stabilizer. An optical image stabilizer is better than a digital electronic image stabilizer. If two digital camcorders are at the same price, plus the same other features, choose the one that has an optical image stabilizer rather than the one with electronic image stabilizer. Photo mode. Photo mode equals to a digital camera in the digital video camcorder. It makes shooting images much convenient, e.g., without changing cameras. However, a digital video camcorder’s photo mode cannot achieve the high image resolution quality of high-end digital cameras so far. Analog line-in. This input on a digital video camcorder will become very useful for those who will deal with analog video at the same time. Built-in speaker. This is a very important feature on a digital video camcorder. It allows you to listen to the sound of the video when playback video on the camcorder. Without it, the camcorder is certainly missing something and should not be a choice. Color LCD viewfinder. A beginner will find the color viewfinder on the digital video camcorder very helpful. There are many other features on a digital video camcorder that need to be pay attention to, but they are beyond the scope of this paper. Companies like Sony, Canon, Panasonic, JVC all have low-end digital video camcorders with prices within $1,500, such as Sony’s DCR-TRV series, Canon’s ZR-10, Elura 2, Optura, Ultura, Panasonic’s PV-DV series. For teachers with some experience in digital video and want to move up to a higher quality level, Canon’s GL1 and XL1, Sony’s DCR-VX1000 and DCR-VX2000, Panasonic’s AG-EZ30, etc. will be a better choice.

2). Computer hardware. The suggestion for teachers to select computer hardware is always go with the latest technology. This is because digital video requires higher computing power, which includes clock speed, bus speed, memory, and hard drive, than normal applications. The higher the computer power, the faster your capturing and editing work. On the low-end, minimum system requirement is: Processor, Pentium II, 300Mhz; system memory, 128Mb; hard drive size, 10Gb (SCSI drive recommended); external bus speed, 100Mhz; sound system, 16-bit sound card; interface, FireWire (IEEE 1394). If the computer does not have FireWire interface, FireWire interface card can be purchased and installed easily. However, most digital video editing system kit today comes with a video capture board that has integrated FireWire interface. Note that the system kit that comes with USB interface for video should not be your choice since it is much slower than FireWire interface.

3). Digital video editing system. Generally the following is the easy editing solutions for digital video editing: editing appliances, turnkey computer editors, and external capture devices (Davis, 2000b). Editing appliances, such as Panasonic Digital Media Editor and Draco Avio ST, are specially designed computer for video editing only. They cannot do anything else as a computer does. For teachers, though almost no hardware configuration and low in price, an editing appliance is still an extra cost if they already posses multimedia computers. Therefore, these appliances are not recommended. Turnkey computer editors refer to digital video editing kits. A turnkey computer editor, like DVGear DV Warrior, is actually a full-function video editing computer with everything you need, except digital video camcorder. If budget is not a problem, this is a good choice for teachers, especially for teachers who teach digital video. However, the price for turnkey computer editors varies greatly between easy ones and professionals. They may range from a couple of thousand dollars, such as DVGear, to over $40,000, like Avid, depending on the system configuration. Low price models in DVGear, DVLine, or Sony are recommended. External capture devices are devices that help capture video. They are inexpensive, but most of them are not for full-motion capturing, e.g., at 30 fps. Of course they are not
recommended. There is another way to get digital video editing system and it is probably the most practical and economical for schoolteachers: Create-by-yourself. It is relatively less expensive if you already have a Pentium or higher speed computer. Create-by-yourself refers to buying a video capture board, choosing video-editing software, and installing them into your computer all by yourself. Sounds difficult? Not at all in practice. Just get a video capture board of your choice. Video capture boards can be purchased between $200 and $4,000 depending on names and brands, such as Pinnacle Miro 30 at about $200 and Truevision Targa 2000 around $3000. These boards normally come with intermediate level video editing software, such as Adobe Premiere. You may choose beginner level video editing software if you like, such as MCI Software VideoWave III and Ulead VideoStudio 4.0 at about $100. At the price of about $800, Pinnacle DV500 gives you almost all you need for video editing. The package includes a video capture board with FireWire interface, video editing software Adobe Premiere 5.x, software for making CD and DVD, and the appropriate interfaces for analog A/V inputs/outputs. Installation and configuration are fairly easy. To go by create-by-yourself, make sure that the video capture board you purchase has the interface to match your digital video camcorder; the board you purchase must be compatible with your computer's hardware (motherboard most of the time) and operating system. We recommend you try this method. Notice that Macintosh computers are not mentioned here simply because of the dominant PC majority user population.

Video Creation

For convenience, Canon GL1 digital video camcorder, Sony PCG-F490 laptop computer, and Adobe Premiere 5.1 LE non-linear editing software are selected to illustrate the necessary steps of how to capture video from digital video camcorder and edit it on a computer. Although other systems may be operated differently, the concepts will be universal and consistent.

Getting Started

First, shoot a piece of video using the digital video camcorder (To save space, how to shoot video with the digital video camcorder will not be illustrated here.) and make sure that the DV tape with the video is in the camcorder. Connect GL1 to Sony computer via the FireWire interface on both the camcorder and the computer with a 4-4 pin FireWire cable. Turn the power switch of GL1 to VCR and rewind the tape to the beginning. Turn on the computer. Go to Start. Under Programs, find and launch DVgate Motion under DVgate. After DVgate Motion program is launched, in MODE box on the program control panel, make sure that IMPORT - Auto is selected. REC DATE should show the current date and time. Other display boxes shall show zeros. On the left side of the program is the Monitor window. On the right is the IN/OUT List, where on display is the number of clips captured, capture in and out points, duration and file size of the video captured. On the GL1's display window, DVin should appear, indicating that the communication between the camcorder and computer is ready.

Capturing

The videotape playback on the camcorder can be controlled both on the camcorder and the DVgate program control panel on the computer. Using the control panel on the computer is recommended. Start the video playback by clicking the play button on the program's control panel. At this time, the Monitor window will display the video on the tape in the camcorder and the TIME CODE, IN, and DURATION boxes will display the relevant number. FAST, SLOW, and STEP FORWARD and FAST, SLOW, and STEP BACKWARD buttons can be used to find the exact point where the starting capture point is on the digital videotape in the camcorder. While observing the time codes and the images being played back on the video display area, click the MARK button when the target-starting image appears. This establishes the IN point and an image of this point is shown in the IN/OUT list. The time code display area shows the time code of the IN point and the elapsed time of the video playback from the IN point. Click the MARK button again when the target-ending image appears. This establishes the OUT point. The marked points can also be cancelled at anytime by using the CANCEL button on the control panel. When the marked in and out points are confirmed, click the CAPTURE button to capture the marked points one after another or click CAPTURE ALL to capture
all the marked points. On the IN/OUT list, the in and out points, duration, and file size of the captured video will be displayed respectively. The captured videos are simultaneously stored in a pre-assigned folder in AVI files. The captured video can also be saved in a different directory. At this moment, video capturing is completed. It is ready to be pulled into an editor for editing.

Video Editing

Find and launch Adobe Premiere 5.1 LE non-linear digital video editor. Select project settings (This is typical in Adobe Premiere.). Premiere displays automatically the monitors, one for the Source video, the other the Target video; Project window; Timeline window (also called Construction window); and some other windows depending on user customization. The program is now ready to accept video. Use Import under File to find the folder where the video files are stored and import the video into the editing program. The imported videos are listed in the Project window. Click and drag a video into Source monitor window. Use the Frame Jogger to move forward or backward. Use the Mark In and Mark Out buttons to mark the video clip. After the marking, click and drag the marked video in the Source window onto the video 1A track on the Timeline. Sound of the video is also dragged to the sound track automatically. If sound is not wanted, deselect the sound icon button on the Source window. Then sound will not be brought onto the sound track but only the video. Once on the Timeline, all the editing features can be added, such as adding transaction, adding another track of video, superimposing, adding title, moving clips around, making the clip longer or shorter by just dragging it on the Timeline to the direction to be longer or shorter. Of course it cannot be dragged longer than its original. Almost unlimited video and audio tracks can be added in Premiere (up to 99 tracks). After the effect and process editing, the edited video must be saved in a directory before Premiere can view the edited video. After it is save, you can preview the edited video and edit it again at anywhere and anytime. When you want to view it again, Premiere renders the video and gets it ready for you to view. The saved edited view now becomes a Premiere project file. It now can be exported according to the editors desire and software encoders in other file formats, such as QuickTime movie, AVI file, Microsoft Video, etc. This is how video is edited.

Conclusion

Digital video technology is advancing fast along with the computing technology. The cost for digital video editing systems will be getting affordable. As the requirement for teachers to use digital video increases, digital video will become commonplace for teachers to integrate this technology into curriculum. With the right tools and knowledge in digital video, teachers will be able to meet the challenge of creating digital video for effective teaching and learning in the twenty-first century.

CHANGING INTERPERSONAL RELATIONSHIP BETWEEN TEACHERS AND STUDENTS USING TUTION

Vladan Zdravkovic
University of Gävle, Sweden
vzc@hiig.se
Leut Riv
Interactive, Sweden

Abstract

In this work we are proposed relocation of teacher's time during process of education. We have analyzed mutual student teacher relationship and proposed relocation of teacher's time as well as combination between tuition and classical teaching. The most common problem in relationship is insufficient experience or knowledge of teachers but as well learners (changing of learning paradigm form secondary school to higher education, or change in level from graduate studies till postgraduate studies). We have proposed different practical approaches and techniques for solving problems in teacher – learner relationship. Results have been obtained in both introspective form and testing form - student's evaluation of courses and marks.

1. Introduction

Mutual student - teacher relationship is key factor in learning process. Students' motivation is significant from that source. Many objective problems during learning process have been solved thanks to good relationship between teacher and students. Also some of the biggest problem during learning have been caused by bad relationship between students and teachers. And proposed relocation of teacher's time as well as combination between tuition and classical teaching. We are proposed different practical approaches and techniques for solving problems in teacher – learner relationship. The most important aspect is reaffirmation of tuition as the form of learning almost forgotten in higher education (mostly from the objective reasons). Results have been obtained in both introspective form and testing form - student's evaluation of courses and marks. Here proposed example is best for the first year starting subject, because as it is stated later could solved additional problems caused by changing of learning paradigm. Of course it is applied on every type of learning.

2. Problems

It is not aim to accuse nor students or teachers but in real life every of us have been witness of mistakes on both sides. If we are excluded problems generated with purpose, we could roughly located motivation as a factor mostly dependent and vulnerable. From students perspective the most common problem in relationship is insufficient experience or knowledge of teachers. Both of those “unperfection” produced loosing of authority and credibility. From learners view the biggest problem is came from changing of learning paradigm form secondary school to higher education, or change in level from graduate studies till postgraduate studies. Several other problems have been monitored. Process of learning have became more pressured for teachers as asks from community raised. Another process is transformation of power channels and strength from teacher to students. Students have today much more rights what is one way positive process, but in other hands they have to take as well responsibilities, which by the line of low resistance they don’t wish to accept. Also have been starting process of some kind of pressures from students toward teachers. Result should be satisfactory mark taken actually by the “force”. Teachers have made negative reactions to whole group of students regarding that kind of respond. All together it leads to process (by the low of negative feedback) which results are negative for both sides. Resulting problems are: Students haven’t confidence in teachers. Students think that teachers don’t care for them. Students don’t understand difference between secondary and higher education. The way for solution of this problem could be building new way of relationships, which has more confidence. But confidence we couldn’t build by the low. Confidence is “wage” received in process. Teacher who couldn’t deserve it with knowledge and skill need to put other assets to have it. Time is one of the resources available to everyone.
3. Proposal

Students needs from the start additional time, because they felt as loosed. In some educational system secondary school is pretty "liberal" and "learner oriented" so students work mostly with teachers help. When they come to university they are faced with completely different atmosphere, mostly without any personal contact with teachers. This proposal could solve some big problems. We are proposed teaching one or two subjects in the first term - semester in different way using combination of tuition and lecturing. It is obviously that teacher time for those subjects have to be almost duplicated because big portion of time should go on building new relationship between teacher and students.

As well proposed system should help in resolving problems caused by new environment and new conditions of living. This is another reason for positioning subject taught on tuition based in the first year of studying. This process is off course not easy, but if efforts come from both side results could be surprising. Ideas in this work have been tested in last four years, and are still in testing. Model which we suggest are modified from basic model, and what is from most interest one of the result is that different culture (but not very different) accepted teaching on completely different way. There for some of methods which were successful in some environment result as completely different in different environment. The big problem is also that different kind of students in way of personal predisposition (for example technical, media and art students) responds to teaching on completely different way. Students need starting week where they get information about process of learning, using literature Internet, distance base education and other types of education and communications whom they haven’t been introduced before. Every university have this introduction but mostly on the wrong way, without results. Students are needed closer communication with teachers. In that sense logical solution is reestablishing institution of tutor. Also each subject should have at least some short interval of tuition [Vladan Zdravkovic. Reaffirmation of tuition in learning, Being Virtual, spring 2000]. It is clear that it is very complicated, especially for basic subject, where the number of student could be 500 per teacher, but it should be solved three assistants or some other form of consultants. Teaching process should be more personalize. It’s means that teaching process should more fit to students needs, abilities and wishes.

4. Solution

The main problem is relocation of teacher’s time. As reintegration of tuition needs more teachers’ time, where from time is came? Some topics actually haven’t needed for human “on line” taught. These topic should be delivered by some form of education on demand: Web, Video, audiotape or as an assignment to read. Time have released by these approach could go to tuition. That concept has been introduced in 1998. First modification has been applied during winter semester 1999/2000, and second modification has been applied during the spring semester 2000. Third modification is still in progress and results will be presented on conference. Here we are presented solution for time saving. Students have been split in several groups (from 2 till 5) regarding their previous knowledge, and abilities to attending the technical level of lessons. On that way teacher were able to offer two kind of lecturing for two kind of students. The time for providing these idea coming from labs lessons where students receives freedom to work on their own (as well taking responsibilities for their own time and work). Also time have came from timing scheduled for theoretical lessons (because theoretical lessons have been performed on video base, giving chapters from book to reading (where they completely match subject) so teacher gave answers on questions during tuition).

5. Results

From the start results have been very unsatisfactory, but analyzing them conclusion were that several mistakes had been performed on start, which have been omitted later process. Understanding those mistakes, we have performed modification. After modification method have performed quite well and responds of students were over expectations. In full version of work is table with students’ mark for subject and teacher.

6. Conclusion

Tuition has reestablished confidence and significant improved students’ confidence toward teacher. It has helped in learning and solved many problems mostly couldn’t be solved without using of tuition.
Solving educational problems during learning computer visualization applications and raising students’ creativity

Vladan Zdravkovic
University of Gävle, Sweden
Vzc@hig.se

Boris Vian
VR LAB – AFPC, Netherlands
Vian@teachers.org

Abstract

Learning visual based application has been one of the biggest problems for most of students. Both in art and technical education. One of the reasons is that education in computer visualization, especially in area of 3D modeling, 3D animation, computer-generated special effects and programming for multimedia and VR applications are not same as education for standard computer application. But any way teachers have been trying to implement standard educational techniques. The solution is in changing learning paradigm and tries in more flexible and differential approach. In this work we are presented combination of project based learning and teaching have been implemented in different proportion and sequence.

1. Introduction

Education in computer visualization, especially in area of 3D modeling, 3D animation, computer-generated special effects and programming for VR applications are not same as an education for standard computer application. Experience has been showed us that we should implement different strategies, methods, motivation approach and even change complete paradigm. Usually way of teaching should be abandoned, and project based approach with flexible, dependent on class dynamics and structure, teaching process should be implement in all steps of learning. In our case teaching has been combined with projected based approach where teacher showed on different types of applications mistakes and good solutions. This approach not even has been raised students knowledge and speed in acquiring knowledge but raised students’ creativity [1].

2. Problems

Because of all differences between learning of visual application comparing with other computer related subjects educators should be careful and specially take care about following aspects:
Difference in way of adoption lecturing in those fields.
Importance of order of teaching and going step by step by subjects.
Group dynamic and structure have been more important comparing with “not visual related” subjects [2], [3].
Interdisciplinary and multidisciplinary of subjects especially connection with artistic problems and specialty, which this connection should bring in process of education for computer visualization. Also, learning animation programs carry problems. It is difficult and time consuming. Students could be unsuccessful and their self confidence will fooling down. Immersed in animation world, students could “forget” about primary task – learning other visual based subjects.
3. Methodology

In those research and presented work we have used some of not popular methodology, as dividing students, making
range between them as more or less gifted for subject, but reality and experience show us that visual based applications
are not kind of software which is immanent to every person. Beside that we have made this grouping on the way that
student didn’t realize that they are in different groups. If some of them had realized that, they didn’t complain.
We have tried to implement different way of learning offering to students’ different speed and type of learning. During
our research terms have been changed, not all groups had have same tests, and not all results are processed. So the
experiment should be treated as is still in progress and development and results as preliminary not as final. Any way
now we are in phase that results could be useful so we are published work.

4. Project

We have made project in 3 phase. First two phases are finished. There is final last phase that should be finished and than
results will be completely valid.
In the first phase we have tried to discover different ways of learning and approach to understanding visual based
computer applications. We had tested students, before they have started education. It has given us base for almost
absolute compression between control groups and different styles of teaching. Based on that we have monitored their
success in learning visual based applications more efficient. Enrolment test had two parts. A psychology test based
(mixture of intelligence, motivation and socialization aspects) and “subjective” test of creativity where students bring
their “artistic” work, what have been upon their choice. Most have brought drawings, some stories or songs. We have
correlated results on these tests and their educational background and their marks during education. During the first
phase of research we have changed application for learning because we had found that some visual based applications
allow faster learning results and stronger base for efficient learning then other correlated applications.
In the second phase we have gone deeply in problems of different way of teaching and learning. During that process we
have tried different strategies in approaching to students and with different styles in learning. As in the previously phase
we have used method of variation of teaching style of teachers. That method has been applied always on main teacher
(teaching theoretical lessons). But instructors (lab assistants) approach for application programming has been a little bit
different. Sometimes when we had been sure that instructor was able for transformation teaching style, we have used
same person. But when we had thought that instructor wasn’t able to change teaching style we have changed person, so
we worked mostly with different types of instructors for learning application programs.
We have generally classified three types of approach to students. Criteria are mixed and complicated for explanation. We
have also developed three different ways in presentation of theoretical topics. One way has been presented theoretical
topics before practical, especially before learning application programming. Another has first used method of learning
application programming without any theoretical introduction and then after finishing that learning working with
theoretical lessons. Finally last method have been combination of that two in the way of positioning practical learning in
the middle of learning process. The method where theoretical lessons had came at the end (after learning application
program) has been rejected. We have tried with this approach several times, but with evidently refusing from the
students. We also have appended learning of animation and modeling even to those who learned just multimedia
programming, because we had believed that by this way students could improve their learning and understanding
abilities [1].
Also there is a place to notify that we couldn’t treat the results of experiment as absolute because for the main subject
interactive multimedia – application program Macromedia Director, we have used results application – CD-ROM as
criteria about successful fulfills of program. Some criteria in marking those kind of application could be absolute as
number of mistakes in programming or consecutive of design or level of interactivity, but some are relative as quality of
design [4].

5. Subject
The chosen subjects have been Computer Animation, Digital Postproduction and Interactive Multimedia. Although name Interactive Multimedia suggests learning multimedia based programming, it covers as well computer animation and modeling. Sometimes originally subject Interactive Multimedia already had included learning animation, modeling and editing (but on a very basic level), sometimes we ad these two areas in syllabus. Digital Postproduction have had also animation and modeling in syllabus. The reason is that we believed that learning modeling and animation could help in learning related topics in multimedia and that it raises student’s creativity.

In process of learning as application programming learning we have used Adobe PhotoShop, Macromedia Director, NewTek LightWave, 3D MAX, formerly Kinetix now Discreet and Adobe Premier. We have used two countries and two educational systems for monitoring results. We have used Sweden and Yugoslavia. Also we have used groups of University students and students taught for company training. Total number of students have been more then sufficient for reliability of results (more then 400) but not all of them had been tested on same conditions, so we could compare smaller groups and building different correlation between different groups. The biggest problem have been impossibility for psychological and creative enrolment (pre-test) for all learners. Another problem has been caused by changing learning application.

6. Mission

In theoretical teaching most emphasis had been given to following topics: Interactivity, Multimedia, Production and basics rules about film making and visual aesthetics.

Main tasks what we had assigned to ourselves have been raising student’s creativity, understanding problems in production of multimedia, animation and special effects, understanding purpose and ways for realization of interactivity.

Finally all that have been implemented to making students able for developing interactive multimedia application by themselves.

Monitoring of success of that process has not been so easy. How to monitor for example creativity of students? Even if such progress could be monitored, what will be defined as creativity? What is creativity for one person could be pattern and monotony for another. So it has been obviously that these task would be unmeasurable. One of ideas had been measuring this progress by intorspection of students. We have abandoned it as completely not valuable method, but we had asked some of the students (selectable those for whom we suppose that could give honest and reliable answer), and those results we have assorted among “not valuable” results.

Students have made two kinds of assignment. One has been modeling assignment obligatory for all groups. First in NewTek LightWave (just in Yugoslavia), then 3D MAX (both Sweden and Yugoslavia). Another assignment has been deepened on group. For Interactive Multimedia it have been programming assignment in Macromedia Director.

Programming assignment first have been made by one student, but later we change it on system two students one project, even it were cases where were 3 or 4 students on assignment (where the project was bigger). In Animation it have been advanced modeling or animation assignment depending of student’s group. In postproduction it have been editing, digital composing and digital effect.

When we are compared results of students work we also compare other marks in their studding (where is possible) and that we also made using two criteria. In the first phase we also marked work in editing made in Adobe Premier, but we have realized that these mark had been mostly based on subject evaluation and on personal preferences. We had decided to abandon this program from those who were relevant for research. Anyway students have received lecture in that program and worked in it, but it was out of evaluation for this research.

Regarding the modeling tasks we have tried with following system. Students’ different ability had received different tasks of different difficulties. It have shown very good results, because by this way very good students produced excellent models and not so gifted students, succeed in producing sometimes pretty good models. It have been much better results from the previous attempts when we have made same way of assignment for all, and where the result were that in case when assignment were to difficult, not so small number of students just quitted from the work. In reverse case when we have given to easy assignment there were not extraordinary works.

7. Methodology for marking
One of the fundamentals have been building stable marking system, which could eliminate as much as it is possible subjective impressions. System of marking have been stable throe hole research, and we build marks from following parts:

Global impression of model has received maximum 10 points.
Model position on surrounding ground has received maximum 2 points.
Economy of model (it means number of polygons used for building the model) received maximum 2 points.
Lighting of model and established atmosphere of the scene have received maximum 5 points.

Number of points in modeling assignments has been doubled if it was group for animation and triplicate for group for modeling. Points for multimedia presentations are followed:

- Overall impression have brought maximum 30 points
- Design have brought maximum 20 points
- Navigation have brought maximum 10 points
- Style have brought maximum 10 points
- Incorporation of sound have brought maximum 7 points
- Concept have brought maximum 5 points
- Implementation of Idea have brought maximum 15 points
- Implementation of topic have brought maximum 5 points
- Story have brought maximum 10 points
- Interactivity have brought maximum 10 points

Technical aspects (speed, mistakes...) have brought maximum 10 points

(Number of points has been 132 points, higher of 100 because it has been combined with modeling.

After finishing assignment all students have received replay on assignment and change their model, animation or application. That we have used because idea is that if students missed some essential aspects it is problem of teacher who hadn’t transferred knowledge on correct way, from any reason. It could be student’s absence from class or teacher mistake in education. But if the problem hasn’t been fixed even after warning, these have been treated as student’s mistake.

8. Results

Because we have got many correlation complete table of results is impossible for showing in work. Here we are presented table with comparison of three groups on the same University, and same subject - Interactive Multimedia. Groups have been worked in half-year delay and group one has worked with classical approach to Multimedia without active implementation of Modeling and completely without learning of animation. For group one teaching in modeling have been actually just learning about interface.

</tr>
</tbody>
</table>

Table 1

Mission from the learning have been conducted in late two groups almost completely (criteria have been nominate as for the professional production. Significant difference in results has proved correctness of method.

Another interesting results have been notified in comparison groups who have worked with complete practical - project based approach (group 9), mixture of project based approach when the process has grouped in two blocs. First theoretical then practical (group 13). Mixture of theoretical and project in order theory - project 1 - theory - project 2 - theory - final project (group 14). This result is not so absolute valid as previously one because group 9 is from different country, and also global abilities of students and their pre knowledge before stating of course was different. Also it have been corporate training in difference from group 13 and 14 where it have been University education. Also training of group 9 have been much longer then training of groups 13 and 14 so we have provided two overall marks after first block of
work (about same amount of work as for the group 13 and 14 and final work (doubled time). Another different is early
differentiation in-group 9 so learners have been divided in-groups as programmer designer and sound editor, what
produced problem in their overall work.

Table 2

9. Conclusion

Marks (objective criteria) and even more subjective criteria as a teacher filing about assignment shows all advantages of implemented approach in teaching. These project any way needs more time for testing, implementation of used techniques in teaching and comparison with others teacher’s results (what is in progress). Any way there is no doubt that some of approaches should be implemented no meter of kind of educational organization or personal teachers approach, as is project based learning, different approach to different students, “quantityization” of assignment and “personalization” aspect during teaching. Although project based learning is evidently more improved method of teaching [5], [6], it has to be implemented with careful and mixed with other methods.

[3] Carling Eva and Olila Marc, SIGGRAPH proceedings, Siggrpah 1999
Designing Constructivist Teaching and Learning Environments
For Visual Learning

Sara G. McNeil
Department of Curriculum and Instruction, University of Houston, Houston, Texas USA
smcneil@uh.edu

Abstract: This paper discusses the design of a graduate course in visual learning based on constructivist teaching principles. The conceptual framework is described, and guidelines and examples of each project are presented. Innovative strategies that contribute to a constructivist teaching and learning environment are discussed. Student and instructor comments are also shared.

The Importance of Visual Communication

Most living things depend on some form of visual communication every day. As human beings, our lives are intertwined with a rich array of visual information that is presented almost every waking moment. Beginning when we get up in the morning and often continuing into our dreams at night, we are continually being affected and influenced by the colors, images, and the media that bombards us. The world is becoming more and more visually oriented as the sheer amount of information increases at an alarming rate, and we struggle to make sense it. We depend on visuals to help us understand concepts and procedures. Visuals can be very useful in solving problems. From Dr. Snow’s maps plotting the location of cholera deaths in a central London neighborhood in 1853 to illustrations showing us how to connect cables to our computer, visuals often show us how to solve complex problems with very little support from text. Visuals are also tools of persuasion; printed and television advertisements influence people in making decisions. Spoken words such as poems or metaphors often create visual images in our minds. In spite of the overwhelming use and influence of visual information in all parts of our lives, educators are often not as knowledgeable about creating effective instructional visuals as text-based materials. More often they use verbal forms of communication to teach rather than visual presentation skills.

Literacy skills for both teachers and students should include visual as well as verbal literacy. Visual literacy is “the ability to understand and use images, including the ability to think, learn, and express oneself in terms of images.” (Braden, 1996)

Constructivist Teaching Environments

Designing effective teaching and learning environments is a complex and challenging task for educators. The course environment should facilitate students’ ability to manipulate the content of the course to fit their specific learning needs and goals. Students should interact with the course information in order to develop proficiencies in both the theoretical framework that guides our understanding of how visuals can be used instructionally and specific technology skills in graphics software. A project-oriented approach seems to meet these goals since the guidelines for each project allow students to create products that are relevant to who they are as learners and reflect on the competencies they need to master.

Course Description

The Visual Representation of Information covers a wide variety of topics related to the effective use of representing information visually in instructional media and materials. The primary purpose of this course is to enhance students’ ability to conceptualize, design and develop visually rich and appropriate
materials that support and enhance active teaching and learning. Although the primary focus of this course is the effective use of graphics in interactive, computer-based instruction, the concepts can be applied to the design and development of materials for other courses, presentations, and instruction.

This course blends theoretical and research issues related to the use of graphics in instruction with production competencies. Students explore and evaluate the design and creation of visual information in a variety of technology-based learning environments. Another purpose of this course is to enable students to get in-depth, hands-on experience with a variety of graphic software programs. The general format of this course is a mixture of demonstration, discussion, and hands-on experiences, and the role of the instructor in this course is one of a facilitator rather than a source of all knowledge. In most technology-related courses, it is impossible to know everything; there is simply too much to know, and it is continuously changing.

Objectives for This Course

During this course, students participate in readings, discussions, and hands-on explorations of the following topics: creating appropriate visuals for instructional content and the intent of the instruction; understanding the role of visuals in facilitating learning and the relationship between learning theory and visual perception; knowledge of the research on visuals in instruction and the resulting instructional design principles; familiarity with the concepts of visual design and communication in computer-based instruction; and skills in creating paper and electronic documents such as storyboards, design documents, and flow charts that convey accurate descriptions of visuals to production units such as illustrators, artists, videographers, and photographers.

Through skills developed in five projects, students develop a personal understanding of design principles for computer-developed media, become able to apply design principles to situations involving the creation and evaluation of both static and animated graphics using technology, and develop a meaningful visual vocabulary that extends to other environments outside of this classroom. In addition, students learn to use creative brainstorming to develop instructional graphics to solve problems and communicate effectively. Finally, through authentic, challenging activities, students develop skills in Adobe Photoshop and ImageReady techniques.

Learner Profile

Typically students in this course are enrolled in the graduate instructional technology program, but few have experience in art or graphic design. At the beginning of the course, most students are interested primarily in the skills development, even calling the course, “the Photoshop course,” but by the end of the semester, they realize that the development of visual literacy skills and the accompanying theoretical framework for design is more valuable.

One student stated it this way:

...the projects made me seek to absorb as much Photoshop as I could for each project. I want to have a good grade in the course, but I will be better served by the knowledge I have acquired from the course. I wanted to learn Photoshop two grades above "A". There was so much other needed knowledge gained in colors, metaphors and interface design, that the whole class was enriching for my use and career-to-come.

Students have many responsibilities since the satisfaction and enjoyment of this course depends, for a large part, on the time and effort that each student dedicates to exploring the issues, learning different techniques, and playing with the tools. There is a great deal of time involved in learning graphic application software, and most of that learning occurs outside the regularly scheduled class. Students often spend as many as 9-12 hours each week working on the concepts and techniques discussed in class.
Course Projects

Project 1: Learning the Language of Art

In order to develop a common language for communicating about visuals and design, students research either an element of art or a principle of design and combine original graphics and descriptive text to create a reference for the Language of Art Resource in the course materials. Students demonstrate competencies in general graphic skills by scanning photographs, choosing correct file formats, appropriate selection areas, and appropriate size. Students also demonstrate general design skills by selecting appropriate type style and size, chunking text to improve readability, and creating appropriate balance between text, graphics and white space. Finally mastery of basic Photoshop skills are demonstrated by opening, resizing, and cropping images, adjusting brightness and contrast, and saving files. Creating a new word processing document, inserting graphics into the document and saving the file in HTML demonstrate Microsoft Word skills.

Students select and sign up for either an Element of Art or Principle of Design (for example: point, simplicity, shape, clarity, space, balance, light, harmony). They take at least 12 pictures with a regular camera that illustrates their concept. Digital cameras are not used because scanning is one of the objectives for this project. They have the pictures developed, then scan and enhance them in Adobe Photoshop by resizing, cropping and adjusting brightness and contrast. Students also research their topic by interviewing art educators, and reading information both online and print-based. Finally they find at least two examples of the element/principle illustrated in artwork in online museums.

The students write a summary about their topic in a word processing program, inserting the pictures in the appropriate places. They are required to have at least 3 bibliographic references and a short annotation describing the instance of the element/principle in a piece of artwork in an online museum with a hyperlink to the site. Finally the documents are saved in HTML format so they can be shared with others.

Project 2: Creating a 3 Dimensional Timeline

In the second project, students contribute to a timeline of computer history and construct a three dimensional "virtual exhibit." Each student chooses a period of time based on important events in computer history such as "The Enigma Machine (1935)" or "Blaise Pascal: Pascaline Calculator (1642)." Then they create an exhibit in an online computer history museum. Supporting information about the life and times of that era must also be represented. Timelines are appropriate topics for this project because they have long been used to represent temporal information in visual form.

Students demonstrate competencies in graphics skills such as understanding perspective and how to create an illusion of 3-dimension space, but they also must decide which images are
needed in the space they create. Students research their era to find appropriate and meaningful historical and computer information. They must evaluate primarily textual information and then determine how it might best be presented visually. Students explore innovative approaches for displaying the visual information for the time period including techniques in color, light, and shadow. Finally students must obtain copyright permission to use any image not in the public domain or one they didn’t create. The 3-dimensional room is placed on a Web page and the student submits information about the images, as well as links to relevant web sites that directly pertain to the computer history of that era.

As each class has contributed rooms to the Computer History Museum, it has continued to grow. Each room is shown on a menu page grouped with thumbnails of the rooms of each particular era. The thumbnail links to a Web page with a larger image and information about the era, important personalities, Web links, and information about the student who created the room.

![The Vacuum Tube](image)

Figure 3: Part of the Menu for the Computer History Museum
Showing Clickable Thumbnails for the Exhibits

Each room is very different since students have considerable freedom in selecting and placing objects and images. Usually the greatest limitation that students have to outcome is the lack of graphic software skills, since many students do not yet have the ability of reproduce what they see in their mind’s eye.

**Project Three: The Visual Representation of Statistical Data**

For the third project, students design two visual representations of statistical educational data. Students create two graphs, one in normal form such as a bar graph, pie chart, or line graph, and the other using an innovative and less formal approach to portraying that same information. Both graphs reflect professionalism in design, but are radically different in both appearance and purpose.

Each graph should reflect a well-planned layout; have consistency in type, appropriate sizing, and a balance of graphics and information. Supporting information about the data - the original source - must also be included. Students design the first graph for a formal publication such as a journal or professional publication. The other graph is designed for a less formal situation such as a presentation at a conference, in which the visual must be more colorful, interesting and compelling.

Although constructing a graph seems simple, graphs are much more complex and powerful tools of persuasion than many other visuals because they contain data that carries with it the perception of research and fact. A good graph portrays correct information, gives the reader information at a glance, demonstrates simplicity of design, and uses color to create emphasis and understanding.
Project Four: Educational Animated GIF

In the fourth project, students construct an animated GIF that teaches an educational concept and demonstrates information in a purely visual manner. The image must show the represented data in a new, innovative and creative way. The animated GIF must be drawn by the student, but objects used in the animation may be from other sources such as scanned from a book or saved from the Web. The bibliographic source for the image, however, must be noted in full, and submitted with this project.

The most difficult part of this project is to narrow the topic down to a simple and straightforward subject that will easy to break into pieces or scenes in the process. Adobe ImageReady software is used to create the GIF, and build on the Photoshop skills already acquired in the previous projects.

![Figure 5: Example of an Animated GIF Showing the Growth of a Seed Into a Flower](image)

Project Five: Interface Design

For the fifth and final project, students must design and build a consistent and meaningful interface for an educational computer-based program. All images and graphics used must be created, photographed, drawn, or scanned from natural objects; no clip art or scans may be used.

The components required for this project include a text-based design document that includes a design analysis, justification for the content and form of information representation, and identification of users. A flowchart that shows where screens fit into the total package must also be included. The visual elements include a collage that combines at least 5 images into a new representation, a tiled, seamless background, and navigational buttons that are consistent with the interface. Students develop five screens including a title screen, a menu screen, two content screens that branch from the menu, and a directions or help screen.

![Figure 6: Examples of Two Different Interface Designs for Project 5](image)

Many students note that this project is their favorite.

My favorite project was the final interface project. I liked it because I had to think in terms of an overall delivery system. It was challenging and the requirement that all of the graphics be our own forced me to be more creative.
Issues

Copyright
Many students wrestle with the issues of copyright. Because Project 2 will be shared with the Web community, students must obtain copyright permission for every image they use in their museum exhibit that is not in the public domain or they did not create. This is a difficult and often time-consuming task, but most students note that the process is worthwhile.

One student noted:

*I really appreciated participating in the process of obtaining permission. If nothing else, you get to see the turn around time required for producing pieces...”*

Making Informed Design Decisions

Because they are making judgments and decisions in new contexts and situations, students deliberate and worry about the selection of topics and then the selection of images, especially in Project 2, the Computer History exhibit, and Project 3, Graphing Statistical Data.

One student stated:

*The hardest one is project 2, showroom. You have to rely on other people's permission and it is quite difficult to find exactly the things you want.*

Evaluation Matrixes

For each project, students collaboratively developed an evaluation matrix. Working in small groups, students develop guidelines for each aspect of the design and submit those for approval to the entire class. Categories for the Project 2 matrix included such headings are “Value of Specific Computer Information,” “Creativity, Originality and Innovative Approaches to Displaying Information,” and “Illusion of Depth and Space.” After completing each project, students first evaluate their own projects before submitting both the project and their evaluation. Students did not enjoy spending the time to construct the matrix for each project, but most felt the experience was worthwhile.

A student stated:

*It (Constructing the matrixes) was the most difficult part of this course for me and I hated it. But when I look back at it now, I find that effort very useful because the effort of constructing matrixes taught me a lot of things about each subject matter and guided me through my projects.*

Portfolios

Students are also required to develop a portfolio of their projects. The portfolio includes each project and any supporting materials, such as an artist's statement. The portfolio has been useful for job interviews, referencing materials used in class, and documenting progress in the course.

Although the course is challenging, the rewards for both instructor and students are great. In addition to acquiring software skills, students noted growth in other areas, noting, “when you create something with your own materials, or you depend on your own thoughts and materials you feel more confident” and “I enjoyed the freedom of not being ‘locked in’ to a particular idea; to scrap one idea for another and devote the time necessary to finish it on time.”

References

This year's submissions in the area of Pre-service Teacher Education fell into three broad themes: Integration, Collaboration and Information Literacy. By far the largest of these categories was Integration, a theme that carried over from years past, and continued to be of major importance. This theme included papers reporting on pre-service teachers learning and using technology in education classes to enhance their own learning and modeling inclusion of technology in their own practice, as well as papers reporting on faculty and colleges' inclusion of technology when teaching courses. The area of Collaboration included papers reporting on pre-service teachers work with in-service teachers, and university personnel collaboration with in-service teachers, community colleges, other universities, government agencies and/or local schools. We introduce Information Literacy this year as a new category of papers that concern efforts to facilitate students' use of technology to gather, manipulate and evaluate information. Subtopics in this area included the development of technology skills aligned with the National Educational Technology Standards (NETS), development of cognitive skills, and employment of technology applications to facilitate learning.

Integration:
Several areas came together under the umbrella of Integration. Kilbane (University of Massachusetts, USA) & Gartland (University of Virginia, USA), Schepise (University of Central Florida, USA), and Zembal-Saul & Gibbert (Pennsylvania State University, USA) discussed theories and practice for pre-service teachers learning about and using technology in college of education methods courses as a tool to enhance student learning. Hartle (University of Central Florida, USA), Wilson (Langston University/ Tulsa, USA) and Swain, Foti, & Dawson (University of Florida) outlined developmental changes in teacher education programs where an increasing emphasis was placed on the inclusion of technology instruction in educational methods and foundations courses. Ferguson (University of Northern Colorado, USA) focused specifically on the role of the inclusion of technology in anchored instruction. While Mize, Purkiss, Burleson, Gibbons, & Mann (West Texas A & M University, USA) called for the seamless integration of technology in pre-service teacher instruction, Keating & Evans (Boston College, USA) stated, in direct opposition, that technology should not be seamless, but explicit.

Runyon & Rose (Robert Morris College, USA), Rose & Runyon (Robert Morris College, USA), Rose & Winterfeldt (University of Wisconsin Oshkosh), Molebash (University of Virginia, USA), Ramirez & Bernard (University of Texas-Pan American, USA), Grabie (NC State University, US), Kény & Sjoerdsm (Calvin College, USA), Rubio & Sedersten (Albion College, USA), Duran (University of Michigan-Dearrow, USA), Bober and Dodge (San Diego State University), and Brown and MacKinnon (Acadia University, Canada) all stressed modeling the use of technology to enhance pre-service teachers' learning. Each provided for the integration of the technology in their practice for the enhancement of student learning. Gibbons & Burleson (West Texas A & M University, US) and Cook (Notre Dame, USA) provided a rationale for the inclusion of technology in education courses as models to be emulated by students. Hutchinson, Sherron, Lynch, Mary & Mary (University of Central Florida, USA), Chen & Crmajdalka (University of Houston-Downtown, USA), Chatterton & Willan (Sheffield Hallam University, England), Casey (St. Bonaventure University, USA), Baker (St. Vincent), Anderson (Shippensburg University of Pennsylvania, USA), Alindia (Universidade do Minho, Portugal), Alibrandi, White, & Hagevik (North
The inclusion of specific technology applications was of interest to those wishing to broaden the use of technology in instruction. Gao (Purdue, USA); Anguita, Osuna, Martinez & Dimitriadis (Universidad de Valladolid, Spain); Henry & Crawford (University of Houston-Clearlake, USA); Baker (University of Missouri, USA); Luca (University of Massachusetts Lowell, USA); Flake (Florida State University); Albion (University of Southern Queensland, Australia); Johnson, Ertmer, & Lane (Purdue University, USA); Wentworth & Monroe (Brigham Young University, USA) and NEWT.com all outlined the use of specific inclusion examples. In this same vein, Bynum & Considine (Indian River Community College, USA) discussed the use of distance learning to model technology integration in teacher education. Kaplan (University of Central Florida, USA) examined the strengths and weaknesses of instructional technology in a discussion of the cognitive and affective aspects of online learning.

Barrclay-McLaughlin & Nonis (University of Tennessee, USA) and Ragan (University of Wisconsin-Greenbay) called for the integration of technology not only in university classroom environments, but also in the practice teaching environment with the placement of interns in technology rich schools.

One paper in this Collaboration category, White & Sprague (George Mason University, USA), bridged the areas of integration and collaboration with a report on the elimination of a single educational technology course and the inclusion of technology skills instruction in all college of education foundation courses using collaboration between technology faculty and foundations area faculty.

Collaboration

Collaboration is an area that continued to be of importance in pre-service teacher education. Golden & Erb (Marietta College, USA); Dutt-Doner (University of Southern Maine, USA) & Powers (Indiana State University, USA); Kerr (Brock University, Canada) & Slepkov (district School Board of Niagara, Canada), and Myhre (Western Washington University, USA) reported on projects where collaboration occurred between pre-service teachers and active classroom teachers. Technologies used included video and e-mail to enhance communication among all participants.

Another area of collaboration involved interaction of the university or college with community colleges, other universities, government agencies and local schools and community groups. Coe & Land (Midwestern State University, USA) described a collaborative effort between the university and in-service teachers in the community. Projects of both Begeron, Wenhart, Hopper, & Barrett (Arizona State University East College, USA) and Sheinkopf (Florida Solar Energy Center, USA) & Krupp (Brevard Community College, USA) involved collaborations of upper level schools of education with community colleges. Sheinkopf & Krupp, Hoffman (Eastern Michigan University, USA), Roempler (Eisenhower National Clearinghouse, USA), Mardis (Merit Network, US), Wiley & Recker (Utah State University, USA), and Banks & Traxler (St. Mary's College, USA) all described collaborative efforts especially designed for the enhancement of science instruction by providing added background instruction or information for teachers. Verkler (University of Central Florida, USA) described a collaborative project that involved language students in the US collaborating with students in France and Spain using technology as the communication tool, thus providing not only a model for collaboration, but also for technology integration.

Information Literacy

Information literacy is a broad topic that embodied cognitive skills, the instruction in and use of applications for learning, technology skills and assessment of educational technology. Templeton, Warner & Frank (Westfield College, USA) provided an in-depth look at information literacy and the need for inclusion in all areas of pre-service education. Zhang (Washburn University, USA), and Jensen & Fowler (University of Nebraska-Lincoln, USA) examined technology language, "cyberjive," as an indicator of technology efficacy while Downs, Repman, Carlson, & Clark (Georgia Southern University, USA), and Hokanson (University of Minnesota) examined the background of entering pre-service teachers to ascertain skill needs. Two other presenters focusing on teacher technology training were Egan (Minnesota State at Moorhead, USA), who examined rural teacher technology skills, and Morton & Bollulo (Laval university, Canada), who presented the CAMITE model for technology training. Sanders (Windrop University, USA) & Sanders (Lander University, USA) addressed the issues of information evaluation and cultural/racial diversity in resources.

Two PT3 Grant status reports were included in the category of cognitive skills. Pittman (University of Cincinnati, USA) reported on using technology to improve cognitive skills while Hoskisson, Thompson, Bass, & Holcomb (Valley City University, USA) reported on the use of technology and learning communities to enhance cognitive skills. Also in the area of enhancing cognitive skills, O'Rourke (Carlow College, USA) and dos Anjos, de Morales, Paas, & Barcia (Universidade Federal de Santa Catarina, Brazil) provided descriptions of the cognitive skills that distance learning requires and offered ideas for
facilitating the development of these skills. Williamson (Brown University, USA) presented an argument for the use of technology at higher levels of Bloom’s taxonomy than currently seen in most instruction where technology is employed merely as a tool. Inquiry learning and culture clash were the focus of two more presentations (Morgan [Bemidji State University, USA] & Bender-Fayette [Horace May Elementary, USA] and McClelland [Kent State University, USA]) where cognitive skills received particular emphasis. Diis & Ayre (King’s College, USA) applied digital video in a constructivist environment for pre-service instruction, thus modeling the integrated use of technology in the classroom; Bennett (Navajo Education Technology Consortium, USA) presented another digital video project designed to assist pre-service teachers in the development of skills necessary to use this tool in the classroom; and Austin (Black Hills State University, USA) tendered a model for the use of Palm Pilot PDAs for faculty supervising intern teachers.

Focus on NETS and development of pre-service teacher technology skills were integral themes in Deek & Kimmel (New Jersey Institute of Technology, USA), Madison & Hutchins (University of Wisconsin-Stevens Point, USA), Wiencze (State University of West Georgia, USA), Melczarek (Troy State University Dothan, USA), Young (Indiana University South Bend, USA), Gregory & DeTure (Rollins College, USA), Ku, Hopper, & Igoe (Arizona State University, USA), McCoy (University of Alaska Anchorage, USA), and Jones (University of Sunderland, United Kingdom). In these presentations, differing emphases were placed on NETS skills with varied program ideas for development of learning opportunities to enhance these skills.

Assessment and evaluation of technology instruction provide valuable insight into what works. Lou & MacGregor (Louisiana State University, USA) examined the use of WebQuest in instruction in terms of its capacity to provide guidance for learning, as well as enhancement of motivation when employed in a cooperative learning environment. Other assessment-focused presentations included Seed (Northern Kentucky University, USA) and Schnorr, Burnell, Robertson & Cope (California State University, San Bernardino, USA), where Seed examined the theoretical concerns of technology implementation in a university college of education and Schnorr et al. looked at the transfer of technology instruction to actual practice.

Faculty attitudes provided the focus for Szware (UNIP, Brazil), while in-service teacher concerns and the need for a concerns-based training model drove theory presented of Rakes & Casey (University of Louisiana at Monroe, USA). Finally, Connell (NTU, Australia) examined the role of Instructional Technology as it may be altering teaching techniques and philosophies to such an extent that it must impact on pre-service training.

Ruth S. Burkett is a Doctoral Candidate in Instructional Technology in the College of Education at the University of South Florida. She is currently immersed in the issues of pre-service teacher education through the teaching and ongoing refinement of a pre-service Web-enhanced teacher technology course. Her interests include communications in distance education and constructivist learning theories, especially as practiced in science education.

Michelle Macy is a Visiting Professor and Doctoral Student in Second Language Acquisition/Instructional Technology in the college of Education at the University of South Florida. Her interests include research on and implementation of IT to improve both pre-service teacher training and student learning outcomes in the areas of ESOL and foreign language instruction.

James A. White is Associate Professor of Instructional Technology and Coordinator of Graduate Studies in Secondary Education in the College of Education at the University of South Florida. His interests include the ongoing development and implementation of the doctoral program in Instructional Technology and research on computing in teaching and learning.

Carine M. Feyten is Chair of the Department of Secondary Education and Professor of Foreign Language Education in the College of Education at the University of South Florida. Her interests include developing and implementing distance learning opportunities and exploring the use of telecommunications and the Internet in the classroom.

Beyond the Status Quo in Preparing Tomorrow’s Teachers

Ronald J. Abate
Cleveland State University, USA
r.abate@csuohio.edu

Abstract: This paper presents a case for rethinking the existing paradigm of the personal computer in educational technology. In particular it examines the nature of failure, the evolution of technology, and the general lack of acceptance of educational technology in today’s classrooms. The paper asks the question what is the role of teacher educators in the development of new technology implementation paradigm, and provides a rationale for a more critical analysis of existing educational technologies.

Introduction

In his book the Evolution of Useful Things, Henry Petroski suggests that failure is the fundamental principle by which products arrive at their form and function. When a product fails to meet expectations it either evolves or becomes extinct. Laptop computers offer an example of Petroski’s notion of failure driven product evolution. Early portable computers were heavy, cumbersome and limited in power. These properties failed to meet the expectations of mobile users. The failures led to lighter, smaller and more powerful laptop designs. Does Petroski’s product evolution hypothesis generalize to other areas of technology such as educational technology? Are the products and processes of educational technology evolving? The relatively rapid obsolescence of school computer labs suggests that the answer is yes. Product failure has played an important role in the evolution of educational technologies. However, if form follows failure as Petroski suggests, does twenty years of technology evolution and the resulting lack of acceptance of educational technology by the majority of classroom teachers constitute a deeper form of failure?

A view of “normal” science may prove useful in understanding deeper forms of failure. Kuhn (1970) noted that much of the knowledge in scientific fields involves puzzle solving - elucidating anomalies to fit an existing paradigm. When the solutions no longer fit the paradigm, they generate a crisis. The existing paradigm no longer explains the phenomena adequately and the potential for a shift to a new paradigm increases.

Is there a view of “normal” in educational technology? What is the accepted paradigm in educational technology? Since the field encompasses numerous technologies, proposed here for the sake of simplicity is a “normal” view that focuses on one common educational technology - the personal computer (PC), in particular the application of the PC and its software as the common paradigm for the classroom implementation of technology. The benefit of this viewpoint is that it provides both a recognizable paradigm with identifiable methods and an opportunity to revisit Petroski’s notion of failure and evolution.

Twenty years of technological advancements have supported the paradigm of personal computers as the primary tool for the integration of technology into classroom teaching. Each new version of PC is faster, more powerful, and in many cases less expensive than its predecessor. Still, despite PC advancements, many teachers cannot justify the time and effort required to integrate PC technology into their teaching. and the cost of accessibility is still beyond the grasp of many schools( Dias, 1999).

If a historian traces advances in educational technology backward for the past twenty years, she is likely to find puzzle solving incremental changes akin to those offered by Kuhn’s “normal” science. Incremental changes are evolutionary. They gauge progress. They clarify methods and importantly in the case of educational technology they proved instrumental in introducing technology into classroom instruction. Clearly, history shows that problems/failures have been overcome. Early personal computers were slow, the
solution was to make them faster. Second generation PC's lacked adequate memory to run complex software. Their descendants gained memory. When teachers and their students needed improved access, PC labs were institutionalized. When teachers suggested that the PC's were too difficult to use, professional development was provided. In these and other instances immediate problems were identified, addressed and solved. All of these advancements fixed problems encountered with educational technology but none solved a key problem evident in the PC paradigm. Even with access to advanced equipment teachers seldom integrate PC's into their teaching.

Is it possible that educational technology evolution efforts have been misplaced? Probably not. The PC paradigm in education followed a path analogous to the one encountered by business users. Only now are standards for educational use entering the mainstream. Even with an absence of educational failures, the PC was destined to evolve as a function of business and economic forces. Nevertheless, the educational community has not asked, “Does the PC as an implementation paradigm fit the work environment and goals of teachers and students?” If the answer to this question is yes then educational technologists simply need to identify failure points, correct them and watch technology evolve. If, however, the paradigm does not fit the goals and environment of the intended audience then no amount of failure, puzzle solving, or evolution will correct it.

Is there evidence to suggest that the PC paradigm is flawed? Seminal research suggests that a wide cross section of middle school teachers do not perceive existing educational technologies as supportive of their classroom teaching (Abate & Jin, 2000). The results are preliminary but revealing. It has been documented elsewhere that lacking a job-imposed requirement, individuals are not likely to use tools that they perceive to make their work more difficult (Ehn, 1993). As failures of technology become more prominent and the public begins to question the efficacy of educational technology (Stoll, 1995) it becomes increasingly important for teacher educators to consider alternative educational technology paradigms.

What is the role of teacher educators in the development of a new technology implementation paradigm? In most professions the design of tools takes into account the work context of the user (Kuhn, 1996). In the field of educational technology few reports discuss the design of the technological tools available in typical classrooms. This is understandable. Most educators are not designers of educational technologies. However, in other fields, medical equipment for example, medical personnel work closely with designers to produce technologies consistent with their work environment. In the design of office furniture, ergonomic experts work with office staff to provide solutions unique to office workers needs. Even in recreation, biomechanics experts work with athletes to design foot apparel for specific sports. The precedent for collaborative design exists should teacher educators choose to assume the role of learning technology designers. One approach is for teacher educators to join forces with classroom teachers to take a more active role in the design of classroom technological tools. The alternative is to continue the present course, a course where existing technologies are adapted for the classroom, and the learning environment is adapted to meet the requirements of the tools.

Talking with computer-using teachers: Insights for pre-service teachers

Peter Albion
Faculty of Education, University of Southern Queensland, Australia
albion@usq.edu.au

Abstract: Access to models of appropriate practice is an important aspect of pre-service teacher preparation. Multimedia materials can be used to supplement uneven field experience. The project on which this paper is based included materials prepared by and interviews with ICT-using teachers. Analysis of the interview transcripts and trials with the CD-ROM confirms that the interviews are likely to be effective in presenting pre-service teachers with appropriate messages about the use of ICTs in teaching.

The development of teachers’ capacity to work effectively with information and communications technologies (ICTs) in their classes is influenced by many factors. Clearly access to, and personal skills in the use of, appropriate hardware and software are important. Another important influence is access to appropriate examples of teachers who work with ICTs.

The importance of modeling for professional development of pre-service teachers in respect of computer use has been argued in previous studies (Albion 1996; Becker 1994; Downes 1993; Sherwood 1993). For students in teacher education programs, the logical context for encountering these teachers is field experience. However, pre-service teachers have reported seeing little use of ICTs during their field experience (Albion 1996). Hence, various researchers (e.g. Albion & Gibson 1998; Chambers & Stacey 1999) have proposed the use of interactive multimedia to present accessible and appropriate models of teaching including the use of ICTs.

Previous papers have described aspects of the design (Albion & Gibson 1998) and development (Albion 1999) of the Integrating Information Technology into Teaching CD-ROM (Gibson & Albion 1999), which presents a set of problem-based scenarios related to planning for the use of ICTs in primary school classrooms. An important goal in the development of these materials was to provide pre-service teachers with access to appropriate models for the integration of ICTs into their curriculum planning by having a small group of teachers provide sample responses to the tasks embedded in the materials. As part of creating a context within which the examples might be better appreciated, video of interviews conducted with these teachers was also included in the materials. In an evaluation of an early prototype of the materials a majority of participants nominated the video interviews as their favorite element (Albion & Gibson 1998). Hence the content of the interviews was analyzed to determine what messages might be conveyed to users of the materials. This paper reports on some results of that analysis and some responses of participants in trials of the completed materials.

The Computer-Using Teachers
