What meaning does this have to CMC learning? The approach used in the asynchronous, collaborative on-line learning environment is one of constructivism. Within this the learners are facilitated, through on-line activities, to collaborate towards a shared goal. The learners themselves are viewed as the greatest resource, each bringing skills, knowledge and experiences that are used to formulate differing perspectives, influences and approaches to the activities. Thus learners organise and reorganise information, or in other words, construct new meaning.

Jenlink & Carr (1996) would also argue that the discussion used within collaborative environments had to be design conversation, as opposed to discussion. This is defined as being goal related and focusing on creating something new. It facilitates contributors to extend their capacity to hear and inquire into other peoples perspectives.

Tutor / Facilitator:

This programme has been heavy on tutor time with, on average, the tutor being available for 5 hours a week. This has been more at the beginning of each programme and less towards the end as learners develop skills in collaborative practice. The majority of learners have made comments about this (both within the programme and during reviews). The majority has appreciated the constant feedback and encouragement given by the tutor and this has appeared to be a big factor in retention of learners.

Many learners have also commented on the tutor as a good role model. However, this has also led to many concerns that the learners had about being able to replicate this role, partly because of time constraints. Concerns were also expressed about whether or not Organisations and/or managers would allocate the right amount of tutor time to development and delivery on-line. The reality of embedding this methodology within mainstream services has always been a concern for learners within the programme.

'I have not particularly missed face-to-face – but I think this is because the tutor is quite a good responder and you always feel she is there.'

Learners tended to like the time limits set for each activity (posted on a Sunday with a deadline of the following Friday). A range of styles was used from individual activities, discussions of a collaborative nature that were summarised by a learner, group product development and small group-work. Although the small group work was the most unpopular (mostly because of the time it takes to form into groups) a lot of learning took place overall from this (often negative) experience.

Finally:

'I feel as though I have learnt as much, if not more, on this course than if I had worked on a face-to-face basis. This may well be due to the time for reflection and the fact that I have been able to read everyone's c

For those who completed the programme there is a sense that this has been a positive experience even though there have been steep learning curves for some, particularly around mastering the technology. Learners have used the words 'positive' and 'challenging', as descriptors of the programme in general but the authors would also add 'fun' and 'enjoyable' as a further two descriptors. Humour has been used to motivate and further engage learners and learners have responded well to this.

Some really serious issues have been discussed in this programme, and these have included current practice around copyright. This has been a big issue when applied to on-line learning and a surprise for many that such tight boundaries exist. In addition, several learners have been keen to debate the cost of on-line learning for Organisations and the issues around how funders view this methodology. Finally, on-line learning assessment has been widely debated and interesting perspectives have emerged for further consideration by all.
This has been a very positive experience for the learners, tutor/developer and managers. The programme is now available within the mainstream services offered by the originating College of Further Education and in demand by those who see the changing face of education and training within the developing new age. The final words we leave to a learner.

"...this is a new methodology and we have a ground floor opportunity to help with getting it right. I hope that between us we can help, if only in a small way. It has helped me, certainly, through a changing time in my life. Not only have I made new friends, but I have also learned a tremendous amount, not only general knowledge but about myself. I have moaned a lot, but hopefully for the right reasons and in a constructive way, because I would like to be part of it'.

The Necessity of Considering Cultural Influences in Online Collaborative Learning.

Ruth Geer
Lecturer, Educational Computing
University of South Australia
Australia
Email: ruth.geer@unisa.edu.au

Abstract: This paper utilises a model of technology-mediated interaction to highlight the importance of social interaction in the construction of a collaborative online learning community. Learning communities are built around relationships. There are many factors that impact on the ability of social interaction to create social comfort and the capacity for mutual consideration in an online learning community. This paper will address the importance of understanding the impact that cultural influences have on the creation of a positive and successful learning community. An understanding of cultural influences has the potential to alleviate some of the misunderstandings and misinterpretations that can occur through such lack of knowledge. Through consideration of cultural influences, social interaction can increase the potential for collaboration and successful attainment of quality learning outcomes. Knowing this, how can we accommodate these differences into our courses?

Introduction

The potential of the Internet to enhance learning through online collaborative learning communities is partially constrained by our understanding of cultural influences that support a framework for ensuring effective collaboration. Research, by Kirby (1999) and Hiltz (1998), clearly points to the value of interactivity and collaboration in any learning community where the exchanges are not only active but also interactive. Three essential attributes of an effective learning community are active learning in construction of knowledge, positive interpersonal relationships and rich discourse among participants in promoting their learning. The online learning environment through the use of appropriate technologies provides an opportunity for interaction and collaboration, which can lead to quality learning outcomes. The technologies that can mediate communication in order to develop such attributes must have a global reach. The effective online educational environment of the future will need to contend with audiences of diverse backgrounds and particularly audiences from a wide variety of cultures.

Literature Review

Although as human beings, we communicate with others in many ways and across many mediums, communication is not always easy, even when we feel we know the other person. Cultural influences are often at the root of the communication challenge (DuPraw & Axner 1997) where misunderstandings and misinterpretations occur. Interaction and collaboration become much harder when communicating with total strangers in the online environment. With our first utterances online we all experience fears of being judged and misunderstood. As well as this we bring our prejudices and biases with us into our discussion. Our cultural background can shape the way we participate in discussion, how we understand the world and how we may approach problems. A key component of effective collaborative efforts is social interdependence when individuals share common goals and each individual’s outcomes are affected by the actions of others (Johnson & Johnson 1989). Positive interdependence is at the heart of any learning community where learning is as much based on relationships as it is on intellectual discourse (Johnson & Johnson 1998). Exchanges at a social level provide the foundation on which relationships can be built and determine how individuals will interact with each other. This emphasises the importance of gaining some knowledge about the other participants in the learning environment. We need to feel socially comfortable and develop the capacity for mutual consideration in order to
become actively engaged in collaboratively supporting each other to develop skills in reasoning, critical thinking, hypothesis formation and reflection. Such social comfort may be achieved by providing time in the course where students can share aspects of their cultural background.

The amount and quality of interaction in a student-centred environment play a key role in the learning process as well as having a significant impact on the learning outcomes. When focusing on pedagogical issues, much has been written about the value of fostering collaboration and cooperation (Agostinho Lefoe & Hedberg 1997). Communication technologies are providing the opportunity to connect people and to foster collaboration and discursive exchanges on a vast array of topics. They are used to build relationships and to provide the scaffolding that guides, supports and develops the construction of knowledge leading to quality learning outcomes.

Johnson & Johnson (1996, 1998) have provided a strong theoretical basis for cooperative learning as outlined in cognitive developmental, behavioural and social interdependence theories. A pedagogy engendering cooperation might require students to work on an agreed, explicit, common goal, which is then sub-divided into component tasks on which the students will work individually until completed. The result is a combination of the individual efforts. Collaboration goes a step further where there is continual interaction and discussion related to the goal. Individual tasks may be relegated and distributed according to abilities, but the goal requires that individuals cooperate and construct shared understanding and knowledge. Through constant interaction, individual efforts are merged resulting in the culmination and achievement of a common and explicit goal. Collaborative interactivity is a combination of collaboration over learning tasks and rich discursive interaction.

Students learn best by interacting with others, rather than working in isolation. Wittrock's generative learning theory, now popularly termed constructivism, also attempts to add support by explaining that people learn best when working together (Susman 1998). Students motivate and encourage each other to remain focused on the task. The resultant interactivity leads to knowledge building, which requires "articulation, expression or representation of what is learned" (Jonassen 1999). Such thinking is aligned with current conceptions of constructivist learning. Out of the notion of discovery and exploration has emerged research on interactive and collaborative learning around meaningful activities. Of particular interest in this paper is the social interactivity that underpins collaborative efforts.

Figure 1: This model of technology mediated interaction indicates the hierarchies of interaction, technologies and learning outcomes, together with the influential drivers affecting learning outcomes.
The Model

There are many external factors or drivers that can impact on the effectiveness of collaborative interactivity and associated learning outcomes in the online environment where time and place are no longer prescribed. These drivers can include cultural variables, student characteristics, informal socialising, prior knowledge, assessment, the available technologies and the lecturer’s involvement. The model, (Figure 1), has been developed in order to explain the relationship between the types of interactivity that can occur and the suitability of various technologies to support interaction. The term “technology-mediated” has been used to characterise interaction through the use of Internet technologies. It also is an attempt to describe a progression of learning outcomes achieved through interaction that show a shift from surface to deep learning (Ramsden 1992).

The model is portrayed in the shape of a pyramid with a series of levels building on from each other and leading to collaborative interactivity at the apex. It is expected that the higher the level, the greater the quality and frequency of interaction that will occur. Collaboration is surmised as currently providing the highest level of meaningful interaction and engagement through the use of sophisticated and often specialised multimedia communication tools. It is not expected that every course will incorporate all levels of the pyramid. However it provides a conceptual framework in which you can identify the entry point of the type of interaction required, utilising the various technologies that support such a level and ensuring that relevant learning outcomes are being achieved.

The Importance of Social Interaction

Social interaction forms the foundation on which all other levels of interactivity are dependent. Web biographies, synchronous chat and asynchronous email can be used to provide opportunities for self-disclosure, an understanding of social behaviours and the capacity for mutual consideration. Interpersonal relationships are critical in a collaborative learning community, as the more individuals care about each other, the harder they will work to achieve a mutual sense of accomplishment. Many of the studies on interpersonal relationships in collaborative learning environments come from the traditional face-to-face framework where socialisation has its place outside of the classroom. As this is not possible in the online environment, social interaction must be built into the course design. Informal or social exchanges have the potential to alleviate some of the misunderstandings and misinterpretations that can occur from the lack of social cues and face-to-face interaction. Informal exchanges help students get to know each other. The view is held that unless opportunities are provided for participants to engage in this type of social exchange that interaction will only occur at the lower levels of interaction and learning will be impeded in achieving the higher learning outcomes. Unless we cater for social interaction as we move up to levels of collaborative interactivity, the pyramid will not be supported. Sophisticated technologies will be unable to support the higher levels of the pyramid without the foundations established for interaction.

Social interaction helps to create a positive online learning environment, by fostering trust and respect amongst learners. Social exchanges help to overcome some of the awkwardness and the reticence that learners feel in communicating with unfamiliar persons on a more formal basis (Romiszowski & Mason 1996). The social community that is created during the learning process can impact on the nature of the learning activities and the learning outcomes (McLoughlin 1999). Information about other learners in the group help to create solidarity, understanding, trust, respect, commitment, and develop standards of group conduct. Instructors are recognising the value of incorporating a communication space into the design of their courses to facilitate interpersonal exchanges, and increase the comfort of students in their exchange with other students. Muffoletto (1997) used web chat to combat feelings of isolation. Hughes & Hewson (1998) and Hiltz (1998) recognise the value of informal socializing and have created the notion of a “Coffee Shop”. There are numerous factors that can impact on how learners interact and relate to each other. They include learner characteristics, demographic details, prior knowledge or education level, technical skills, literacy level, verbalisation and cultural background.

Cultural Factors

An appreciation of cultural differences can assist the process of social comfort and respect of others. Students of different cultural backgrounds may have different attitudes about and knowledge of the technologies, cross-
cultural communication patterns and learning processes when learning in the online environment (Freedman & Liu 1996). Different cultures generally have different rules and norms. Through interaction we seek to reduce anxiety and uncertainty about other’s attitudes, feelings, behaviours and beliefs (Gudykunst & Kim 1995). DuPraw and Axner (1997) have identified a number of fundamental patterns of cultural differences:

Different communication styles
Verbalisation is an essential skill and active participation tends to be restricted to those who are literate and are able to express themself through competencies in language and rhetoric. Many learners from non-English speaking backgrounds can have difficulties in understanding some words and phrases as well as struggling to express themselves in a foreign language. Even native English-speakers can experience difficulties as some English speaking countries can give different meanings to the same words or phrases; for example, the meaning of “yes” can vary from “possibly” to “definitely”. Where language is a problem, learners find it easier to communicate in written form rather than orally. The Internet offers learners the opportunity to reflect and formulate their response, alleviating some of the difficulties experienced by non-English speakers.

Different attitudes towards conflict
Some cultures view conflict positively encouraging discussion and debate around the various viewpoints, while others go out of their way to avoid it. In many Eastern countries differences are best worked out quietly as open conflict is considered embarrassing or demeaning (DuPraw & Axner 1997). Japanese are generally reluctant to debate in an argumentative fashion in public forums (Rheingold 1998). Chinese educated in Confucianism are taught to respect teachers as ultimate authority figures whose opinions should not be challenged. Hence anyone considered to have some authority would not be questioned and students would feel nervous about interacting with him or her. “[One] student found his learning attitude affected by the look of his tutor, [and stated that] after seeing her picture [I thought] she looked like a teacher. Then I started to feel nervous while writing formal letters to my teacher” (Cifuentes & Shih 1999). Titze (2000) in her discussion on issues relating to efforts to aid foreign teaching assistants at the University of Utah noted that they are trained to have total respect for their instructors and are discouraged from asking questions in case the teacher does not know the right answer and hence would lose face. This hinders the willingness to exchange ideas and the development of competing or opposing ideas.

Different approaches to completing tasks
Cultures can differ in the value they place on task completion, how relationships are built and how they collaborate together. DuPraw and Axner (1997) in their study found that Asian and Hispanic cultures attached more value to developing relationships at the beginning of a shared project and more emphasis on task completion toward the end, whereas European-Americans tended to focus immediately on the task at hand and let the relationships develop as they worked on the task. Shive & Row (1999) in their study found that Hong Kong students took the assignments more seriously than their American counterparts.

Different decision making styles
The individual roles that learners may play in the collaborative group will vary from culture to culture and personality to personality. Southern European and Latin American cultures place a strong emphasis on having decision-making responsibilities, whereas the Japanese prefer to have consensus. The willingness to initiate ideas will be more prominent in some cultures than others and so interaction and collaboration will be more natural for some groups than others.

Different attitudes towards disclosure
People differ in what they feel comfortable revealing about themselves. Some learners have found they can disclose more online than they would in a face-to-face classroom. Blum (1999) found that female students included more personal information in their messages than males. Self-disclosure can overcome some of the awkwardness that students feel in communicating with unknown persons. A student once sent me the following e-mail; “the fact that I was expected to comment on other’s work when I would not know of their situations in work or life ... nor would I appreciate anybody commenting on my work when they have no idea about my life and work”. The student recognised the importance of having some knowledge of the other group members in order to be comfortable with discussion around issues in the learning environment.

Some instructors have encouraged the use the pictures so that learners have a visual image of other participants when they communicate. This strategy has been successful in a number of courses at the University of Waikato, New Zealand. On the other hand others may feel very self-conscious about displaying a their picture. Those who do not have their pictures displayed, may sense some exclusion from the discussion. Instructors need to be
sensitive to culturally different attitudes to personal photographs.

It has also been argued that the anonymity of the Internet can be a real advantage. A person's age, gender and economic status can be masked within online environments and this may be a positive aspect that ensures equal participation. The benefits of online anonymity for teaching and learning have included increased equity and higher participation rates (Hartman, Neuwirth, Keisler, Cochran, Palmquist, & Zubrow 1995). On the other hand antisocial behaviour has been suggested as a consequence of anonymity (Rheingold 1994).

This conflict in determining how much should be disclosed, challenges instructors to be flexible in attaining a level of comfort for the students. In some cultural groupings extended disclosures and self-evaluations may sit comfortably with all, while in other groups learners may feel inhibited in providing more than a basic introduction. This illustrates the strong need for consideration of cultural differences and the need for flexibility in catering for the various groups. It is crucial for instructors to have some background cultural knowledge about the learners in their courses so that they can accommodate these differences through flexible approaches.

In referring back to the model, it may be important to increase the height of social interaction and allow more time for certain groups to feel comfortable with each other, while for other groups tension may be apparent in the time spent initiating social interaction and the desire to meet course expectations. The amount of time spent ensuring social comfort and mutual understanding will be dependent on the type of interaction and its related learning outcomes.

Different approaches about knowing
DuPraw and Axner (1997) identified the following differences as occurring among cultural groups. European cultures tend to acquire information through cognitive means, Africans preferred an affective way of knowing while Asian cultures tended to emphasise that the validity of knowledge was gained through striving towards transcendence. The Hmong culture has historically been about traditions of knowing rather than questioning. It is considered better not to try a particular skill and save face, just in case you fail (Freedman & Lui 1996). Understanding the learning processes used by students will assist instructors with their instructional design of the course. This knowledge is possibly best acquired by experience rather than reading a book.

Conclusion
An understanding of the culture of the learners and an appreciation of the patterns of cultural differences is important in helping instructors ensure meaningful learning outcomes for all students. Generalisations about cultures however should be avoided, as there are numerous variables within each culture. Such knowledge will provide guidance in determining the extent of social interaction needed for learners to move from more generalised discussion to more topic focussed discussion and task orientation. Consideration of cultural differences is critical at the higher levels of the pyramid in relation to the increasing complexity of the technologies, their associated learning outcomes and the necessary negotiations for successful collaboration.

The availability and complexity of multimedia technologies assist learners to move through the various levels of the pyramid. With further developments in technology, cultural specific overlays on design and language translation, may lessen the impact of cultural differences in a learning environment. However for the moment the instructor will continue to face cultural challenges in an effort to improve learning outcomes through collaborative interactivity.

This paper has attempted to identify the various cultural influences that can impact on creating a collaborative learning environment. It has not been able to provide a generic recipe of solutions for this problem. Considerable effort is needed to ensure social comfort, particularly where there might be open conflict between cultures. Everyone brings with them cultural baggage, including the educator. We must identify methods that recognise and value the cultural differences rather than trying to discount them. Many of our educational systems are basically western, and the expectation is that other cultures adapt to the system. It becomes important to try to deconstruct the system to accommodate the cultural diversities. Awareness, adaptability and sensitivity will ensure that students feel comfortable working together in this environment. Students are more likely to be sensitive to cultural differences with increased knowledge about group members. Smallen and Leach (1999) argue that “successful collaborations are built on a foundation of respect” where respect is about building on the strengths and compensating for the weaknesses. Through an awareness of cultural influences, social interaction can increase the potential for collaboration and successful attainment of quality learning outcomes.

Abstract: Roles in online learning environments are changing towards leading learners or demand based learners if you wish. Learners do take ownership of their own learning process, and do take an active role in collaborative knowledge construction and knowledge sharing.

Main questions:
- How to re-engineer the learning activities in such a way that the student become a self-regulating learner, takes the lead in information gathering, uploading new information, discussions and giving feed-back to other learners and the teacher?
- What are the new role definitions and task specifications needed for both students and teachers in online learning environments?
- Is a competency-based learning approach appropriate for those students who can be given their own responsibility for proving their competencies, thus actively contributing to the assessment?

The panel will raise a discussion about the above questions among the audience and will give input and answers based on their experience.

Tasks panel members:
- Audience: input and questions on the learner led learning or self-regulating learner approach
- Prof W. Veen: lead the panel, introduction, summary
- Prof. B. Collis: pedagogical changes involved with learner led learning: old ideas in new forms or something new?
- Prof. S. Santema: changes in the role of teacher, the use of content and the benefits for the course caused by the use of learner led learning
- Ralph Genang: changes in the role of the students and the benefits for the course caused by the use of learner led learning

**Background and input of the panel members:**

**Prof. Dr. Wim Veen**

*Background:* Wim Veen roots’ are geography teacher in secondary schools. He has been working at the Institute of Education of Utrecht University since 1978 where he started as a teacher trainer for initial as well as for inservice training. He has been a consultant for educational institutions and for private companies and governmental authorities.

Wim Veen is now leading the Centre of Educational Innovation and Technology at Delft University (DUT). This centre provides professional development in the field of teaching in higher education, and consultancy in curricular change and innovation for faculties.

He has been involved in a number of IT projects related to the implementation of computers in schools, the development and translation of courseware, the uses of telecommunications and policy and planning issues with respect to support of telecommunications in education.

He is currently leading an institution-wide initiative for implementing ICT in education at DUT. His work as a researcher is strongly related to the pedagogy of online learning environments.

*Input to panel by Prof Wim Veen:* Prof Wim Veen will draw his experiences from the online seminars he is leading for the European Schoolnet. The European Schoolnet, and other online activities within Delft University is in the process of creating virtual professional learning communities. Prof Wim Veen’s contribution to the seminars aim at:

- Creation of virtual professional networks in which participants can learn and work collaboratively on educational issues related to their work as teachers, researchers and policymakers
- Building of expertise of new technologies for professional development at a European level
- Constructing of pedagogical models for effective way of collaborative learning in online learning.

He will mention the experiences and progress of implementing these ideas at Delft University of Technology. As program director of the bureau of ICT in Education, Wim Veen is responsible for the introduction of ICT in education at the TU Delft and is aware of all the problems and resistance against the increasing role of the learner in learning.

**Prof. Dr. Betty Collis**

*Background:* Since the beginning of the 1980s, she has been intensively engaged in the study of computers in education, and since the mid 1980s, of information and communication technologies in education. Prof. B. Collis is a researcher and evaluator of the impact and implementation of computer-related technology in education who also is a designer and developer of pedagogy and products making use of this technology; a theorist about technology who also teaches with the technology.
My major activity at the moment is being Chair of the TeleTOP Project (http://teletop.edte.utwente.nl) in which my own faculty is re-designing its way of organising the learning process, through the use of a combination of good pedagogy and innovative uses of technology. This initiative is particularly based upon our Faculty's experience with innovative uses of the WWW in our teaching since March of 1994; for example, see one of the courses for which I am the instructor, a course called Tele-Learning (http://education2.edte.98193524.nsf/framesform).

Input to panel By Betty Collis: Betty Collis will talk about the approach to pedagogical re-engineering, in which students are not only active participants but also contribute to the learning materials of the course. She will enrich the panel discussion with her experiences on how student learning is evaluated at the University of Twente. Her knowledge as developer and user of the TeleTOP system - a system focused on extending the Faculty of Educational Science and Technology's innovative technological profile through integrating telematics applications in their own courses for more-flexible learning – will give input on how the University of Twente is re-using student contributions.

Prof. Dr. Mr. Ir. Sicco Santema

Background: As teacher of the Business to Business marketing classes at The Delft University of Technology, prof Sicco Santema started with Ralph Genang the B2B marketing development project on the use of ICT instruments in 1996. The first instrument was the use of e-mail as a means of interactive communication between instructor and learners. The second instrument, videconferencing (PictureTel), enabled us to interact real time with learners on a remote basis. In 1998, the use of real-media resulted in the first life online course (on the Internet) in the Netherlands. During the last three years we developed a third instrument: the learning environment. In the learning environment we created Bodies of knowledge. We divided the course material in 100 subjects. Each of the subjects represents a body of knowledge. We recorded a video clip for each subject where the instructor explains the subject in about two minutes, and we started building a database of related publications to the subjects. By the time our next course started in the spring of 1999, all the course content was available online in multimedia mode. Prof Santema did not teach in the classroom anymore. According to their own learning habits, students who use our online learning environment are free to choose the medium that fits them best, per body of knowledge and context. The content has become dynamic. The context has become dynamic. The learner has become self-regulating, self-teaching, his own communication creates his own solid foundation.

Input to panel by Prof. Santema: Prof Sicco Santema has a lot of knowledge and experience of the impact of Learner Led Learning on the teacher and the way it affected knowledge transfer in his marketing classes. The introduction of Self-Directed Learning or Learner Led Learning did result in a spectacular educational reform. The multiple media based reform has resulted in better grades for our students as compared to the traditional classes. The commitment, time spend and the grades did statistically significant change with previous years.

Ralph Genang

Background: As developer of the online Business to Business Marketing classes of Prof Santema, Ralph Genang conducted research on the usage of online marketing classes. With a tracking and monitor tool Ralph could identify the different learning paths of each individual learner. He knew how much time students spend on the course site, how much questions they asked, how they used the answer and how the learners cooperated online and compared the results with learner paths in traditional teaching? To improve the learning efficiency and usage
of online courses Ralph developed the bodies of knowledge and the dynamic content. In 2000 Ralph introduced Learner Led Learning. Next to teacher led and community led learning, learner led learning is a learning method where the learning has become a learner responsible and individual process in balance with cooperation in an appropriate context with other learners and a coach (teacher). This process is made possible through online communication in online learning communities.

Each year Ralph organizes New Media Tours to visit authoritative international Online Learning projects (universities and companies)

At this moment Ralph Genang has started a small research company in E-learning, Tri-L. He is still part-time related to the Delft University of Technology and continuing his Learner Led Learning research.

*Input to panel by Ralph Genang:* Ralph Genang will share his knowledge of and experience Learner Led Learning has on the student and the way it affected knowledge transfer in the classes. He created an online learning environment where students could lead in information gathering, uploading new information and discussions. The learners in this environment became each other’s instructors.

Abstract: An educational situation implies presence of individuals, objects of knowledge, mediate and immediate objectives and methods or processes. We developed in our educational situation, the Business-to-Business marketing classes at the Delft University of Technology, a method: Learner Led Learning. In this method we challenge the learners to teach each other. We offer our learners a database with 180 subjects related to the course. The learners have to discover the mutual relationship of the subjects, they have to define their own learning path and share their ideas or knowledge with other learners and the teacher. This paper describes the process how communication of ideas and knowledge has changed in our courses from a teacher led approach to a learner led approach and the important roles of context and content in our Business-to-Business marketing learning community.

About the authors

1. From Teacher Led to Learner Led Learning

In a period of three years we changed our course Business-to-Business marketing from a Teacher Led Learning environment to a Learner Led Learning environment. The change process was the result of a combination of using new media tools in our classes and monitoring the communication users (both teachers and learners) experienced and conducted through these new media.
Teacher Led Environment

This environment is also known as a lecture approach (figure 1 Gilbert Paquette, 2000). The heart of communication is the classroom. The content is fixed and preset. The Teacher leads the show. He lectures the course subjects at one place on specified times during the week. During the preset timeframe the course is given, the only continually available course material to the learners is the textbook and his or her personal notes. So the course content is limited to the book plus what the learner memorizes from the classes. The majority of learners are passive listeners. The learning path they follow is based on the index of the book and the index of the lecture given by the teacher (he most likely starts at chapter 1). This is an educational environment where education is limited in time, place, content and didactical format. There is no room for another context or no easy access for new content (notice the thick black border around figure 1). But at that time we were not aware of possible improvements until new technologies entered the classroom.

Reason to change: Because of new technologies, new tools were introduced in educational environments. We name them community tools. Learners were able to communicate via e-mail outside class hours with their teachers. Internet gave them access to new sources of information (content). The teacher led classes were available online. Learners followed classes online from a distance and learners had a reference video of earlier classes. The community tools started to lead the learning environment: Community Led Environment (Figure 2). Slow learners and teachers got used to new technologies and used these technologies to improve their influence and “communicate” their curiosity. The thick border is gone (see dotted line in figure 2) and communication is open. Teachers can monitor how students learn, how much time they spend on certain packages; how many times individual learners ask a specific question or certain answers where understood. Since borders are gone, new content enters the course. The course site is also accessible for the industry. The industry reacts on events taking place in the classroom, the industry is invited to share the knowledge on subjects related to the course. The learners become active listeners; they give reflection and input to the teacher. For teachers the question remained: Do learners take over control?

Learner Led Environment

This is a virtual learning environment where all the course material is available for learners at any time and any place (Figure 3). Besides that, learners have access to other sources of information. Knowledge widens and deepens as learners continually build links between new information (content) and experiences (context) and their existing knowledge base. Within Learner Led Learning the teacher does not give lectures anymore: Now the learners do, to each other and to themselves. The learners can (individually or in a groups) create meaningful, coherent representations of knowledge, knowledge they acquired through their
own curiosity for information, knowledge they had to discover through research, curiosity, misunderstanding, understanding, mistakes and discussions amongst each other. They discovered knowledge through teamwork; joy because they found sole mates with the same curiosities and the same learning goals. A key element in the success of learner led learning is the individual learning goal. The learners are asked to describe their learning goals. What do you want to learn, how do you want to learn, how do you want to share your knowledge? The role of the teacher is to follow the learning paths of their learners and guide them if necessary. The teacher remains the responsible person for the course content. He will have to accept the situation that he could receive a question about any subject at any time. We even had situations where students found opposite theories from other marketing professors on the Internet and asked for an explanation.

The tools available in a Learner Led Environment are: textbook material on the subject, bodies of knowledge containing PowerPoint slides with streaming media explanation by instructor, with bullet points on the subjects, articles (papers) on the subjects, streaming media (real media), video of last years lectures, news forums, where students can discuss a subject, cases, other subjects (if any), e.g. links to companies working in the field or famous for their marketing efforts, or links to other universities, monitoring tools for teachers, homepages for learners or groups of learners, in summary everything learners ask(ed) for.

2. The three C's in a Learner Led Environment: Communication, Content and Context

Three important aspects of Learner Led Environment are Communication, Content and Context (figure 4). These three C's make creation of new knowledge possible.

**Communication**, between learners through e-mail, forums, chat, workshops, f2f meetings and between learners and teachers, feedback, questions, exams, assignments. Sometimes the communication aspect is also called ‘systems’, especially when ICT support is needed to establish the communication.

**Content**, entertainment, video, text, bodies of knowledge, virtual trainer, etc. It is very important that the content or information is provided in such a format that it challenges the learners to investigate it, to explore it and to find its relations with other available information. The content should be presented as a hieroglyph, beautiful but with a lot of hidden information (Santema Genang Edmedia 2000).

**Context**, It is important to understand that knowledge is personal and related to the environment or the situation of the learner. It is crucial that this context information is recorded and included in the knowledge developed in this situation.

3. Conclusions

Paulo Freire had a message to educators: “I'd like to say to us as educators: poor are those among us who lose their capacity to dream, to create their courage to denounce and announce. Poor are those who, instead of occasionally visiting tomorrow, the future, through a profound engagement with today, with the here and now, poor are those who, instead of making this constant trip to tomorrow, attach themselves to a past of exploration
and routine." (Paulo Freire). Learner Led Learning enables teachers to listen to the learners and help them with support and instructional guidance to build their future knowledge. With Learner Led Learning we achieved a situation where former graduated learners come back to our environment, and help today's learners reflect their ideas on their current job positions. Borders are down. The participants build new (future) knowledge through dynamic content and build a sense of group identity, cohesiveness, and uniqueness; to encourage continuity and the integration of diverse curricular and co-curricular experiences; and exclude isolation that many learners felt before.

Our learning goal for this coming year will be a test environment where we can match learners with mutual interests and on the other hand match learners with different interests. We will try to match learners who are connected to our learning environment in complete different time periods. Questions we ask ourselves are:

- Will this improve the quality of reflection and online discussions?
- Will this lead us to new insights?

As the next experiments run until May 2001, we will be able present this results at Edmedia 2001.

About the authors:

Ralph Genang

As developer of the online Business-to-Business Marketing classes of Prof Santema, Ralph Genang conducted research on the usage of online marketing classes. With a tracking and monitor tool Ralph could identify the different learning paths of each individual learner. He knew how much time students spend on the course site, how much questions they asked, how they used the answer and how the learners cooperated online and compared the results with learner paths in traditional teaching? To improve the learning efficiency and usage of online courses Ralph developed the bodies of knowledge and the dynamic content. In 2000 Ralph introduced Learner Led Learning. Next to teacher led and community led learning, learner led learning is a learning method where the learning has become a learner responsible and individual process in balance with cooperation in an appropriate context with other learners and a coach (teacher). This process is made possible through online communication in online learning communities.

Each year Ralph organizes New Media Tours to visit authoritative international Online Learning projects (universities and companies)
At this moment Ralph Genang has started a small research company in E-learning, Tri-L. He is still part-time related to the Delft University of Technology and continuing his Learner Led Learning research.

Since learning is a habit learned in your first years at school, Ralph will focus on primary and secondary education as well.

Prof. Dr. Mr. Ir. Sicco Santema

As teacher of the Business-to-Business marketing classes at The Delft University of Technology, Prof Sicco Santema started with Ralph Genang the B2B marketing development project on the use of ICT instruments in 1996. The first instrument was the use of e-mail as a means of interactive communication between instructor and learners. The second instrument, videoconference (PictureTel), enabled us to interact real time with learners on a remote basis. In 1998, the use of real-media resulted in the first life online course (on the Internet) in the Netherlands. During the last three years we developed a third instrument: the learning environment. In the learning environment we created Bodies of knowledge. We divided the course material in 100 subjects. Each of the subjects represents a body of knowledge. We recorded a video clip for each subject where the instructor explains the subject in about two minutes, and we started building a database of related publications to the subjects. By the time our next course started in the spring of 1999, all the course content was available online in multimedia mode. Prof Santema did not teach in the classroom anymore. According to their own learning habits, students who use our online learning environment are free to choose the medium that fits them best, per body of knowledge and context. The content has become dynamic. The context has become dynamic. The learner has become self-regulating, self-teaching, his own communication creates his own solid foundation.
A WWW-Based Multimedia Framework for Medical Case Teaching

Department of Medical Computer Sciences, University Vienna, General Hospital,
Währinger Gürtel 18-20, 1090 Vienna/Austria

Abstract: We describe a software framework designed to build multimedia presentations out of typical medical cases. These presentations simulate the common clinical examination. Starting from a picture of a patient and his main complaints, the user can ask predefined questions and carry out examinations. Answers and findings are updated step by step in a patient's history. The user can make a diagnosis and propose a treatment. Errors are corrected by the program. The case presentations are currently used in students education at University of Vienna as well as in continuing education of medical specialists. The software provides an easy-to-use interface to define the data-structure of a clinical case and to enter the data. The automatically generated presentations can be worked through either on the internet or on a CD.

Introduction

A great part of medical knowledge derives from and is thought by means of typical patient cases. Aim of this project is to provide a framework for clinical case teaching with emphasis easy but powerful input facilities for MD's and widespread access for students. Therefore WWW is a promising approach.

Methods

Case Presentation (a teaching tool for students)

The main educational goal of this application is to present typical case reports. Possible users are students preparing for their examinations as well as medical doctors. Until now 30 case reports are in the system. Due to the "easy to use"- case input interface (see Cap. 3) the number grows rapidly. This case-presentation is currently available in German (http://www.akh-wien.ac.at/augen/waf/cases/waf.htm) and in English (http://www.akh-wien.ac.at:8080/wafenglish/waf.htm, only few cases)

At the start of each case the patient's complaint is presented and the case history is empty. The student may select different examinations to be performed with the findings be inserted into the patient record. (Fig.1.) If the user has acquired enough information, he may stop the simulated examination and proceed to the diagnosis section. where she/he is asked several multiple choice questions concerning the diagnosis. Upon completion of the diagnosis face a set of multiple choice questions concerning the therapy is presented, similar to the diagnosis face. Cases are selected so as to end up in an unique therapeutic intervention which must be selected to proceed. Finally the user is offered to monitor the follow-up therapy which completes the case report presentation of a single case.

Entering the Patients Case History (the MD's point of view)

Developing this application, a great amount of work was put into building an "easy to use", but powerful data input interface. The goal was to transfer the patients case history which grows during routine work unchanged into the system. To meet the demand of different fields of medical research, first the structure of specific cases histories has to be modeled within the system. Afterwards single case histories can be entered easily.
Figure 1 Clinical Case Presentation

Technical Environment and Database Design (the programmers point of view)

Since the demands to contribute the case presentations also on CD's, we decided to program all interactive parts in Java Script. So only a webbrowser is needed and the cases can be worked through either locally (from a CD) or on the Internet.

Data structure and the actual case data can be entered only on the internet. JAVA-Servlets provide the communication with the SQL-database MySQL. Doctors can test new cases and if everything is correct, a new case in HTML and JavaScript is generated by a servlet and stored in the webservers filesystem.

Discussion, Conclusion, Prospects

The program provides a rather poor simulation of a clinical examination due to the restrictions on JavaScript. No special clinical skills can be trained. On the other hand an effective training of clinical skills will be impossible without special computer hardware (models of patients..). The aim of this project to put a little interactivity to static case presentations. It is used currently in medical education at the Department of Ophthalmology, University of Vienna. Other departments (Radiology, Surgery...) are under development.
“Do no Harm”
A First Measure of Effectiveness in Small Distance Education Programs

Gerald "Jerry" E. Nelson, Ph.D.
Director, Distance Education
Casper College, USA

Abstract: Records of 406 students registered in both traditional and distance classes over six semesters were examined. There is a small but significant difference between the mean grades earned in traditional (2.99) and distance (2.81) classes, but the group as a whole outperforms the college overall average of about 2.75. Performance in subsequent distance delivered courses was as predicted by performance in the traditionally delivered prerequisite course. We can conclude that we are “doing no harm” to the academic progress and success of distance students.

Introduction

Is distance education as effective as traditional classroom based education? This is the first question asked by opponents and proponents alike, and it is one of the major areas of research by those involved in distance education. Many studies (see, for example the California State University Special Projects, 2000) focus on learner outcomes, comparing the amount learned by a group of students using one mode of instruction with that learned by a group of students using a different mode. Numerous studies purport to show “no significant difference” (see the website by this name maintained by Russell) between the learning that takes place in traditional and distance settings. Criticism of such studies is common—the bottom line is that it is very difficult to control for all possible variables that may influence the outcome.

Small colleges and universities worldwide are quickly developing a presence in the distance education arena. While we certainly have an interest in the question, “is distance education as effective as traditional classroom based education”, our concerns are more immediate and driven by rapid growth. We do not have the time or resources to perform large-scale, long term investigations to help us decide our most important questions: 1) Should we continue offering an increasing number of distance classes to an increasing number of rural Wyoming students without knowing for sure if these classes are as effective as traditional classroom based courses? 2) What is our measure for “effective as” traditional classroom based education?

Any measure we use not only has to comply with state and regional accreditation organizations, but also with the philosophy, mission and purposes of our institutions. The mission of Casper College, a comprehensive community college serving central Wyoming and the surrounding region, states that the college will develop and maintain educational programs appropriate to the needs of the communities served. In a statement of philosophy, the college supports the belief that equal opportunity for quality higher education should be available to all who can benefit. To fulfill this mission, one of the purposes of the institution is to provide innovative course designs, instructional methodologies, and delivery systems.

A college philosophy and mission statement in support of equal access to quality education and support of innovative course design and delivery systems gives us a starting point, but does not help insure that distance courses are as effective as traditional courses. We have chosen as our initial measure of effectiveness a concept borrowed from the medical profession, “do no harm.” If effectiveness is measured in terms of access and numbers of students served, we are effective. However, our fear (and that of many faculty, administrators, and members of the public) is that distance students would not gain what they need in order to be successful in subsequent courses at our school and beyond, in traditional or distance delivery modes.
Distance students at Casper College are more likely to be non-traditional students that are female, older than typical freshman and sophomores, with family and work responsibilities in addition to school responsibilities. An analysis of a group of students taking both traditional and distance classes demonstrates what others have discovered: distance students are generally dedicated, hard working, self-disciplined, motivated, and they get good grades.

Results of the Study

We have chosen as our initial measure of effectiveness a concept borrowed from the medical profession, “do no harm.” If effectiveness is measured in terms of access and numbers of students served, we are effective. However, our fear (and that of many faculty, administrators, and members of the public) is that distance students would not gain what they need in order to be successful in subsequent courses at our school and beyond, in traditional or distance delivery modes.

Records of 406 students registered over six semesters (fall 98-summer 00) were examined. To investigate our “do no harm” concept as an initial measure of effectiveness, we compared average grades within a group of students (n=406) who took both distance and traditional classes. There is a small but significant ($\alpha = .05$) difference in this group between the mean grades earned in traditional (2.99) and distance (2.81) classes, but the group as a whole outperforms the college overall average of about 2.75.

As a second test of “do no harm” grades of students were compared by pairing courses consisting of a prerequisite and follow up course in mathematics or English composition. One of the pair was a distance class and one was a traditional class; in 46 of the 51 cases the prerequisite course was a traditional class, in 5 cases the prerequisite was distance delivered. Performance in the follow up courses was as predicted by performance in the prerequisite course. We found insufficient statistical evidence ($\alpha = .05$) to rule out the hypothesis that the mean grade (3.12) for the prerequisite course was different than the mean grade (2.92) for the follow up course.

Conclusions

We cannot state that learning outcomes for distance classes are the same as for traditional classes, although we obviously suspect this to be the case. We can conclude that we are “doing no harm” to the academic progress and success of distance students. We should continue to develop our program because of the demonstrated increase in opportunity for access to education that it provides – the program is meeting the needs of the students.

Abstract: The Community Access Through Technology Project (CATT) is developing and implementing virtual reality software that persons with disabilities can use to experience a physical location prior to visiting it in person. A virtual scenario of one physical location has been developed, implemented, and tested, and work is underway on two others. Using a computer mouse or an adaptive device, individuals can "navigate" through various environments and view short movies of processes. Detailed maps and annotations about access issues are provided for each site. The premise that a facilitated virtual tour prior to visitation to a new site would reduce anxiety was supported by the data. In addition, the data supported the premise that a virtual tour would increase knowledge about the facility.

Introduction

The promise of virtual reality (VR) technologies to provide powerful and unique educational and informational experiences is well known (Heim, 1998). Unfortunately, the public has often turned away from these technologies when expectations went unfulfilled due to hyperbole on the part of the media. Despite setbacks, however, use of VR is growing and will soon become commonplace, according to some researchers (Von Schweben, 1998). Currently, researchers at Metropolitan State College of Denver are using VR to assist individuals with physical disabilities become more self-sufficient. Specifically, VR software is being used to model various public buildings and
other sites that individuals with disabilities may want to visit. Therapeutic recreation specialists then use the software with patients to allow them to virtually preview sites that they may later want to tour in person. This approach may build confidence in the clients and may lead to greater independence once they reenter society. By enhancing this social self-efficacy, it is anticipated that carry-over will occur into employment, independent living, family support, and economic independence.

Review of Literature

One in seven Americans, or 35 million individuals, have a disability severe enough to interfere with life’s day-to-day activities (Scherer, 1996, p. 4). Of those individuals, 305,000 reside in the City of Denver, Colorado (United States Census Report, 1990). Providing avenues for these individuals to maximize their full inclusion and integration into varied aspects of community life is essential.

Statistics support the need for inclusive, transitional services. Figures indicate that over 1,500 youth with disabilities are preparing for transition into the community from the public schools (Denver Public Schools, 1994). Furthermore, clinical agencies (e.g., rehabilitation hospitals) in the Denver Metropolitan area have over 1,600 new patients each year (Denver Parks and Recreation Special Needs, 1996), with over 200 referred to community-based services annually (Denver Parks and Recreation Transition to Recreational Activities in the Community, 1994, 1995).

Virtual reality literature discusses many benefits for patients. Rothbaum, Hodges and Kooper (1997) reduced the fear of heights in patients after virtual reality exposure therapy. Wilson, Foremen and Stanton (1997) demonstrated that spatial information acquired by physically disabled children from exploration of a virtual environment will transfer to a real-world equivalent environment; Ring (1998) has suggested that patients with disabilities can be trained with virtual reality to judge architectural barriers and tackle environmental obstacles. The researcher advocates the use of virtual reality as a significant assistive technology in the future (Ring, 1998). This clear support of technology deserves the opportunity for development, not just to provide individuals with simulated experiences but to use the technology for the integration of people with disabilities into society.

Methods

Subjects

Thirty-six subjects with physical disabilities were recruited through advertisements in local newspapers, and through direct mailing to local hospitals, community housing facilities, non-profit agencies, and disability advocacy groups. All subjects were initially screened to ensure that they met minimum guidelines for participation in the study, which included being age 18 or older, no prior participation at the 20th Street Recreation Center, no cognitive deficits, and having a physical disability that impaired mobility. Subjects were randomly assigned to one of three groups: control group, virtual reality treatment group (VR), or the leisure education-virtual reality
treatment group (LE-VR). Thirty-four subjects, 21 males and 13 females, with a mean age of 47.5 years (range = 23 to 84 years) completed the study. Disabilities of the subjects were varied and included persons with Spina Bifida, paraplegia, quadriplegia, cerebral palsy, brain injury, and multiple sclerosis.

Instruments

Self-Evaluation Questionnaire

The State-Trait Anxiety Inventory (STAI) (Spielberger, 1983) was one measure used to assess anxiety. The state anxiety scale (Form Y), used to measure a temporary condition of apprehension, tension, nervousness and worry, was completed by subjects. The scale is comprised of 20 statements with a range of 4 possible responses to each. The STAI has been used more extensively in psychological research than any other anxiety inventory (Buros, 1978). Data indicate that the state scale of the STAI has reliability coefficients above .90 for samples of working adults, students, and military recruits, with a median coefficient of .93. Additionally, it is reported that alpha reliability coefficients are typically higher for the state-anxiety scale when given under conditions of psychological stress (Spielberger, 1983, p. 14). Extensive research into the validity of the STAI has been conducted, and it is reported that the state-anxiety scale repeatedly has demonstrated sensitivity to environmental stress. Furthermore, the STAI has been shown to have excellent psychometric properties for the assessment of anxiety in elderly persons (Spielberger, 1983, p. 20).

Visual Analog Scale (VAS)

Each subject was asked to perform a self-evaluation of anxiety at baseline and at the conclusion of their site tour. An 11-point Visual Analog Scale (VAS) (McCall, Fischer, Warden, Kopcha, Lloyd, Young and Schomaker, 1998; Vogelsang, 1988) was used. Lower scores (0-3) indicated greater comfort with the environment; middle scores (4-7) reflected moderate comfort, while higher scores (8-10) indicated severe discomfort.

Heart Rate (HR) Measurement

In order to assess physiological changes as a result of anxiety, heart rate data were collected. Heart rate data were recorded every 5 seconds and stored using a Polar Accurex Plus Heart Rate Monitor (Polar Electro Oy, Kempele, Finland). All HR data were downloaded from the HR monitor’s wrist receiver to a computer via a Polar Interface Plus (Polar Electro Oy, Kempele, Finland). Each subject had his or her HR measured to establish (A) a baseline and again while touring (B) the 20th Street Recreation Center.

(A). Baseline

Heart rates were measured during an hour of “normal” daily activity while at home or in another “comfortable” environment chosen by the subject. An average HR was determined for this time period.

(B). 20th Street Recreation Center

While touring the 20th Street Recreation Center, the heart rate monitor was used to ascertain physiological changes due to environmental anxiety. Subjects completed 11 assigned tasks while touring the Center. The subject pressed an event marker on the HR wrist receiver while also identifying the task by talking into a voice-activated cassette
recorder. This enabled the identification of a specific heart rate during a specific time interval.

**Recreation Information Questionnaire (RIQ)**

A 12-item Recreation Information Questionnaire (RIQ) was developed to ascertain the subject's knowledge of recreation-related information, frequency of recreation center use, and community independence. Composite scores were calculated by adding correct responses for each statement.

**Technology Questionnaire (TQ)**

A technology questionnaire assessed the subject's technology sophistication, such as their ability to utilize voice mail, e-mail, FAX machines, word processing, and search for information on the World Wide Web. This instrument was adapted from the Flashlight Project (Ehrmann and Zúñiga, 1997). Flashlight™ is comprised of various assessment tools useful in helping to answer questions about technology, and it has been subjected to content validity testing.

**Demographic Data**

Each subject was requested to provide demographic information that included their age, sex, ethnicity, disability, current employment status, living arrangement, health status, use of assistive devices, and methods of transportation.

**Experimental Design**

The 20th Street Recreation Center, a large multi-purpose facility operated by the City of Denver, Colorado, Department of Parks and Recreation, was created into a virtual environment that included photo-realistic panoramas of the facility, digital video of recreation equipment use, access annotations, and interactive maps of the facility. Potential subjects were initially screened to ensure meeting eligibility requirements and then were randomly assigned to either a control group (n=13), treatment group one that received virtual reality only (VR) (n=10) or treatment group two that received leisure education using the virtual reality scenario (LE-VR) (n=11). All subjects were pre-tested in their home or “comfortable” environment to determine baseline anxiety levels (i.e., Self-Evaluation Questionnaire, HR, and VAS), recreation knowledge (i.e., RIQ), technology sophistication (i.e., TQ), and demographic data.

Control group subjects independently toured the 20th Street Recreation Center, completing 11 assigned tasks such as signing up for a recreation center pass, locating specific exercise equipment, and viewing the swimming pool. During the tour, subject's HR was recorded and tour data noted on voice-activated tape recorders. At the conclusion of the tour, subjects were met by project staff to complete their post-evaluation questionnaires and paperwork for receiving a stipend for participation.

Similarly, subjects in the VR only treatment group and LE-VR treatment group followed an identical protocol for their 20th Street Recreation Center visit. However, the subjects assigned to the VR treatment group had an opportunity to view and “navigate” through the Center virtually prior to their actual on-site tour. Each VR only subject, either coming to a computer lab of the CATT project or by having staff bring a laptop computer into the subject's home, virtually toured the facility, navigating through the various rooms, examining equipment, and viewing the digital video clips. Staff had been
instructed to assist subjects in using the computer only and not to provide explanation or information about the facilities.

Subjects in the leisure education-virtual reality (LE-VR) group also utilized the 20th Street Recreation Center virtual environment but had this computer tour facilitated by a certified therapeutic recreation specialist (CTRS). A leisure education program, created through a modified program planning process (Peterson & Stumbo, 2000), was used by the recreation therapist to assist LE-VR subjects in using the community facility. Content of the program included information about transportation, facility accessibility information, fees/costs for participation, equipment and adaptations available, and services provided through the Special Needs Program of Denver Parks and Recreation Department.

Results

The premise that a facilitated virtual reality tour administered prior to visiting the 20th Street Recreation Center would reduce anxiety, was supported by a difference in means from the STAI (p=.104).

The premise that a virtual tour prior to visitation to a new site would provide detailed, necessary information about that facility also was supported by the data. Analysis of data from the RIQ showed significant differences between both the VR-Only and the LE-VR treatment groups and the control group (p=.003).

The premise that use of a virtual tour alone prior to visitation of a new site would alleviate anxiety in subjects with mobility impairments, was not supported by the data. Subjects in the VR only group were administered three instruments, then provided the treatment of the virtual reality experience, and then measured again at the 20th Street Recreation Center location. Data indicates an increased level of discomfort, anxiety, and heart rate. While mean HR site data was lower for this group of subjects than for similar subjects in the control group, the range was much greater.

The Technology Questionnaire was administered to all subjects prior to site visitation. It assessed the technology sophistication of the subjects, including their ability to use voice mail, e-mail, FAX machines, word processing, and the World Wide Web. In order to determine whether an individual’s knowledge of technology was a factor in levels of anxiety, a technology score was formed by adding together individual responses to technology questions. A significant negative correlation was found between technology composite scores and pretest anxiety scores. This would indicate that those who score higher in technology knowledge tended to score lower on self-reported anxiety in the pretest.

Future Research

Future research may attempt to recruit subjects with mobility impairments from rehabilitation hospitals that are involved in active rehabilitation. This population may include persons with more recent disabilities, and these persons may exhibit greater anxiety when utilizing community-based facilities.
Additionally, more analysis needs to be performed on the HR data since it is suspected that physical exertion at the site may result in increased heart rate in addition to anxiety. A second physiological measure, such as salivary cortisol, may be useful in measuring neuroendocrine responses to anxiety in a natural environment (Bandelow, Wedekind, Hüther, Broocks, Hajak, Pilz and Rüther, 1997).

Finally, the production technology used for the virtual reality experience was only marginally immersive since it relied on Hypertext Markup Language (HTML) and Virtual Reality Modeling Language (VRML). Newer, more immersive and interactive technologies may be more effective in reducing anxiety. The use of these technologies needs to be explored in field-based settings. In addition, the virtual reality experiences need to be more “user friendly” and easier to use for persons without extensive technological experience.

A Project for Supporting Photonics Development as a Modern University Research Centre

Mihaela Ghelmez (Dumitru)

*Physics Department, Politehnica University of Bucharest, 77206, Bucharest, Romania,*
e-mail: dem@physics.pub.ro

**Abstract.** The paper presents a programme that aims to prepare, by education and research activities, specialists with high qualification in the field of photonics. Within the context of a modern educational system based on internationally accepted standards and in close relation with other master and doctorate programs having a similar field of activity and profile, this programme will use computer, networking, hypermedia and multimedia facilities, designed to play a crucial role in this activity. A financial support from the National Higher Education Research Council and Mondial Bank is using for creating the base of this centre.

**Introduction**

According to the organising regulations, there are two important types of activities taking place into this Photonics Centre (PhotoCen "Focum"): postgraduate programmes and performant scientific research. Consequently, the main objectives are determined by the requirement of ensuring the conditions of a high quality activity in these sectors, contributing to the postgraduate programmes and scientific research development, as essential objectives for the Romanian education and research reform, as follows:

a) 1st Stage: Establishing and efficiently using PhotoCen "Focum".

The centre is established having given initial users and a large number of potential users, national-wide: universities, research centres, manufacturing centres. International co-operation, computer and network based are constantly used. (Woltz et al., 1997)

b) 2nd Stage: Nation-wide development and use.

"Focum" is developing with a national base of teaching and research by increasing the number of the steady users to many universities and research institutes, based on conventions and contracts. Exchange with other units from abroad is also compulsory, in order to maintain the high level and to up-date the methods. Computer software, www sites and multimedia facilities have to be daily tools for all users. (Becker, 1996)

c) 3rd Stage: Improvement as nation-wide teaching and research base.

The centre-accessing program is improved together with the increase of the user number and an appropriate database is built. Constant advancing as modern teaching and research centre having possibilities of sustainability is required. One will constantly have in view international affirmation of the centre by participating to congresses, conferences, publications, etc. (Dumitru et al, 1994). Likewise, the centre Program will be initiated with the aim of supporting external teaching and research programs and capitalising the results of the own research. The whole activity has to be accompanied by computer, network, multimedia and hypermedia use.

**Description of activity**

Organising University is "Politehnica" University of Bucharest and other involved Institutions in Romania are Politehnica University of Timisoara, Tehnical University "Gh. Asachi" of Iassy, Technical Military Academy, University of Craiova, University of Pitesti; University "Valachia" of Targoviste; PROOPTICA - Research and Design Institute Bucharest; MATPUR - Research and Design Institute for
Semiconductors Bucharest, National Institute for Microtechnology, Bucharest. External relations and co-operation were established with Royal Inst.of Technology-KTH, Stockholm; Technische Hochschule Darmstadt, Univ.Paris, Univ.Sofia, Chalmers Inst. Göteborg, Politecnico di Torino, Abdus Salam Physics Centre Trieste, Lab. De Chimie Physique des Polymers et des Membranes, Lausanne, Univ. Grenoble, University of Aalbory - Denmark, Strathclyde University Scotland, University of Amsterdam. In the PhotoCen "Focum" team there are internationally recognised researchers, by their remarkable scientific work, published papers, active participating in international congresses and conferences, members of many scientific societies and committees, recipients of different awards and grants.

The program describes in details the centre organisation: management; didactic and research activities; organization and the coordination of mixed research collectives (teaching staff, researchers, Ph.D. students, master students, other students) as some interdisciplinary collectives; elaboration of an internal research plan connected to the research in the advanced countries; reference materials and publications (Ghelmez, 2000); laboratory equipment and experiments (Ghelmez, 2000); mobility and specialization; intensive lectures of foreign specialists in different fields of photonics and in applying computers in Romania.

We appreciate that at the PUB there are favourable premises for the development of the existing master and doctorate programs in the field of photonics. The photonics integrated laboratory is constituted of 4 operational units: Lasers, Optoelectronics apparatus and equipment, Photonic materials and technologies, Specialised computation technique. There are also a library and some mechanics, electronics and optics workshops. Concerning the specialised computation technique unit, it is achieved on the UNIX network installed at the Physics Department, with Internet accessing. We are using usual and specialised software, employed in researches using numerical analysis and computer experiments. Matlab, Mathematica, and Maple are currently used by students and teaching staff. Graphs and some calculations and processing the experimental data are made by using Excell, TableCurve3D, Microsoft PhotoShop etc. Interactive Physics, CUPS software, Work & Energy CAL, Bede Lab for Windows, Mouse-LCD, Reliable Energy, Optisk Data Lagring, Molecular Probes, etc are also used for helping the teaching and work in our field. Labview and PCTex programs were just now installed, together with other usual programs for use of the photonics' students. The present endowment, the equipment and installations has to be completed. Some examples of using such computer capabilities and obtained results at this stage are detailed in (Ghelmez, 2000), (Ghelmez et al, 1999).

The proposed program is related to the nowadays stage of development of the educational system in Romania, submitted to the reform process during latest years. In the top field of photonics, which has as main purpose the study of lasers and their interdisciplinary applications, the master and doctoral activity, rather restrictive or just inexistent until 1989, belong today to the most dynamically domain of modern science and technology, having an impressive affairs figure. Computer, networking, hypermedia and multimedia facilities are designed to play a crucial role in this activity.

Abstract: Two problematic concerning information technologies and communication, one related to the new constraints of access modality, communication and organization of information on process of knowledge making. The second one more related to new cognitive skills required by the learning environments that integrate these technologies in order to understand and exploit all their potential. From concern we conceptualized a Pedagogical Mediation Structure (PMS) object. A set of pedagogical principles and strategies allowed us to elaborate a theoretical model and an operational model. The first prototype gathering nine cognitive tools, was accomplished in a partnership agreement with the company Novasys Inc of Montreal. This research focused on the skills related to the process of negotiation, argumentation and knowledge restructuring. We sought to make the theory of cognitive flexibility operational using cognitive tools that manage and organize the interaction process with the pairs within accessible information in a mediated and distributed learning space (MDLS).

Introduction

In the framework of this research, we were interested in the skills related to the process of negotiation, argumentation and knowledge restructuring. We sought to make the theory of cognitive flexibility operational using cognitive tools that manage and organise the interaction process with the pairs and with accessible information in a Distributed Mediated Learning Space (DMLS). This research supports the systematic reflections of the impact of a pedagogical intervention on the problems raised by using the new technologies in developing learning environments. We want to know by developing a PMS which relies on validated and imposed pedagogical principles, whether we can better exploit the new contexts of communication and exchange in (DMLE) for developing a high level cognitive skills. The purpose was, during students interaction with PMS’s cognitive tools to observe the behaviours, the process and the strategies that were used and manifested related to the negotiation, the argumentation and the restructuring. We also explored what comprehension the students make, if possible define it as flexible comprehension, knowing the context of socio-cognitive and meta-cognitive in which it is elaborated. The problematic that motivated us is centred on the difficulties of several research workers, on exploiting and integrating the potentials and possibilities that information and communication technologies and pretend to have on the learning. This research aims to observe, describe and analyse the effects of cognitive tools on skills and competence promoted in several rapport and recommendation in the educational domain.

Emergence of New Conceptual Framework

The new occupations offered in information era with the network technologies, cannot be learnt in working place, because they don’t rely only on know-how of industrial society. They require relatively hard theoretical and practical training that brings a refinement and a new reflection on the definition of expertise. This kind of reflection emphasises on the definition of learning and the purpose of learning. Learning becomes consequently the use of knowledge that allows the learning capabilities to be expanded.

To establish this prospect, there are three approaches:

1. The first is inspired from the socio-cultural approaches and integrates the concept of learning, the concept of cognitive ecology (Bateson 1972) and the concept of cultural mediation of learning process (Vygotsky 1978;
Salomon and al., 1991). So, the learning spaces are promoted for providing the learner with a responsibility and allowing him to participate and be incumbent in a new social dynamic.

2. The second prospect, more constructivist, orient the research towards the conception and design of learning spaces that helps the learner to make and exploit them conform with his previous knowledge, his learning profile and his motivations (Linn and al 1998, Chan 1996).

3. The third prospect, allows adapting learning environment to learners' needs and expectations, by presenting interactive dimension, social and the inherent potential of environment in the interaction process (Salomon 1993; Brown and Campione 1986). So, cognitive dimension apparently jeer more and more to social dimension for circumscribing a learning process that is more and more distributed and more complex (Salomon 1993; Chan 1996); whose reach relies on the appropriate arrangement of components of immediate context of the learner (learning task or activity, tool– artefact activity mediator, the partners or the community in interaction with the learner) (Salomon 1993).

Pedagogical Mediation Structure

The PMS relies on pedagogical principles, from theories of learning, communication, collaboration and interaction. It aims to support developing cognitive, metacognitive and socio-cognitive competencies and also aims to develop new knowledge in DMLE. More specifically, our theoretical framework is made around the concepts based on the theory of cognitive distribution (Salomon 1993) and intelligence distribution (Pea 1993), cognitive flexibility (Spiro and al 1991) and theory of epistemic games (Morrison and Collins 1995). The three theories specifically focus on the problematic of learning and knowledge acquisition, and they specifically focus on cognitive skills development within DMLE. By the means of pedagogical principles and strategies, we developed the operational model of the PMS, this allowed us to make a prototype that includes nine cognitive tools. These tools allowed students to structure the messages during the interaction and to diversify the feedback and retroaction.

The validation of the prototype and conclusion

The functional and empirical test and pre-test sessions took place in the company's locals with participation of 22 university students and an observatory group for gathering the data. The methods and the instruments used to gather the data were computerised trace, verbal protocol, observation grid and semi-structured interview. A questionnaire for factual data was also submitted to the students.

To analysis the data, we used several descriptive scales, for the knowledge construction activity (Scardamalia and Bereiter 1991), and for the awareness level (Pontecorvo 1987) that allowed the analysis and the description of epistemic action and of cognitive involvement of students during their interaction with PMS. This allowed us to relate on the mechanism and the predisposition of how student face restructuring and refinement of knowledge. We used the coding system of intimate negotiation (Ting-Toomy 1982) and the strategies of communication of Wallace and Skill (1987) for the analysis and description of the student's negotiation processes. For the argumentation, we analysed as suggested by Toulmin and al. (1979) and Kuhn (1992), the elements of the argument that allowed to describe and to identify the nature of the argumentation process.

The analysis of the students messages allow us to observe the knowledge construction activity in which students were involved, it was mainly focused on inference process, new information seeking and interpretation with 56% on the category: "Explicit Knowledge Construction". The category of "Direct Assimilation Knowledge Construction" was less present (23%) and no indicators about "Sub-Assimilation" (Bereiter and Scardamalia 1991). The analysis of indices related with "Meta-Cognitive Reflection", shown a predominance of the "Level 3 of Awareness" (Pontecorvo 1987), which is related with knowledge epistemic value (65%). The observed indices of the argument within the student messages, clearly shown a predominance of the categories like "Opposition", "Response to Opposition", "Warrants". A deeper analysis of these categories, shown a predominant interaction among peers focused on "Parasupporting" of the person I am speaking to (justification/support), "Compromising" (negotiating deals, probing alternatives) among peers, "Agreement" (compliance, assertion) to the statement of the person I'm speaking to. The predominant category was the "Task Oriented Question" (48%) with the activation of strategies like argument assertion, question, counter-support statement.

The analysis of the indices related to negotiation process (learner behaviour/strategy) shown three main aspects: first the presence of an integrative behaviour (Ting-Toomey 1982) with 42% of indices on negotiation process (confirming, compromising and agreement) (Oubenaissa 2000). Second, the predominance of categories focused on "Task Oriented Question" supporting the negotiation as goal-oriented process: rich an objective, achieve a task or state an agreement. The third aspect was the predominance of argument assertion, question, and agreement as communication strategies (Wallace and Skill, 1989) supporting "disintegrative behaviour" (23%) in terms of disagreement, and confrontation. These aspects confirm the student involvement in an argumentation process (Oubenaissa 2000).

Concerning with flexible understanding, all the results of the messages analysis, verbal protocols, interaction profile and use of the tools of PMS by the students, as well as the comments and perceptions gathered
during the interview, allowed us to proceed with a conception of what could be the flexible comprehension like a learning product as defined in the new taxonomy of Jonassen and Tessmer (1997).

A deeper analysis of all indices related with negotiation process allowed us to show that students integrative behaviours focused the interaction on "negotiating alternatives" and the "support of peers statement", by justification, explanation and new information contribution. Concerning the disintegrative behaviour, the students not only reject the peer statement, but express their point of view making critics, attacking the consistency of the information received.

Finally, the data collected about the knowledge construction activity, awareness level, students negotiation strategies, as well as argument elements, clearly shown that the students were involved in a cognitive activity where argumentation and negotiation process were juxtaposed. These same elements are considered as indices of knowledge re-structuring activity in the learner (Chan and all. 1997, Hafner and Steward 1995).

Media and Innovation Take Technology Off-campus:
The Institute for Technology Transfer

David C. Gibbs
Computer Information Systems Curriculum
University of Wisconsin-Stevens Point
United States
dgibbs@uwsp.edu

Daniel V. Goulet
Computer Information Systems Curriculum
University of Wisconsin-Stevens Point
United States
dgoulet@uwsp.edu

Abstract: Linking a university’s computing technology resources with local businesses provides a
win-win scenario for improving the technological life of both. The Institute for Technology Transfer, residing at the intersection of several traditional roles of the university, establishes this
connection using the ideas of virtual workgroups, virtual workshops/courses, and virtual projects to
bring both parties together. The result is an environment for outreach education in technology,
professional certification for workers in technology, and technological consulting to the business
community.

The Problem:

Businesses need technology professionals. The former Wisconsin Governor wants to double university
computing graduates in Wisconsin's public universities to meet this need. However, even if this doubling takes
places the need for technology professionals will not go away. Businesses need to upgrade and re-tool their current
technology professionals both to retain these technology professionals and to stay competitive.

Pre-professional computing students need to be prepared to enter the business community. Traditional
university curricula limit student horizons mainly to the textbook, and have few mechanisms for bringing the outside
world environment into the classroom arena. Hence, many computing students enter the business community
without a good understanding of the challenges and requirements of the job.

A Solution:

The Institute for Technology Transfer is a proposed organization (see graphic below) forging a special link
between the University of Wisconsin-Stevens Point's Computer Information Systems curriculum, students and
faculty, and the Central Wisconsin Business Community to improve the technological health of Central Wisconsin.
In short, the Institute is a three-part enterprise. It is:

an incubation center where business computing professionals, high achieving UWSP computing
students and UWSP CIS faculty work together to solve computer technology problems important
to businesses,

a training center where computing professionals from the business community, as well as pre-
professionals [UWSP students] can advance their knowledge and become skilled in the latest tools
for software systems development and project management,

da certification center that documents and recognizes the learning and productivity activities of
Institute participants.
The Institute’s design will:

- establish a program that reaches out to the Central Wisconsin Business Community with technology rich solutions to business problems,
- have an ongoing outreach educational program,
- have a certification program leading to a Bachelor’s Degree, a Certificate Program, and a Master’s Degree in software development and management for both traditional and non-traditional students.

![Diagram of the Institute for Technology Transfer](image)

Figure 1: The Institute for Technology Transfer in Conceptual Form

The Strategy:

The virtual workgroup is the basic building block for all Institute activities. The workgroup will be composed of students and professionals working in both face-to-face activities and at a distance using synchronous activities of compressed video technologies and/or asynchronous activities over the web. Each workgroup will be guided and mentored by a faculty member. The focus of the workgroup will be an actual business problem from the professional’s work environment. Just-in-time training using both face-to-face workshops and virtual classrooms will provide pre-professionals and professionals with skills to solve business problems.

For those businesses associated with the Institute but not involved in virtual workgroup activities, workshops, seminars and coursework will be provided using all available instructional capabilities.

A systematic collection of workshops, seminars and coursework will lead professionals to Certificate Programs and Master’s Degree programs. The key to both certification activities will be a creative integration of existing curriculum coursework with Institute seminars and workshops.
PDAs: Learning in the Palm of Your Sweaty Little Hands

Carol Gilley, University of Arkansas, USA; Donetta Ginn, University of Memphis, USA

Abstract: Personal Digital Assistants are small, portable, and inexpensive. You can surf the Web and have e-mail capabilities. Software is available and titles are growing because of the ease of development. PDAs will soon become commonplace in the world as well as the world of education. Therefore it is important that educators and instructional developers look at PDAs and their operating systems as the newest medium of delivering instruction to the busy learners of the present as well as the future.
Computer and Internet Attitudes of Adult GED Students

Carol A. Gilley, Ed.D. Candidate
University of Arkansas
Graduate Education Building 339
Fayetteville, AR 72701
cgilley@uark.edu

Abstract: This study measures the computer attitudes and Internet attitudes of adult General Equivalency Development (GED) students in the United States. Age, gender, education, location, income, computer/Internet experience and computer/Internet access are also measured to see if these factors effect computer or Internet attitudes. The instrument used to measure attitudes is the Loyd and Gressard Computer Attitude Scale (CAS). The CAS was modified to create an instrument to measure Internet attitudes. Both scales measure computer or Internet a) anxiety, b) confidence, c) liking, and d) usefulness.

Preparing learners for the General Equivalency Development (GED) exam has been the job of adult education centers for a number of years. These centers are usually open during the day, and several have classes available in the evenings and weekends for working people who are trying to get their equivalency diploma. If the pretests, practice exams, and instructional materials were accessible to students twenty-four hours a day, seven days a week, there is a strong possibility this would open the door to a diploma so more people could be served. Workers on a third shift at an industrial plant could practice their math skills during their breaks at 4:00 in the morning, long before the doors of a typical educational center opens. A parent who works could take a practice exam at midnight, long after the children went to bed. A person who has to travel for their job, could work from any location across the country. Not only could they solve problems and take exams, they could also have the benefit of immediate feedback on their work after each question or problem. People could work toward their diploma at their own convenience and schedule, not at the mercy of someone else’s time clock.

Statement of the Problem

The instructional audience this study is seeking to serve and better understand is the GED candidate. To ensure successful design and development of web-based GED programs in the future, we must first see how the current GED students feel about computers and the Internet. More specifically, this study will measure both the computer and Internet attitudes of adult GED students in the United States. Other things besides attitudes will also be measured. In other words, does age, gender, education, location, income, computer/Internet experience and computer/Internet access effect the computer and Internet attitudes of these students? And finally, do the computer attitudes differ from the Internet attitudes of these students? All these factors are important to measure in order to better serve GED students in the future so that instructional materials and methods developed in the future can accommodate the learning needs of the GED student as well as other adult learners.

Questions to be Answered

Within the limits and range of this study, the following questions are answered.
1. What are the attitudes toward computers of adults enrolled in GED programs in the United States?
2. Are there any differences in these attitudes toward computers based on age, gender, education, location, income, computer experience and computer access?
3. What are the attitudes toward the Internet of adults enrolled in GED programs in the United States?
4. Are there any differences in these attitudes toward the Internet based on age, gender, education, location, income, Internet experience and Internet access?
5. Is there a significant difference between the computer attitudes and Internet attitudes of adults enrolled in GED programs in the United States?
Importance of the Study

The GED population has been typically understudied (Bates, Holton, & Seyler, 1996). Attitudes toward computers and the Internet are important areas of consideration for instructional designers who create instructional materials for GED students as well as other adults. Creators of computer-based technologies use information about user attitudes as well as demographic information to create computer or Internet-based applications. Therefore this study is important to increase the knowledge base in adult education, instructional design, and computer-based technologies.

Research

The research will be based on the initial questions posed by this study. Questions one and three as seen above, will be answered using the measures of central tendency and variability. Each participant will be administered a Computer Attitude Scale (CAS) or Internet Attitude Scale (IAS). Total scores will be computed for each participant. A higher total score corresponds to a more positive attitude toward working with and learning about computers and the Internet. Means and standard deviations will be computed for the total scores as well as the four subscales for both computer and Internet attitudes. Questions two and four will be answered using the measures of central tendency and variability as well as multivariate analysis of variance (MANOVA) procedures. Means, standard deviations, frequencies and percentages will be computed for each of the seven demographic areas: age, gender, education, location, income, experience and access. In the MANOVA procedure, the total score for computer and Internet attitudes will be the dependent variables. The independent variables will be age, gender, education, location, income, experience and access. Statistical significance of the demographic factors will be determined from the MANOVA. A level of significance of 0.05 will be accepted as the level of confidence. Question five will be answered using a t-test for independent samples. Total scores of Computer attitudes will be compared to total scores of Internet attitudes. A significance level of 0.05 will be accepted as the level of confidence.

Selection of Participants

The sample selection will be completed using stratified random sampling. To determine the sample sites, a current listing of all GED program centers for each state will be obtained. From this listing, two sites from each state will be chosen using a random number generator. The first site chosen will receive 10 Computer Anxiety Scale surveys and the second site will receive 10 Internet Anxiety Scale surveys.

Instrument

The instrument that will be used in this study is commonly known as the Computer Attitude Scale (CAS). Loyd and Gressard developed the CAS in 1984 at the University of Virginia and has been found to be a valid and reliable instrument. This scale is a Likert-type instrument with 40 statements representing attitudes toward computers. Participants must respond to one of four responses: a) strongly agree, b) slightly agree, c) slightly disagree, or d) strongly disagree. Four types of attitudes are measured with the CAS: 1) anxiety or fear of computers, 2) confidence in the ability to use or learn about computers, 3) liking computers or enjoying working with computers and 4) perceived usefulness of computers in current or future work situations. Permission has been granted to use the CAS scale in this study.

A new scale created by modifying the CAS to reflect Internet attitudes has been developed for this study. Permission has been granted to make the changes to the CAS. The same format and statements were used to solicit Internet attitudes. The word computer was replaced with the word Internet in the instrument's statements. For example, the statement computers do not scare me at all would be changed to the Internet does not scare me at all.

This study is a work in progress that will be completed by June 2001. Explicit details about the results of this study will be available on-line and will be presented in Tampere Finland at AACE EdMedia 2001 Conference in late June.

Designing a Pedagogically Sound Web-based Interface: The Critical Role of Prior Knowledge

Thanasis Giouvanakis, Haido Samaras, and Konstantinos Tarabanis

Educational Technology Laboratory
University of Macedonia, Thessaloniki, Greece
156, Egnatia Street Thessaloniki, Greece
Tel: +30-31-891589, Fax: +30-31-891544
E-mail: thgiouv@uom.gr, hsamara@uom.gr, kat@uom.gr

Abstract: In this article we present our research and development efforts to design a pedagogically sound multimedia web-based learning interface. We take into consideration recent findings from the area of cognitive psychology regarding the use of text, animation and voice. The logic is based mainly on the presentation modality effect and the principles of spatial and temporal contiguity. We consider the state of the learner’s prior knowledge to be of critical importance. We present a flexible user interface supporting the use of animation and voice as default modalities and the existence of text in the same interface as an essential part of the learning process. The SMIL language is used for the implementation of the Web-based interface.

Introduction

Recent studies have emphasized the significant implications of multimedia for the learning process. Even those researchers who take a less enthusiastic stand do not hesitate to assent that when blended with suitable pedagogical techniques and a proper design, the combined use of multiple media for the viewing and study of educational material can enhance the quality of the learning environment. In this article we discuss the theoretical background and the development efforts which have led us to create a flexible interface design that is used for a series of graduate and post-graduate courses.

We distinguish two stages in the learning process:

- the presentation of the instructional material, for which we can assume learners have no prior knowledge and
- that material’s study and critical investigation

We seek to provide an integrated support for both stages via the same user interface which will combine the use of animation, voice, and text labels on the one hand for the presentation of the course material to the learners; and alternatively, the use of hypertext and pictures for its in-depth scrutiny. We analyze the reasons that have led us to the adoption of this particular interface design based on the findings of cognitive psychology studies. Commencing with the notion of working memory, we pursue ways to optimize its limited resources, in order to use them as guidelines for our design decisions. Understanding working memory limitations and sensory modality benefits is essential in order to create courses that may reduce cognitive load and enhance the learning process. To this extent, cognitive psychology theories such as Paivio’s dual coding theory (1971, 1986, 1991) and Baddeley’s model of working memory (1986, 1992) as well as recent evidence provided by cognitive load psychologists can serve as the basis for the instructional design of multimedia courses that will facilitate learning.

The flexibility of the user interface is a crucial matter. Learning outcomes can be increased by creating an interface that provides a combination of modes and modalities from which to select, according to the prior knowledge of the learner.

The Internet has been chosen as the implementation environment due to the additional capabilities it has to offer to the learner and SMIL has been selected because of its ability to synchronize and coordinate diverse multimedia elements.

Finding ways to overcome the limits of working memory

According to the traditional three-stores model of memory (Atkinson and Shiffrin, 1968), a way to conceptualize memory is the following: a) one part of memory, known as sensory memory, is capable of storing limited amounts of information for very brief periods of time b) a second component, short-term memory, is capable of storing information for somewhat longer periods of time but is also of relatively
limited capacity and c) a final constituent, called long-term memory, is of very large capacity and capable of storing information for very long periods of time, perhaps even indefinitely.

Working memory is defined as being the part of long-term memory, which also comprises all the knowledge that has been recently activated in memory including the short-term memory. This implies that memory comprises three concentric circles, the inner one corresponding to short-term memory, the intermediate circle to working memory and the exterior one to long-term memory. Information resides within long-term memory, and, when activated, moves into long-term memory’s specialized working memory, which will actively move information into and out of the short-term memory contained within it (Sternberg, 1996).

Many memory theorists have assumed that working memory comprises multiple memory systems, which most frequently are associated with auditory or visual processing. For example, one of the most acceptable models of working memory proposed by Alan Baddeley (1990) consists of at least the following: a) a visuospatial sketchpad, which briefly holds and deals with visual images and b) an articulatory (phonological) loop, which briefly holds inner speech for verbal comprehension and for processing verbal information. It is believed that the first two systems process their different types of information in a largely independent and parallel fashion.

In relation to the role and characteristics of working memory, our basic suppositions are the following: a) working memory has a limited capacity and duration, that is, we are able to hold and process only a few items of information at a time, b) working memory includes an auditory working memory and a visual working memory, according to Baddeley’s theory, c) each system operates in parallel d) meaningful learning occurs when a learner retains relevant information in each system and is able to make referential connections between them (Mayer & Anderson, 1991).

Prior knowledge, Schema acquisition and Chunking

An average person can retain up to a few chunks of information at a time in working memory. Working memory is believed to be capable of storing seven plus or minus two chunks of information at a time (Miller, 1956). In other words, we can think about about five to nine distinct items at any given time. A general way to overcome the problem of limited capacity of working memory is by creating a schema. A schema is identified as a cognitive construct that allows us to treat multiple elements of information as a single element classified according to the manner in which it will be used (Bagui, 1998). Therefore, a schema puts less pressure on working memory, facilitating understanding. Schema acquisition is facilitated by the existence of prior knowledge. Learners who know a great deal about a subject have more well-developed schemata for incorporating new knowledge.

Dual coding and the sensory modality effect

With his dual-coding theory, Alan Paivio (Paivio, 1971, 1986, 1991; Clark & Paivio, 1991) suggested that information is processed through one of two generally independent channels, modes or codes. That is, our imaginal and verbal mental representations may be viewed as two different codes (analogue and symbolic), which organize information into knowledge. Learning is better when information is processed through two channels instead of one.

Connections can be made only if corresponding nonverbal and verbal information is in working memory at the same time. Information processed through two channels is called referential processing and has an additive effect on recall (Mayer & Anderson, 1991; Paivio, 1967, 1991; Paivio & Csapo, 1973). This happens because the learner is able to create more cognitive paths that can be followed to retrieve the information.

The research to date thus suggests that dual-mode input (verbal and nonverbal) helps people learn. But humans can also input information through various sensory modalities. Recent studies have addressed the problem of the combination of modes and modalities that should be preferred in order to promote meaningful learning. For example, should an animation (nonverbal mode, visual modality) be accompanied by an explanation presented as a narrative (verbal mode, auditory modality), an explanation presented as on-line text (verbal mode, visual modality), or by both of these forms of explanation simultaneously? Drawing from Baddeley’s (1992) theory of working memory and Sweller’s (1988, 1989; Chandler & Sweller, 1992; Sweller, Chandler, Tierney, & Cooper, 1990) cognitive load theory, several researchers have shown that working memory capacity can be enlarged by using dual-modality presentation techniques (Mousavi, Low, & Sweller, 1995; Mayer & Moreno, 1998, 1999, 2000).
This evidence supports the view that instructional designers should not only be concerned about combining verbal and nonverbal information consistent with Paivio’s dual coding theory; it is essential that they take into consideration the role of sensory modalities when designing multimedia presentations with pictures and words. Mixed modality presentations are superior to the most integrated text and visual presentations (Moreno & Mayer, 1999).

The contiguity principle

The contiguity principle was proposed by Mayer & Anderson (1992) as a way of increasing the effectiveness of multimedia instruction when words and pictures are presented contiguously in time or space. They proposed the use of the term spatial-contiguity effect to refer to learning enhancement that results when text and pictures are physically integrated or close to each other rather than when they are physically separated. One interpretation of this result is that students might be missing part of the visual information while they are reading the on-screen text or, vice versa, missing portions of the text while focusing on the pictures. This forces the learner to search for relations between them. The cognitive load associated with this search is extraneous (Mousavi, Low, & Sweller, 1995).

Similarly, the term temporal-contiguity effect has been proposed for cases when visual and spoken materials are temporally synchronized resulting again in the enhancement of learning. In these cases, learners are able to hold a visual representation in visual working memory and a corresponding verbal representation in verbal working memory at the same time, allowing them to build referential connections between them, consistent with the dual coding theory. Therefore, differences in synchronicity between verbal and nonverbal materials that need to be integrated in a lesson also affect learning. Evidence associated with the spatial contiguity effect is provided by several studies (Mayer, 1989a, 1989b; Mayer and Gallini, 1990).

Therefore, another critical aspect of designing instructional software, is to physically integrate the corresponding pictorial and verbal information in a multimedia lesson as much as possible, both spatially as well as temporally.

Two alternative combinations for presenting information based on the learner’s prior knowledge

The previous discussion has led us to adopt two different and complementary approaches for presenting instructional material. We take into consideration two states of the learner’s knowledge domain: a) no prior knowledge and b) prior knowledge.

There appears to be an enhancement in learning with multimedia, especially for learners with low prior knowledge for whom the rich multimedia environment may also positively influence motivation and engagement. Mayer (1993) believes multimedia information is more effective for learners with low prior knowledge or aptitude in the domain being learned because it helps them build a cognitive model or to connect the new knowledge to prior knowledge.

On the contrary, learners with high domain knowledge have a rich source of prior knowledge that can be connected to new knowledge. In other words, they can make referential connections or build cognitive models with text alone. Furthermore, it is also believed that for learners with prior knowledge in the domain being learned, textual information may force them to expend more effort to read and understand the information resulting in improved long-term encoding of the information (Najjar, 1996).

In the following sections we discuss the characteristics and advantages of each of the two combinations.

Hypertext and pictures

Reading text is a complex process. Learners expend more effort when reading, in order to understand information. This results in improved long-term encoding of the information. In many cases, the use of text alone is not sufficient to help the reader understand concepts and ideas. It has been proven that by incorporating pictures within text, the learning process is enhanced. Visual illustrations make abstract ideas and complex information more concrete and easier to comprehend. Pictures seem to allow very rich cognitive encoding that allows surprisingly high recognition rates (Najjar, 1996).
The combination of text and pictures is effective because it allows for the concurrent coding of verbal and non-verbal information. There has been evidence to show that adding voice to textual presentation degrades learning.

**Animation, voice and text labels**

Voice is a more realistic and natural mode of presenting information than displayed text, because of the perception of the person behind the voice and the verbal loop (acoustic) we use to store information. Voice does not distract visual attention from stimuli such as diagrams, and is therefore more engaging. It is good for conveying temporal information (Shih & Alessi, 1996).

Despite the potential advantages discussed above, voice suffers from a) the problem of being ephemeral. Text remains in front of the eyes of the reader for a longer period of time. This makes it more suitable than voice when studying and critically analyzing the educational material. Voice lasts only for an instant in time and is more difficult for a learner to control and b) the problem of being difficult to search through for a specific piece of information, something with does not occur in the case of text. The above characteristics point to the view that text is more appropriate for the in-depth investigation of the educational material.

Animation is a motivational way to present information visually. Studies (Najjar, 1996) have shown that information presented in this form of animation appears to be more effective for learners without prior knowledge or aptitude in the domain being learned. In contrast, learners with high domain knowledge have a rich source of prior knowledge that can be connected to the new knowledge. In this case, we could exploit the advantages of combined text and picture presentation techniques.

By using text labels, we facilitate the creation of a schema by giving a cue to learners to focus their attention on the most important points during a certain portion of a narration. The combination of animation and voice is effective because we use non-verbal and verbal information through two sensory modalities.

**The interface design**

The above research has important implications for the design and practice of multimedia instruction and has served as the basis for the particular user interface design we have adopted. On the one hand, an effort was made to be consistent with the findings of previous studies of working memory resource limits and cognitive load principles. On the other, we have tried to create a flexible interface that can accommodate diverse learning preferences. Flexibility refers to the learner's ability to select a different presentation style from the one initially recommended.

![Figure 1](image1.png)  ![Figure 2](image2.png)

*Figure 1* shows the default user interface displayed to the learner upon commencement of a typical instructional unit. The screen has been divided into three frames, one of which (the frame containing the text and static pictures) is not initially visible to the user. In trying to benefit from the processes of schema acquisition and chunking, we have taken care not to present learners with too many different pieces of information or ideas at the same time.

Each lesson has been divided into smaller chunks of related information called **instructional units**. The top frame contains the title of the lesson as well as links to associated chunks which comprise the particular lesson. The frame below the title contains the multimedia content including animation, explanatory text.
labels as well as the accompanying auditory information. The explanatory text labels have been incorporated into the animation, in accordance with the principle of spatial contiguity, ameliorating the ephemeral characteristic associated with voice. This frame also includes buttons for controlling the flow of the presentation. For example, the learner can pause and restart the animation and voice, change the volume of the voice, etc. Links to related chunks of information are also provided through the use of hot spots (temporal or spatial links) on the diagram. This navigational feature is supported by the SMIL language (discussed below).

The learner can reveal the hidden frame, as shown in Figure 2. This allows for simultaneous viewing of on-line text and animation with the option of listening to the corresponding narration.

![Figure 3](image)

Figure 3 portrays an alternative presentation mode. After the learner has viewed the presentation once (the recommended but not obligatory viewing method), the animation frame may be completely closed so that the learner may study the material in the form of text together with accompanying static pictures. This process is believed to:

- initially increase learner motivation and engagement during the first viewing stage when prior knowledge of the domain being learned is still nonexistent or at a considerable low level,
- increase learning outcomes during this first stage through a combination of animation and voice and,
- have a positive impact on understanding and retention of the presented material due to the use of text and static pictures in the second stage of its viewing.

**Smil and other implementation issues**

The implementation of the flexible user interface for the multimedia material is based mainly on the SMIL Language. Using SMIL, it is possible to define screen regions, associate media objects with the regions, and synchronize the appearance of media objects.

The main reasons that we selected SMIL were:

- it can integrate and co-ordinate many diverse types of multimedia information, synchronizing one or more animation files with voice and also text labels,
- we are able to define spatial and temporal links
- it can be considered as an "open", platform-independent technology based on W3C XML.

One of the fundamental problems encountered during the implementation of a multimedia, Web-based course is undoubtedly the limited bandwidth of the Internet. This is perhaps one of the main factors that justify the lack of extremely high-quality multimedia material. We use streaming technology to address this problem.

The product selected was RealServer created by Real Networks. The specific streaming technology makes use of the RTSP (Real Time Streaming Protocol) instead of the HTTP protocol. Figure 4 shows the architecture of the system. There are two servers: a Web server provides conventional html pages while a streaming media server supplies rich multimedia content to the learner.
Conclusion

Until recently on-line courses available to university students worldwide were in the form of text-based material with static pictures. Recent studies have provided evidence for the claim that multimedia has a positive effect on the learning process. However, we need to take into consideration many factors regarding the way learners receive, encode, store and process information. In addition, a central matter of concern seems to be the level of prior knowledge. Bearing this factor in mind, we have proposed a specific user interface design suitable for use through the Internet.

Social Work Education, Teaching Pedagogy, and Computer-Facilitated Instruction in the United States: Results from a National Survey

Debra Gohagan, MSW, Ph.D. Assistant Professor
Department of Social Work; Minnesota State University, Mankato
Mankato, Minnesota 56001 USA
Email: d.gohagan@mnsu.edu

Abstract: This paper reports results from a national survey in the United States of the pedagogical practices used by social work educators who use and social work educators who do not use computer-facilitated instruction (CFI). Respondents completed three instruments that measured teaching styles, teaching goals, and instructional strategies. The primary outcome is the preliminary identification of the pedagogical activities of educators who used and who did not use technology in their teaching activities. Results provide information about a.) Educators’ teaching styles, b.) Their perceptions of essential teaching goals, c.) The types of software applications currently used by these educators and the Level of CFI Use, d.) The effect of gender, rank, level of program in which the educator taught, and curriculum emphasis of the educator on the Level of CFI Use, and e.) The ability of teaching styles or teaching goals to predict CFI use.

Introduction

Students in today's colleges and universities face multiple learning demands in rapidly changing educational environments and educators are finding themselves moving quickly into uncharted territory to teach these students. Educators also face increased expectations to include computer-based technologies in their teaching activities. Roblyer, Edwards, and Havriluk (97) suggest that educators who lack a teaching model to support the integration of computer-based teaching into the curriculum frequently adopt computer-based teaching for reasons unrelated to sound teaching pedagogy. These reasons range from a desire to match their colleagues, enjoyment of a new activity, or because they ‘feel pressured’ to add some type of technology to their instructional strategy repertoire. The lack of an empirically supported educational technology model has led many educators to adopt a pragmatic or ‘add and stir’ approach. This often contributes to chaos, frustration and high levels of failure when using technology in the classroom. In addition, there is concern that educators who use computer-based instruction, because of the demands placed on them to learn, use, teach, and maintain the technology in their courses, may not place as much focus on the importance of teaching goals and course objectives as do their counterparts who do not use technology in their teaching and learning activities. The foundation for all teaching, with and without the use of computer-based technologies, should begin with an identifiable pedagogical teaching approach. In addition, this approach should support and inform educators about the use of technology for instruction, thus placing technology in the supporting role as an instructional strategy, not at the forefront of the pedagogical process (Fiorini, 89). In order to better prepared for the integration of computer-based education, educators must increase their understanding of the best teaching practices for using computer-facilitated instruction in their teaching activities.

Literature Review

There are many models and multiple definitions for educational technology which is defined as the systematic application of processes and procedures for the development of instructional strategies using a comprehensive array of technology-based systems (Astleitner & Leutner, 95; Bell-Gredler, 86; Gagne’, 77, 87; Herermann, 88; Jonassen, 1988; Laurillard, 93; Merriam & Brockett, 97; Reiser & Ely, 97; Roblyer, Edwards, & Havriluk, 97; Romiszowski, 88, Sheeley, 86). However, educators are untrained in the field of educational technology and many have minimal contact with professionals trained in instructional design. Preparing educators to use computer-based technologies in their teaching activities requires knowledge about how educators teach. This requires that all educators possess knowledge about their teaching styles, teaching goals, and have access to a wide range of instructional strategies. This information is crucial for both educators who do not use computer-facilitated instruction and educators who do use computer-facilitated instruction in their teaching. However, very little information is available about the impact of CFI on the educator’s teaching pedagogy; for is there is much information about the specific teaching practices used by educators who integrate technology into their teaching activities. Thus, there is a significant lack of information to guide educators in the systematic integration of CFI into the curriculum.

Five terms are relevant to this research project: pedagogy, teaching styles, teaching goals, instructional strategies, and computer-facilitated instruction (CFI). Knowles (75) has suggested that the body of theory and practice on which adult learning is based should be referred to as ‘andragogy’ (Bell-Gredler, 86; Merriam & Brockett, 97); thus, the use of the term ‘pedagogy’ to describe the teaching of adults in higher education may cause concern for readers. Pedagogy also describes the art and science of teaching, but its tradition is in the teaching of children. However, the term ‘pedagogy’ has long been associated with adult education. For this paper, the term pedagogy describes the process of teaching in higher education.

Teaching style is defined as the educator's patterns of beliefs, behaviors, and needs. These patterns when employed in the classroom can reflect the teaching pedagogy of an educator (Airasian, Guillecson, Hahn & Farland, 95; Axelrod, 80; Conti, 89; Grasha, 96; Singer, 96). Knowledge of their teaching style can make a difference in how educators organize their classroom, how they deal with learners, and how well their students do in learning the course content (Conti, 89). Two of the most widely recognized teaching pedagogies are referred to as traditional and constructivist teaching practices.

Teacher-centered instructional pedagogy is a well-known term for ‘traditional teaching pedagogy’ and is the most widely practiced teaching approach (Bell-Gredler, 86; Roblyer et al., 97). For this paper, the term teacher-centered pedagogy refers to this traditional teaching pedagogical approach. Many faculty in higher education are products of this teaching philosophy. This process is referred to metaphorically as the ‘empty vessel’ (Walz & Uematsu, 97) or the 'banking' approach (Freire, 93). The teacher-centered approach is a process in which the educator deposits knowledge into the student's head. As the recipients of this knowledge, students develop skills in receiving, filing, and storing this knowledge ‘deposit’. The sharing of information is usually one-way, that is, from teacher to student, with the student acting as the passive recipient of information.

The second teaching approach, 'constructivist teaching pedagogy', is classified frequently in the literature as student-centered teaching. In this approach, the teacher places the student at the center of her or his teaching activities. For this paper, the term student-centered pedagogy refers to the constructivist teaching pedagogy. The often-quoted phrase “sage on stage to guide on the side” is an apt description of the philosophical differences in teaching concepts represented by these two theoretical practices (King, 93). Student-centered pedagogy reflects a constructivist perspective that explains how people come to know their world (Bruner, 66; Freire, 93, 94, 96; Knowles, 72, 75). Knowles suggested that it was ‘no longer realistic’ to define the purpose of education as transmitting what is known in a world where the half-life of facts and skill may be ten years or less, half of what a person has acquired at the age of twenty may be obsolete by the time that person is 30 (p. 15). Student-centered educators place the student at the center of their education.
teaching and make use of available resources in the environment such as the student’s knowledge and prior ‘lived’ experiences (i.e. the student’s social, historical, personal, and community context). This teaching style benefits the student’s capabilities for critical and creative thinking, for solving problems and for making decisions, and for the development of reflection skills (Schon, 91), analytic skills, and communication skills. This approach is particularly useful when teaching students to become self-directing and self-initiating learners and is particularly effective with students in higher levels of learning programs such as junior, seniors, and graduate programs (Grasha, 96; Weston & Cranton, 86).

Teaching goals for all instruction are to develop and strengthen lower order and higher order thinking skills in the cognitive, affective, and behavioral or psychomotor domains of learning (Bell-Grederler, 86; Bloom, B. 56; Frayer, 97; Gagne, 77, 87; Grasha, 96; Heermann, 86; Jonassen, 88; Jonassen, et al., 93; Knowles, 75; Larrillard, 93; Merriam & Brockett, 97; Reigeluth & Curtis, 87; Roblyer et al., 97; Romiszowski, 88; Schon, 91; Singer, 96; Vayda & Bogo, 91; Wagner & Gagne, 88; Weston & Cranton, 86). Teaching goals, in this paper, refers to activities directed primarily to the development of thinking skills within the cognitive, affective, and psychomotor domains of learning.

Weston and Cranton (86) define instructional strategies as the teaching methods, medium, or materials used in instruction. Computer-facilitated instruction (CFI) describes the merging of instructional processes and procedures with computer-based technologies and support systems to form an instructional strategy. For this paper, the term computer-facilitated instruction describes the merging of instructional processes and procedures with computer-based technologies and support systems to form an instructional strategy. Thus, CFI, in this research, refers to the act of teaching with and through computer-based technology rather than the act of teaching without the use of technology.

Method

This research used an exploratory survey design to identify the pedagogical and educational technology practices of undergraduate and graduate social work educators in the United States. Participants completed 3 survey instruments. These instruments were placed in a packet which incorporated suggestions by Dillman (83) to increase mail response patterns and contained (a) a cover letter; (b) an informed consent form; (c) the Teaching Styles Inventory (TSI) (Grasha, 96); (d) the Teaching Goals Inventory (TGI) (Cross & Angelo, 93); and (d) the Instructional Strategies Survey (ISS). The ISS contained a checklist using software categories adapted from Roblyer, Edwards, & Havriluk (97) which were integrated with Taylor's (83) tool, tutor, tutee taxonomy: (1.) Tool—using technology as a tool to present access, store, or disseminate information for use in my instructional activities. (2.) Tutor—using technology to learn new information or as drill & practice to develop skills in using this information. (3.) Author [tutee]—using this technology to author or develop course related materials. It also reported sociodemographic variables. This research employed a two sample approach. Sample 1 was a national, proportionate, stratified random sample of undergraduate and graduate social work educators (N = 461) and who were mailed a pen and paper version of the packet. Sample 2 was a convenience sample of social work educators (N= 79) known to be interested in CFI and who completed an online version of the survey packet. Response rates of 45.55% (n = 210) for sample 1 and 64.56%, (n = 51) for sample 2 were achieved with an aggregated response rate of 48.33% (n = 261).

Data from both samples were aggregated for the statistical analysis and results were reported for the overall sample and for CFI Users and Non Users. Although the mail survey sample was a proportionate, stratified random sample, the electronic and online sample was a convenience sample for their interest in computer-facilitated instruction. Given a possible bias effect, all parametric tests were computed for the total sample and for each of the two samples. Results are reported for the total sample for each parametric test and findings for sample 1 and sample 2 are reported only when significance was found. See Table 1 for descriptive data for the total sample and Table 2 for descriptive data related to CFI Users and Non Users groups. Sums for the Levels of CFI used as instructional tools, tutorials, and to author (create) projects/materials can be found in Table 3. The results from ‘Levels of CFI Use’ were analyzed, using Multivariate Analysis of Variances (MANOVA) to determine the effect of (a.) gender and rank and (b.) the level of social work in which respondent taught and the area of the curriculum in which the respondents taught on the ‘Levels of CFI Use’. Table 4 contains reliability estimates for this administration of the TSI and TGI and Table 5 contains mean scores for the subscales for the TSI and TGI for CFI Users and Non Users. The extent to which respondent taught and the area of the curriculum in which the respondents taught on the ‘Levels of CFI Use’. Table 4 contains reliability estimates were analyzed, using Multivariate Analysis of Variances (MANOVA) to determine the effect of (a.) gender and rank and (b.) the level of social work in which respondent taught and the area of the curriculum in which the respondents taught on the ‘Levels of CFI Use’. Table 4 contains reliability estimates were analyzed, using Multivariate Analysis of Variances (MANOVA) to determine the effect of (a.) gender and rank and (b.) the level of social work in which respondent taught and the area of the curriculum in which the respondents taught on the ‘Levels of CFI Use’.

Results

Tables 1 summarize the sociodemographic data for the total sample of respondents. There were more respondents in public institutions, more female respondents, most were full time employees and most taught in combined (undergraduate and graduate programs). Respondents indicated that they averaged 13.81 years (SD 9.66; Range = 40.75) of teaching experience and their average age was 51.08 (SD 9.02; Range = 46).

Table 3 summarizes the data related to the Levels of CFI Use and the categories of CFI Use. Interestingly, more females than males were using technology for all Levels of CFI Use: tools (58.6%, n = 78); tutors (58.2%, n = 78); and authoring agents (57.9%, n = 31). However, males were much more likely to report higher rates of CFI Use for each user at all Levels of CFI Use: tools (M = 2.09, SD = 3.36), tutors (M = 4.45, SD = 3.91), and authoring agents (M = 2.04, SD = 3.3). Proportionately, more respondents in combined programs used technology as tools (67.2%, n = 90), tutors (66.7%, n = 90), and authoring agents (66.4%, n = 89). Slightly more undergraduate (bachelors) faculty (n = 24) reported using technology use as tools (17.9%), tutors (17.8%), and authors (17.9%) than did faculty in stand-alone graduate (masters) programs. Despite the fact that fewer respondents from graduate programs were using CFI, these respondents reported a higher rate of use of technology as tools (M = 6.55, SD = 2.8), as tutors (M = 4.48, SD = 3.19) and as authoring agents (M = 1.9, SD 2.64) per user than any other group of respondents.

The contribution that the gender, rank, level of program (undergraduate, undergraduate, combined) in which respondents taught, and the area of the curriculum in which respondents taught made to the Level of CFI Use was examined. Neither gender nor rank had any effect for CFI Users (p > .05). Overall, it would appear that educators were not significantly different in their Level of CFI Use by gender or by rank. For sample I (mail survey), however, gender was statistically significant but accounted for only 8.2% of the variance in the Level of CFI Use (F = 3.048, Eta squared = .082, p = .032). Significance was found for the difference in means between males (M = 6.22) and females, (M = 4.5) at the tool (M difference = 1.724, p = .01) and for males (M = 3.76) and females (M = 2.43) at the tutor (M difference = 1.327, p = .023) Level of CFI Use; thus, suggesting that gender could have an effect.
on CFI use at the tool and at the tutor level. While gender may have had an effect on the Level of CFI Use as tools and as tutors, its contribution to explaining this difference was minimal (8.2%). Thus, when data from sample 1 was examined as part of the overall analysis, the effect of gender on the Level of CFI Use was no longer significant.

Further, no significance was found for the effect of the level of social work educational program in which respondents taught and respondents’ primary curriculum teaching areas on Level of CFI Use. It would seem that, overall, educators do not differ for Level of CFI Use by level of social work educational program in which respondents taught nor in their primary curriculum content teaching areas. However, for sample 2, significance was found for the main effect of the level of social work educational program in which the respondents taught (F = 2.878, Eta squared = .798, p = .028) and it accounted for 79.8% of the variation found in the dependent variables (levels of CFI use). Significance was found at the tool level (M difference = 2.850, p = .049) for CFI Use suggesting that the differences between undergraduate (M = 8) and undergraduate and graduate (combined) programs (M = 10.85) was significant enough to affect CFI use as a tool. However, sample 2 is a very small, convenience sample (n = 51) and when analyzed as a part of all CFI Users, statistical significance is no longer found.

The reliability estimates for the TSI fell within an acceptable range (a = .54 to a = .69). The reliability estimates for the TGI also fell within an acceptable range (a = .78 to a = .97) (See Table 4). Mean scores for teaching styles of the total sample suggested that educators were more likely to employ ‘Expert’, ‘Facilitator’, and ‘Delegator’ teaching styles. Both CFI Users and Non Users reported higher mean scores for ‘Expert’, ‘Facilitator’, and ‘Delegator’ teaching styles (See Table 5). For the TSI, characteristics of the ‘Expert’ teaching style are more closely associated with teacher-centered teaching styles while ‘Facilitator’ and ‘Delegator’ teaching styles are more closely associated with student-centered teaching style. On the TGI, in general, Non Users reported higher means for all six goals than did CFI-Users. While all educators reported perceiving higher-order thinking skills as the most essential teaching goal, Non Users perceived this teaching goal as more essential than CFI Users.

Logistic regression analyses, using backwards-stepwise procedures, were computed to determine if teaching styles or teaching goals could predict CFI Use. After removing the teaching styles subscales, Expert (R = -.1299, p = .0053) and ‘Personal Model’ (R = -.1357, p = .0039) teaching styles appeared to be best predictors of CFI use, even though their contributions were minute (1.6%, 1.84%, respectively). However, there was evidence of an inverse relationship for the use of ‘Expert’ teaching styles and CFI Use: the more likely the educator was to report ‘Expert’ teaching style, the less likely s/he was to be a CFI User. In the final analysis, the results of the logistic regression indicated that teaching styles could classify CFI Users (62.14%) more accurately than Non Users; however, this classification was not substantially better than random chance.

For teaching goals, ‘Higher order thinking skills’ was the only significant subscale of the six teaching goals (R = -1375, p = .0013) and accounted for 3.02% of the variance. This relationship was also found to be inverse; that is, the higher a respondent scored on this subscale for teaching goals, the less likely that person was to use CFI. The results indicated that teaching goals could classify CFI Users (79.73%) more accurately than Non Users (49.40%). In particular, higher order thinking skills as a teaching goal was most likely to contribute to this classification, except that it was more likely to predict Non Users; but this classification was not substantially better than random chance either.

Discussion

The results of this research while certainly not definitive due to its exploratory nature, found trends in the data that offers potential areas for discussion and future research. Of particular interest are the data related to (a) gender and CFI Use, (b) levels of program in which respondents taught, and (c) the results from the teaching styles and teaching goals and CFI Use. Not only were females well represented in the overall sample, but also more females reported CFI use in their teaching activities than did their male counterparts. However, even though fewer males were CFI Users, they were using more technology per user than females. These results suggest that future research efforts should examine gender equity in relationship to teaching and technology use in higher education. First, it is possible that female social work educators find themselves with less time to learn and integrate technology into their teaching practices, as do many of their peers who report increased stress in managing multiple roles related to career and family (Magner, D., September 13, 96). In addition, there is much history in higher education in the United States for institutional patterns of gender biases as well as programmatic biases in technology support and equipment towards the less scientific programs in higher education may further complicate this situation. A final factor to consider related to gender equity and technology use may be related to curriculum assignments. For example, the assumption in the field is that educators who teach in the practice related courses are least likely to be CFI users. Females often comprise the majority of faculties in social work education who teach in the direct practice course content. Male faculty are more likely to teach in the research and policy curriculum content areas of helping professions. Finally, gender-equity research related questions should address similarities and differences for female educators and their patterns of CFI Use across multiple programs in higher education. Do the patterns found in this research hold true for female educators in other disciplines? There is a perception that females experience higher levels of anxiety and attitudes that are more negative towards the use of technology. Thus, if the numbers of
female faculty are increasing in higher education and, if it is true that females are more likely to experience technology anxiety and perhaps even technology phobia, then it is conceivable that women would be slower to adopt technology in their teaching activities. Furthermore, female educators who do adopt technology are perhaps more likely to use technology simply as a tool, rather than to proceed to higher levels of CFI use.

Another result that merits discussion is that more faculty in combined (undergraduate and graduate) social work programs reported CFI use than in any other level of social work program while graduate programs were least likely to use technology. However, this same graduate faculty also reported the highest number of instances of CFI use per faculty member. First, research-based institutions, which are more likely to house combined social work programs, are more likely to have increased access to technology-related resources, thus increasing the likelihood of CFI use at all levels (Green, 59). Stand-alone undergraduate and graduate programs are often less likely to be housed in colleges and universities with these types of institutional resources. In addition, faculty in graduate programs tend to have decreased teaching loads with increased emphasis on research productivity rather than classroom instruction. This frees graduate faculty to develop and use more technology than their peers teaching exclusively in undergraduate programs.

It should not be surprising that mean scores for 'Expert,' 'Facilitator' and 'Delegator' teaching styles were significantly higher in conjunction with 'Expert' and 'Formal Authority' teaching styles. The 'Expert' teaching style characteristics are consistent with teacher-centered teaching philosophy while the 'Facilitator' and 'Delegator' teaching styles characteristics reflect a more student-centered teaching philosophy. One would expect that social work educators, as well as educators in other helping professions, are more likely to use student-centered teaching styles, thereby empowering students to experience learning at a personal level in the classroom. These educators have to train their graduates to work collaboratively, while balancing the need to think for themselves and use critical thinking and problem-solving skills in their professional practice activities. In many of these helping professions, their graduates need the skills to make decisions that affect the safety and well being of their future clients.

The data from this research are also similar to the research data for teaching styles in the general population of educators. The trend in higher education has been for educators, most often male tenured faculty, to report the use of teacher-centered teaching styles and for female educators to report the use of student-centered teaching styles (Grasha, 94, 96; Magner, D., September 13, 96). In this research, male educators tended to report higher mean scores for teacher-centered teaching styles while females were more likely to report higher mean scores for student-centered teaching styles. Grasha (96) also found that faculty at the rank of professor tended to employ 'Expert' and 'Formal Authority' teaching styles more often than did faculty at other ranks. This finding should not be surprising and is, potentially, a reflection of the historically larger number of males in the higher education at the rank of professor in the United States and the age of this faculty.

Further, the findings from this research suggest that teaching styles do not significantly influence CFI Use or Non Use and, overall, the decision to use CFI or not to use CFI is unrelated to teaching styles with one exception. Social work educators who scored high on 'Expert' were less likely to be CFI Users. This finding is consistent with the information available for educators who do not use CFI. Educators who report or use the 'Expert' teaching style (teacher-centered) are interested in 'depositing knowledge' into students' minds; are more likely to use lectures as their primary instructional strategy; and may often teach to the lower order thinking skills required for learning in introductory courses. Thus, it is possible that they will not use CFI except as a tool to present information (e.g., using PowerPoint to deliver lectures for large classes) (Grasha, 96; Magner, D., September 13, 96).

For teaching goals, Non Users perceived all six teaching goals as more essential than did their counterparts. However, more importantly, Non Users perceived 'higher-order thinking skill's' to be the most important teaching goal regardless of gender, rank, social work program, or curriculum emphasis. In fact, 'higher-order thinking skills' made the most significant contribution to the prediction Non Use. Again, the finding that all educators, regardless of CFI Use or Non Use, perceived higher-order thinking skills to be the most essential teaching goal should not surprise the reader given the need to provide our graduates in helping professions, such as social work, with the problem-solving and thinking skills to make life and death decisions. However, what does it suggest when CFI Users perceive all teaching goals, including 'higher-order thinking skills', to be less important than Non Users? This finding gives credence to the public belief and professional concern that educators often add technology to their curriculum for reasons unrelated to sound pedagogical purposes. If, as this research suggests, CFI Users perceive higher order thinking skills and other teaching goals to be less important than do Non Users, what does this reflect? Institutional issues related to resource allocation and support?, The educator's difficulty in balancing the learning outcomes and integration requirements for CFI use?, The inability of technology to be a conduit for effective teaching and learning?

Implications for faculty curriculum activities, faculty development, faculty training, and research are apparent. First, information about teaching styles of educators can be an important consideration in assigning primary curriculum content areas for faculty and in understanding issues related to student evaluations of teacher effectiveness. For example, if an educator who uses primarily a 'Facilitator' or 'Delegator' (student-centered) teaching style is assigned to teach introductory classes, large classes or research classes, a mismatch of teaching styles may occur which could negatively impact student learning and student perceptions of teacher effectiveness. Further, alternative structures for curriculum development for should be explored. For example, educators who primarily use CFI in conjunction with an 'Expert' teaching style and who's goals are to develop lower order thinking skills may expect primarily computer literacy as a basic technology skill for students. However, educators who use student-centered teaching styles and integrate CFI as tutors or authoring agents in their courses may require more of their students in terms of computer competency. Thus, programs may need to rethink their current practices to course assignments and credits. For example, while educators who use CFI as a tool with an 'Expert' teaching style may be able to adapt to a traditional three-credit hour approach, but educators, employing CFI as a tutor or authoring agent and a student-centered teaching style, may benefit by offering courses for four credit hours, thereby providing the additional time needed by students to develop skill and competency in technology use. What is important to note is that one teaching style does not necessarily fit all teachers, nor all curriculums, nor all students.

Certainly, faculty development activities should offer opportunities to strengthen and reward the use of pedagogically sound teaching practices with and without use of CFI. Doctoral programs, which train the next generation of educators, should ensure that their graduates have a foundation in teaching pedagogy and in CFI best practices. In addition, training programs should provide opportunities and resources to move beyond the use of technology as a tool to more advanced and pedagogically based integration of technology in teaching and learning activities. One of the largest barriers to technology use for faculty is the lack of institutional rewards and recognitions. Institutions can ease this burden by examining their tenure and promotion policies and by enlarging their vision to include the development, integration, and research of CFI use.

Summary

The primary outcome of this research project is the preliminary identification of the pedagogical activities currently employed by educators who use and who do not use technology in their teaching activities. Certainly, the results of this research should provide an impetus for further discussion, use, and research on pedagogical issues and educational technology. It seems while educators in general have been slow to engage in dialogue (written or verbal) about teaching from a pedagogical perspective, educators do have consistent ideas about which teaching practices are most essential. Framing CFI use as an instructional strategy in the curriculum provides educators with a reference point for knowing when and what types of technology to use to achieve course-specific teaching outcomes. Further, the findings from this research suggest that teaching styles do not significantly influence CFI Use or Non Use and, overall, the decision to use CFI or not to use CFI is unrelated to teaching styles with one exception. Social work educators who scored high on 'Expert' were less likely to be CFI Users. This finding is consistent with the information available for educators who do not use CFI. Educators who report or use the 'Expert' teaching style (teacher-centered) are interested in 'depositing knowledge' into students' minds; are more likely to use lectures as their primary instructional strategy; and may often teach to the lower order thinking skills required for learning in introductory courses. Thus, it is possible that they will not use CFI except as a tool to present information (e.g., using PowerPoint to deliver lectures for large classes) (Grasha, 96; Magner, D., September 13, 96).

For teaching goals, Non Users perceived all six teaching goals as more essential than did their counterparts. However, more importantly, Non Users perceived 'higher-order thinking skill's' to be the most important teaching goal regardless of gender, rank, social work program, or curriculum emphasis. In fact, 'higher-order thinking skills' made the most significant contribution to the prediction Non Use. Again, the finding that all educators, regardless of CFI Use or Non Use, perceived higher-order thinking skills to be the most essential teaching goal should not surprise the reader given the need to provide our graduates in helping professions, such as social work, with the problem-solving and thinking skills to make life and death decisions. However, what does it suggest when CFI Users perceive all teaching goals, including 'higher-order thinking skills', to be less important than Non Users? This finding gives credence to the public belief and professional concern that educators often add technology to their curriculum for reasons unrelated to sound pedagogical purposes. If, as this research suggests, CFI Users perceive higher order thinking skills and other teaching goals to be less important than do Non Users, what does this reflect? Institutional issues related to resource allocation and support?, The educator's difficulty in balancing the learning outcomes and integration requirements for CFI use?, The inability of technology to be a conduit for effective teaching and learning?

Implications for faculty curriculum activities, faculty development, faculty training, and research are apparent. First, information about teaching styles of educators can be an important consideration in assigning primary curriculum content areas for faculty and in understanding issues related to student evaluations of teacher effectiveness. For example, if an educator who uses primarily a 'Facilitator' or 'Delegator' (student-centered) teaching style is assigned to teach introductory classes, large classes or research classes, a mismatch of teaching styles may occur which could negatively impact student learning and student perceptions of teacher effectiveness. Further, alternative structures for curriculum development for should be explored. For example, educators who primarily use CFI in conjunction with an 'Expert' teaching style and who's goals are to develop lower order thinking skills may expect primarily computer literacy as a basic technology skill for students. However, educators who use student-centered teaching styles and integrate CFI as tutors or authoring agents in their courses may require more of their students in terms of computer competency. Thus, programs may need to rethink their current practices to course assignments and credits. For example, while educators who use CFI as a tool with an 'Expert' teaching style may be able to adapt to a traditional three-credit hour approach, but educators, employing CFI as a tutor or authoring agent and a student-centered teaching style, may benefit by offering courses for four credit hours, thereby providing the additional time needed by students to develop skill and competency in technology use. What is important to note is that one teaching style does not necessarily fit all teachers, nor all curriculums, nor all students.

Certainly, faculty development activities should offer opportunities to strengthen and reward the use of pedagogically sound teaching practices with and without use of CFI. Doctoral programs, which train the next generation of educators, should ensure that their graduates have a foundation in teaching pedagogy and in CFI best practices. In addition, training programs should provide opportunities and resources to move beyond the use of technology as a tool to more advanced and pedagogically based integration of technology in teaching and learning activities. One of the largest barriers to technology use for faculty is the lack of institutional rewards and recognitions. Institutions can ease this burden by examining their tenure and promotion policies and by enlarging their vision to include the development, integration, and research of CFI use.

Summary

The primary outcome of this research project is the preliminary identification of the pedagogical activities currently employed by educators who use and who do not use technology in their teaching activities. Certainly, the results of this research should provide an impetus for further discussion, use, and research on pedagogical issues and educational technology. It seems while educators in general have been slow to engage in dialogue (written or verbal) about teaching from a pedagogical perspective, educators do have consistent ideas about which teaching practices are most essential. Framing CFI use as an instructional strategy in the curriculum provides educators with a reference point for knowing when and what types of technology to use to achieve course-specific learning outcomes. Purposefully matching CFI congruencies with teaching styles and teaching goals can improve the practice of teaching with technology. In addition to the benefits for educators, students will benefit as technology literacy and competency skills are addressed through a ‘planned infusion’ for CFI use; thus decreasing the frustration and confusion often associated with an ‘add and stir’ approach. The responsible integration of technology into today's teaching activities can provide tomorrow's graduates with the skills to shape the future of technology use in practice.

Webering a Brazilian University: A successful case of change

Pericles Gomes, Pontificial Universidade Catolica do Parana, Brazil; Sonia Vermelho, Pontificial Universidade Catolica do Parana, Brazil;

At the Pontifical Universidade Catolica do Parana information technology and distributed learning were considered strategic goals since 1998. This did not mean at all that human resources and technology were made available to reach these goals. The ongoing mentality in many institutions in developing countries is that physical buildings (rather than skilled people combined with proper information technology) is the still the best kind of investment. The paradox to solve, then, is the following: Even though distributed and virtual learning are perceived as strategic and inevitable, higher administration decision-makers insist on traditional ways of investing. How then the transition or CHANGE will ever occur?

EUREKA, a Virtual Collaborative Environment isn't any better or worse than most existing similar. Two factors, however, made a great difference on its adoption by the University: the software was free for faculty and departments and any needed changes and improvements could be implemented quickly, since the development team are faculty and students of the university.

More than 500 virtual classrooms were opened and 15,000 people did take the chance and tried this new idea. The process was made simple: Any faculty could try the concept: all that was necessary was a phone call, a visit or an email! A virtual learning space would be instantly made available to the professor. Preliminary data shows that areas such as Civil Engineering, Economy and Administration were the fastest to try and truly adopt these new ideas. It also shows that some areas such as Teacher Education and Architecture did open quite a few virtual rooms but did not fully understand the potential that IT could offer.

Abstract: The design of user interfaces adapted to the cognitive, perceptive or motor features of certain kind of users implies the development of different versions of the system, which is frequently too much expensive to appeal the software industry. In this paper we describe GADEA, a general framework for the development of applications whose interface is able to adapt itself to the specific features of its users, observing them by mean of intelligent agents. This framework is not only easy to use by programmers but flexible enough to guarantee a universal access to users with different kind of physical disabilities.

Introduction

Traditional design of user centered interfaces is based on the identification and definition of the target audience of an application. Some design guidelines include the identification and understanding of the target audience as the most important first steps to start designing a product (Apple Computer Inc. 1992; Microsoft Inc. 1998]. The idea is that once the target audience –also known as typical user– is understood, then an interface that effectively satisfies their needs can be designed.

However, the search for the typical user of an application is opposite to the individuality and diversity that makes up some much of our identity. If the design of interaction mechanisms aims to make interfaces accessible and appealing to all users, it cannot rely on abstract generalization (Reynolds 1997). For applications, targeted to an extremely wide range of users for example, there is no way to determine a typical user without falling in dangerous misconceptions. Is it possible to describe the typical user of Microsoft Office? Is it possible to identify the typical user of a generic web portal such as Lycos, Terra or Netscape visited by thousands of users everyday? For some
authors such as Schneiderman, (1997) the answer is definitively no as there is no average user, either compromises must be made or multiple versions of a system must be created.

Following this approach, we have developed GADEA, a general framework for the development of low level adaptive applications. This system is able to create multiple versions of an application dynamically, depending on the individual features of the user’s cognitive, perceptive and motor system. GADEA provides a universal access to the interface by mean of automatic adaptation mechanisms, specially designed for different degrees of physical, visual or hearing disability.

GADEA as an Expert System

GADEA is based on the classic expert system paradigm, simulating the behavior of a human agent who establishes an interactive discourse with other human through a multimodal communication channel Wahlster (1991). The agent will be able to select the most suitable interaction style, depending on the unique cognitive and perceptive features of its counterpart, adapting the appearance, contents, locations etc. of the interaction mechanism employed along the interactive discourse.

![Diagram](Image)

Figure 1: Modified design pattern for the GADEA’s expert system module.

An slight modification of the classic pattern for the design of an expert system has been used by GADEA to include an external Knowledge Acquisition module (Fig. 1). This module is able to obtain new facts and rules from the user, including them in the knowledge base, which was previously fulfilled with the facts and rules provided by an expert in HCI. The facts provided by the user include knowledge about the specific low-level features of its cognitive, perceptive and motor system. For example, the age and sex of the user, the user’s perception system accuracy (tactile, visual, auditory, etc.), the user’s motor system preciseness (for tasks such as key pressing, mouse dragging, mouse pointing, etc.), the reaction and decision time of the user’s cognitive system, etc.

GADEA’s Modules

GADEA is based on three modules: CodeX, ANTS and DEVA (Fig. 2). CodeX represents the interface between GADEA and the application, converting the user interaction requests in calls to specific methods inside of the application domain’s object space. At execution time, the application binary code (Java class files) is automatically inspected by CodeX, who looks for any kind of user processes and data requests, who are then sent to DEVA.

DEVA is the GADEA’s proper expert system. It converts the application and user data request into an adaptive interactive discourse. Based on the general knowledge provided by the HCI expert and by the specific knowledge stored in the user model, it uses its fuzzy inference engine to evaluate and to select the best interactive discourse available.

Finally, the ANTS module, employs different kinds of automatic remote agents to obtain information about the state of the specific user’s features, which are stored in the appropriate user model entry.
Conclusions

The automatic code exploring system provided by GADEA allows an easy adaptation of the low-level aspects of a user interface with little or almost no programming effort. The information captured by ANTS along every interactive discourse allows DEVA to adapt the user interface of any application to the current state of the user’s cognitive, perceptive and motor system, which tends to fluctuate over time.

Currently, we are working on the design of a low-level adaptive Internet browser based entirely on GADEA’s technology, able to be used with the same utility by sighted and blind users, as well as users with physical disabilities.

Abstract: We have developed, tested and assessed a novel educational system for teaching electronics. To implement this system we have developed an "Interactive Lab" application program based on Visual Basic and PSpice. The system was first used to teach the Electronics 2 course at SUNY New Paltz in the spring 1997 semester with much success. It has since been in continual use to teach both Electronics 1 and 2.

INTRODUCTION

The challenges in teaching electronics are to educate the students in the following aspects.
- **Theoretical.** Grasp the fundamental concepts and learn how to apply them to the analysis and design of electronic circuits.
- **Simulation.** Learn how to write simulation code using a powerful circuit simulator such as PSpice.
- **Experimentation.** Verify experimentally theoretical knowledge by assembling and troubleshooting the circuit under study.

The task described above is a formidable one, considering the limited time duration of the theoretical and laboratory classes. Many years ago, educators did not have to include simulation, but by today’s standards, a student who does not know circuit simulation will not be able to become a competent engineer. On the other hand, some modern educational systems (Mosterman 1996) exclude the experimentation step and utilize virtual laboratories purely based on software. However, in our opinion, this approach defeats the main purpose of designing and analyzing a circuit, which is to construct the circuit and be able to make it perform close to theoretical expectations.

Therefore, in our view, laboratory experimentation is too valuable to be eliminated. Since the total laboratory time is fixed and reducing the time allocated to experimentation is not desirable, efficient use of the time spent on theory and simulation is essential. Despite the time constraints imposed for theory and simulation, their emphasis needs to be retained. We believe that a computer-assisted application will enhance a student’s theoretical understanding and allow for rapidly producing simulation results within the time constraints. For many years, we have worked on developing and improving such a computer-assisted interactive educational system (González & Mandado 1998) (González 1997).

The remainder of the paper is organized as follows: Section 2 establishes our educational objectives and strategy, Section 3 presents a functional description of the Interactive Lab application program, Section 4 discusses the system's educational performance, and Section 5 summarizes the paper's conclusions.
EDUCATIONAL OBJECTIVES AND STRATEGY

Our primary objective is to replace the student's traditional passive role in class with an active one. Our strategy to fulfill this objective is illustrated in Figure 1.

![Figure 1: Diagram of developed educational system.](image)

In this system, the professor provides the theoretical explanation of the circuit under consideration in the usual manner. Then the student proceeds to perform calculations on paper to analyze the circuit or to meet the required design specifications. After that, the student interacts with the Interactive Lab application.

The following list of goals was considered in designing Interactive Lab.

- Provide students with an insight into the operation of a circuit through simulation.
- Provide an interface that is intuitive and easy to use and that does not require any programming.
- Provide a method that allows students to perform circuit simulation without requiring any previous knowledge of a simulation program such as PSpice.

After several years in development, Interactive Lab was created as a computer-assisted interactive application program to meet the objectives above. The application, which was written in Microsoft Visual Basic for the Microsoft Windows environment, provides an easy-to-use graphical interface to the simulation program PSpice. This idea of interfacing with PSpice has been extended to other environments such as HTML (Valdés, et al. 2000) (Salaverria, et al. 2000), extending a multimedia application into a hypermedia one. Interactive Lab is written in a modular fashion that presents several choices of circuit simulations that operate in a similar manner. This modularity also allows the program to be easily extended to include additional circuit simulations.

Other than a basic familiarity with the Microsoft Windows environment, no other special computer knowledge is needed. The student can then focus on analysis and design. The application only requires the student to input appropriate values for the analysis or design of a circuit. Time need not be spent learning PSpice commands and syntax.

While at the same time not requiring a student to know how to use PSpice, the student becomes familiar with it because the application reveals the underlying PSpice code used for simulation. This gradual introduction to PSpice should make its formal introduction to PSpice less challenging, as the student is already familiar with some of its commands and capabilities.

FUNCTIONAL DESCRIPTION OF INTERACTIVE LAB

Interactive Lab presents two types of laboratories: theoretical and practical. For the theoretical laboratories, the student is expected to analyze a given circuit and determine some theoretical characteristics, such as gain, cut-off frequency, input resistance, etc. For the practical laboratories, a student is required to calculate component values of a given particular to meet given design specifications. To illustrate the system's functionality, let us consider the practical laboratory "Saw-tooth" which deals with the design of a saw-tooth waveform generator. This laboratory is selected from the Interactive Lab menu as shown in Figure 2.
After selecting the saw-tooth practical laboratory, the student is presented with a window as shown in Figure 3. This window contains a circuit schematic, circuit data and design specification. In addition, there are text boxes for the student to input the values resulting from his/her design.

The student transfers the calculated values to the text boxes one at a time. If a value entered is correct, the student will be allowed to access the next text box. However, entering an incorrect value, that is a value outside a specified range, produces a message box “value out of range.” The student will not be allowed to access subsequent text boxes until a suitable value has been entered. We call this feature “Knowledge as a Password.” This feature forces the student to review the calculations and thereby prevents a clueless student from obtaining simulation outputs that would be completely meaningless to him/her.

Another useful feature is hints, which assists the student in reviewing their calculations. When the student places the cursor over the corresponding component in the circuit diagram, a hint is given. This hint provides useful information that the student can use to calculate the component value.

Once all the correct values have been entered, the student will be able to select the button Start Lab. Upon selecting this button, the application generates PSpice code (a .cir file) created from a template that is completed with the values that the student has entered. The application next invokes PSpice to execute that code to perform the simulation. The student is then given access to the PSpice environment to examine the simulation results. Utilizing the PSpice “Probe” window the student can view a graphical presentation of the simulation output as shown in Figure 4. This allows the student to see whether the simulation has performed according to theoretical expectations.
The student can also select the **View Code** button. This opens a window that shows the PSpice code used to perform the simulations as shown in Figure 5. By relating this code to the circuit schematic and the simulation output, the student is able to progressively become familiar with PSpice commands and syntax.

**RESULTS**

Evaluating educational technology is a difficult task that constitutes a research topic by itself (Belfer 2000). Our evaluation approach although primitive is sufficient to point out the advantages of our system. Table 1 shows the average grade obtained by students taking the courses Electronics 1 (E1) and Electronics 2 (E2) at the Department of Electrical and Computer Engineering at SUNY New Paltz. The first author of this paper was the professor in all of these courses. This helps to ensure that the level of difficulty and grading criteria was consistent. To see if implementing the system had a positive effect on the students understanding of electronics we examined the overall grade of the students. We looked at 10 students who had taken both E1 in the fall of 1994 and E2 in the spring of 1995. These students showed an average grade decrease from E1 to E2 of less than 1 point. ($\bar{x} = -0.73, s = 4.96$). The system was first implemented in the spring 1997 semester in E2. Therefore, in order to study the effects of the system, we looked at the 8 students who had taken both E1 in the fall of 1996 and E2 in the spring of 1997. These students showed an average grade increase from E1 to E2 of about 5 points. ($\bar{x} = +4.96, s = 8.47$). We concluded that these improved student grades (one-tailed $t(6)=1.82, p < 0.05$) were due to the use of the system.
While the method used to assess the systems impact is somewhat rudimentary, it substantiates the opinion of the authors that this system provides an incremental benefit to the teaching of electronics. It was also felt that the students who benefited the most were the ones who made a stronger effort to grasp the fundamental concepts.

Table 1: Average course grades for students of the first author in Electronics 1 (E1) and Electronics 2 (E2). The system was first implemented in the spring 1997 semester.

CONCLUSIONS

We have developed an educational interactive system that increases a student's active participation in class. This system has been satisfactorily tested and shown to improve understanding as reflected in student grades.

Interactive Lab has many beneficial features. The “View Code” feature enables the student to learn PSpice progressively and efficiently. The incorporation of the “Knowledge as a Password” feature requires the student to develop an expectation for the result of the simulation. This reinforces the concept that simulation by itself cannot replace mental effort.

Abstract Higher education in the UK, as in many other countries, is experiencing a period of rapid change, not only because of advances in technology but also because the constructivist paradigm (understood in its broadest sense) has begun to have an impact upon the teaching context in virtually every department of every institution. Change on this sort of scale brings with it many opportunities for renewal and improvement, but also provokes stresses, strains and conflicts that could hinder or even derail the process, so negating potential benefits. By providing a synoptic view of the current state of play in H.E. at the national level, this paper will highlight some of the key issues that need to be addressed if UK institutions are to be successful in integrating information and communication technologies (ICT) into their mainstream provision.

In order to make sense of what is happening in the UK at the moment it might be useful to consider the model of tertiary education proposed by John Biggs (Biggs 1993) just before the technological and educational changes referred to above really began to gather momentum. Drawing upon the work of Ludwig von Bertalanffy (von Bertalanffy 1971) in general system theory, Biggs sees tertiary education as an open system with its own ecology:

"In the ecology of a system, a change to any one component will, depending on the state of equilibrium already achieved, either effect change throughout and thereby create a new equilibrium and hence a new system, or the changed component will be absorbed, the system reverting to the status quo."

The model he proposes consists of several nested micro-systems wherein "each subsystem attempts a steady state of equilibrium not only internally between its own components, but also with other systems, the immediately superordinate one in particular". Visually, the model is represented like this: (Fig.1)
At the time when Biggs' article was written, the key relationship, in macro terms, was still the one between the teaching context and the surrounding departmental structures, even though Biggs readily admitted that the balance of forces tends to favour the larger sub-systems:

"It is true that classrooms can affect departments, departments faculties, and faculties institutions, but it is more likely that the lines of force will go from the larger to affect the smaller system."

But what we have seen since 1994 has changed the situation quite radically.

Despite the abundance of published material on the implementation of ICT, little mention has been made, within the UK context, of the significance of the impact of the Quality Assurance Agency for Higher Education (QAA) but this body has played a major role in defining the educational context in which ICT implementation is being debated. Over the last seven years, first the Higher Education Funding Council for England (HEFCE) and then QAA have been conducting a national review of the quality of teaching, learning and assessment across all academic subjects throughout England and Northern Ireland (alongside a very similar process in Scotland and Wales). Its methods are based on teaching observation, an evaluation of the quality of student work and scrutiny of the systems in place to monitor standards in teaching and learning (e.g. student evaluations, external examiner reports, etc). The significance of these subject reviews for Higher Education should not be underestimated. Firstly, the review process itself is very demanding and resource intensive, particularly for the subject staff under review, and it has come under fire from the Committee of Vice-Chancellors and Principals (CVCP) for this very reason. Secondly, as is made clear in HEFCE's consultation document “Learning and teaching: strategy and funding proposals” (see HEFCE consultation document 98/40 at http://www.hefce.ac.uk/Pub/default.asp) HEFCE's strategy will be to “encourage and reward high quality teaching and learning” and institutions are advised that the results of QAA subject review should be a central element in their bids to the Council for additional funding from the Teaching Quality Enhancement Fund set up by HEFCE. In other words, success at QAA review will impact upon further improvements in funding for Teaching Learning and Assessment (TLA) and universities are very conscious of this.

From the rather narrow perspective of ICT implementation, the impact of QAA subject review has had important consequences, mostly positive. On the positive side, it has succeeded in focusing attention on the quality of students' learning experience and the structures that support it and has thus strengthened the position of those arguing that the role of ICT is to support and enhance student learning. Whereas previously the champions of technology based learning were perhaps seen as peripheral to the main work of departments, their enthusiasm and commitment have become positive assets in the climate engendered by the advent of QAA subject review. Making the change to a more constructivist, student-centred approach, if only in order to meet the standards set by QAA, has greatly helped the case for ICT based learning. On the negative side, however, subject review absorbs large amounts of staff time and, by focusing attention on the effectiveness of routine administrative matters, it might be seen as a distraction, taking away time and resources from other developments.

What then are the criteria applied with respect to TLA at subject review? Its key features are that the review teams, made up of subject experts with a non-specialist review chair, investigate the strengths and weaknesses of provision within the following framework:

- Providers are expected to have a TLA strategy.
- The programme of work should develop and assess appropriately (in relation to the subject’s aims and objectives): knowledge and understanding, key (transferable) skills, analytical skills, subject-specific skills, including practical / professional skills.
- Strengths and weaknesses in teaching are to be identified with regard to clarity of learning objectives, quality of materials, student engagement and participation.
- Clear and appropriate learning outcomes are expected and learning should be effectively facilitated in terms of workloads, guidance, supervision and resources.
- Assessment should match learning outcomes, be clear and transparent and promote student
learning.

In terms of what goes on in classrooms, this is a rather coarse-grained approach and there are some significant gaps (there is no specific mention of student-student collaboration for example) but at least it has the merit of concentrating attention on aspects of the learning experience that are central to the constructivist approach: student engagement, the relationship between learning and assessment and the cultivation of understanding as well as the acquisition of skills and knowledge. Clearly, the approach to teaching and learning implicit in this framework is far removed from the "transmission" model which is among the favourite targets of some educational technologists seeking to promote computer-based alternatives to "traditional" or "formal" classroom teaching. But what is perhaps more significant in these developments is that classroom teaching is now embedded in a much wider system of which the QAA is a key component.

To return for a moment to the Biggs model of the educational ecosystem. "When any aspect of the learning/teaching context is the focus of attention," he writes, "the micro-system of which that is a part, and the adjacent systems with which it may interact, need to be taken into account". This is precisely the perspective adopted by the QAA when it expressly links the TLA aspect to the other five aspects, namely:

- Curriculum Design, Content and Organization
- Student Progression and Achievement
- Student Support and Guidance
- Learning Resources
- Quality Management and Enhancement

For example, a subject's overall TLA strategy is linked to curriculum design, content and organization and learning resources. The teaching component of that strategy is linked to resources and staff development, and student learning is linked to student support and guidance and resources. So, largely as a result of the QAA methodology, what has changed in the UK, in terms of Biggs' model, is that the departmental structures that are relevant to TLA are now strongly conditioned by institutional bureaucracy (in the form of Universities' quality procedures) and these in turn are strongly conditioned by political pressures in the form not only of QAA subject review but also of QAA institutional audit which scrutinizes quality management and enhancement at institutional level. In Biggs' terms, what we are currently witnessing is the re-balancing of the entire system to create, in effect, a new system. It is no longer primarily the components in the next micro-system in the hierarchy (departmental structures) which are having the greatest effect on the teaching context. The most important pressures are coming from the periphery, from HEFCE and QAA, and are being transmitted directly to departmental level by the institutions.

The QAA's overview reports (at http://www.qaa.ac.uk/revrep/subjectrev/overviews.htm) indicate that a process of change is certainly underway. Reviewers' conclusions do much to dispel the myth that the bulk of TLA in UK universities can still be characterized as "traditional" or "formal" in nature. It was perhaps only to be expected that Communication and Media Studies should be praised for "a wide range of well-considered teaching and learning approaches" which include "lectures, seminars, workshops, demonstrations, tutorials, peer group learning, production projects, small group and team work, film screenings, case studies and critical reviews." What may be a little more surprising to some is that engineering subjects, which in the past have been perceived to fail to develop deep approaches to student learning (see Ramsden 1992), now appear, in the case of the better providers at least, to be embracing change:

"Providers achieving the highest grade generally deploy a wide range of teaching and learning methods, including CAL and use of the Internet. In the best examples, the use of directed and independent learning is well integrated with taught elements."

(Electrical and Electronic Engineering)

The reports also show that specialist reviewers are aware of the importance of IT and the Internet for TLA and that implementation varies greatly both within and between subjects. Comments made in the Sociology overview will strike a chord with a great many university teachers in the UK:

"Where there are close links with the central services and staff are committed to IT, the
associated software, databases and support are usually available. In such institutions, students were keen and competent in the use of E-mail and the Internet and made full use of the existing resources. However, considerable improvement could be made in the development and application of IT skills."

As this comment implies, the use of IT and, latterly, ICT, in teaching and learning, has in the past largely been a function of the enthusiasm and commitment of small groups of staff within particular subjects, but there is now evidence, in the form of universities' strategies for teaching and learning, that more coherent policies are being formulated with regard to ICT based learning. An analysis of these strategies reveals that most institutions:

- are still in the planning and target setting phase,
- have adopted a gradualist approach,
- are committed to a model where the centre (through teaching and learning units/centres and IT services) supports departmental initiatives,
- are not planning to use ICT to integrate teaching and learning with other student support systems,
- are using a centrally controlled competitive bidding strategy as a way of promoting ICT materials development,
- do not regard materials-based learning (whether ICT based or not) as a viable replacement for classroom contact.

So there are hopeful signs that UK universities may succeed in adapting their teaching and learning to the new technological realities. On the one hand, the technologies themselves are becoming more robust and can provide the performance and functionality that are required. On the other, it seems likely that the continuing influence of QAA in shaping institutions' policies in terms of quality control will have a positive impact on the institutionalization of ICT based learning. QAA has already published a Code of Practice which covers the main elements of "a comprehensive quality assurance process for higher education" (see http://www.qaa.ac.uk/public/COP/codesofpractice.htm). One element of this Code of Practice, published in January 1999 in draft form, consists of guidelines for distance learning (see http://www.qaa.ac.uk/public/dIg/contents.htm) which is seen as having four dimensions, two of them directly relevant to ICT based learning used to support students whether on, or off, campus:

- "Materials-based learning ... refers to all the learning resource materials made available by the programme provider".
- "Learning supported from the providing institution remotely from the student. This dimension of a system of distance learning refers to defined support and specified components of teaching provided remotely for individual distant students by a tutor from the providing institution."

The purpose of the guidelines is "the assurance of quality of provision and the security of academic standards of programmes of study and awards" and they take the form of a set of precepts defined as "those key matters which an institution might reasonably be expected to be able to demonstrate that it is addressing effectively through its own relevant quality assurance mechanisms".

As far as the implementation and development of ICT based learning is concerned, it would appear that institutions will be expected to conform to a set of standards whose scope is the whole institution, not just the subject or department. The standards cover six main areas:

1. System design
2. Programme design, approval and review
3. The management of programme delivery
4. Student development and support
5. Student communication and representation
6. Student assessment

and the approach is rightly systemic:

"The strength of the chain of system and programme design, implementation, delivery, support, student communication and assessment ... lies in its weakest link."
Of the 23 precepts, spread across the six aspects listed above, four in particular are worth emphasizing in this context (the full list is at http://www.qaa.ac.uk/public/dig/append2.htm).

Precept 3 (System design)
"Prior to offering programmes of study by distance learning, an institution should explicitly design and test its system for administering and teaching students at a distance..."
The guidelines supporting this precept make specific reference to designing and preparing learning materials, identifying appropriate media, testing lines of communication and field testing materials.

Precept 5 (System design)
"A providing institution’s plans for offering programmes of study by distance learning should be financially underwritten for the full period during which students will be studying on them and at a level that safeguards the quality and standards to which the institution is committed."
The guidelines ask for “realistic projections” and “financial policies” with regard to the expenditure and income associated with the distance learning system.

Precept 6 (Programme design, approval and review)
The academic standard of the awards “will be demonstrably comparable with those of awards delivered by the institution in other ways and consistent with any benchmark information recognized within the UK.”

Precept 13 (The management of programme delivery)
“The providing institution is also responsible for ensuring that each distance learning programme of study is delivered in a manner that provides, in practice, a learning opportunity which gives students a fair and reasonable chance of achieving the academic standards required for successful completion.”
The guidelines stress the need for training and staff development for administrative as well as academic staff and also the need for effective communication between all involved in the provision.

Satisfying the quality requirements in regard to system design in a purely technological sense implies the use of a single, institution-wide system, professionally supported. Administratively speaking, the system will have to embrace a range of functions much wider than the programme of study, and this means the integration of administrative functions within the same technological framework (e.g. student registration, student records, support and guidance and so on). The purchase and maintenance of an integrated system is only a small part of what needs to be costed. As far as materials production is concerned, staff development in instructional design will become essential, even if certain elements of the production process are devolved to a specialist centre, and the training needs of administrative staff cannot be ignored. All of this will be expensive and will need careful central planning even if ICT based learning for on-campus students is the institution’s main objective, rather than the full-scale distance learning option.

The precept on academic standards embodies an important principle as far as ICT based learning is concerned. Provided that the quality of the learning experience is demonstrably equivalent to face-to-face delivery, the switch to ICT based learning can be justified simply in terms of efficiency gains for students (more flexible study times and reductions in travel and accommodation costs, for example) and for the institution (provision of classrooms and levels of classroom usage).

In terms of the management of the programme, the relevant precepts and guidelines stress the issue of students’ prior skills, knowledge and experience, the need for interactive materials and the importance of effective communications. There are a number of issues here. First of all, a full introduction for all new students to the on-line learning and support system is a necessity and also, incidentally, a natural target for a materials based approach, perhaps in the form of a CD-ROM which simulates the on-line system. Secondly, students should be involved in the progressive development of the whole system, not just the learning materials and the design of the interface, and they have to be listened to. Finally, it is not enough simply to set up administrative structures; what matters is the flow of information between administrators, teachers and students. Course management issues need to be addressed rapidly and effectively and, as the guidelines point out, administrative inefficiencies could easily undermine the whole structure.
“... poor general management or an inadequate administrative infrastructure can negate otherwise good practice in the provision of distance learning.”

If a home-based student is able to save significant amounts of time by engaging with ICT, (s)he will not want to have to spend time in a bureaucratic paper-chase around the University’s offices trying to get administrative issues resolved.

The growth of ICT in recent times has opened up channels of communication and access to information which have changed higher education irrevocably. What ICT cannot do, however, is to change the way in which students come to understand the process of learning itself. The work that William Perry conducted at Harvard some thirty years ago (Ramsden 1988), is still relevant to teachers in higher education today. Perry, like others in the phenomenographic tradition, is interested in the stages of learning which students go through rather than their individual differences, “academic ability, special talents or disabilities” and he describes a process whereby students progress from thinking that “authorities know, and if we work hard, read every word, and learn Right Answers, all will be well”, to the point where they realize that:

“This is how life will be. I must be wholehearted while tentative, fight for my values yet respect others, believe my deepest values right yet be ready to learn. I see that I shall be retracing this whole journey over and over – but, I hope, more wisely.” (page 146-7)

and finally accept the full relativity of knowledge. We have all of us watched this type of process unfold over the duration of our students’ careers at University, and helping them to make these changes is perhaps one of the best ways of capturing what it is that teachers in higher education really do. By working together with colleagues, as well as with outside agencies such as those described above, and by exploiting the power of ICT, we can make the process by which students gain their intellectual autonomy less arduous and less frustrating, but, in the final analysis, it is the depth and quality of the communication between teacher and student within the learning context which counts.

How to implement WBT into higher education

Anna Grabowska, Technical Univ. of Gdansk, Poland

Two examples of WBT courses for university students are presented. The first one is TeleCAD (Teleworkers Training for CAD Systems' Users) and is oriented to teaching basic drawing skills in AutoCAD program and current technology and methodology of teleworking. The second one is MDEC (Multimedia Distance English Courses for Polish Users in Legal, Banking and Finance, Science and Technology, and Safety Training Sectors with Elements of European Union Regulations and Standards). Both projects are based on advanced ICT technology (multimedia, WWW). TeleCAD and MDEC projects were developed under Leonardo Da Vinci programme (1998-2001). Pilot courses for international groups were delivered. Monitoring systems and evaluation procedures online were developed. DE project management support system and online dissemination activities were implemented. Details of Leonardo da Vinci projects are presented at the URL: http://www.dec.pg.gda.pl/dec/index.phtml?id=projekty_leo_en
ABSTRACT: At a time when learning is finally recognized as a critical component to an organization's success, manufacturing industries are facing an overwhelming challenge to increase efficiency, effectiveness, and competitiveness. Organizations are becoming more centralized, more global, and more competitive, and the traditional classroom model is rapidly losing its value and appeal. Educators and performance improvement practitioners are looking to technology as a tool for effectively growing and maintaining a skilled workforce. Increasingly, companies are using distributed learning technologies to provide timely, economical, and effective learning solutions.

Introduction

Learning has become the most important part of everyone's job. The continuously changing skill and knowledge requirements of workers create a continuous need for learning. Today's organizations require learning to be delivered faster, cheaper, and more effectively. Organizations are reexamining the entire learning process - when, how, and where learning occurs.

The Cost of Training

Most training initiatives in the manufacturing world are classroom driven, led by trainers who were not educated as educators. They deliver content that is often irrelevant, to passive and disinterested learners, on an overtime basis requiring 12 hour shifts, with little or no effective measurements [1]. The costs associated with traditional methods of training are impeding our ability to compete. In 1998, the largest U.S. companies spent over $70 billion on employee training [2]. Half of this was on travel costs, wages, and benefits for employees while in training. A substantial portion was spent on inefficient or outmoded approaches to delivering workforce education.

Perhaps the greatest single issue that impacts classroom learning is time. Most training delivered by instructors is delivered at the pace of the slowest learner in the class. At the same time, companies are applying pressure to limit the amount of time employees spend in the classroom. This dilemma, coupled with an increased demand for training, creates a need for new and innovative methods to develop and deliver more effective training.

The Challenge

Today's technology is reshaping our workplace. As job skills are becoming obsolete, tomorrow's jobs will require a whole new set of worker skills. Not only will the skills of low-skill level employees need to be strengthened, but also employees in jobs requiring high skill levels will require continuous retraining. It is only through company-wide learning systems that organizations can survive. Companies today have little choice but to become learning organizations.

The Learning Organization

The learning organization empowers people to learn as they work. It uses technology to collect, store, organize, customize, and transfer vast amounts of knowledge. The learning organization provides training that is just in time - when it's needed, where it's needed, and how it's needed. The learning organization has four distinct characteristics:

1. It is performance-based; tied to business objectives.
2. It emphasizes skills, and how people process information.
3. It assumes learning is part of work and not separate from work.
4. It incorporates distributed learning applications.
The challenge of learning faster than one's competitors is being met through distributed learning technologies, which include the intranet, internet, computer-based training, and electronic performance support systems (EPSS).

**What is Distributed Learning?**

Distributed learning is a system and process that optimizes learning and productivity. It considers both presentation (how information is presented to learners) and distribution (how information is delivered to learners) using a combination of technology; learning methodologies, on-line collaboration, and instructor facilitation to achieve applied learning results. Results that are not possible from traditional education are achieved in a flexible, anytime/anywhere fashion.

Whether the training is provided by CD-ROM, the Internet, or the company's intranet, distributed learning provides the power to speed up learning and make knowledge more accessible and economical. Today's corporations are using distributed learning applications to train and retrain both their centrally located and globally dispersed workforces.

In a survey of 700 training professionals conducted in February by the Masie Center, 80% of respondents said that they expect the demand for web-based training to increase in their organizations this year. By contrast, 75% said they expect more demand for web-based training, and more that 60% said they expect the same for classroom-based training [3]. Corporations are using distributed learning applications to address the following needs:

- Job skills technical training and retraining
- Management development and leadership
- Employee orientation
- Customer education
- Government compliance training
- New product and policy information
- Product sales training
- Sales force automation training

**Synchronous and Asynchronous Learning**

Distributed learning applications can be either synchronous or asynchronous, and generally include a combination of both. The power and flexibility of distributed learning technologies make them suitable for meeting a wide range of education and training needs.

**Synchronous learning occurs in real time.** It creates a virtual classroom environment with no time delay. For example, an instructor located in Atlanta may conduct a class on Programmable Logic Controllers with students in 20 or more different locations and countries. The instructor can share applications with the students, ask and answer questions, and let a student take control of the screen or simulation software. All that is required of the students is a browser and an audio hook-up, accomplished by a telephone line. Responses to learner interactions and tests are uploaded to a central location for scoring.

Researchers have reported that there is no significant difference in the achievement of students in systematically designed virtual learning environments and the achievement of those in systematically designed face-to-face environments, based on standard performance measures [4]. And with shorter contact times, supplemented with asynchronous technologies, synchronous learning yields superior results.

Synchronous classroom learning has been widely recognized as an effective means of teaching and learning with benefits to the learners and the organization. For example, in 1989 AT&T obtained cost figures for courses delivered via distance learning technologies such as satellite up-link and down-link technologies. The courses were systematically designed using criterion-referenced methods note 1 (the author was involved in both designing and evaluating the impact of these courses). During that year, 3,650 students attended distance delivered sessions of the courses. Savings in airfare, lodging, and daily expenses resulted in a total cost savings for the 3,650 students of $1,825,000. These figures do not include downtime while traveling.

**Asynchronous learning allows participants to learn anytime, anywhere.** For instance, students may download and print articles, flowcharts, P&ID drawings, electrical diagrams, or policies and procedures from the company's intranet. Or they may download a computer-based course on Lotus notes from the company intranet. They may take the course later from their seat on a plane. Or a student may elect to take a course on Hazard Communication directly on the Internet from home, at a time that is convenient. When the student takes the test or completes an assignment or exercise, the responses are uploaded to a central location for scoring.
Development and Assessment of a Graduate Level Statistics Course Online

Candace L. Gunnarsson
Department of Economics and Human Resources
Xavier University
Cincinnati, Ohio 45242
United States
gunnar@xavier.xu.edu

Abstract: This paper is a report on the development and assessment of a graduate level statistics course taught in an online setting. Students taking the newly developed statistics course online were compared to students taking the course in a traditional classroom. Achievement along with three mediating variables was investigated. The three mediating variables included: prior computer experience, prior math knowledge and experience, and attitude toward the subject of statistics. The participants were forty-two graduate students in their first year of the MBA program. Students’ attitudes toward learning in an online environment were favorable. Differences were found in their attitude toward the subject of statistics and prior computer experience; however, no causal relationship in achievement was detected. Students who learned in an online environment achieved comparably to students learning in a traditional classroom.

Introduction

Web based instruction is becoming a convenient and popular means to higher education. Course offerings utilizing web-based instruction are multiplying at unprecedented rates. Although there are many examples of web-based courses, it is now clear that much more is involved than just presenting the components of a conventional course via the Internet (Kahn, 1997). Lectures are not improved by posting them on a web site and discussions do not automatically happen when students are connected to a mailing list or computer bulletin board.

As with any new technology, often the draw is to the technology itself instead of the technology as a tool to enhance learning. When a course is delivered in an online environment, old roles between student and teacher and student and subject become redefined and new roles emerge. Issues involving equity of access, the needs of the learner, and the role of teacher as tour guide and site facilitator emerge. With any college course, the mode of delivery and the design of the course content can make the difference between a learning experience that is truly excellent to an experience that is considered fair or even poor. This holds true for online learning as well. As online educators, it is not enough to utilize new technology, the technology must be accessible to all students and it must enhance learning.

The Statistics Course

Instructivist and constructivist models were utilized to design a Managerial Statistics course for graduate students pursuing their Masters of Business Administration Degree. The course covered principles and applications of descriptive and inferential statistics and was designed to familiarize students with basic techniques for understanding, organizing, describing and computing research data. The course was taught using two different instructional settings. One section of the course was taught once a week in a traditional classroom. The other section was taught in an online environment where a virtual classroom was established utilizing the LearningSpace option of the computer package, Lotus Notes.

Each week using LearningSpace, the online students viewed a slideshow, submitted weekly homework assignments for a grade and participated in online discussions. Students were also responsible for three collaborative learning assignments. The traditional class met once a week for 2.5 hours. The same PowerPoint slideshow viewed by the online class was shown in the traditional classroom setting. Class discussion and problem solving took place during scheduled class time. Traditional classroom students sat for the same three examinations did the same
individual homework problems and were given the same three collaborative learning projects as their online cohorts. Furthermore, both courses had the same instructor.

The Study

A holistic approach incorporating both qualitative and quantitative procedures was utilized in this study. Students' attitudes toward learning statistics in an online environment were analyzed using a qualitative approach whereby, questionnaires were distributed and individual interviews were conducted at the end of the course. All data retrieved from the questionnaires were stored, categorized and coded. Individual interviews were built into analytic files, which were sorted using a simple coding scheme. The purpose of this analysis was to assess attitude and the amount of relevant interaction, not just content.

To examine achievement, a quantitative approach was taken. First, an exploratory analysis was conducted whereby, classroom setting (online versus traditional) was analyzed on a number of key variables, which included: prior computer experience, prior math knowledge and/or experience and attitude toward the subject of statistics. To measure attitude, Schau, Dauphinee, & Del Vecchio's (1993) Attitude Toward Statistics test was utilized. Having substantive knowledge in the field of statistics, prior math knowledge and/or experience and attitude toward the subject of statistics are known predictors of success. Second, these key variables were used as predictor variables along with classroom setting in a multiple regression analysis in an attempt to uncover any relationships that may have existed among the predictor variables and achievement.

Findings

Although these groups were self-selected, when the online class was compared to the traditional class, there were no apparent differences in demographics, prior math knowledge/experience and the feeling of value toward the subject of statistics. However, there were significant differences on two variables. These two variables were students' affect toward statistics and their prior computer experience. The online class had a higher average positive affect toward statistics and had more computer experience than the traditional class. The affect score was statistically significant at the .05 level and computer experience was significant at the .10 level.

The significance of affect is consistent with the literature that discusses variables that attribute to success in statistics. This result is to be expected. Student's who are feeling the least bit anxious or who have lower affect toward the subject matter would be dubious to trying an online environment. Furthermore, students with less computer experience could find the online environment threatening. Given the differences in affect and prior computer experience, there is no statistically significant causal relationship between class setting and achievement.

When examining the online students' attitudes toward learning managerial statistics in an online environment, overall students' attitudes appeared to be favorable. However, although traditional barriers to a statistics class online did not appear operational, i.e., lack of computer experience and math anxiety, there was a small subset of the students that did not enjoy learning in an online environment and clearly felt cheated from the experience.

Conclusions

It appears from the quantitative analysis that students who learned in an online environment achieved comparably to students learning in a traditional classroom. From the qualitative analysis, for the majority of the students, online learning is convenient and effective. However, there is a small group of students who need face-to-face interaction with their instructor and their peers to feel that learning is taking place. For these students there is no substitute to the traditional classroom setting. Therefore, as online educators, we need to be mindful of a technologically driven pedagogy that could have the potential for leaving students feeling disenfranchised in a virtual learning environment.

Abstract: An evaluation of distributed computer supported co-operative work (CSCW) in a project workshop for students utilising Internet-based videoconference technology, is presented. The workshop has been evaluated in light of relevant theoretical communication factors and according to feedback from the students based on questionnaire data. Conclusions are presented as guidelines for instructors.

Introduction

Computer-supported co-operative work (CSCW) is concerned with how both large and small groups of people can co-operate using computer technology. This paper describes our experience with students participating in a "Project workshop" in a distributed CSCW setting. The aim of the project workshop was to create distributed project groups that enable students from Switzerland and Germany to co-operate as naturally as possible in order to complete assignments related to different aspects of human-computer interaction. Further, the students should be given the possibility to learn, use and explore the actual state-of-the-art in web-based communication. The choice of Internet-based CSCW tools was motivated by the intention to increase participation through the employment of easily accessible technology. Because of the high technology diffusion in Germany and Switzerland, the participants could run their activities for the project workshop both at the university and at home. The distance between the two institutions ensured that the students had to use the infrastructure to communicate and to co-operate.

The project workshop

The project workshop (URL in References) started in 1998 as a co-operation between the University of Karlsruhe (TH), Germany, Institute of Applied Informatics and Formal Methods (AIFB) and the Swiss Federal Institute of Technology (ETHZ), Institute of Hygiene and Applied Physiology (IHA). Students form project groups for co-operation during one semester. Each project group consists of between 2 and 5 students and involves students from both sites. The students' motivation for participation is either to follow a self-chosen course to gain study credit (AIFB), or as a means to perform an obligatory assignment (IHA).

The workshop enhanced the acquisition of experience with the technology in four ways. First, the students used web-based technology to communicate. Second, Web-based technology is employed to present the end results. Third, the assignments are related to problems using the technology; and fourth, the assignments could be designed as Web pages.

At the beginning of the semester the project workshop starts with an introductory course in the use of the technology (at each site). Then, the students "meet" in a videoconference and discuss the assignments in detail. The group formation is performed online in the first videoconference. The teams exchange names and addresses, and leave the videoconference with the task to contact the other members of their group and to stay regularly in contact to work on the assignment with the available tools. The students at each site are supervised independently, the general schedule is to meet the administrator once per week during the semester.
Infrastructure

We optimised the technology to fit our needs, taking into account that we still have to accept inferior communication quality. To support and augment co-operative group work, special software, so-called GroupWare, is needed. We combined several standard systems to form our GroupWare. The communication-and workspace offered the following functions:

- Audio and video communication between the team members.
- Sharing of workspaces (information and application sharing, co-ordination of shared objects and tools)
- Organisation of the work process, e.g. project management, workflow management and administration of project data, e.g. document management.

To communicate, to share applications and to present results, we used Microsoft Netmeeting© (point to point) with its video conferencing capabilities, white board, chat board, screen capture, file transfer function and application sharing. For co-ordination of our work and for administration of documents, we used BSCW© (Basic Support for Co-operative Work). The BSCW software is cross platform compatible, and supports synchronous (planning and organisation of virtual meetings) and asynchronous (e.g. shared workspace for document transfer) for interactive co-operation. The students have access to BSCW from the project-server via a web-Browser. Presentations and project reviews were presented with Microsoft PowerPoint or as for Web-presentations. In addition the project homepage, e-mail and telephone extended the information and communication possibilities.

The hardware configuration was optimised for our purposes, a powerful computer is essential in order to gain good audio and video transmission quality. At home the students could run videoconferences with lower quality with a minimal equipment, basically with a web-cam and a video-capture-board + microphone. The videoconference equipment at the university is shown in Figure 1 and consisted of:

- 1 PC-workstation (300 MHz, 5 GB Hard Disc, 128 MB RAM, 2 video capture boards, 1 duplex soundboard);
- 1 high resolution colour screen;
- 1 high resolution colour beamer;
- 1 cordless mouse and 1 cordless keyboard;
- 2 VHS-video cameras (for the face of the current speaker and one for the audience);
- 2 microphones (one fixed and one cordless).
- A telephone is available in the conference room, which has been very useful, whenever we had difficulties due to PC-breakdowns or Internet overload.

Figure 1: The video-conferencing room

Theory

In a CSCW setting many questions about how to support real communication and co-operation are still open. One of the most present questions of the Ed-Media'2000 conference was how to enhance co-operation in a distributed context (Ed-Media, 2000). In order to approach an answer it is important to understand the basic elements of communication and co-operation. When working at distance with technical tools to enhance the communication, the tools take on an important function in supporting communication, task management and co-operation.

Communication in the CSCW context

Computer mediated human communication is less "rich" than direct human communication. The challenge not yet achieved with current videoconference technology is to support the different modes of communication we know from real face to face meetings. Communication aspects relevant for CSCW are those directly affecting human task related information exchange. With videoconferencing the communication mode, e.g. verbal and visual information becomes important (Guttormsen & Voorhorst, 1999). The content of the communication can be expressed differently as verbal and visual information. Table 1 shows different modes and contents of communication. In the following we will look at different aspects of communication. The
problem for distributed communication is how to enable optimal communication under conditions in which the natural float of information is impaired.

Table 1: Different content and modes of communication

The Communication Studies Group (CSG) considers person-orientation to be the core-category in understanding communication mediated by teleconferencing. Short et al. (1976) from the CSG distinguish between person oriented and non-person oriented communication categories. These categories are based on Bales analysis of communication, which took place in simulated meetings (Bales 1955). From these experiments Bales elaborated four main categories: positive reactions and negative reactions (person-oriented), problem-solving attempts and questions (non-person oriented). Later Bales offered a more differentiated, three dimensional, view on the person-oriented factor: (1) Dominance vs. Submissiveness, (2) Friendliness vs. Unfriendliness, (3) Acceptance vs. Non-acceptance of Authority (Bales 1999).

Also the non-person-oriented category has been analysed. Thorngren distinguishes between three kinds of communication in business (Thorngren, 1972). Programmed communication activities are routine, repetitive and standardised, e.g. giving or receiving orders, or making sales or purchases. The involved people usually are well acquainted with one another. In contrast, orientation communication activities are novel, unstructured and complex, e.g. developing ideas for new products. Between these two extremes are planning activities. They result in the development and realisation of alternatives suggested by the orientation activities. Other theorists use similar categories: Ansoff (1965) distinguishes between strategic, administrative and operating activities, or Simon's (1960) concepts of intelligence, design and choice.

Co-operation

Successful co-operation pre-imposes that the involved people can establish satisfying communication on the different levels mentioned above. Besides communication between people, CSCW also involve sharing of information and of task-space, co-ordination, organisation and decision-making (Ohlson et al., 1993, Macaulay, 1995). In a co-operation context an important distinction can be drawn between the person space and the task space. The shared task space (Buxton 1992), or action space (Harrison et al. 1996) can be distinguished from the space where people are physically or virtually present, i.e. a place (Harrison et al. 1996), or a person space (Buxton 1992). When people share the same person space and the same task space communication and the exchange of information are facilitated naturally. The flow and quality of several modes of communication (e.g. speech, gestures, expressions, text and graphics) arrange itself almost automatically. Co-operation pre-imposes that people share the task space. Distributed CSCW implies that the task space is being shared, but only a part of the information concerning the person space. Reducing the information from the person space has impact on the content of the communication. Hence, a rich CSCW context should offer communication tools that also support person-orientated information.

Evaluation

We evaluated the project workshop according to tool use and satisfaction by the termination of the spring workshop 2000. The intention was not to perform a quantitative statistical analysis, but rather to get an impression of the most successful communication channels. Data was collected by means of a questionnaire.
addressing the frequency and related satisfaction of tool-use. The return rate of the questionnaires was 85% (n=7) from Zurich and 75% from Karlsruhe (n=9). Table 2 shows an overview over tool use and satisfaction.

</tbody>
</table>

Table 2: Overview over tool use and satisfaction

The table shows the mean number of times a tool was used over the semester. Satisfaction is the mean of ratings on a scale from 1 to 7, where 1 was excellent, 4 neutral and 7 too bad. Prior experience in distributed CSCW: mean = 5.2 on a seven-point scale where 1 was much and 7 was none. 25% of the students performed the videoconferences at home. General satisfaction: 76.9% of the students would recommend a study colleague to participate in the project workshop, 23.1% did not know. The students were also asked to express their experience with the workshop. The feedback could be sorted in three categories: positive and negative reactions related to co-operation. On the positive side the experience with the new technology is prevalent. The reactions show that videoconferencing was given high importance:

- "This is THE chance to work with new media and communication possibilities as well as applications. The world talks about videoconferencing, the project workshop is the best way to learn about the technology in a playful way, about what is possible already, and how it functions."
- "It is a great experience to work with videoconferencing although it didn't always work."

The negative feedback was mostly related to technological factors:

- "The quality of the videoconferences was often bad."
- "Good experience but hard to communicate. Technology is still a steep threshold."

Much of the feedback was related to the new co-operation context:

- "There are lot of possibilities in videoconferencing and Internet, but I think it will take some time before communication in co-operative teams is as effective as a face-to-face meeting. It needs a lot of learning on both sides."
- "The co-operation across such a long distance as well as locally repeatedly, presented new challenges. It was very interesting because it was different from traditional student assignments. The co-operation between the universities should be continued and even extended."

Discussion

The most used tools were e-mails, BSCW, e-mails with attachment and videoconferencing, in this order. The use of telephone was low in comparison to e-mails. Some students reported that telephone calls were used to spontaneously address the need for a group session. E-mails accomplished asynchronous communication needs. Distribution of information with e-mail is more time independent than telephone calls. The frequent use of e-mails with attachment shows that the BSCW tool did not reach full acceptance among the students. Some students also spontaneously reported during the semester that they preferred e-mails for the transmission of smaller files. However, the co-operation often implicated the generation of large files and applications, which only could be shared and distributed effectively with the BSCW tool.

In spite of the unstable video-quality, the students still preferred to run videoconferences at an average rate of almost once per week during the semester. In light of our observations and their comments the reason is most likely to be first, that they were inclined to want to experience this technology and second, that it did offer the only way of demonstrating their on-going developments: the feature program sharing enabled on-line and synchronous co-operation sessions. Further, the accessibility of the videoconference equipment must account for the relatively low usage. Due to the fact that the videoconference-room was used for many activities in the institutes, the students could not access it spontaneously. This certainly resulted in less use of videoconferences as a means to communicate for some, while other compensated for this by installing the necessary equipment at home. Videoconferencing from at home impairs the video/audio quality more than at the university because of slower transfer via modem. The reported complaints may also reflect this.

Person-orientation seemed not to be the major reason for the use of the videoconferencing tool. The videoconferences did not offer enough information about all the modes of communication to satisfactorily support person orientation. In line with recent research we found that the video image was less important for the
perceived communication quality than the voice. Good video-quality, without satisfying voice-quality can not enhance communication. Some students even reported that they closed the video-window in order to focus on the shared application. The voice quality during videoconferencing reached telephone quality, consequently the verbal information mode was feasible.

In general, our CSCW setting made co-operation possible. All of the groups produced accepted assignments, some of the assignments were outstanding with a quality and volume not to be expected from single person effort. The reported dissatisfaction concerning co-operation may reflect poor person-oriented interaction. Obviously, the students noticed that distributed co-operation did influence their collaboration style. Most clearly this was expressed as loss of personal contact.

General discussion

We recognise a general positive effect of the creation of distributed co-operation teams. The combination of two universities/countries results in an extended information transfer and larger information space. The students take advantage of the extended pool of knowledge resources and experience.

We found the assignments to have a key function in stimulating the distributed co-operation. Earlier experience taught us that the assignment is an important key to real co-operation. When we first started, the assignments comprised theoretical work and literature reviews. These tasks did not really require the students to work in a close co-operation. The result was rather that they adopted a kind of parallel work style. Co-operation was only initiated by the end of the semester in order to co-ordinate the presentation. We predicted that more direct interaction throughout the semester could be achieved by giving assignments with more components of design, also integrating work with a graphical representation and the development of interactive demonstrations related to the topics. To reinforce this development we required the students to present their work as Web pages, which also were accepted as a replacement of a printed report. As results of these actions, we have noticed a remarkable improvement in use of the tools and active co-operation during the entire semester.

The intention to keep up with new technological development was a major motivation for this workshop, both for the students as well as for the organisers. Our distributed co-operation concept invoked a pioneer spirit, which positively influenced the groups and also implied more tolerance towards the technological deficits. The project workshop enables the students to practice and experience new communication and co-operation methods. This serves as preparation for the increasingly computerised environment they may be expected to meet when leaving the university to work.

Some problems were, however, obvious. First, high motivation can not completely make up for the immature videoconference technology. The video frame-rate for Internet based videoconferences does not guarantee fluent movement, and the audio quality when the load on the net is high, makes long conferences too exhausting. Other practical consequences were related to the fact that two different institutions co-operated. The semester schedules between the two universities were not always identical. Consequently, the project workshop could not always start at the beginning of the semester for both sites, and also not end according to the semester brake for both sites. Last but not least, the student’s motivation for participation differed between the two universities because of different credit systems. This resulted in an unequal pool of students at the two sites. Some students expressed that a more equal distribution of students from each site would have been better.

Practical implications

Our experience is formulated as a set of guidelines for communication, co-operation and technology use. Further guidelines for how to optimise communication, co-operation and tool use CSCW in a student setting are offered by (Bordeau et. al., 2000; Mcculay, 1995).

Utilise assignments that support co-operation. The assignments have an important role in initiating real co-operation. Theoretical work does not encourage co-operation to the same extent as assignments that incorporate practical design (e.g. interface design, web publishing).

Ensure that the assignment is interesting for the team. Fascination for the use of new technology is not enough for a close co-operation. A good team is motivated by the possible outcome of the teamwork.

Let the team members modify the assignment to fit their qualifications and interests. Present the initial assignments as a concept idea with a rough strategy for how to proceed. This is a means to increase the motivation in the team and to support autonomous team organisation. Students often interpret the assignments differently to the organisers, hence use this as an opportunity to start a discussion about the content of the assignment. Setting the final aim of the assignment is a part of the learning process in the team.
Reinforce the technology employment in the assignments. Reinforce multiple ways to employ the technology, if possible. (In our case the students developed solutions to various software ergonomics problems presenting both the theoretical work and eventual applications in web pages.)

Make the technology accessible. If at all possible, offer the teams portable videoconference equipment, to be used at computers available within the university or at home.

Employ user friendly software. Students have an educated preference for good software. When alternatives exist, they will automatically use the tools that are easily available and easy to use. (The BSCW-tool in our context, in spite of its powerful potential, may not have come to its full employment for the co-operation management, because of the easier alternative with e-mails.)

Offer multiple communication and co-operation channels. People have different preferred means of communication and different means for co-operation. If a variety of tools are available everybody should be able to find their preferred method.

Practice correct videoconference behaviour and presentation techniques. Videoconferencing is for most students a new experience, and even under good conditions it demands a new behaviour. A small communication guide for an Internet-based-setting, is given at the Project Workshop Web page (URL in ref. list). We have repeatedly observed that it requires some hours of practice until the students adopt these rules, and before they do, the videoconference sessions are often dominated by communication relating to misunderstandings.

Further research

In spite of the existence of different conferencing system satisfaction and usability with such systems still have to be improved. The remaining problems are caused by low usabilit and low platform compatibility, related both to technology and applications. Due to such problems the use of videoconferencing in a CSCW setting is still not widespread. Important questions to be addressed in this context are:

- How do communication and co-operation tools influence communication content and modes?
- How can different contents of communication be achieved in a distributed CSCW context, and to which extent?
- How can we optimise the employment of existing tools to enable a rich communication?

Abstract: The need for novel approaches to attract high school students to information technology-related careers is huge. At the same time, very few high school teachers have been trained to teach these topics. In collaboration with high school teachers in the rarely populated district of North Karelia, Finland, the department of Computer Science of the local university created a program to teach university-level Computer Science studies for high school students. The goal was to provide a flexible and reliable learning environment for the students to ensure a meaningful way of learning. The educational design is based on a Candle model: the students get help to their authentic learning needs from the web-based environment, in terms of exercises, learning tools, and feedback. However, the learning material consists of real textbooks. Preliminary results indicate that the scheme chosen has motivated the students to carry on their learning efforts.

1 Introduction

In Finland, the Ministry of Education is funding a three-year project to establish the Virtual University of Finland, during years 2001-2003. One of the particular goals in the project is to develop new methods for science education. The three universities in eastern Finland, University of Joensuu, University of Kuopio, and Lappeenranta University of Technology, work jointly in the virtual university project. One of the concrete objectives is to create a web-based learning environment in introductory Computer Science, intended for high school students. From the research perspective of educational technology and Computer Science education, this task is a particularly challenging one. We have aimed at designing a solid model for building the environment.

The project is called Virtual Certificate, indicating that high school students can take 15 credits of Computer Science studies in one and a half year via the Internet. In the Finnish system, each credit equals 40 hours of studying; 160 credits are required for the Master’s degree. Thus, after passing all the 15 credits of the program a student has the first year Computer Science studies completed. Moreover, if the student passes the program with grade 2/3, she is free to enter the university as a Computer Science major.

Why are we offering Computer Science studies for high school students? There are three major viewpoints to support our decision.

1. There are very few qualified Computer Science teachers in most of the schools. Moreover, most of the students live far from universities and each other; therefore, it is not possible to solve the problem by sending temporary teachers to these schools or invite the students to the university.
2. There is a great need for professionals in the computing industry. As a partial solution, Computer Science departments have to be able to attract more students. By entering the university with the first courses completed already at high school, the students will have better chances to finish their studies.
3. From the research point of view, it is important to assess the Internet as an educational tool. Like the extensive popularity of mobile technology in Finland indicates, high school students are enthusiastic about new opportunities in web-based education. Moreover, they are open to give very frank and well-grounded feedback on the systems they use.
The main educational dilemma to solve in the project consists of several interrelated factors:

- High school students are used to an instructional setting different from that at a university.
- The opportunities of the Web are limited in compensating for a missing, face-to-face teacher.
- Complete web material covering 15 credits of Computer Science courses was too much to compose within the given time constraints.
- Synchronous communication or even delivery of asynchronous video lectures was out of question because of the low bandwidths available at students’ homes.

Therefore, we had to create a model to support designing web-based instruction. We ended up to a scheme that we call a Candle model. The main principle was to create a package that helps the student at authentic learning problems or critical situations, in a simple and meaningful way. We wanted to provide him with electronic candles to show the learning path, step by step. However, we assumed that he has got the required facilities by himself, like a textbook and an encouraging tutor.

Basically, the Candle model of web-based learning requires an intelligent technique for accessing the needed support for authentic learning needs. For the time being, the system is not yet adaptive. However, approaches based on prerequisites for learning a given topic and outcomes of learned material, like used in AHA (De Bra & Calvi 1998) and InterBook (Brusilovsky et al. 1998), may be utilized in our model. However, contrary to the common uses of these systems, we will not compile the basic learning material to the web. Even in the future, we will make full use of textbooks, and the Candle-based environment will consist of various targeted tools. These tools support the user in the authentic learning needs while studying the textbook-based material.

Theoretically, the problem of locating information relevant to a given user is a challenging one. However, in the area of computer-supported learning, different schemes have presented. For example, the Ahmed environment for special needs education models the learning process as a path in space; the learner moves from one learning seed another (Kurhila & Sutinen 1999). These seeds can be learning tasks, and the system suggests the learner to proceed to the next seed based on the system’s assessment of his or her performance at the previous seed.

Most of the discussion around web-based education, like virtual universities, stresses the importance of users’ needs. After all, distance learning by technology, with little human touch compared to regular education, requires a highly motivated student. Whereas in the traditional setting face-to-face instruction or hand-to-hand guidance compensated for obscure learning goals, the very same obscurity often shadows a web-learners path, or learning process. Therefore, at least the final goal must be clear enough to encourage a lonely learner’s walk. The Candle model is designed to enlighten the path as well.

2. Overview of the Offered Courses

In the program, the 15 credits include nine different courses. Courses will give students basic knowledge of three main domains: introduction to Computer Science, basics of programming, and preliminaries of computers. The emphasis in this project is to give students good programming skills. We chose to use Java as programming language. This gives students a chance to present their work via Internet after completing the courses. The timetable and structure for the courses is illustrated in Table 1. We use the abbreviation cu to denote a credit.

Table 1: Timetable for the courses

Most of the courses have a similar structure: students have material to work with, they do weekly assignments, and their learning outcomes are evaluated by an exam. However, we have tried to add flavors to studies by employing a few other teaching methods. Group activities: A few courses will be implemented so that students work in small groups. We hope that this encourages students to work collaboratively and brings about interaction into the learning process. Learning by writing: Students compose an essay on a certain subject. This is hopefully done in cooperation with local newspapers: the students will be reporting on what they learn. Netbus consulting: An Internet-connected bus will visit each school for a few hours. A Question & Answer session will be organized, as well as individual consulting. Days at campus: To make the students experience themselves as members of the academic community, they are invited to the campus on four days during their studies. Camp at campus. The theoretical course on algorithm will be arranged at campus, as a one-week intensive period.

3. Design Principles

The educational and instructional design of the package is based on a close collaboration between high school and university teachers. In fact, the expertise of the high school teachers was invaluable since it helped us to coordinate the courses to the schedules of the schools – which differ quite a lot from school to school! Moreover, the teachers made the designers to understand the limitations of the students. Furthermore, they emphasized that the students want to be a part of the university: therefore, it was essential to give at least a few real lectures, and examinations. A group of teachers is monitoring the course during the whole period of 1.5 years. In fact, the contribution from the teachers was crucial for the development of the Candle model.

3.1 Educational Design: the Candle Model

The Candle model is designed to support a student locally in her Authentic learning Needs, by Electronic tools served in a Light way. Thus, candLe emphasizes real human contacts for the learners. The web site helps the students to communicate with the instructors and each other in multiple ways. Instructors are Master’s level Computer Science teachers working at university. Furthermore, each school has a tutor-teacher who supports students in different situations. Tutor-teachers do not need to be experts in Computer Science but their pedagogical knowledge is crucial. They are experienced teachers who can support the students’ learning process sufficiently. The students also help each other, both locally and over the Web.

Another major design principle in candLe is to link the printed learning material with an activating learning environment on the web. The printed material gives a main structure and knowledge of the domain while the web materials guide the learners step by step. Activating visual tools like Jeliot, Excel, and BlueJ serve as students’ virtual laboratory. Exercises play an important role in the learning process. Especially in programming the learning-by-doing principle is effective. Each student must complete at least 1/3 of all the course exercises; those who exceed the minimum requirement get bonus points for the grade. The bonus point system has been a motivating factor to the rate of answers. Although we have restrictions about the amount of exercises, we have been as flexible as possible to the students concerning practical matters like timetables, to meet the needs of most students.

In Candle, almost all teaching is carried out via Internet because the students come from all around the district of North Karelia. Students do not have to waste their time and money by travelling from their home to the university.

In our experience, sophisticated user interfaces in many web-based educational settings might be confusing for a novice. The features tend to be superficial or shallow, and often of no pedagogical importance. Therefore, candLe
keeps the user interface simple. To make the interface of the learning environment more student-friendly, we hired a fresh high school graduate to design the pages.

3.2 Learning Environment and Course Materials

We have built a specific learning environment for the students by WebCT. The students can connect to the environment with commonly used browser (Internet Explorer, Netscape) and the use of the environment does not require any special equipment. WebCT works with a low bandwidth. This is essential because the students connect to the environment often at home by modem. The environment includes learning materials, discussion forums, chat, personal homepages, etc. Every student has a personal username and password for the courses so the environment is closed for outsiders.

Course materials on the web are composed mainly by HTML and they mainly support the printed materials. The course textbooks give a complete information of the subject, and web material is designed to help students in critical situations. The web material brings the most essential parts of the course to the learners and it quickly shows the structure of the domain to the student. Furthermore, web materials provide examples, visualizations, and interactive experimentation to the students. We hope that the web material will provide active learning experiences and helps the students in their learning process.

In addition we are planning to use video clips as mini-lectures. These lectures will give extra information and improve comprehension in specific more complicated areas. The clips will be approximately 5 minutes long because we think that the longer clips would be boring for the high school students. With short clips we can focus on one or two narrow pieces of information or skill.

3.3 Tools

Visualization has long been an important pedagogical tool in Computer Science education. The use of the web and interactive animations provide opportunities to expand the availability of visualization-based teaching and learning tools. We have been experimenting with BlueJ, Jeliot and Excel that provide activating learning tools. BlueJ is an integrated visual teaching environment and language, developed at Sydney University and Monash University. BlueJ helps students to understand object-oriented concepts such as objects and classes, message passing, method invocation, and parameter passing (Kolling 2000). The aim is to concentrate on solving programming problems without becoming distracted by the mechanics of compiling, executing, and testing Java programs.

The Jeliot environment allows a web user to animate algorithms of his own over the Internet (Haajanen et al. 1997). The user writes a Java program in a text field of a Web page, submits it and gets back its animation. The animation is generated automatically from the source code, and it is displayed on the user’s screen. Built on an extensible architecture, Jeliot can be modified to animate most common data structures. Jeliot 2000 is a program animation system intended for teaching Computer Science especially to high school students (Ben-Ari et al. 2000). The emphasis is on program animation that demonstrates the execution of input-output, assignment, selection, and loop statements. The original Jeliot was structured as a server application together with a client applet so that it could be run from a web browser. It was decided to change the implementation of the Jeliot to a single application for the following reasons: simplicity, reliability problems with browsers in newer versions of Java and the availability in the school laboratory of PCs powerful enough to install the Java runtime environment on them.

We have also been studying how to prepare animations of simple algorithms with Microsoft Excel spreadsheet program. Excel offers a light, adaptive and inspiring platform for creating visualizations of various needs in Computer Science (Dybdahl et al. 1998, Rautama et al. 1997). A teacher can prepare visualizations for teaching or visualizations can be student assignments. Two standard features of Excel, i.e. data visualization and macro programming with VBA provide together an environment to animate algorithms. Jeliot and Excel have been successfully experimented in Computer Science courses in the University of Helsinki.

4. Evaluation
The first 93 students of the program started in August 2000. After the first two months, there were approximately 80 active students, coming from eleven different schools in the district of North Karelia, as far as 100 km from the university.

4.1 Case: Basics of Programming

We evaluated the second completed course, Basics of programming, which covers the introduction to the concepts of programming in Java. The general feedback from the students and the teachers has been mainly positive and we got enthusiastic answers for our exercises. There were 50 exercises in the course so if the student wanted to take part in the exam he had to complete 17 of them. Out of the enrolled 84 students, 76 returned at least one exercise and 62 of them answered compulsory amount of exercises. Hence, 62 students were allowed to participate in the exam. Figure 1 (n=76) illustrates the distribution of the returned exercises.

![Figure 1: Distribution of the completed exercises.](image)

Out of 62 students allowed to participate 56 took part in the exam. Figure 2 shows the results of the examination (3= highest mark, .., 1= lowest mark). The average mark of the exam was 2- which is a little bit higher than marks received in normal courses in our department.

![Figure 2: Results of the exam](image)
Although the amount of low and failed marks was quite high we think that the results were satisfying. One can clearly figure out three categories from the results of the exam. The first group is managing rather well (above 2-) and they have got pretty good chances to reach the average mark of 2/3, which allows them directly to continue their studies in our department in future. The second group consists of students who had trouble both in exercises and in the exam (marks 1+,1). Next courses have revealed that they have got good chances to pass the virtual certificate but they probably won’t get the average mark of 2/3. The third group is comprised of students having major difficulties even in passing the first courses. These students have in many cases ended their studies either after this course or in following courses.

5. Future Work

From the tutoring point of view, the Candle model needs to be developed further. By default, the model assumes that the learner is motivated. Thus, the teaching intervention can be focused on the authentic difficulties, not his or her long-term goal itself. However, it would probably be useful for even a highly motivated learner to understand the relationship of a local learning step in the framework of the overall learning process. To manifest this relationship, one can make use of several visualization schemes where the life-long learner can explicate his or her learning status with respect to the larger educational context. Therefore, the model will be developed further in collaboration with the experts in student counseling.

Many Computer Science professionals think of their field as a truly universal one. However, learning difficulties identified at early stages, like when doing the first programming assignments at high school, might help us to recognize different ways of comprehending even abstract structures. Therefore, we are localizing our environment to other cultural contexts, in order to analyze this problem.

Traditionally, elementary school teachers, especially those working at small village schools in rural areas, have been called folk candles, bringing the light of the civilization even into most remote places. Hopefully, our Candle model can work in the same direction, at the time when most of the people in the industrialized countries are moving into cities, like the misled children in the famous folklore story on the pied piper of Hamelin. The Candles remain as long as these areas belong to the rest of the networked civilization.

Abstract: To investigate the use of mental-model reasoning about mechanisms in design, we had 12-13 year old students design a Mars Colony including physical, biological and social systems. Unlike previous research, we did not find significant gender differences in the designs. We found more reasoning about mechanisms from the beginning with physical systems than with biological and social systems. However, this mechanism reasoning did not increase across three design sessions for any of these systems. We did get increases in the initial relations that the students included in their designs. However, this was countered by a decrease in component and relational thinking during the final trouble-shooting task. We suggest that a more guided design environment starting with physical systems and then moving on to biological and social systems will be needed to foster mental-model reasoning about mechanisms with students this age during design.

INTRODUCTION

We investigated to what extent 12-13 year old students would use mental model thinking when designing an artifact, and how we might increase that kind of thinking during design. We examined whether a constructivist design task would facilitate sophisticated mental-model thinking (Hmelo, Holton and Kolodner, 2000; Jacobson & Archodidou, 2000) and whether there were gender differences in mental-model development (Honey, Moeller, Brunner and Bennet, 1991). From this study, we drew implications for the creation of a computer-mediated learning space that would foster mental-model thinking during design. Our specific questions were: 1. What types of think do these students do when designing and how do these types of thinking change with experience and instructional support? 2. Are there gender differences in types of thinking during design and are thinking differences when designing in different domains?

MENTAL MODELS
Most cognitive theories about mental models concur that they consist of objects and their relationships (Johnson-Laird, 1983; Kearney and Kaplan, 1997; Jonassen, 1999). However, this definition is limited in that it does not address the greatest power of mental models: the ability to mentally simulate mechanisms to infer rules or make predictions about the operation of a system (Schwartz and Black, 1996; Koffijberg, 1996). From this mental-simulation perspective, a mental model is a dynamic mental structure whose behavior can be used to show how the systems modeled will function under different circumstances (Gentner and Stevens, 1983; Aronson, 1997). Thus, in the fullest sense, mental models consist of the structural components of the system, knowledge of the inter-relatedness of those components and a causal mechanism describing and predicting the performance of the system (Jonassen, 1999).

Therefore, an adequate mental representation (components and relationships) of a system is not sufficient for understanding. There must be the capacity to reformulate or restructure the model and incorporate the consequences of this manipulation (Newton, 1996). This transformation or running of a mental model pertains to adjustments made through the application of the causal reciprocity found in the system. Our definition of mental models involve images of interacting parts that are animated (Schwartz and Black, 1996b). Thus, transformations involve the delineation of kinesmatic information into mental spatial representations (Newton, 1996; Aronson, 1997; Koffijberg, 1996). It is this act that allows the thinker to visually infer how or why a complex system works. A prevalent way of expressing this transformation is as mechanistic.

Understanding is more than the regurgitation of superficial facts and procedures. It is a product of mental processes that infer dependence between elements of information (Newton, 1996). Koffijberg (1996) avers that understanding may even equate with acquiring an accurate mental model. Therefore, research that focuses on mental-model development is essential to facilitate software instructional design aimed at developing student understanding of complex systems.

CONSTRUCTIVIST DESIGN TASKS

Design tasks, as instructional tools, have been proposed as facilitating the development of mechanism thinking, and thus, understanding (Honey et al., 1991; Jonassen, Peck and Wilson, 1999; Hmelo et al., 2000). The act of design concentrates student efforts on the elements needed to build robust and sophisticated mental models: that is, student designers focus on acquiring the necessary information, its underlying structure, generating model examples and using the foundation entailed by the subject matter to justify the design (Jonassen et al., 1999). Therefore, the purpose of a design task is to allow the student to determine the relevant components and the ways they influence each other, and allows for the exploration of how systems work (Koffijberg, 1996; Hmelo et al., 2000). However, the context of the constructivist design environment itself influences the kind of knowledge acquisition and the potential for the formation of a mental model. (Wood, E, Woloshyn, V. and Willoughby, T. (ed), 1995; Koffijberg, 1996, Jonassen et al., 1999). Therefore, analysis of the levels of mental-model development that occur during design tasks is necessary to provide guidance in devising the kinds of scaffolding, modeling and effective modes of transmitting information that need to be present in technology to support understanding.

GENDER ISSUES

Psychological and sociological research suggests that females approach, interpret and understand various aspects of life differently than males (Honey et al., 1991; Gilligan, 1982). Two studies (Hawkins, Brunner, Clements, Honey and Moeller, 1990; and Brunner, 1990) pointed to gender differences in domain content concentration during design tasks performed by adults and children. The researchers found that females focused on the Social domain (communication and affective aspects) while male designs tended to focus on the Physical domain (transportation). Further, females were less concerned with describing the internal mechanisms of their designs than males. These findings recommend an
examination of gender differences in types of mental-model thinking across differing domains of content and their consideration in a computer-based design environment.

THE DESIGN STUDY

We investigated student thinking during design by having them design a Mars Colony. In using this particular task, we were able to utilize the Mars Millennium Project (see www.mars2030.org), which a number of organizations (e.g., NASA, NEH, etc.) were conducting in order to inspire students to be more interested in science at a time when several space probes would be reaching Mars. Thus, were able to use the information on Mars that this project put on the WWW and exploit the excitement that had been generated. Also, designing a Mars Colony had the advantage of being multidimensional (unlike previous design studies) involving physical, biological and social systems. In the study, we had students design the colony twice on different days, then take part in a trouble-shooting task with the Mars colony.

METHOD

PARTICIPANTS

Twenty-seven eighth grade students, nineteen females and eight males, participated in this study. The students attended a model middle school in the South Bronx section of New York City. Entrance to the school was selective and students were conscripted from surrounding neighborhoods, consisting of African-American and Hispanic populations. This middle school was lodged within a high school and was characterized by reduced class size (between 20-28 students). All students were involved in a daily science curriculum.

PROCEDURE

This study took place during the regularly scheduled, eighth grade, science hour. Two researchers, along with the science teacher, were in the classroom for three days (Monday, Wednesday and Friday), henceforth referred to as Time 1, Time 2 and Time 3. Each time involved a general introduction, content share and presentation of a variation of the Mars Community design task, and an individual, student problem-solving period. Content for the Mars 2030 design task was obtained through the Mars Millennium Project at www.nasa.gov.

Based on Newton’s (1996) outline of Model Processing Failure, we investigated three, slightly modified design tasks. The first task (Time 1) involved the least amount of instructional direction. Students were instructed on minimal base knowledge regarding the intent of the task. Further, there was a purposeful withholding of a conceptual model, which allowed students to formulate their design from only their mental resources. The second task (Time 2) entailed more instructional direction than the first design task. In addition to the previous base knowledge, 10 essential concepts in the complex system were highlighted and students were instructed to focus on the “how and why” of their design (Newton, 1996). Finally, the third task (time 3) contained explicit instructional direction. While still maintaining a strong design element, focused questioning on the mechanistic aspect of the student’s mental model and forced prediction were employed.

Following the introduction and content sections of Time 1, the students engaged in approximately 30 minutes of individual work. Each student was supplied with an 8 ½ by 11 piece of white paper and a pencil. (More paper was provided based on individual requests.) The class was then told: “Based on everything that we’ve just talked about, we now want you to design a community for 100 humans on Mars, for 1 Martian year, in the year 2030. We want your design to be as clear and understandable as
possible, so if you need to explain things, please do.” The researchers stressed the need for the designs to be comprehensible to outside viewers and gave the analogy of the designs as being comparable to a blueprint. Further, the students were encouraged to complete their work on their own, in an attempt to cut down on collaboration.

A reiteration of the introduction and content sections from Time 1 initiated Time 2. In addition to Time 1 content, the researchers highlighted 10, pre-established categories as important to community design: culture, food, communication, shelter, government, water, transportation, air, health & safety and sanitation. This was followed by 30 minutes of individual work creating another paper and pencil design. The class was instructed: “We want you to design a community for 100 people on Mars again. However, this time, please consider the 10 categories we just talked about as you design your community. You can incorporate any of your first design into your new design.” The students did not receive the design they had created during Time 1.

For Time 3, after the introduction and content sections, the researchers posed the following situation to the students: “An emergency situation has arisen within the context of your second community. A third of your community members have become seriously ill.” This was followed with the following questions: (1) What do you think happened in your community that affected the members? (2) Why do you think it happened like this? Justify and explain your answer. Then complete the following tasks: (3) Show us how you think this happened. (4) Make a prediction of how this will effect the future of your community. (5) Design a research plan to investigate whether or not your theories/ideas about what caused a change in the community are true.” Each student received a pencil and a stapled packet of five pages (8½ by 11). Each page had a question or task at the top, with the rest of the page blank. All of the packets were ordered as shown above and the researchers read through the packet with the class before they began the task. Further, each student also received a copy of his/her Time 2 design to be used as a reference. The students were given approximately 30 minutes to design their answers.

DATA ANALYSIS

The raw data for this study are the pencil and paper designs created by the students each day. The student’s mental models (what we ultimately want to investigate) are just that—mental. One method of externalizing these models is to have subjects draw or write them out (Wood et al., 1995). Thus, we view the student’s designs as cognitive maps (Kearney & Kaplan, 1997) or concrete models (Getner & Stevens, 1983), which characterizes each student’s general knowledge regarding his/her Mars community. Specifically, we use the students’ designs to assess the level of component (i.e., objects), relational and mechanistic thinking found in their renderings, with the intent that this reflects the level of processing happening in the students’ heads.

The coding of each of the three levels of thinking were couched in 10 researcher, pre-determined categories, which we later classified in four domains. These 10 categories where chosen by the researchers to promote coding consistency, because we believe they are all necessary for community survival, and also because they cover physical, biological and social aspects of community development. Further, the 10 categories remained constant for the coding of Time 1, 2 & 3 designs. For Time 1, students during the design task were completely unaware of the pre-established categories. For time 2, the 10 categories were outlined and stressed at the beginning of the design task. During Time 3, students were aware of the categories because of their Time 2 experience, however, the 10 categories were not reiterated or highlighted before the design task began.

Within each of the 10 categories, three scores were tabulated for each student. First, the components within each category, whether pictorial or written, were counted. Second, scores were gathered for relationships among components. Relationships were identified by explicit pictorial or written connections between components. To promote coding consistency, spatial distance was not taken into account.
consideration as indication of a relationship. Thus, components bunched close together were not counted
as connected unless specifically indicated in some way by the student. Finally, scores were collected,
within each of the 10 categories, for the depictions of mechanisms. Mechanistic representations were
coded as being present when objects were pictorially or written with explicit, directional relations that
conveyed movement. That is, the relationship between objects were depicted as causal and directional.
Based on the coding method explained above, each of the 27 students received 90 scores (3 levels of
thinking X 10 categories X 3 sessions).

During the analysis process, the 10 category scores in each level were reduced, through summation, into
four domains. The Physical domain consists of the categories of Transportation and Shelter. The
Biological domain consists of the categories of Food, Air and Water. The sum of Communication,
Culture and Government make up the Social domain. Health & Safety and Sanitation, key elements of
communities, did not fall into any one of the three previous categories, so their scores were summed into a
Multi-dimensional domain.

RESULTS AND IMPLICATIONS

For brevity, we are only including information on results with specific implications for the instructional
design of a Mars 2030 computer environment. We conducted three (one for Time 1, Time 2 and Time 3)
GML mulivariate tests in the four domains, for each type of thinking, with Gender as a fixed factor. For
Time 1 and Time 2, there were no significant differences, at any type of thinking, in any domain, between
females and males. Time 3 results indicate non-significant differences between females and males, with
the four domains, for relational and mechanistic thinking. There was a significant difference between
females (5.556E-02) and males (1.5556) in component thinking in the social domain (p<.000) [all other
component-domains were non-significant]. Evaluation of the direction revealed that males had more
components, which counters what Honey et al. (1991) might have expected. Thus, our research indicated
no instructional implications for domain design with gender as a factor.

Next, we conducted individual 2-Tailed T-test for each type of thinking (components, relational and
mechanistic) on each day (Time 1, Time2 and Time 3). All levels on each day were significant (null
hypothesis = 0) at the .05 level, thus in general, these types of thinking did occur during the design
process. This was followed by Time 1 T-tests for each domain. In Time 1 mechanistic-type thinking, all
domains were non-significant except physical-mechanistic (2.126, p<.043). This may imply that a
computer environment that initially focused on the physical domain and gradually moves to more abstract
domains would foster learning. Further, Time 2 T-tests for Social-mechanistic (3.704E-02, p<.327), Time
3 Social-relational (3.704E-02p<.327) and Social-mechanistic (.0000) thinking yielded non-significant
results. These results may indicate that more structured or supported instruction than what we provided
over the three-day experience should be included for this domain in a computer design environment.

Finally, we summed domains and conducted 2-Tailed Paired-Sample T-test comparing Times within types
of thinking. (Note: we did not conduct a repeated measure because although all the measures are designs,
Time 3’s measure was altered compared to Time 1 and Time 2). Results indicated significant differences
between Time 2-component (23.0741) and Time 3-component (5.5926) thinking (p<.000), Time 1-
relational (1.6667) and Time 2-relational (6.3704, p<.000) and Time 2-relational (6.3704) and Time 3-
relational thinking (2.3704, p<.001). These results suggest practice in addition to instruction on key
concepts fostered relational thinking, however, forced prediction actually had a negative effect on the
number of components and relations in the students’ thinking. This seems counter to Newton’s (1996)
proposal for decreasing mental processing failure and may imply that the trouble-shooting task shifted
students’ attention from the components and relations in their mental models. One would have hoped that
the shift would have been to mechanistic-type thinking. However, no significant differences were
indicated for mechanistic-type thinking from Time 1 to time 2 or Time 2 to Time 3. Several reasons
could be responsible for these results. First, the trouble shooting task was in the Multi-dimentional
domain (specifically, Health & Safety) and earlier results indicated initial focus should concentrate on the Physical domain. Further, students only had 2 experiences designing and this may not have been enough practice to foster mechanistic thinking. Finally, the static nature of the medium of instruction and student design (paper and pencil) may have inhibited both the mechanistic thinking of the students and our assessment of their work. This indicates that repeated exposure to a dynamic design environment (one where students could run simulations on their creations), rather than a computerized version of the paper and pencil task (such as a drawing tool) and one that initially focuses on Physical domain trouble-shooting might be the best format for a computerized instructional and assessment tool of complex systems.

CONCLUSIONS

In the study reported here, we had students design a Mars Colony including physical, biological and social systems. Unlike previous research, we did not find significant gender differences in the designs. We found more reasoning about mechanisms from the beginning with physical systems than with biological and social systems. However, this mechanism reasoning did not increase across three design sessions for any of these systems. In contrast, we did get initial increases across the sessions in the number of relations that the students included in their designs. However, this was countered by a drop in component and relational thinking during the final trouble-shooting task. We suggest that a more guided computer-based design environment starting with physical systems and then moving on to biological and social systems will be needed to foster mental-model reasoning about mechanisms with students this age during design.

Abstract In the past years, different course management systems for the World Wide Web have been developed. Usually they assist in providing courses for distant or distributed learner communities (tele-learning). Most course management systems are quite restrictive concerning the way to be taken through a course material and the tests and assessments to be done to complete the course [Hornung and Wang, 1997, WBTSystems00, 2000]. This paper suggests a different approach to tele-learning: a less restrictive environment for the learner to work with and modify the course material provided and to communicate with other learners and experts of the field. The system design is deduced from experiences with the course management system CMS-W3 which has been developed and used at Fraunhofer IGD Rostock since 1996.

The Course management system CMS-W3

CMS-W3 supports composition, administration and study of course material via the World Wide Web. Integration of all document types common in the WWW is possible. User interaction is provided by a highly functional but still easy-to-handle interface. [Hambach et al., 1999, Voskamp, 1997] describe CMS-W3. The most important concepts will be explained in the following.

Basic Concepts

Introduction of modern communication structures into traditional education scenarios like distance education substantially improves the information processing and interaction between course attendants. Course material is no longer restricted to written paperwork or video tapes. It is now possible to integrate new media like online lectures, interactive tutorials and simulations.

CMS-W3 supports composition, administration and study of distance learning course material via the WWW, which means that it supports the students in studying a course, and the course manager in managing and administrating a course.

The system is based on a distance learning scenario, having

- experts, who are responsible for course integration and management,
- students, studying courses and
- tutors, being responsible for technical support for the students.

Starting from the distance education scenario described above, four user roles are supported by CMS-W3: experts, tutors, students and administrators (see Figure 1).

User Roles

An expert is the central course manager. He composes and maintains courses and modules, integrates new material, defines the course structure with a sequence of modules, provides online lectures, and gives marks.
A tutor gives regional support to students. He forms the link between students and experts or administrators by controlling the work of a student group or giving technical support to participating students.

The student studies one or more courses using CMS-W3. While attending a course, he is member of a student group, has access to his own results, to his user profile and to the course specific or group specific Newsgroup. An administrator is responsible for creating and maintaining courses and user accounts (experts, students, tutors) in his area. CMS-W3 supports a hierarchical user administration structure.

Courses and Modules

Courses in CMS-W3 have a hierarchical structure and consist of sections and a discussion forum. A section is defined by a module. Modules may be HTML structures, printable documents, exercises or test files (see Figure 2).

- At study time, the student can study the HTML structure online. It may contain HTML files as well as other document types like VRML models, Java Applets, video, audio etc.
- Files can be downloaded and printed for offline study. They also can be changed by the students and again uploaded for download by other students of the student group.
- Exercises and Tests for knowledge assessment are written in the CMS-W3 test description language. CMS-W3 interprets them using Java Applets.

Every expert has his pool of modules. He prepares them with other tools than CMS-W3 and integrates them remotely via a WWW browser. He also structures these modules in courses, thereby defining dependencies between different sections.

Practical use of CMS-W3

In the past, CMS-W3 was practically used several times in an institutional framework. At the University of Rostock, materials for the lecture "Multimedia Communication" of the Institute of Computer Graphics were made available in CMS-W3. The system was also used for the tele-course "Webdesign" for computer assisted instruction and education (see Figure 3). Other educational institutions offered their own courses using CMS-W3. In addition, the system is used to publish instruction manuals for different software systems.
Different curricula were selected depending on the respective basic conditions. The spectrum reaches from meetings with supplementary self study to self study only. Thereby, the provision of further written materials was handled very differently. In the case of self study only the whole communication took place via Email and Newsgroup. Different observations have been made based on courses already held. A generally safe and directed handling of CMS-W3 was observed. However, some problems led to further conclusions.

Concept of learning

The fundamental concept of CMS-W3 results from learning independently of place and time. This was very welcomed by the learners. However, the missing guidance proved as obstacle in some cases. Learning successes depended on the non-standard self learning authority, meaning the ability to perform a study conscientiously without any special direction. If the appropriate authority lacked, the own motivation to experience learning successes was missing. Therefore it was necessary to promote the motivation of students by additional didactical interventions. Constant care and guidance were guaranteed by Email, Newsgroup or telephone.

Communication

CMS-W3 provides different means of communication (Newsgroup, Email, etc.). However, these were not widely used so far. They are not a central part of CMS-W3 and they are not dynamically linked to important sections of a course. Additionally, two more factors for not communicating could be observed:
Till now, only a few students took part in a single course; Second, the learners simply did not know about the tools and how to use them. For this reason, extra promotion for communication had to be done in the past.

System operability

The work with CMS-W3 was designed for different user groups. Each user fulfills a function according to a given user role. They all require basic knowledge in handling IT systems and a minimum of technical openness. The graphic interface covers the extensive functional spectrum of CMS-W3. It is arranged consistent and promotes intuitive navigation. The requirements of the complex interface in expert mode are rather dedicated to IT specialists. Therefore, it is fewer suitable for other experts outside of this area. Insufficient screen resolution leads to a disturbance of the balance between window contents and window navigation.

Learning material

The quality of courses and the supplied material influence equally the acceptance of CMS-W3. Therefore, materials badly edited can easily be understood as a weakness of the entire system. Exactly the same, a course structure without a definite line can lastingly disturb the navigation concept of CMS-W3 and mislead the user.

The observations during practical work led to the following conclusions: CMS-W3 strongly depends on internal and external factors. The internal factors result from system properties, particularly from system operability. The external factors are quality of teaching aids and the characteristics of individual users. On one hand those factors are influenced by the attractiveness of the provided material, on the other hand by the amount of self learning authority and appropriate user knowledge. Beyond that, the acceptance of communication tools available in CMS-W3 is strongly bounded to purpose and motivation. Therefore, the interaction of individual factors should also sufficiently be considered in the future.

Developing an Open Learning Space

The course management system CMS-W3 was developed to provide knowledge. However, following the constructivists approach to learning, knowledge can not be supplied. It can only be achieved by actively working with material and applying content in different contexts. A learning environment should support active learning: material addressing different senses, complex practical work, communications and collaboration with other learners, modifying the material according to the own understanding. Like similar systems ([WebCT00, 2000, BSCW00, 2000] beside others), CMS-W3 supports communication and collaboration in different ways. However, experience showed, that the tools are not easy enough to find and to handle.

Grune [Grune, 2000] describes an open learning environment (according to learning psychology) transferring the approach of constructivism into practice. The only obstacle: His approach is based on the ideal learner: a competent user of new technologies, highly motivated for continuous learning, able to adapt to material of different qualities, self-organized and always able to coordinate his aim and the way to reach it.

Learners in real settings are not usually like that. Our observation of tele-courses in different scenarios show: material has to be of good quality, the learner asks for continuous support in using the technology and in working with the material and, most important, he needs gentle pressure to finish the course. Based on our observations we suggest to include the following tools into a course management system in order to support orientation, communication and cooperation.
Structure of content

Our intention is to provide as much material online as possible. The material is organized in courses. In the moment, each course consists of different sections containing single modules. The granularity of this structure is too coarse, so we decided to change it in the following way: each course will consist of different clusters which themselves consist of different sections containing modules (HTML-structures, downloadable documents or tests) as shown in Figure 4. A module may be used in different clusters as well as a cluster may be used in different courses.

Due to high modularization the material is highly reusable. However, it is more important that the thematic organization of clusters results in non-sequential studying for advanced learners: Different clusters of a course are organized in thematic plans and may be accessed via a visualization of the plan (described later).

Orientation

In CMS-W3 the learner has the table of contents as the only means of orientation. It is used for navigation purposes at the same time. He has to follow the given sequence and is not able to re-arrange the different units according to his own plan of how to work with the material. A few learners were not able to execute all steps to be taken in order to reach the course aim because they could not grasp the complete program or did not fulfill the prerequisites. Other learners studied just the parts of the material providing new information. To support orientation in a course material we now use three tools, the learning plan, course descriptions and subject cards. All three of them support the learner orienting within a course.

The learning plan is derived from the sequential course structure given by the expert who planned and prepared the course. For the unconscious learner it possibly is the order in which to work with the material. However, the conscious learner is able to adapt the learning plan to his own needs. He may rearrange the sequence or even exclude single units to get his individual learning plan. Working progress will be measured according to the given or individual learning plan. At each time the learner is able to compare his learning plan and a survey of the work he completed. This tool is an important addition because the learner will be able to structure and study “his own” course. He may include or exclude different clusters and define their sequence.

Each course is described by a set of data including title, description, scope (hours online and hours present), form of learning (tele-learning, seminar, presentation, etc.), pre-requisites, agenda, material (online, written, CD-ROM, etc.), certification. These data are for the learner to be informed about the setting and development of a course.

Thematic plans visualize the contents of a course as a hyper-medial network. They are an ideal way to show semantic connections between different clusters and may even be used to access them. Advanced
learners will appreciate the possibility to randomly access all clusters and to study non-sequential (see Figure 4).

Cooperation and communication

Based on our experiences in using CMS-W3 we decided do provide the tools to support cooperation and communication as well as to force learners to communicate and cooperate with each other and with the tutor of their course as the centerpiece of the system.

An important means of supporting communication are personal cards. They are an instrument for each learner to introduce himself to other learners of his group. The account name and a dummy picture are given by the system before logging in the first time. The learner is obliged to complete his card by adding his personal picture, his name and Email address and a short comment. That way, the system as a whole as well as the single course are less anonymous. Communication is easier because the partner to communicate with is “known” through his personal card. In differentiating between pre-set data and data to be added by the learner, anonymity is guaranteed if the learner wishes to stay anonymous.

A forum is an essential tool for communication and cooperation. In CMS-W3 we had classical Newsgroups. Experiences with different target groups showed, that Newsgroups are difficult to handle by non-computer experts. For this reason, a forum is provided for each course for learners to interchange with each other and the tutor of a course. It is much easier to handle than a Newsgroup and will surely enforce communication.

Annotation will be provided for each cluster to add comments about the content close to the information itself. They are not specific to a group of learners. All comments are listed together with the user name of the learner providing the comment. Annotations may be accessed by clicking a small icon near the cluster name either in the sequential course structure or in the thematic plan. Using this means of collaboration the learner will be able to actually change the material.

In adding the tools described we provide a learning environment much opener for self-directed learning, much more motivation for the learners to study materials and to communicate with other learners. According to our observations with CMS-W3 this learning environment will better be able to support the learner in learning self-directed and on demand.

Germany, {astralhampel}@uni-paderborn.de

Abstract: The primary goal of the Magellan concept is the development of individual and cooperative semantic structures on side of the students by using tools that both support and accompany the cooperative learning process. With regard to this the Magellan system functions as a communication media for fellow students and lecturers and as a collection- and structuring system for all materials that accompany the learning process. The conceptual approaches of the Magellan system concentrate on the aspect of the establishment of cooperative and individual link- and navigation structures which might be described as paths or trails over learning materials. One of the key ideas for the integration of external web resources into such trails is the concept of annotations. First implementations of Magellan concentrate on the integration of an universal annotation mechanism inside virtual learning rooms. The following paper will discuss various approaches of semantic representations of web structures and annotation mechanisms for web documents. It will introduce our architecture based on the sTeam (structuring information in teams) system and will shortly describe our first prototypes.

A new concept of learning: cooperative knowledge organization

Both, individual and cooperative forms of learning need documents, graphics or other graphical representation for the purpose of structuring the learning process. Developing tools and methods for the computer supported cooperative learning (CSCL) has a long tradition and has been developed parallel to the growing World Wide Web. Our research group “Computers and Society” now aims since more than 5 years at the integration of net-based graphical representations—so called semantic maps and semantic rooms—into learning supportive infrastructures at our university (Hampel & Selke 1999).

In the following section we will shortly introduce the main approaches and concepts for the development of navigational structures. Based on our experiences we will motivate our Magellan approach which is in large parts based on the development of an cooperative system called sTeam (structuring information in teams).

During the last years various tools and environments for representing navigational structures of the WWW have been developed. These representations are based on the idea of offering guidance and general maps of a field of knowledge. Resultant from an inherent navigational problem (lost in hyperspace syndrome), (see Theng 1996) within large hypertext structures and especially within the WWW, the necessity of these structures has been rapidly recognized.

The basic approach to the support of a cooperative knowledge management fits primarily in the area of cooperative creation and use of knowledge, which generally means the structure might be changed. With this in mind the form of generation of maps, structuring the informational room by the users or students respectively is an important criteria in regard to the following differentiation of existing basic approaches.

Here we have to differentiate automatically generated maps from cooperatively created maps or also maps created by authors for users. On the side of the generated maps and graphical representations we have to differentiate completely automatically generated maps from semi automatically generated ones, which means from maps created by the influence of an author or of a user.

Beneath automatically generated site maps there belong a variety of 2D or 3D representations to this class of generated maps, in order to represent large quantities of data, which also may be used for navigational aims. Early examples show the „self-organizing semantic maps for information retrieval“ created by Lin, Soergel and Marchionini (Lin et al. 1991). Here semantic connections among documents are represented as a
self-organizing map that is used as a guidance instrument in a library research system. A typical example of a topological map is the representation of semantic relations by spatial proximity. This gives the viewer an overview of a field of knowledge to be worked on. However, the demand of navigational support is not in the centre of attention among the authors within this context.

On the other hand there is a variety of semi automatically generated maps. Even the trail-concept of Memex (Vannevar Bush), which might be the father of many approaches, is an example for this: "The owner of the memex...runs through an encyclopedia, finds an interesting but sketchy article, leaves it projected. Next, in a history, he finds another pertinent item, and ties the two together. Thus he goes, building a trail of many items. His trails do not fade." (cf. Bush 1945). Here the learner takes his/her path through hypertexts by following existing references. This trail is recorded and after it has been revised and recreated by the author, the trail is given to other learners as a basis for navigation through the learning materials. This idea of trails was transferred on hypertexts by the Brown University within the inter-media project (1985-1990) (Utting & Yankelovich 1989). Here paths of users are visualized by references in form of a map beneath a survey of connections between documents. A really new quality in the research approach results in the possibility for users, to annotate references and maps and to keep these annotations without regard to later modifications of the document. During the last years different research teams have worked upon parts of the question of this idea, to offer a widely automatically generated path through a field of knowledge by recording and later edition and reorganization as a guidance for other users.

In this context, Wexelblat provides important preparations in his "Footprints"-approach. The paths of users through the WWW may be traced and may be used for a later navigation—but may not be exchanged and communicated between learners. As a second component, the traces of other users in the net are offered as a navigational assistance in form of graphical maps. This means a navigational assistance is created by the cooperation of the users on basis of their actions. The amount of the visited knot is shown by different colours (Wexelblat 1999). This idea of considering social components—the amount of informational visits by other users, which means a form of information sharing in creating navigational structures and representations—is characterized as "social navigation". It has been decisively researched by Dieberger (Dieberger 1998) as a combination of a virtual environment (Juggler) with a web-client. Especially the creation and management of own references, lists of so called "bookmarks" and their transmission to other users is interpreted of him as a phenomena of "social navigation". This is similar to navigation in virtual environments (special MOOs); Dieberger gets information about the behaviour of user-navigation by tracking paths in the MOO (Dieberger 1994).

In addition to the generated maps and graphical representations there is a big group of spatial structures created by authors. In this context the author means the intervention of a man in the process of creation of a mostly graphical navigation assistance. But there exists a high number of mixtures between an automatic generation and a guidance that is completely created by man.

Important impulses are delivered by the works of Furuta and Shipman (Furuta & Shipman 1999). In their "Walden's Path"-project they researched in particular the generation of linear paths by means of the materials of teachers for students. An important aspect in this context is the generation of paths through the WWW by active composition of addresses, which means that the generated map resp. the generated path is not restricted to a limited quantity of documents. (Furuta and Shipman developed an architecture consisting of a path-server, which communicates between a web browser and a web server. On the site of the author they provide a Java-tool, the "Path Authoring Tool", to create and modify paths connected to a simple Java-database for registration of the paths). Therefore Furuta and Shipman focus on the creation of paths by materials of authors for students and not on their cooperative work upon the materials or a specifically graphical representation.

The main difference in regard to the researches in the field of the Magellan project is to consider the degree of cooperation within the creation of these navigational structures. The most primitive group of structuring assistance, the given overviews, directories, site maps (or graphical "click able maps") by the authors of a website resp. the authors of learning materials, give few possibilities of cooperative creation, modification or annotation. Although Pilgrim and Leung (Pilgrim & Leung 1999) differ four different basic types of site maps (differentiation in the degree of presentation knots and links of a site—representation of all or selected knots and links of a website, as well as maps, which are based on a temporal dimension, a "history") these author-based navigational structures offer nearly no possibilities for the cooperation of learners in the development of such navigational structures. These are unfortunately moderated, a strictly given navigation
assistance representing the present standard of the WWW.

Only a few advanced approaches exist; for example the one of Heuer and Meinel (Heuer & Meinel 1999) within the area of temporal dimension based concepts uses a database to store the paths through hypertexts (the WWW) and represent them as graphical paths and maps. In combination with the implementation of a proxy-server (Luotonen & Altis 1994), the annotation and the referencing of hypertexts which are not restricted to one WWW-server is also possible.

Our current prototypes

After studying existing concepts and approaches it seems clear that a learner centred approach which allows the creation, structuring, and communication of navigational structures by the learners themselves needs a well designed infrastructure. We have chosen a web based client-server approach to allow learners to arrange media in a room based virtual world. The Magellan project especially focuses on all mechanisms for the integration of various web materials into such learning supportive infrastructures.

The basis for all the tools is our open-source sTeam server that brings together all activities and serves as a persistent platform for any client. For a more detailed description of the sTeam server confer (Hampel & Keil-Slawik 2001). Different components of the client-side include a whiteboard, an annotation tool, a trail mapping tool and of course a chat. Each of these can work both independently or as part of a more extensive client framework that allows the individual composition of the client. Different windows can be docked at each other and can be positioned freely on the screen, which means that each tool is basically a module—and a sTeam client is a composition of such modules. Unfortunately most modules are currently only prototypes and the work on a usable client is still in progress. On the other hand the server design is more settled, although there are minor details changing every week. In order to get a stable system we are currently developing test scripts to guarantee the functionality and backwards compatibility in each version.

One of the most important clients for the integration of the Web into the sTeam system is the sTeam annotator (STAN) (Tappe 2000), a tool for annotating external web pages. To better understand it’s design we shortly introduce some existing approaches. Technically there are two main approaches: They can be differentiated into browser based or proxy based architectures. The proxy based version merges the content and the annotations in a proxy server while the browser based approach modifies the content right before displaying it.

An example for a browser based implementation is DreamView, which is part of the CSCW platform DreamTeam (Roth 1997), using an own cooperative browser. web pages are displayed on the left side of the browser, it’s annotations are displayed in an separated window on the right side. Connections between the annotated part of the web page are illustrated by links from the annotation text on the right side to the annotated position on the left.

Another implementation is CoNote (Davis & Huttenlocher 1995) which works with a standard web browser. Annotations are composed in ASCII- or HTML-format and are directly integrated into the web page. Again the annotation is related to a specific position inside the document. Access permissions play a role here—the visibility of certain annotations depend on the membership in groups. Unfortunately CoNote only allows the annotation of web pages, that have been modified to enable annotation.

The latest annotator is CritLink Mediator (Jones 2000), a part of the discussion environment CritSuite. Like CoNote it works in a normal web browser, but allows annotations on any web page. Therefore the content of each page is modified dynamically when it is loaded by the web browser. To accomplish this, it uses some
kind of proxy mechanism—each HTML page passes through the so called mediator and the current annotations of the page are added. Apart from this a toolbar at the top of the page is added featuring the target URL edit-box, a GO-Button and some help functionality. The annotations are identified by a context-phrase and a target-phrase—the target phrase is the annotated area of the document and is part of the context phrase.

The sTeam STAN annotator can be described as mixture of the tools mentioned above. It uses the browser based approach and allows the annotation of specific parts of the document. Annotations are stored within the sTeam server. The content of each web page is dynamically modified while loading and afterwards is displayed in the browser. STAN is started by going to an initial URL displaying the top navigation frame and loading the mediator (an applet). The navigation frame includes an edit box for the target URL and a “GO”-labelled button. The content of a page will be shown at the bottom frame—at first there appears a short introduction page for STAN. As soon as someone enters an URL and presses return or the “GO”-button, the applet will fetch the document and patch it according to the present annotations on the sTeam server (see figure 2).

To annotate an element of the document one has to click at the corresponding word and an additional window will pop up to enter the annotation text. Apart from the text, the type of annotation can be appointed—the different types are visualized as icons positioned right behind the annotated text. Clicking the icon will reveal the annotation text in a small window below the icon—clicking the icon a second time, will close that window. If the annotation text is short enough it will be displayed as a tool tip text when moving over the icon. Each new annotation will be sent to the sTeam server as an HTTP-request. The context of the annotation is at present only identified as the position of the annotated word inside the document. Of course this leads to problems when used with dynamic or constantly changing content (especially if a database generated site such as http://www.altavista.de would be used).

The Magellan/sTeam architecture – technically viewed

Form the technically point of view the Magellan system basically consists of a client which is connected to the sTeam server. This client allows one to cooperatively create, modify and maintain personal views on the structure inside the server. To understand the relation between Magellan and the sTeam server we must take a closer look at the server:

The sTeam server architecture is based on MUD/MOO technology (cf. Hampel & Keil-Slawik 2001). Incoming commands are processed and the results are subsequently sent back to the clients. Furthermore the execution of any command triggers events that are distributed among the users. For example the current user might move a document into another user's inventory. In this case, the target user would of course desire to be notified about this, thus the move action itself would run the event „enter-inventory“ which the user is able to observe.

In order to keep the communication at a minimum, each user/client is able to decide which events he wants to subscribe to, obviously there might be lots of things going on outside the users' focus of attention—for example in another room. This event-orientated architecture is very important when it comes to synchronous working—an object is moved on a whiteboard and the event is distributed to all clients currently running the same whiteboard. The communication between client and server takes place through COAL, the client object access layer, a simple binary protocol allowing the calling of functions inside objects—quite similar to RMI (Remote Method Invocation)\(^1\). While the client sends a command to the server, in the other direction the server

returns the results and events that are originated by commands of this and other users. This means even if the user is not doing anything, the client may receive events about objects entering or leaving the users current environment, conversation, changing attributes of objects, etc.

There are two separate implementations of COAL. One is in Java on the side of the client, the other one is in LPC (Lars Pensjoe C), an object oriented interpreter language, as the server is written in this language (cf. http://www.lysator.liu.se/mud/lpc.html). Due to this design the protocol must be able to handle all data types of LPC and the Java implementation and must especially be aware of those types such as LPC types which differ from Java types.

The reason why sTeam is implemented in LPC is, that—as a language designed for MUDs—, it is well suited for a multi user application in the sense that client/server communication can easily be established and it allows the extension of the system at runtime. To further improve the easy extensibility of a MUD, the sTeam system features a so-called proxy-object. This may be described as a special object type that is actually only a pointer to the real object, but every single reference to the object keeps the proxy instead of the object itself. When it comes to changing the code of an object/class at runtime it is possible to drop all instances of a class and recreate them (the data is kept inside a database). Even though a pointer to the object would be invalid after destruction of the object, the proxy object updates its pointers automatically and the relation is maintained. Note that this is the default behaviour of the DGD (Dworkins Generic Driver, another LPC implementation) that implements it on the driver level. Due to copyright issues we have been forced to use another implementation called Pike. Fortunately the Roxen IS Company backs up Pike and so a future development is certain.

As mentioned before on side of the system architecture the Magellan system is subdivided in the Client and the sTeam-Server. In this relation the sTeam server is the central part that controls all the activities and synchronizes communication between several clients. Inside the server exist different types of objects that are kept persistently inside a database (for example MySQL).

The object structure of sTeam is quite similar to that of a classical MUD—key elements are objects, containers, rooms, exits and users. The most important objects regarding Magellan are the rooms and their connections. The users create objects and documents and place them somewhere inside the room. Exits between rooms represent the semantic connections between different topics.

Each room (like any other object of the sTeam system) features an access control list that keeps track of the privileged users. (e.g. A room administrator gets some additional permission on the objects inside the room — this behaviour is required as someone must be able to maintain the room) Each client or client module may create a different view on the server’s objects. So the present structure inside the server is represented by different clients/modules. For example the room display module shows the current state of a room. Another module is the room-map visualizing the connections between several rooms and allowing the creation of new rooms and exits between them. Objects inside a room can be positioned in the room display and users may create links (references) to other objects. Furthermore any document can be annotated and previously added annotations are directly shown by the client. The server automatically synchronizes any action taken.

The STAN annotator belongs to the asynchronous parts of the sTeam system and is implemented as a special client module. Technically the sTeam annotator is implemented as a Java applet, which uses the sTeam server to allow the annotation of external documents (HTML pages/documents not present on the sTeam server). To accomplish this a lookup-table is integrated into the sTeam database keeping both track of the URL and the related annotation container. This container contains all annotations to the document – each an object of its own — including relevant data like type, annotated area of the source document and the annotation data. Due to the fact that an annotation document is handled like any other object in sTeam, it also features an access control list. Thus, individual permission can be associated with each annotation (nevertheless by default they are public). Right now there are only two options supported by STAN, public and private annotations. In this sense private means the annotation belongs to it’s creator (the annotating-user) and cannot be read by anyone else. In the nearer future it should be possible to assign the annotation to a specific group.

The only way to display a document including its annotations is apparently through the annotator — in this relation the sTeam server functions as the annotation repository. The annotations of a given URL are transferred to STAN by an XML wrapper.

Conclusions

Our Magellan approach aims at the integration of semantic representations into a room-based virtual world. Annotations play an important role for the integration external documents into any learning environment. To set up cooperative learning processes a computer supported cooperative learning environment has to integrate documents, graphics and links to external web resources, which can be easily created, arranged and communicated by the students themselves. This cooperative process, which we call self-administration, can be characterized as the key idea of successful cooperative learning.

The majority of currently existing solutions need learning materials to be integrated into the learning environment. The most important idea of Magellan is to allow the integration of external materials freely available on web servers into the learning process. Therefore powerful annotation mechanisms are necessary, which work both on internal and external resources. For the nearer future we plan to intensify this connection between internal and external learning materials. All clients should leave the prototype status and will be used in real learning situations at our university.

On the technically site we will further develop the usage of standard interfaces, for example the RDF\(^3\) (Resource Description Framework) format for annotations should be considered. This would bring together various annotation solutions and make them work with the sTeam system.

A student model for web-based intelligent educational system

Binglan Han, Kinshuk and Ashok Patel*
Massey University, Palmerston North, New Zealand
kinshuk@massey.ac.nz
*De Montfort University, Leicester, United Kingdom

Abstract: This paper describes the structure, functionality, and implementation of a student model used for web-based domain independent educational system. It is designed to take advantage of Internet based group inferencing while providing adaptivity in offline, online and mobile scenarios.

1. Introduction

The intelligence of an ITS is largely attributed to its ability to adapt to a specific student during the teaching process. The adaptation involves choosing and presenting each successive teaching activity as a function of entire scope of student’s knowledge of the subject being taught and other relevant features of the student, which are in turn maintained in a student model. A prototype student model is under development as a part of the Technology Integrated Learning Environment (TILE) project. It is able to provide adaptive features in various scenarios including offline, online and roaming profile environment.

2. Initialization and update

The student knowledge base is represented by an overlay model in which the current state of a student’s knowledge level is described as a subset of the domain model. The domain-independent part of individual student model includes student’s personal information, background, experience, goals, and preferences of learning style. The domain-specific part contains student competence levels for each concept node and each unit in the content tree, and an overall subject competence level. A group student model is constructed by averaging corresponding values in the models for all individual students within a group. The data in previous group student model may be used to initialize current individual models if no reliable information is available.

The student model is initialized by a simple but carefully designed questionnaire which is presented to the student in first session. The initial overall competence level is decided by checking the student grades of prerequisite courses and previous experience data, if available. The student learning styles are assessed by tracking student learning behavior. The students are allowed to set and modify their learning preferences and goals. The competence level of each concept is dynamically updated at each interaction, which are then used to update the competence levels of the related leaf units in the content tree. The competence levels of non-leaf units are determined by their child units. Finally, the overall competence level is calculated from all concept competence levels.

3. Usage

Two types of adaptation features are implemented in the student model: navigation adaptation that mainly decides the sequence of the presentation, and content adaptation that involves selectively presenting learning materials in various hypermedia forms. The domain independent information supports content adaptation. The system is able to create an individualized content presentation based on the student learning preferences and goals. The domain-dependent information supports both content and navigation adaptation. For example, the contents dealing with difficult details may be hidden from students with 'unsuccessful' competence levels, and additional explanations may be provided. The competence levels of content tree units are used to decide the recommended learning paths.
4. Current state

This student model is implemented in a client-server architecture in accordance with the framework of TILE system (Jesshope, Heinrich & Kinshuk, 2000). The presentation interfaces run in a Java applet. The model adaptation and update application resides in the middle layer. This architecture is flexible and easier to maintain.

Abstract. Two promising developments have emerged: 1) Electronic Performance Support Systems (EPSS); and 2) scaffolding approaches. The link between these developments, however, is relatively new. The purposes of this paper are to introduce EPSS design and implementation issues, to describe the relevance of scaffolding to EPSS design, and to present a case study involving the application of different scaffolding approaches.

An EPSS Primer

Simply stated, performance support systems help users do or accomplish things as they attempt to perform (Dorsey, Goodrum, & Schwen, 1993); EPSSs do so using computational technologies (Hoschka, 1996). An EPSS is a system of task-integrated online job aids, support tools and information systems that assist users with workplace performance (IETI, 1995; Stevens & Stevens, 1996). While some have expressed the need for caution (e.g., Clark, 1992), EPSS technology has gained broad acceptance in the education and training communities (see, for example, Banerji, 1999; Gery, 1991, 1995; Huber, Lippinott, McMahon, & Witt, 1999; Raybould, 1995). Interest in EPSS technology has been evident in professional organizations, corporate training and education environments, and academic R&D settings (Carr, 1992).

According to Gloria Gery (1995), two simple goals define what any EPSS should provide: 1) software to integrate knowledge, data, and tools required to help a performer succeed at a task; and, 2) task structuring that guides performers to create deliverables. In a sense, EPSS technology is not so much a unitary design concept, with fixed features and components, as it is a perspective on designing systems that support learning and/or performing. This, however, can prove elusive and deceptively complex. A recent volume describing the development of EPSS and other tools to support instructional design (van den Akker, Branch, Gustafson, Nieveen, & Plomp, 1999) highlights both the advances realized in the 1990’s as well as needed research and development.

A Scaffolding Primer

Scaffolding is the process through which efforts are supported while engaging a learning or performance task. Scaffolding can be differentiated by mechanisms and functions. Mechanisms emphasize the methods through which scaffolding is provided, while functions emphasize the purposes served.

Scaffolding complexity varies according to different contextual variables; scaffolding approaches, therefore, vary accordingly. In some instances where the problem or task is very explicit, scaffolding can be closely linked to the specific performance demands; when the task is not well-known or is ill-defined, scaffolding of a generic nature is generally provided. A number of different types of scaffolds are possible, including Conceptual, Metacognitive, Procedural, and Strategic.

Conceptual Scaffolding

Conceptual scaffolding is provided when the task is well defined and guides users regarding what to consider. At times, this is accomplished by identifying key conceptual knowledge related to a task or creating structures that make conceptual organization readily apparent. These structures can be made available through a variety of mechanisms, ranging from the graphical depiction of relationships, to outlines featuring ordinate-subordinate relationships, to information and hints provided by experts.
Conceptual scaffolding can be designed to help users reason through complex or fuzzy problems, as well as for concepts where known misconceptions or misunderstandings are prevalent. Hints can guide users to available resources or tools where understanding is typically problematic.

**Metacognitive Scaffolding**

Metacognitive scaffolding supports the underlying self-management processes associated with performance, i.e., it provides guidance in how to think. Metacognitive scaffolding can be either domain-specific, such as where performance contexts are externally induced, or more generic where the performance context is not known in advance. Metacognitive scaffolding might also remind users to reflect on the goal(s) or prompt them to relate a given resource or tool manipulation outcome to the problem or need at hand.

**Procedural Scaffolding**

Procedural scaffolding emphasizes how to utilize available resources and tools. It orients to system features and functions, and otherwise aids the user while performing. For example, some users become disoriented in complex or fuzzy performance contexts. Procedural scaffolding is frequently provided clarifying how to return to a desired location, how to “flag” or “bookmark” locations or resources for subsequent review, or how to deploy given tools. Users need not develop facility with all procedures until they have established, on an individual basis, the need for a given tool or resource.

**Strategic Scaffolding**

Strategic scaffolding emphasizes alternative approaches that might prove helpful. It supports analysis, planning, strategy, and tactical decisions. It focuses on approaches for identifying and selecting needed information, evaluating available resources, and relating new to existing knowledge and experience. Another type of strategic scaffolding involves alerting the user to available tools and resources that might prove helpful under given circumstances, and providing guidance in their use. Expert advice regarding approaches that might be helpful can also be embedded. Finally, strategic scaffolding may take the form of response-sensitive guidance at key decision points.

**Scaffolding in an EPSS: A Brief Case Study**

The Tactical Readiness Instruction, Authoring, and Delivery (TRIAD) project is developing a set of authoring and delivery tools that will enhance the quality of tactical guidance disseminated through the U.S. Navy.

**Introduction to TRIAD**

Decision-makers are faced with increasingly complicated and stressful tactical environments characterized by situational uncertainty, time compression, and capable adversaries. To cope with such environments, today’s decision-makers must have absolute command of a vast and varied knowledge base. Decision-makers must be familiar with situational cues, their ship and fleet capabilities and limitations as well as those of potential adversaries, and tactics at his or her disposal as well as those that potential adversaries might employ.

The bulk of requisite knowledge and skill is developed through experience and personal study of tactical publications (including Tactical Memoranda [TACMEMOs]) and combat system doctrine (Cannon-Bowers et al., 1994). TRIAD is a PC-based system being designed and developed to improve the coherence and usability of TACMEMOs. TRIAD will provide authors with an integrated tool set to enable them to create tactical documentation (i.e., TACMEMOs) using a variety of multimedia presentation techniques, and to create associated interactive multimedia instruction (IMI) to support the documented tactic/doctrine. In turn, readers will receive a multimedia tactical documentation “product set” that supports tactic/doctrine presentation and briefing, instruction, quick reference, and facilitation of electronic feedback regarding tactic/doctrine evaluation. In the following sections, we emphasize TRIAD’s on-line author interview scaffolding of efficient and effective TACMEMOs.
Author Interview Overview

The TACMEMO development process consists of three stages: interview, edit, and review. During the interview stage, the author creates and/or imports existing resources regarding the tactic in response to TRIAD-supplied interview questions. Using the information gained from the interview, TRIAD generates a draft TACMEMO product set consisting of the following integrated components: Base Document, Tactic Training Component, Quick Reference Guide (QRG), Feedback, and Brief. The Base Document contains the core TACMEMO content and procedures. The Tactic Training component addresses training requirements keyed to specific tactics knowledge and skills identified in a given Base Document. The QRG is an on-line job aid designed to distill the most essential aspects of the tactic for ready reference and to enable the user to link to associated Base Document and Tactic Training sections of the TACMEMO. Feedback, of a formative nature related to the tactic's usefulness, is elicited from users and recorded electronically. Finally, TRIAD generates a PowerPoint® presentation Brief containing the primary information contained in the tactic. The Brief can be edited and otherwise modified to provide greater or lesser breadth and depth, per audience needs.

The process begins through progressive decomposition of the product set's content. That is, the author is first asked to specify broad categories of information that the product set will address (e.g., Threats, Weapon Systems, Tactical Employment) and to specify one of these categories as the main thrust of the product set. For example, a given product set may focus on how to use a certain weapon to defeat a certain threat. In this case, the Tactical Employment, Weapon, and Threat categories would all be uses, but the Tactical Employment category would be marked as being the central theme or frame.

After specifying the broad categories of concern, the author breaks each category into smaller and smaller units. For each category, the author is asked to specify which of a set of possible anchors are important to the product set. For example, within the Threat category, the possible anchors include Type, Mission, Design Characteristics, Identifying Characteristics, etc. This process continues as the author determines which aspects of the anchors themselves to discuss. For example, within the Identifying Characteristic anchor, the author could choose to discuss Identifying Features and/or Indicators via Equipment.

The interview process continues by further decomposing the material to be presented (e.g., creating sub-sections for the base document or learning objectives for the tactic training component) and by eliciting content associated with a particular element (e.g., creating a description of a piece of equipment or a particular practice exercise). Content is added to the skeleton created through decomposition through tools that allow authors to create novel content or select from a library of existing knowledge objects.

The process continues with a guided elaboration and augmentation of the draft product set. The process consists of three iterative strategies, confirming, elaborating, and fine-tuning, designed to help authors refine and augment content. Confirmation assists authors in validating content accuracy and completeness as well as confirming TRIAD-generated structures and sequences. Confirmation is critical because it safeguards the accuracy of both the content and structure of TRIAD-generated documents. Elaboration helps authors to extend, amplify, and otherwise augment TRIAD documents. Authors elaborate and detail descriptions and supporting examples, especially those considered critical to the user's knowing and implementing the tactic. Fine-tuning enables the author to clarify information, directions, instruction, and presentation. At this step, the author amplifies key information, reducing or eliminating ambiguity and unclear or non-essential information.

Once the interview is completed and the draft product set generated, the edit stage commences. Here, the author is again presented with the draft product set and can choose to edit any or all of the product set components. The author can add new media and edit existing media (text, graphics, animation, simulation, etc.). The author can import related media from the local TRIAD database, or from a remote database, into a product template and then edit as desired.

The review stage commences after all TACMEMO product set components have been developed. Reviewers will be able to comment within the document and return these comments to the author. Comments received electronically will be stored in the TRIAD database for use by the TACMEMO author to revise components as required. The capability to merge comments into the document will be provided. As in the edit stage, the author can create/import new media and edit existing media (text, graphics, animation, simulation, etc.) in response to review comments.
TRIAD's Scaffolding

TRIAD is essentially an EPSS authoring environment for producing EPSSs. That is, the authoring environment must support authors as they attempt to produce a TACMEMO "product set" that supports the performance of field users (readers). It is useful, therefore, to consider TRIAD as a family of EPSSs, some designed to aid the author's performance and others to support readers' performance. In Table I, we summarize TRIAD's scaffolding features.

Scaffolding assists individuals as they engage various activities. For example, conceptual scaffolding assists the learner in defining what to consider. Within TRIAD, the searching mechanisms described earlier also function as conceptual scaffolds by directing the users' attention to product sets and sections that are likely to contain the most relevant information. At a macroscopic level, the majority of conceptual scaffolding actually takes place during authoring. By enforcing a performance-focus during authoring, TRIAD ensures that the base document, tactic training component, QRG, and brief indicate to the user the key concepts within a given product set.

Metacognitive scaffolding is provided through the practice and assessment area in the tactic training component. These sections provide a definitive indication of what each user knows. Rather than just providing an indication of correctness, these spaces try to capture "teachable moments" and deliver guiding feedback to users. Procedural scaffolding is provided through a task-oriented help system and results-oriented tool tips. Rather than defining buttons and functions, TRIAD's help system and pop-up tips describe how to complete tasks and explain the consequence of using a control. The TRIAD navigational construct is another procedural scaffold. Depending on user actions, this construct provides a table of contents, an index, or a list of the active bookmarks.

Conclusions

Scaffolding is a natural "fit" in EPSS design since, by definition, the systems guide or facilitate task completion. Scaffolding provides a more principled approach, however, in that it differentiates among the different types of both performance support needed and the methods/media used to support performance. This paper and presentation focused on defining and differentiating among scaffolding levels and illustrating their applicability in an ongoing R&D initiative. We believe the principles are more broadly applicable across a range of both performance support and knowledge system support. Future efforts should demonstrate scaffolding's viability accordingly.

<tr>
<td><strong>Guidance</strong></td>
<td>Context-task-sensitive advice and clarification for performing, completing, or understanding the task at hand.</td>
<td>If a topic discusses a new piece of equipment, an illustration may improve the discussion by showing the new features or changed aspects of the equipment. Likewise, a textual discussion of complex information often benefits from a tabled summary of the presented data and information. Use the following ‘Select if table’ to help you decide how the information can best be presented. Select ‘Table’ if it is important to summarize complex data &amp;/or information. Tables organize information &amp;/or data to be summarized into rows &amp; columns labeled in ways that make sense given the information. For example, create a table that lists different types of equipment in rows and the conditions/constraints for employment in each column. Select ‘Graph’ if it is important to visually present data for two or more critical variables in order to aid the reader’s understanding of how variables interact along a particular continuum. For example, create a graph that illustrates trajectories of various projectiles. Select ‘Illustration’ if it is important to identify the visual aspects, features, or variations of parts, components, or processes for the reader. For example, create an illustration that displays numbered sequences indicating the path water follows when flowing through a particular valve system.</td>
</tr>
<tr>
<td><strong>Definitions</strong></td>
<td>Operational definitions of important terms that need to be understood in order to complete, perform, or understand the task at hand. The following are example definitions, “A good annotation is a concise statement that provides a critical explanation or description.” “A performance goal describes the expected performance of the trainee and it helps focus the author’s writing on the required performance.”</td>
<td></td>
</tr>
<tr>
<td><strong>Examples</strong></td>
<td>Completed exemplars or models demonstrating the task at hand, e.g., an example summary statement; an example assessment item.</td>
<td></td>
</tr>
<tr>
<td><strong>Explanation</strong></td>
<td>Additional related information regarding the task at hand. The following is an example of AI provided after receiving Guidance to review a particular performance goal for clarity, accuracy, and completeness. To determine if a goal should be edited: Read for clarity. Read the goal aloud and if you ‘stumble’ while reading, the statement is probably too wordy. Edit it by removing any unnecessary words. Read for accuracy. If the verb does not reflect the desired performance, select another verb from the verb table. Read for completeness. Read the goal and make sure it describes the required performance completely (subject, verb, object).</td>
<td></td>
</tr>
<tr>
<td><strong>Wizard</strong></td>
<td>Provides two types of information: 1.) a numbered step-by-step listing of the sequential steps to be followed when completing a given task; and,</td>
<td>This task requires you to refine and clarify the text by either adding missing detail or deleting unnecessary detail. Read each section and ask yourself the following questions: Is the text understandable and able to 'stand alone' without further detail or explanation? That is, is the information complete? If not, you’ll need to add additional detail or explanation. As you read each topic, ask yourself if the information presented is complex (e.g., involves multiple steps) or is difficult to understand (e.g., easily confused with similar concepts). If so, emphasize each important step in a bulleted or numbered list. If the concepts are difficult, underscore how the concepts are dissimilar/similar by developing a list which compares/contrasts the similarities and/or differences. Additionally, as you read each section ask yourself if too much information or too many examples have been included. If so, edit to be more concise. Delete any descriptions/explanations that are not unnecessary. 2.) guiding questions or reminders aimed at helping the author think about initiating, completing, or confirming a to-be-completed task. The Wizard is a 'pop-up' feature and can be disabled by the author.</td>
</tr>
<tr>
<td><strong>SCREEN CAMS</strong></td>
<td>Screen Cams introduce and demonstrate new procedures, e.g., dropping &amp; dragging topics into an outline. Screen Cams combine the 'live' movement of the cursor with a simultaneous voiceover that describes how to complete each required step in the procedure.</td>
<td>This task requires you to inventory all existing media and documentation. Gather together all supplemental documentation and media that you’d like included in the memo. Read each topic heading and click “Yes” to indicate you have an existing piece of media or documentation that is relevant to the topic. Type the name of the item so that it can be easily identified later. For example, Graph: Typical trajectory of a … When you have completed inventorying all existing items, press ENTER to continue. Remember, if you’d like to read your memo in its entirety, select the ‘View’ button.</td>
</tr>
<tr>
<td><strong>HELP</strong></td>
<td>System-wide TRIAD HELP. Includes editing, navigation, etc. rather than task-specific guidance.</td>
<td>SCRIPT: In this section you’ll indicate which topics are essential and which are supplemental. This distinction determines where topics are placed within the document’s main text or appendices. Review the displayed topic headings. Notice as you roll the mouse over a topic heading the drafted content appears. You are going to click on each topic heading you consider essential to Knowing/Performing the tactic. You will continue this process until all topic headings are reviewed. Remember, your goal is to develop a concise memo and the main text should contain only the information and procedures that are essential to Knowing/Doing the tactic.</td>

Lesson Plans on the Internet: A Critical Appraisal

Robert Hanny, College of William and Mary, USA; Robert Hannafin, College of William and Mary, USA; Ella Donaldson, College of William and Mary, USA

This study focused on the abundance of lesson plans available on the Internet and while no judgement was made about the “goodness” of plans, the study attempted to determine if the lesson plans contained generally accepted qualities that increase usefulness to teachers. 271 Plans were examined for Objectives, Activities, Resources, Usability, and Assessment, across the K-12 spectrum in English, History, Mathematics, and Science. 51% of the sites had objectives that were behavioral, specific and complete. 45% of the Activities were complete enough to be easily followed. 55% presented adequate resources. 53% were usable without adaptation, while only 24% presented valid, usable assessments. Clearly, based on this sample of lesson plans, great care should be exercised when using most of the lesson plans on the Internet.
Humanities on the Internet:  
A Collaborative Model for Faculty Development

Catherine Zublin, Associate Dean  
College of Arts and Humanities  
Weber State University  
Ogden, UT, USA  
czublin@weber.edu

Abstract: This brief presentation includes a summary description of a Web enhanced, team taught course, Humanities on the Internet (http://library.weber.edu/humanweb). This course demonstrates how faculty and students can enhance their learning through collaboration and active learning in an electronic classroom. Presenters will describe the development and implementation of the course focusing on new technologies and new pedagogies. Collaborative methods and increased learning by faculty will be described.

Introduction

The Humanities on the Internet is a General Education course designed for first or second year college students. Although the purpose of the course is to enable student learning of Humanities content and information literacy skills, a major outcome is increased learning for faculty. This use of this course as a model for faculty development and collaboration within the Humanities will be described.

Background

The faculty development team were most interested in implementing a multidisciplinary, multicultural Humanities course providing students with the writing, speaking, and information literacy skills they would need throughout their college careers. Most of the faculty involved have long histories of collaborative activities. They have a strong interest in seeing the connections among different cultures, communities and disciplines. They wanted to learn to incorporate new technologies in their courses. The development of the course was as collaborative as its teaching methods. A strong motivation for course development was the Liberal/General Education reform movement in the US. Over 13 faculty, the Dean of College of Arts and Humanities, University Librarian, five department chairs, academic advising, three campus committees and over 60 students have been involved in the development of the Humanities on the Internet course. The course was accepted by the Curriculum and General Education Committee as a three credit hour semester General Education Humanities course in Winter 1998. The course has been taught regularly since Fall 1998. Student interest in the course is high, as sections fill quickly. Student end of course evaluations are very positive. The course is co-funded by the University Library and the College of Arts and Humanities.

Teaching Methods

The course is team taught by four faculty from the College of Arts and Humanities and one librarian. Faculty and students collaboratively developed the course Web site at http://library.weber.edu/humanweb. The Web site contains the complete syllabi, calendar, gradebook, links to faculty homepages and email, links to all of the readings, many online discussions and all the course assignments. Each faculty member teaches a two-week segment of the course. Faculty teaching the course have varied levels of experience with technology. Faculty with strong technology skills and experience work with others that are just beginning their involvement with Web delivered course materials. The
Learning Outcomes

Faculty see this course as a wonderful way to introduce students to the variety of subjects within the Humanities, within one course. Students have learned multiple ways to access more information on and off campus. Students feel more confident and comfortable expressing themselves via E-mail, Internet discussion and Web publishing after taking this course. Students acquire information literacy and computer skills within the Humanities context. The classroom and the pedagogy are designed to promote independent learning and to enable students to learn much from each other. Students are expected to work cooperatively in, and outside of, the class. Many active learning methods are introduced in this electronic classroom setting, which also contains 6 round tables and chairs for small group work away from the PCs. As students see faculty collaboration they have a practical model of a learning community to work from as they begin to build their own learning community of students. Assignments may include reading responses, Web research, developing Web sites on Humanities topics. Students are expected to engage in the arts virtually and experientially. For example, they visit a local art museum and view Web museums and art works. Faculty are particularly pleased with student performance on their last group assignment. Here, as a group, they attended a performing arts event, researched the event and prepared a summary of their research on the Web. The Web site was presented to the class in an oral presentation with the use of large screen projection. The instructors felt the faculty collaborative model assisted students as they worked together on their assignments.

Impact of Collaboration on Faculty

The course has become an important faculty development tool for the College of Humanities. The faculty have learned a great deal from each other. This course offers an excellent opportunity to teach new technologies to faculty. Faculty are able experiment with developing Web and large screen instructional media for two weeks of course work, then later they may be much more willing and able to use the same technologies within the larger context of a complete course or program. Each faculty member involved has gained insight into:

- New uses of technology to enhance learning
- New ways to plan, execute and deliver Web enhanced assignments
- New ways to present content, particularly using small groups, on the Web and with hands on computer use
- Using electronic information resources including Web syllabi, readings and EReserve
- Techniques for successful collaboration in course development, teaching, assessment and grant writing
- Modeling learning community behaviors for students

Students are encouraged to comment on the content, assignments and pedagogy throughout the semester, and they do! Faculty benefit greatly from the students willingness to collaborate. Students learn something about the process of designing and refining a new highly technologically driven course through this collaboration and ongoing dialogue.

Overall Quality of Collaboration and or Results of Collaboration

Both students and faculty have worked together to develop effective learning communities. Collaborative teaching and learning was enhanced through the use of an electronic classroom and through Web delivered course materials, assignments and assessment tools. Faculty strived for and gained new skills and new levels of teaching excellence by collaborating with their peers. Students benefited from learning from several faculty within one course; they were able to view different perspectives, attitudes and teaching styles. Students witnessed first hand faculty interaction and collaboration. Faculty use the experiences gained in this course to enhance their other courses. They see the student's appreciation of Web enhanced materials and better understand the new role of the Web for instructional delivery, even within a "face to face" course setting. This experimental team-taught course has become an effective and popular learning center for both students and faculty and a significant instructional model.
WWW-based Multimedia Training System Linked with Teaching Materials

Yamato Harada, Waseda Univ., Japan; Yusuke Yanagida, Waseda Univ., Japan; Shinichi Fujita, Waseda Univ., Japan; Chun Chen Lin, Tokyo Foreign Language Univ., Taiwan; Seinosuke Narita, Waseda Univ., Japan

Recently, a WWW-based CAI/CAL system has been needed as the Internet spreads rapidly. We also have been engaged in developing a WWW-based CAI/CAL system that supports to learn and teach foreign language. In this paper, we present a WWW-based training system that supports to learn German. This system, which enables the learner to learn the language at a level, has the following three features: First, this system is closely linked with WWW-based teaching materials (lexical and grammar materials) which we have devised, second, the teacher can edit exercises on WEB browser, third, the form of this exercises is often used in examinations of foreign languages at universities in Japan. This system has just been used by the students at our university, and we receive good evaluation from them. We intend to improve this system in order to make it easier-to-use to satisfy the needs and requests of the learner.
A Review of Virtual Learning Environments From a Learner Centred Approach

Abstract: This paper is a report on the findings of a study to investigate a range of approaches to Virtual (Managed) Learning Environments which the United Kingdom’s National Health Service might take in its implementation of a ‘virtual classroom’ for health informatics. The paper describes the detailed methodology employed, provides a brief analysis of some of the representative VMLEs identified, and discusses the need for new or integration of existing technologies to support a learner centered (rather than curriculum centered) approach.

Introduction

This paper arose from a study commissioned by the National Health Service (NHS) Information Authority in Spring 2000 which aimed to assess possible approaches towards developing a ‘Virtual Classroom’ for the NHS in the United Kingdom with reference to current and evolving developments in Internet technologies, learning and teaching, for a disparate, dispersed workforce of over one million employees.

"It is required for the purposes of this study [approximately] 10 Internet based learning environments are explored... It is known that significantly more than 10 environments exist and this work will require an initial top level 'sift' of the many examples found, such that the 10 environments selected provide the broadest view of approaches to Internet based learning." (NHS Information Authority, Invitation to Tender, 2000)

The study produced a high level review of over one hundred virtual (managed) learning environments (VMLEs), components of VMLEs, the results of Higher Education (HE) research projects and example case studies, and mapped these against the requirements of an NHS learner together with an envisaged technology architecture (previously defined in a confidential report Towards a Virtual Classroom Phase One Scoping and Needs Assessment, 1999). The term VMLE was adopted to reflect the projected implementation of the Virtual Classroom as stated in Working Together with Health Information, 1999, and as concluded in the previous study:

"A [VMLE] linked to a supporting physical network, which dynamically responds to the learner and their individual learning needs, which are continuously assessed, and where relevant information is ‘pushed’ to the learner, whilst also allowing personal sourcing of resources." (Towards a Virtual Classroom – Phase One Scoping and Needs Assessment, 1999, TVC-P1)

The paper describes the methodology employed, provides a brief analysis of some of the VMLEs identified, and discusses the need for new or integration of existing technologies to support a learner centered (rather than curriculum centered) approach.

The study was undertaken by a partnership experienced in life-long learning, e-learning, health and technology standards, and consisted of Ms S Hardy, Dr G Nestor, Dr M Quentin-Baxter, Dr K Lawrence, Dr EH Smith, Dr A Drury, Dr NJ Fox, and Professor IN Purves, drawn from the Sowerby Center for Health Informatics at Newcastle (lead partner, University of Newcastle), the Faculty of Medicine Computing Center (University of Newcastle), a Salford collaboration between Academic Enterprise (University of Salford) and the Salford Royal Hospitals NHS Trust, and The WISDOM Center for Networked Learning (University of Sheffield).

Major goals of the study

1. Assess current learning and teaching strategies in Internet-based learning via a review of current known VMLE products and projects in relation to the needs of the NHS, as outlined in Information for Health (1998) and Working Together with Health Information (1999).
2. Consider the suitability for transfer of a VMLE to a UK-wide learner centered continuing professional development environment, specifically the NHS, based on an adult learning model, incorporating sophisticated portable reflection and recording tools.

3. Examine the conceptual models of both 'teacher' and 'learner', and how these definitions might affect the assessment/construction of a VMLE based on the required adult learning model and applied to a hugely disparate and distributed workforce.

Background

The TVC-P1 study outlined an envisaged topology and associated learning process, which encompassed access to information, eCommunity technologies, and distributed learning resources (Table 1). It was assumed that issues of hardware, connectivity and access were resolved in the NHS environment, although this is not yet the case (NHS Plan, 2000; p49). The heart of the flexible adult learning model was person-centered, including a learning record and continuous needs analysis (Kaufman, Mann and Jennett, 2000). This model personalized learning, facilitating a lifelong educational process with emphasis on tutoring, mentoring, personal reflection time, quality assurance of the learning experience, personal development planning and certification (Vescoukis and Retalis, 1999). Coding and classification could be used to describe each of the components of the system to facilitate matching relevant information to learners and information exchange. This is fully learner-centered, focused on supporting learning and teaching requirements (Patel and Kaufman, 1998), as opposed to the more traditional curricula centered style adopted by many commercial providers of VMLEs, and has the potential to accommodate new audiences and wider learning and teaching needs (D'Alessandro, et al., 2000).

Method

Outline of the basic approach

The methodology for identifying and evaluating the possible approaches attempted to reflect pedagogic and process issues as well as recording product features. It included an initial review of journal literature, electronic databases and the Internet, employing standard literature search techniques and a range of electronic search tools (based on Berry et al, 1998). The filtering process used a complex matrix to yield a representative group of c.10 VMLEs, which subsequently underwent an individual in-depth evaluation according to an agreed In-Depth Evaluation Protocol (IDEP) (Figure 1).

Figure 1: Illustration of the approach and methodology schema for determining the final VMLEs to be considered for in-depth evaluation using the IDEP.

High Level Literature & Resource Review

On-line Database of VMLEs: An on-line, web-based database was designed using MySQL, Zope and interactive extended Wikipages. Researchers were asked to contribute as many unique entries as possible. These ranged from descriptions of components of VMLEs (e.g. web based assessment tools) to detailed descriptions of complete VMLEs or enterprise resource packages. There were also case studies of applications of particular VMLEs (e.g. University of Wollongong makes use of WebCT) and details of published comparative analyses of VMLEs. The database contained over 120 entries by May 2000. [Since the cut off date further information has been added, and more than 300 entries were available at the time of writing. http://www.ltsn-01.ac.uk/vle]

High Level Review: An initial rich overview of the structure, functionality and usability of c.100 VMLEs was undertaken. The home web site of each VMLE available in the database in May 2000 was visited by one of the researchers and graded in terms of three parameters which were used to inform the development of the ‘League Spreadsheet’ and ‘Selection Matrix’ below:

- Technical sophistication (‘Technology’)
- Pedagogical model appropriate for adult life-long learning (‘Pedagogy’)
- Whether already applied in health context (‘Health’)

Identification of VMLEs for In-depth Evaluation

A League Spreadsheet was designed and linked back to the original requirements identified in the TVC-P1 study, the High Level Review and cross-referenced against the proposed IDEP. This method also corroborated the results of the High Level Review, and limited subjectivity in the choice of representative VMLEs to compare (Table 2). Each feature was scored according to the agreed system ranging from Not Present (0) to Good (3).
Pedagogical Foundation – overall educational philosophy and approach of the VMLE; encompassing pedagogy, user types and facilitation, synchronicity, etc.; examples of effective use in practice

Needs Assessment – profiling of user as point of entry into the learning environment

Learning Record – continual dynamic record of activities facilitated by the VMLE, incorporating support for reflection in addition to the development of a simple transcript

Communication – community, collaboration, and facilitation of communication, architecture, functionality and range of features

Standards – conformity to accepted and emergent Internet and database standards, encompassing technology options and requirements, architecture, potential scalability, and cost implications

Functionality – ease of use, fit for purpose, user requirements, ease of content provision

Table 2: League spreadsheets feature headings with explanations.
League spreadsheet reviews were performed with reference to the VMLE web site, access to full installations or demonstration copies. The mean feature scores, mean total score and standard deviation for each VMLE were calculated by adding the results from the separate assessments performed and adjusting for number of reviewers. Standard deviations were used to indicate the level of agreement between reviewers, and another reviewer investigated VMLEs with high standard deviation in any category. Using a Selection Matrix VMLEs were ranked according to their mean total score and examined in detail to ensure that the required representative breadth had been realized. The top two VMLEs for each of the six feature categories were also identified for possible inclusion in the final selection by ranking all VMLEs by feature, in order to identify potentially strong component parts of a VMLE. An IDEP was developed and one reviewer for each of the representative VMLEs identified completed a pro-forma. In-depth evaluations documented detailed specifications, scalability, features and functionality, pedagogic focus, usability, strengths and weaknesses, risks and benefits, cost, implementation issues, standards and compatibility of the identified VMLE (available from authors). In-depth evaluations were performed with reference to the VMLE web site, and at least one of the following: access to full installations or demonstration copies, demonstrations by sales team and interviews with key stakeholders. Each evaluation took between one and three days to compile.

Major points of results
The twelve representative VMLEs yielded from the range of research tools employed, mapped against the study requirements, are detailed below alphabetically. These represent the top eight results from the selection matrix, the remainders were chosen as examples of strong components of a VMLE, or representative of an under-represented area.
- Blackboard Course Info – commercial on-line learning delivery environment, with extra functionality and additional management and administration tools provided as higher levels are adopted.
- British Aerospace – large-scale company Intranet focused on training and mapping needs. The BAe systems Virtual University received the ‘U.S.A. Corporate University Xchange Excellence Award’.
- Centra Symposium – commercial NT based server product using Java to deliver mostly synchronous tools to web clients. Used a didactic teaching model, although it supports a range of mentoring functions and could probably be adapted to other styles of learning.
- Colloquia – example of a HE research project taking a user-centered pedagogical approach which functions off-line and without a central server.
- Learning Space - commercial online learning tool aimed at providing a learning platform for corporate and HE clients.
- Microsoft Learning Resource Network (LRN) Tools – major software supplier and LRN Tools might meet many of the identified user needs.
- Mindlever - commercial web authoring and course management software aimed at the corporate market.
- Open University – primarily asynchronous curricula centered HE on-line delivery method built on the Centricity First Class software.
- Internet Personal & Academic Records – a HE research project implementing a sophisticated tool for maintaining on-line personal development plans and recording achievement (component of a VMLE).
- Prometheus - A web based course management and design system, built using ColdFusion on a Windows NT platform, iteratively developed as a HE research project, which may become commercially available.
WebCT - commercial online learning delivery environment, facilitating course delivery and learning community activities developed from HE research project.

WISDOM - provides an integrated method for accreditation of on-line learning, and facilitates dynamic learning community activities - a good example of a community of practice (component of a VMLE).

In order to map the representative 12 VMLEs to the range of characteristics of an NHS learner, the in-depth evaluations were analyzed for relevant pedagogy, continuous needs assessment and learning record, flexibility and scalability to potentially one million users (Table 3). The price of VMLEs varies widely from nil (HE research projects) to over US$500,000 per annum for a limited user license. In addition, there were costs associated with start-up, support, infrastructure, content provision, training and maintenance.

Table 3: Summary of the representative VMLEs indicating whether they are curriculum centered or flexible, range of features supported, presence of a pedagogic foundation relevant to the NHS needs, needs analysis and learning record, and evidence of whether the VMLE could scale to support a large number of users.

It should be noted that these results are limited by the rate of change in technological developments, and by reliance on the outcomes of the confidential report TVC-P1, which mapped the NHS learner requirements and the envisaged technology architecture.

Discussion

The very large number of VMLEs identified is indicative of many institutions taking a homegrown approach to implementing VMLEs in order to engender ownership and produce systems which are tailored to their unique situations. The 12 representative VMLEs examined in-depth ranged widely in terms of their pedagogic approach, features, functionality, implementation, and application. None exhibited all of the characteristics identified to deliver a VMLE for the NHS, but there was evidence of the availability of the appropriate components (many of which did not make it into the final 12). Most of the
more robust and scalable commercial VMLEs were only weakly relevant to the learner centred ('androogic') approach required, particularly with respect to a continuous cycle of learning needs analysis and establishing a reflective learning record, while those with a stronger relevant pedagogy lacked a variety of functionality or could not scale as easily.

The pedagogic approach identified is essential to facilitate the establishment of content in the VMLE suitable for adult learning and continuing professional development for the NHS. The development of content is a shared responsibility as part of the two-way conversation of learning, and the process of developing content is the outcome, not the content itself, as identified over a decade ago by Laurillard (1987).

Many of the preferred curriculum centred systems being trialed in the UK to support institutional distributed course delivery present a traditional metaphor of 'teaching'. The implications of this for continuing professional development demands a review of the nature of courses offered to the new wave of mature, part time students who are being encouraged back into education as part of the national agenda to widen participation and promote lifelong learning. To adapt to the need for novel approaches to the delivery of curricula brings the model much closer to the NHS learner model outlined above, and necessitates a more learner centred approach than is currently available via any of the proprietary products or research projects reviewed or evaluated as part of this study. Whilst may be possible for curriculum focused and learner centered solutions to co-exist, this requires institutional organisational and technological convergence, and an understanding of the potentially conflicting functions of the two systems.

The evolution of IMS standards may bring about a change in the functionality of VMLEs, whereby they move away from trying to deliver complete solutions, and adopt a more component-style architecture. Interestingly, as this becomes more sophisticated, a new architecture model based on learner objects emerges, which maps more closely the learner model and architecture envisaged in the initial TVC-P1 study. This has been described as moving towards 'second generation virtual learning environments', where coding and classification are used to richly describe all of the objects in a learning system, and rules dynamically determine 'communities of practice' (Wenger, 1998) through the relationships and associations between these objects (Malet, et al., 1999). This model enables 'server push' whereby relevant information is made available to learners, and the system monitors new opportunities or needs, and provides updates to the individual, according to their characteristics, attributes and preferences. NHS learner information would enable the system to dynamically identify new learning opportunities or needs, based on these changes in the learner profile.

The NHS has yet to determine its preferred way forward, however this study highlighted a number of issues that suggest to the project team that the NHS learner centred model may align closely with current VMLE developments both in commercially available proprietary products or research projects.

New Designs for Web Based Learning Environments

Barry Harper, Digital Media Centre, University of Wollongong, John O'Donoghue, Deputy Director/Head of Pedagogic Research, Delta Institute, University of Wolverhampton, Ron Oliver, School of Communications and Multimedia, Edith Cowan University and Lori Lockyer, Digital Media Centre, University of Wollongong

Abstract

With the continued advances in information and communication technology comes the interconnectivity of education institutions, businesses and industries. Either by default or association, the traditional education system will need to change and adapt to these new demands and opportunities. With these changes we are in danger of losing the focus of the learning process and not recognising the importance of maintaining a balance between technology and pedagogy. This paper will review these issues and examine an investigation of new learning designs which take advantage of the affordances of the Web and the opportunities which arise.

Focus for the web

In today's society, greater demands are being placed on education systems at all levels to produce citizens who can use knowledge in new domains and different situations. Members of society at every level are being asked to demonstrate advanced levels of problem-solving skills to retain their level of employment. Learning to think critically, to find, analyse and synthesise information to solve problems in a variety of contexts and to work effectively in teams are crucial skills for modern employees and thus consistently appear as attributes of the graduate in the prospectus of many universities.

Whilst these demands are being expressed in a variety of contexts, strong claims are being made for the role of information and communication technologies in supporting learners in achieving these goals. Authors such as Joo (1999) are proposing that the possibilities for improving educational practices using the Internet seem to be boundless. Higher education institutions are seeking innovative ways to provide flexible courses through new media (Barnard, 1997) and the possible era of a truly inter-connected global schoolhouse (Knight, 1996) is no longer considered to be extreme in the age of technology-mediated learning and the transmission of information at the touch of a button.

One of the difficulties for higher education institutions is to develop an understanding of the focus of their endeavours, that is, how to balance the demands of technology against the need for strong pedagogy. The technology is not universally seen as a panacea for our current educational systems woes. As long ago as 1984 Cuban warned "there should be a page in the Guinness Book of Records on failed ....... reforms, for few ever seem to have been incorporated into teachers' repertoires". Alfred Bork (1995) has argued in his critical review of the failure of computers in universities that the effective use of new instructional paradigms, supported by technology, requires a shift in instructor's pedagogical approaches.

Additionally, many authors, such as, Hutchison, (1998), fear that institutions are rushing into this technological dimension too quickly. He warns that there is a need to think carefully about the implications of technology on society and specifically on higher education.

"All aspects must be deliberated to ensure that we get the idea of virtual universities right in order to envelope the rapid expansion of the university sector and the ever growing dependence and recognition of formal qualifications."

Morrison (1999) shares this fear and debates whether something essential to higher education is being sacrificed when college and university courses take place on-line rather than on-campus. Hayes (1996) argues that "a catalogue of courses is not really a university", and it is simply not possible to learn the skills of teamwork and leadership, so vital in today's employment market, at a virtual university (Hayes, 1996).

Whilst the change predicted is transformational, and according to many writers, damage may be inevitable, a focus on the impact of IT on education not being detrimental to the education process must be maintained. Additionally, the focus on the web to support learning does raise a raft of additional issues not previously faced or fully resolved by tertiary institutions. Issues such as teleworking, ownership of intellectual property, transfer of student management to the instructor, technology risk management, 24 hour service and access, etc. are being often overlooked or not recognised before implementation.

As Reeves and Reeves (1997) suggest, "despite all the interest, little research evidence exists to support claims for the effectiveness of Web-based instruction" (p. 59). One of the key issues appears to be the pace of change of emerging web technologies which is so rapid that learner-centred pedagogical models are urgently needed.
Gavriel Soloman (1998) has supported this concern and has noted that for the first time in history, technologies could be outpacing pedagogical and psychological rationale.

**Learning Design Characteristics**

The speed and rapid growth of information and communications technologies (Moore's Law, 1965) has enabled many new and exciting developments in the last few years or so, opening up new possibilities in all sorts of different fields, including higher education. On-line delivery is still of an embryonic nature (Morino Institute, 1994). However, evidence suggests that the maturation of on-line delivery is starting to be realised as innovators develop realistic pedagogical models (Britain & Liber, 1999). For example, a body of literature is now starting to report on innovative tools, with strong pedagogical underpinning. Bonk (1998) has reported on interactive tools for on-line portfolio feedback, profile commenting, and Web link rating, while Oliver and McLoughlin (1999) are building tools for on-line debate, reflection, concept mapping and student surveying and discussion. There is a determined effort in the research community to investigate the key issues which we will need to address if we are to match pedagogy with technology affordances. Research agendas will need to address issues such as; design models to support development teams in re-conceptualising traditional modes of instruction for on-line delivery; academic instructional design skills which are not well represented in higher education; information about the learner's experience and their needs in on-line mode; student preparation and supported through the initial stages of using on-line environments; options for specific groups; drop-out rates for distance education; cohesion in on-line delivery; resource implications for infrastructure, personnel, professional development and administration; comprehensive costing and cost-effectiveness studies.

**A Collaboration in Developing Learning Environments**

In this information age of global competition universities, both in the UK and abroad, Universities are moving into on-line delivery. In support of the need for a better understanding of moving quality student learning into this domain, the Digital Media Centre at the University of Wollongong, Edith Cowan University and the DELTA Institute, at the University of Wolverhampton, are working on a series of ideas to develop our understanding of moving academics forward in the design of learning i.e attempting to move pedagogy forward to keep pace with the technology. The collaboration will build on an Australian University Teaching Committee project, Information and Communication Technologies and Their Role in Flexible Learning, being developed by the University of Wollongong and Edith Cowan University. The AUTC project is seeking to construct an evaluation framework for technology based learning products that can identify and articulate underpinning learning designs which have he potential for redevelopment outside the immediate context in the form of generic learning environments which can be adapted for use in different knowledge domains. This collaboration will make use of the outcomes from development of the WOLF web environment, at the DELTA Institute, to investigate a series of exemplars which will illustrate the application of a number of the generic designs developed in the Australian project. The exemplars will attempt to address the less traditional learning designs, and illustrate the extended range of learning environments which the affordances of the Web offer. Additionally, the project will seek to incorporate additional media elements, such as broadband signals, into the designs.

Abstract: The most common interaction with the Web is visual and accomplished through the use of the keyboard or mouse. Currently, the user cannot interact with a Web page using speech. This orientation limits the mobility of the user and his interaction with the Web because both hands and eyes must be involved in the task. Speech technology will promote an increased use of the Web in untapped environments in a similar way that cell telephones have promoted the increased use of telephones. One of the limitations to the development of voice systems is the lack of easy-to-use tools for creating spoken dialogue systems. One of the most promising emerging technologies for solving this problem is VoiceXML. VoiceXML brings the Web and content delivery together in voice response applications in an easy-to-use manner. This paper presents an editor for creating VoiceXML documents and narrates the research behind the tool.

Introduction

Currently, the most common interaction with the Web is visual and accomplished through the use of the keyboard or mouse. While sound files can be incorporated as part of the presentation, the user cannot interact with a Web page using speech. This orientation limits the mobility of the user and his interaction with the Web because both hands and eyes must be involved in the task. In fact, most pervasive computing devices today are used in a hands and eyes busy mode. The use of speech recognition and synthesis will remove this limitation and promises to be the next wave in Web interfaces. The use of speech recognition frees the user from the windows, icons, menus and pointers (WIMP) interface. It will enable the user to interact with the Web in a hands-free or mobility required manner (e.g., while traveling in the car) with no manual intervention [1,3,7]. Speech technology will promote an increased use of the Web in, as yet, untapped environments in a similar way that cell telephones have promoted the increased use of telephones.

Currently most of the speech interfaces are similar to telephone response systems in which the user is expected to enter a preset number from a menu of choices. While these systems are commonly used today, these systems have been viewed as limited because the user must remember the mapping to keys, there may not be an appropriate option, and navigation must proceed through a prescribed set of options, even if the user knows exactly what he wishes to do [1].
A review of the recent literature indicates that researchers are working diligently to understand speech interaction and when its use is most successful. Several recent articles have reported on studies of the voice interaction of humans with computers and how to make speech interfaces more conversational and adaptive than voice response systems [1,2,4]. Boyce investigated the use of key word driven and spoken dialogue systems and found that spoken dialogue systems were more flexible, but more complex to design. She also found that users preferred to interact with systems that referred to themselves as “I”, but found no significant differences in the preference for casual versus formal speaking style. Other results indicated that the right initial system greeting is essential for establishing user expectations and helping users determine how to proceed [1].

Schneiderman investigated the limitations of current speech interfaces, particularly the interaction of speech and physical activity (e.g., keyboard manipulation), in interfaces. He found that most humans find it easier to type and think concurrently than to speak and think concurrently. Thus, voice command users needed to review their work more often than keyboard users in a word processing environment. He concluded that an understanding of the cognitive processes utilized in speech will aid interface designers in integrating speech in a more effective manner. Schneiderman also indicated that future uses of speech in Web environments will not be as standalone components, but as complements to visual interfaces as part of a multimodal interface [7].

Multimodal interaction, which includes speech, is part of a paradigm shift away from the use of WIMP interfaces. These systems have the potential for functioning more robustly than a single recognition-based technology such as speech. The design of these systems requires a knowledge of the properties of the individual modes, such as speech, and the information content that accompanies them [6].

One of the limitations to the development of voice systems is the lack of easy-to-use tools for creating spoken dialogue systems, particularly by non-experts who have no experience with or desire to learn the low level details of speech technology [2,3,7]. This lack of tools inhibits the development of applications and the portability of existing applications. It also results in a scarcity of skilled application developers and high costs of development and deployment [3].

One of the most promising emerging technologies for solving this problem is VoiceXML (Voice eXtensible Markup Language). VoiceXML is an XML-based markup language that brings the Web, content delivery and voice response applications together in an easy-to-use manner. XML is a specification for designing markup languages that are used in the Web and is an accepted standard for providing structure to Web documents. It specifies a standardized text format for representing structured information on the Web. HTML, which is a markup language, as it is currently designed, is not an XML application, but could be redesigned to be one. XML documents consist of data and markup components (e.g., element tags, processing instructions, data elements, comments, etc.) that are parsed and interpreted by an XML processor (such as a Web browser). Each component of an XML document (e.g., page, image, audio clip) is stored independently from the document. SMIL (Streaming Media Integration Language) and VoiceXML are just two of many XML vocabularies that have been developed. Currently, there are a limited number of browsers that support XML documents, but both Netscape and Internet Explorer have committed to supporting XML 1.0 [5].

VoiceXML was released in March 2000 and accepted in May 2000 by the World Wide Web Consortium (W3C) as a basis for developing a dialogue markup language for voice [8]. Basing VoiceXML on the existing standards of XML (eXtensible Markup Language) has the benefits of allowing the re-use and retooling of existing tools for creating, transforming and parsing XML documents. Several vendors including IBM and Motorola have implemented versions of VoiceXML 1.0 [8].

The purpose of this research was to develop a prototype for an easy-to-use editor for creating VoiceXML documents. Such an editor allows novice users, as well as experienced ones, to create or edit Web-based speech systems easily.
Objectives

The objectives of the research project were:

1. To determine the attributes of an effective voice interaction interface.
2. To identify the components that are needed in an editor for developing VoiceXML applications using the attributes identified in objective one.
3. To design the interface and supporting system for a VoiceXML editor that incorporates the components identified in objective two.
4. To develop a prototype of a VoiceXML editor using Java.
5. To determine the effectiveness of the editor in creating new VoiceXML documents and editing existing documents.

Significance of Research

As indicated previously, the lack of tools for creating voice dialogues for the Web is inhibiting the development of voice applications on the Web. This project will help to fill that gap. Additionally, the project is timely since voice systems are the next frontier of Web-based interfaces. Advancing technology has finally reached the point that it can support speech synthesis and recognition systems in voice applications in a reliable and efficient manner. It is expected that many E-commerce applications will soon support voice [4]. Web-based voice applications also have potential in academics. The tool created in this project has the potential for assisting non-technical developers in developing voice applications.

Hardware and Software Environment

The language used for development of the VoiceXML editor was Java since it is portable. The system was developed as a Java applet that enables anyone with a Web browser to create voice applications for the Web. The editor was developed and tested using a personal computer, although the code was developed using JDK1.3 (Java Development Kit) which makes it possible to develop and execute the system on any platform that has JDK1.3 and a Web browser that supports VoiceXML 1.0.

Methodology

The first step in the project was to determine the attributes of an effective voice interaction interface. Current voice response system dialogues represent paths through a decision tree. An investigation of approaches to the representation of a voice dialogue in the development environment was conducted. Because the editor interface is visual, a review of the literature on the development of graphical user interfaces was also conducted in this step. Since the dialogues are not visual, the usual procedure used in developing graphical user interfaces by laying objects out in a window as they would appear in the interface was not be appropriate.

The second step was to identify the components that were needed in an editor for voice applications using VoiceXML. During this phase of the project, the attributes identified in the literature above, along with a review of the VoiceXML syntax and the attributes of existing language editors, were used to decide what support was required in an editor for creating VoiceXML applications. First, the VoiceXML syntax was reviewed to determine which syntactical constructs of VoiceXML needed to be supported by a prototype editor. It was decided that because of the scope of the language syntax, that only a fundamental set of components would initially be supported, with plans to implement support for the entire VoiceXML syntax in a future...
project. Second, existing language editors with a visual interface (e.g., Visual Basic, Visual C++) were reviewed to identify the basic set of editor functions that were needed in the editor.

The third step was to design the interface and supporting system for an editor that incorporated the components identified in objective two. Standard systems analysis and design methods and tools were used to design the software components of the editor. The design approach was object-oriented so that components could be easily modified and new features easily added to the system at a future date. Java is an object-oriented language so this approach is most suitable for supporting the subsequent implementation.

The next step was to develop a prototype of a VoiceXML editor using Java. The system was developed as an applet so that it can be executed in the Web and distributed to interested users. The editor is similar to other visual language editors. The editor includes the typical file operations (new, save, open), editing capabilities (cut, paste, search), a tool box representing the objects that compose a VoiceXML application, a development window, formatting capabilities, the ability to switch to and edit the code behind the application, the ability to switch between different components in the application, and a visual layout of the components of the application.

No attempt was made to reverse engineer an application that was created outside the environment into the graphical components that are used by the editor to create a new VoiceXML application.

Several applications were identified for development in VoiceXML and created using the editor. For each, a list of predicted behaviors and outcomes was manually generated. Each application was tested within a browser and the behavior matched to the predicted outcome.

Successful integration of learning technologies in school classrooms (SILT)

Elizabeth Hartnell-Young
University of Sydney
Australia
ehy@results.aust.com

Abstract: This paper reports on the progress of a research program based in Victoria, Australia, where teachers are strongly encouraged to integrate technology in their classrooms. The teachers in this study are generally positive in their view of the potential benefits for students of learning with technology, and many have their own government-subsidised laptop computer which provides the opportunity for regular access for their own learning. However their classroom behaviours vary widely. Preliminary findings from classroom observation, surveys and a series of reflective conversations with teachers have identified some reasons for these differences and ways in which teacher professional development might be enhanced.

Introduction

Kerr (1996) and Fisher, Dwyer and Yocam (1996) suggest that the increasing use of technology results in greater student involvement in project learning, increased learning in groups, a shift in the teacher's role and attitude from being a source of knowledge to being a coach and mentor, and a greater willingness on the part of students to take responsibility for their own learning. However a recent Australian study (Cuttance et al. forthcoming) found that teachers, overall, appeared to find the acquisition of the skills to lead learning in these environments a major challenge and there was a major gap in the provision of high quality professional development.

The Study

This two-stage ethnographic study was conducted in Victorian state schools during 2000. Teachers participating in the larger Successful Integration of Learning Technologies (SILT) project participated in conversations and classroom observations, through which broad issues affecting teacher's practice and their professional learning have been identified.

Stage One

The context was established through 53 observations of classes in 27 schools. Twenty-seven observations (51%) took place in Year 5/6 primary classrooms, while 25 observations were in secondary settings, mainly Years 7 and 8. Each observation was written up by the observer and coded using QSR N4 Classic™ (Richards 2000). The data were analysed to identify the range of teacher roles currently in use.

It appears that teachers are engaged in a variety of behaviours in relation to the classroom. Jones (1995) describes the teacher as facilitator providing rich learning environments, experiences, and activities; creating opportunities for students to work collaboratively, to solve problems, do authentic tasks, and share knowledge and responsibility. The observations in this study showed numerous behaviours falling into this description. As a result, the term "facilitator" is taken to be a broad term conceptualising an approach to teaching which is more student-centred and constructivist than the teacher-directed approach, rather than a set of specific behaviours. The roles observed were planner, content manager, people manager, technician, instructor, demonstrator, coach, monitor and assessor, guide and reflector. Data from Stage Two reveal additional roles including confidant (when students reveal personal information in private communication) and learner (when teachers acknowledge that they don’t know and embark on seeking knowledge). Teachers as a group exhibited the full range of behaviours, but individually their repertoire was generally smaller.
Stage Two

After the commencement of the observations, a purposive sample of teachers spanning the middle years of schooling was chosen by inviting teachers from six schools in the SILT project to participate in a structured conversation to identify their attitudes to learning and to technology. Thirteen teachers from six schools participated.

Preliminary Findings

Teachers in this study were generally positive about student learning, but half of them admitted that this was not always the case in their own context. All but one felt that technology brought with it a range of benefits to student learning. On the assumption that teachers who enjoy working with technology will explore new uses and create learning opportunities for their students, they were also asked whether they enjoy working with technology in the classroom. As Tab. 1 shows, responses were spread across gender and across primary and secondary settings. Six teachers (3 males, 3 females) stated clearly that they enjoyed using technology, while six others (3 males, 3 females) stated that their enjoyment was dependent on factors such as access and ease of use.

Table 1: Teacher enjoyment of using technology in the classroom

The teachers might appear to be open to using technology to support constructivist learning and they supported the notion of students being autonomous learners. Yet the classrooms observed displayed a wide range of activities and behaviours from teacher-centred to student-centred, and varying amounts and levels of computer use. Students and teachers in primary and secondary schools appear to have very differing levels of access to computers and in the classroom observations it was rare to see a teacher using technology. Some teachers appear to allow students to take control of their learning with minimal intervention, more because of a lack of knowledge of technology rather than a commitment to constructivism.

There are clearly some contextual factors which affect teacher behaviour. The data were analysed to identify teacher comments which would identify such factors, revealing an important difference in organisational arrangements and timetabling in primary and secondary settings. The timetabling in primary schools allows for longer sessions with one teacher than is common in secondary settings. The primary classrooms, although hives of activity, were also able to spend time in reflection, with one outcome being increased efficiency. In contrast, many secondary schools have computer labs rather than a few computers in each classroom. When classes want to use computers in lab settings, as is frequently the case, scheduling is critical, and a different culture develops. The lab settings themselves often allow little space for other activity, such as writing, and demand a focus on the computer. Congruence between the whole-school culture and the individual teacher's beliefs appears to be important in supporting the use of technology, particularly in the secondary setting, where teachers have less time to interact with each class of students. Community issues included the range of students' prior experience and access at home. In some cases, teachers reported personal concerns such as a need for time to learn, to gain greater technical knowledge or alternatively support to ensure smooth functioning of technology. Professional development clearly must focus on issues of school organisation as well as individual teacher development.

Abstract: In the four examples of pedagogic integration of Internet in a “multimodal” university situation reported herein, we bring into light an innovative process whose central objectives were improvement of the quality and relevance of the training strategies provided to students. This article will contribute to the characterization of the Internet integration continuum, from enhancing a traditional course with a minimal integration of Internet (level 1) to a complete integration in the form of what has been called a virtual campus (level 3). We suggest that the more or less intensive use of distance communication in the various modalities of integration does not reflect the quality of the learning. Indeed, we are convinced that, whatever the level of integration of Internet to the system, coherence of the proposed activities and pedagogic value of the tools implemented is the most determining factors for success.

1. Introduction: Levels of Internet integration in the university syllabus

The “unimodal” university, that is an institution almost exclusively dedicated to open and distance training or learning, is a familiar form of the use of Internet in university curricula. Students there are mostly involved in courses mediated through remote access. The mission of the unimodal university is clear and exclusive. Here, the integration of Internet is seen as the logical end to the evolution of pedagogical means. Despite this technological bias, the training often continues to rest mostly on the traditional media, even in the most avant-garde universities in this field, such as the British Open University and the Télé-Université (UQAM).

At the outskirts of these dedicated universities, more traditional institutions have begun to integrate the use of Internet at different levels in their various syllabi. Those “multimodal” universities exploit the potential for modern remote communications in some courses or some classes while continuing to dispense courses on their premises by the traditional method. Because of their pedagogic use of Internet, multimodal universities are generally endowed with a much more diversified teaching strategies than are unimodal institutions. The implementation of Internet-based pedagogy is often the result of individual initiatives by energetic teachers eager to enhance their pedagogic arsenal. Also, Internet integration is sometimes viewed by academic authorities as the means to attain some short or long term objectives (e.g. increasing student enrollment, reducing costs, improving the offerings). Infrequently, Internet integration may underlie the need to replace outdated teaching strategies as a means of meeting new requirements in a specific professional environment (Rogers, 2000).
In the four examples of pedagogic integration of Internet in a “multimodal” university situation reported herein, we bring into light an innovative process whose central objectives were improvement of the quality and relevance of the training strategies provided to students. In the first two instances, we describe a first-level integration that can be characterized as the juxtaposition of Internet into a traditional course. The third one pertains to the total integration (level 2) of a complete course in a multimodal university situation. In the last example, we present an integrated device of long distance teaching with Internet (level 3).

2.1 Practicum, a case solving system on Internet in a juxtaposition scenario.

We chose the Practicum system, which has been in operation for five years at the Faculty of Psychology and Education of the Université de Mons-Hainaut in Belgium, to illustrate the first level of integration of Internet. Practicum completes the theoretical part of a course given in class on the learning models given each year to approximately 100 undergraduates. Practicum is structured around three functionalities (figure 1). First, a well-defined task, consisting of situation analysis, problem identification, and solution elaboration is provided. Secondly, a set of help tools is given students to assist in the contextualisation of task and approach, and finally there is a distance dialog with the supervisor. Essentially, the system is viewed by the student as an opportunity to put into practice the concepts and principles that have been studied during the theoretical course. This is a classic example of the juxtaposition of Internet into a traditional course.

2.2 “Simul”, a medical simulator on Internet in a juxtaposition scenario.

The Simul program was developed in the late 1980’s for the students of the Faculty of Veterinary Medicine of the Université de Montreal so they could apply their procedural knowledge to the resolution of problems submitted to them in class during the theoretical part of the course. The system has been available to the students for more than 10 years in the context of practical sessions that took place in the computer lab of the faculty. Last year, the system was completely remodeled so it could be put online. The objectives of this transformation were multiple: facilitate the updating of the system, enable the enhancement of interactivity and, most of all, allow distance access to the simulator. This new version of Simul is based exclusively on databases, which allows for a personalized monitoring of the students’ work and a feedback adapted to each situation. Before being allowed to take the final exam, each student is required to complete, within six work session, all the 15 clinical cases of the Simul program in accordance with prescribed steps for resolution of problems in veterinary medicine. A supervisor is made available for the students at specified times to answer questions. Students also have access to the simulator at all times via Internet.

2.3 Learn-Nett, an example of complete class integration to Internet.

This second level of integration of Internet implies a complete restructuring of the pedagogic approaches used in a course. The system allows the creation of a virtual space within which students from five universities in the French part of Belgium and four outside Belgium (Great Britain, Spain, France and Switzerland) can get together to accomplish activities associated to the new technologies in education (project Learn-Nett’).

The Learn-Nett project is supported by the European Commission via the SOCRATES program. Activities proposed are structured through a website endowed with a number of functionalities devised to further the pooling and sharing of knowledge. To make it more user-friendly, the site is based on a spatial metaphor: the space is divided in three distinct compartments, one public and two private. In one of the private zones, student groups can create a customized work environment in which they work together on their term work. Supervisors can occupy the second private space that gives them access to all the functionalities available to the students as well as to their own specific tools. Within the student’s space, some functionalities, such as the public forum and the news are opened to all, but others, such as the private forums and the synchronous communication space are restricted to specific users. This approach can be assimilated to a project pedagogy in which members of a group create a virtual community with the help of communication tools. The supervisor intervenes to facilitate distance interaction, to encourage students to reflect on their approaches, to assure that the deadlines are met and to stimulate the active seeking of information. This course, which is entirely presented on the Internet, is unique to this university, as the rest of the curriculum is taught in the traditional manner.
2.4 The virtual campus, a fully Internet integrated system

The expression “virtual campus” refers to an integrated system of distance learning. This initiative results from a collaboration between the Université Louis Pasteur (Strasbourg), Université de Genève, Université de Dakar and Université de Mons-Hainaut that is financially supported by the Agence universitaire de la francophonie. Its purpose is to offer integral training to graduated students from francophone countries outside of Europe, namely Africa, Southeast Asia, the Islands of Indian Ocean, the Caribbean region and the Maghreb.

The course is divided into six modules of which each module comprises a unit. One unit includes two sequences of activities: one with self-correction, the other with distance supervision. For example, there is one the conceptoscope which consists of a virtual space divided into several rooms, including a center of documentation that offers a basic glossary, an office for each student, a meeting room for each group and a bank of maps for the eventual publication of conceptual maps.

The conceptoscope was inspired by the constructivist paradigm. The modules are designed to give students the opportunity to learn through discussion of their point of view with their supervisor with respect to the basic glossary, or with their fellow students inside or outside the group. In addition the modules provide the basis for critical analysis of conceptual maps elaborated within each group. Student activities can then be characterized in three areas: elaboration of a student’s position with respect to a definition submitted by the supervisor, comparison of the results from each group and finally, negotiation and dialog within the group to obtain consensus on the definition of concepts with respect to the conceptual maps to be submitted. In passing through these three successive stages, students will experience deepening of their understanding of the concepts and, through discussion of the various points of view, they will more readily comprehend the scope of the semantic field associated to the concepts examined.

3- Pedagogic implications of observations made.

Evaluation of the outcome of these projects provided the opportunity to highlight some interesting observations.

Quality of the apprenticeship depend, above all, on appropriateness of the activities offered to students.

As emphasized by Gillette (1996) and, more recently, by Anderson (2000), no matter the level of Internet integration, the appropriateness of all the activities proposed to students with respect to the objectives of the course seems the most important variable. Hence, the decision should not be made on the basis of more or less Internet, but rather of the complementarity of the different pedagogic activities proposed.

Regarding integration of the first level or juxtaposition, important indicators of learning context appropriateness are the degree of success, the good comprehension of theoretical elements and the capacity to put the knowledge into practice. On the other hand, when training takes place in an environment such as a virtual campus (third level of integration), it is of utmost importance to develop pedagogic scenarios coherent with other current training paradigms on the campus. To meet this requirement, it is essential that the virtual campus be built around a clearly identified pedagogic model and that the functionalities available to the learner be coherent within this model. Access to a human supervisor is more important in the context of a virtual campus environment than when isolated activities are involved. The supervisor may step in spontaneously or at the student’s request to provide guidance or supplementary information or to orientate research. The supervisor supplies what some authors (Bioca, 1997) call a social presence, which corresponds to the subject’s awareness of another person’s presence in the context of distance interaction (Scott, 2000).

Quality of the learning depends on the relevance of the tools available to the students.

Use of the different tools included in Practicum has been the object of an exhaustive study (De Lievre, 2000). The results of this study have clearly demonstrated that help tools are used according to the expertise level of the students. Hence, low and high performing students more readily use the tools available, in contrast with
intermediate students, who use them significantly less frequently. This observation has been corroborated by other studies (Person et al, 1994) and it can be explained in the case of low-performing subjects by the fact that they are unable to process the situation without resorting to help. The high-performing students realize more fully the benefits they can derive from using the tools. The fact that the use of a certain kind of auxiliary tools can be positively correlated with the expertise of the student it is strong indication that the quality of the training is not entirely based on the nature of the tools available, but also on the subject's capacity to make good use of the tools. The same observations have been made in the case of Simul: students who can process a case more rapidly and more efficiently seem more inclined to use all the tools at their disposal in contrast to other students that fail to grasp the utility of the tools.

In the Learn-Nett system, some tools of dialog seem to have been more frequently employed over others with respect to the evolution of the tasks required. For example, the cafés and the forums were mostly used during the period allowed for the constitution of the group and the selection of the work teams. Later with more personalization of the communication, email became more popular. Very quickly though, the limits of those asynchronous instruments became evident in terms of managing efficiently the process of negotiating special issues relative to common tasks. When it came time to agree on some aspect of the work or to solve problems pertaining to group management, implementation of more interactive forms of exchange appeared indispensable.

Globally, as noted by the authors of the annual report (Learn-Nett, 1999) the use of synchronous communication tools such as the IRC, videoconference (Net-Meeting) and also telephone and personal contact proved crucial at certain times in the evolution of distance cooperation. Those observations seem coherent with others made few years ago (Salgado, 1998) from a quite similar system. The frequency with which synchronous tools were used is, in fact, closely related to the specific evolution of each group. Those who used it most were also the groups that had the most difficulty reaching consensus or, in some cases, those whose collaboration and interactions were the most profound.

The quality of learning depends on the tutor intervention quality and the framework of pedagogic activities.

Studies of the Practicum have stressed the role of the supervisor in the apprenticeship. The results from learners who had access to human supervisors are slightly better than those obtained by learners who did not have this access but the difference observed was not significant. In this context, the proactive intervention of a system supervision (supervising by the program itself) has some effects on the use of tools comparable to those obtained with a human supervisor who could adopt the same proactive attitude. So it seems that, with this type of device, rather than the presence of a human it is the pertinence of the intervention that is most important.

Observing students working with Simul and analyzing the work of a group of students with Learn-Nett has brought to the fore the relevance of supervisor to the great variability in learning quality. These observations lead us to hypothesize that the determining variable in these learning devices is the global level of the framework for the learner’s activities. When this is deficient, it seems advisable to plan for a vigorous involvement of the human supervisor, but if the device allows for strong activity framework, the learning process does not seem impaired by less intrusive supervision. As it has been shown by Bandura (1977), social presence is essential to learning by imitation, that is, learning by mimicking the behavior of an expert. The same can be said about other types of learning in which social interactions take place. Such is the case with the socioconstructivist approach where distance interaction with peers reinforces the social presence. Although the effect of social presence on learning has not yet been clearly established, it seems that this factor exerts an influence on motivation and perseverance, as well as on the regulation of activities.

4 Conclusions

The four examples that have briefly presented in this article will contribute to the characterization of the Internet integration continuum, from enhancing a traditional course with a minimal integration of Internet (level 1) to a complete integration in the form of what has been called a virtual campus (level 3). It is important to emphasize that the more or less intensive use of distance communication in the various modalities of integration does not
reflect the quality of the learning. Indeed, we are convinced that, whatever the level of integration of Internet to the system, coherence of the proposed activities and pedagogic value of the tools implemented is the most determining factors for success.

Just as the CD-Rom has not killed the book but rather contributed to diversification of our reading habits, we believe that the Internet-enriched university will be different from the institution we know today. By that, we do not imply the all universities will evolve in virtual institutions, but rather that a diversification of the didactic environment will take place.

For these modifications to happen and most of all to make sure they meet the expectations of students, universities will have to demonstrate flexibility and adaptability so that the various pedagogic approaches can coexist harmoniously. The Internet is surely not a panacea for all existing problems in training and education, as has been sometimes said. Nevertheless, it should be considered among the pedagogic tools to be used complementarily with other types of pedagogic strategies.

A Local Indexing for Web-based Learning Resources

Shinobu Hasegawa, Akihiro Kashihara, Jun'ichi Toyoda

hasegawa@ai.sanken.osaka-u.ac.jp

Abstract: Learning with existing hypermedia-based resources on the Web has become popular and important. However, most resources do not usually have clear description how they should be learned. This makes it difficult for learners to select web-based resources according to their learning contexts. We have accordingly proposed a way to reorganize existing web-based learning resources with indexes representing their characteristics to build a learning resource database. An important issue towards the reorganization is how to do the indexing because there exist a large number of resources and because they may be frequently updated. This paper proposes a new approach called local indexing, which allows teachers/instructors to assess indexes of web-based learning resources from their own points of view. This paper also describes a support for the local indexing and a demonstration system. This support enables teachers/instructors to simply and consistently find out how learning resources should be learned.

Introduction

Over the past several years, an increasing number of hypermedia-based resources have been available on World Wide Web, and it has become a popular approach to use them as learning resources. Learning with such resources becomes more and more important, particularly as the realization of lifelong and distance learning (Kashihara, 1998).

On the Web, there are currently a great number of learning resources with the same topic. However, most web-based learning resources do not have clear description of what kind of learners should use, what kind of learning goal can be achieved, and so on. Learners consequently have difficulty in finding some instructive learning resources.

In order to resolve this problem, we have proposed a way to reorganize web-based learning resources with indexes called resource indexes representing their characteristics to build a learning resource database. Using web-based learning resources, learners would usually think of what to and how to learn. These should be accordingly represented as resource indexes. As for "how to learn", in particular, learning phase is an important index, which is divided into several detailed phases such as augmenting new knowledge/information, deepening understanding of knowledge, applying/stabilizing knowledge, etc (Hasegawa, 1999). We have accordingly provided "how to learn" indexes including the learning phases in addition to conventional "what to learn" indexes.

An important issue towards the reorganization is how to index existing web-based learning resources. In the general approach to this issue, the authorities concerned provide the resources with indexes so that the public users can share. However, this approach would not be realistic since there exist a large number of learning resources and since they may be frequently updated. In this paper, we accordingly propose local indexing, which enables teachers/instructors to assess resource indexes of web-based learning resources from their own points of view.

This paper also discusses how to support the local indexing. The key idea is to allow teachers/instructors to identify "learning phase" indexes in a simple and consistent way, which indexes cannot be often assessed from a glance over learning resources. We have implemented a support system that provides teachers/instructors with a checklist in regard to the structure and function learning resources have, and that assesses the "learning phase" indexes from the marked checklist.

In the following sections, we first describe the way to build a learning resource database. Next, we present the local indexing and support system. Furthermore, we report a preliminary experiment to evaluate the usefulness of the system. In this experiment, we compared "learning phase" indexes that the system assessed with the checklist marked by subjects and "learning phase" indexes that subjects identified with careful reading of learning resources without the system. The result of this experiment suggests that the system can assess "learning phase" indexes, which teachers/instructors would apply to learning resources, in a simple and consistent way.

Reorganizing Learning Resources
Learning with Existing Web-based Resources
Before discussing the way to reorganize existing learning resources on the Web, let us first consider learning with them. In this paper, a learning resource means hyperdocuments, which describe a learning topic within a Web site. It provides learners with hyperspace that consists of a number of Web pages. Learners can explore the hyperspace to learn domain concepts/knowledge (Conklin, 1988, Kashihara, 1997). On the Web, in addition, there are diverse learning resources with the same topic, which could facilitate several learning phases such as augmenting and applying domain concepts/knowledge. Properly using these learning resources according to learning contexts, learners can study the topic from diverse points of view. This is a prominent merit of learning a topic on the Web.

On the other hand, most existing web-based learning resources do not usually have clear description about which learning phase could be facilitated. Therefore, the proper selection of learning resource is not so easy for learners. One way to resolve this problem is to reorganize learning resources so that learners can select a proper learning resource according to their learning contexts.

Resource Index

There organization of learning resources requires resource indexes, which are available to learners. There currently exist many Web sites, which collect URLs of web-based learning resources. In these sites, they are classified with resource indexes that mainly represent learning subjects/topics. These indexes allow learners to select learning resources from a "what to learn" point of view. However, such indexes are not enough since the learners would usually think of not only "what to learn" but also "how to learn" especially in which learning phase they should learn. Without indexes representing "how to learn", for example, a learner could select a learning resource suitable for augmenting knowledge about a topic even if he/she wants to stabilize his/her knowledge of the topic.

We have consequently provided resource indexes that consist of "How To Learn" indexes (HTL indexes for short) in addition to conventional "What To Learn" indexes (WTL indexes for short), and have proposed a way to reorganize learning resources. As for HTL indexes, learning phases are most important for supporting learners' selection of learning resources. The learning phases are as follows (Eklund, 1995):

- **Accretion** phase is the one in which domain concepts/knowledge are augmented.
- **Understanding** phase is the one in which known concepts/knowledge are understood with examples, simulations, illustrations, etc.
- **Stabilization** phase is the one in which known concepts/knowledge are stabilized by means of problem solving with exercises.

In addition, some HTL indexes are necessary for differentiating learning resources that could facilitate the same learning phase. Considering web-based learning resources with the same topic, we can see various media for representing the contents such as text, diagram, chart, illustration, etc. We can also see various interactive/real time environments such as simulation, chat, BBS, etc. Such media and communication channels would have an influence on how to learn. In addition to learning phase, we accordingly regard them as HTL indexes as shown in Table 1.

Reorganization

are classified with WTL indexes so that learners can see from a "what to learn" point of view. Next, they are classified may have two or three "learning phase" indexes. Finally, "media" and "communication channel" indexes are attached learning phase.

**Local Indexing**

*What is Local Indexing?*

An important issue towards the reorganization is how to apply the resource indexes to existing web based learning resources. The general approach to this issue, the authorities concerned provide the resources with indexes so that, this approach would not be realistic since there exist a great number of learning resources and since they may be frequently updated. It is more realistic that individual teachers/instructors index learning resources from their own points of view. Here is called local indexing. In the local indexing, each teacher/instructor can index a learning resource from his/her own point of view. Diff 2. In the local indexing, the resource indexes identified by a teacher/instructor are available only to his/her learners. It is not sure whether they are help learners select some instructive learning resources according to their learning contexts. tructors to identify the WTL indexes, "media", and "communication channel" indexes since a glance over learning resources gives them sufficient information for the the indexing often requires careful reading of the contents of learning resources. This paper accordingly proposes a support for the local indexing, urce indexes except "learning phase" indexes to be assessed by teachers/instructors without support.

**Local Indexing Support**

Let us next explain how to support the local indexing. Assuming a learning phase, designers of learning resources use the structure and function. Assuming Accretion a learner concepts/knowledge, for example, a designer would well construct the contents of a resource with diagrams, charts, etc., to facilitate his/her knowledge phase assumed (Kalyuga, 1997) for assessing the "learning phase" indexes.

cognitive load that a learning resource imposes on learning process. Exploring in hyperspace provided by the learning resource, learners would read up a knowledge structure, reflect on to what extent they learned,

![Different teachers can index a learning resource with different "learning phase" indexes.](image)

**Figure 2: A Key Idea of Local Indexing**

![Cognitive load explains the correspondence indirectly.](image)

**Figure 3: Correspondence of the Structure/Function to the Learning Phase**
load, which would enhance learning (Chan, 1993, Kashiwara, 1995). The cognitive load can be divided into selection, contents-structuring, knowledge-structuring and reflection load (Hasegawa, 1999).

Learning resources are not always intended to provide learners with all of these loads. The designers usually compose them so that specific loads can be mainly provided and specific learning phases can be facilitated. Diagrams or charts, for example, enable a learning resource to mainly provide learners with contents-structuring load in a proper way. On the other hand, what kind of loads should be provided depends on the learning phase assumed in the learning resources. In the learning phase where learners are assumed to augment new domain concepts/knowledge, for example, contents-structuring load should be particularly imposed.

Following the above discussion, the "learning phase" indexes can be assessed from the structure/function of learning resources via the cognitive load imposed as shown in Figure 3. In order to make this indexing possible, we make clear the correspondence among the cognitive load, the structure/function and the learning phase.

Considerations of the structure/function of learning resources is divided into sixteen items, which are classified into seven groups according to the cognitive load that each item enables the resources to impose on learners as shown in Figure 4 (Paolucci, 1998, Thuering, 1995, Wilson, 1989). These items are presented to teachers/instructors in the form of checklist, by which they can assess the "learning phase" in a simple and consistent way. On the other hand, there are three learning phases as shown in Table 1. Figure 4 also shows the correspondence between each learning phase and the cognitive load to be imposed.

**Procedure and System**

Let us explain the procedure of indexing learning resources, which is executed by the support system. Figure 4 shows an example of local indexing. First, the system requires a teacher/instructor to read the resource roughly and to mark the checklist items. In Figure 4, this is indicated by *Mark* column. Next, the system calculates the proportion

Score = Marked Checklist Items × Related Checklist Items (in each phase)

**Figure 4: Example of Indexing**

of marked items to all items that are related to each learning phase, and regards it as the score of the learning phase. The system then regards learning phases, whose scores are higher than threshold $a = 0.6$ in this case, as resource indexes. In this example, the leaning phase of Accretion is regarded as resource index.

Figure 5 shows the interface of the system, which incorporates the local indexing support as described above. The system has been implemented with Common Gateway Interface (CGI). The right window displays a learning resource that a teacher/instructor tries to do the indexing. The left window displays the checklist. The top frame on the left window provides form fields for him/her to mark the checklist items. The bottom frame displays explanations of terminology included in the checklist items. In using this system, each learning resource and resource index is stored in our learning resource database.

**Preliminary Evaluation**

**Experiment**

We have had a preliminary experiment with the support system. The main purpose of this experiment was to evaluate the usefulness of the local indexing support. Comparing the "learning phase" indexes that the system assessed with the checklist marked by each subject after reading a learning resource roughly (system-indexing for short) and the "learning phase" indexes that the subject assessed after careful reading of the contents of the resource (subject-indexing for short), we ascertained the usefulness of the local indexing support. The correspondence of system-indexing to subject-indexing means the system can assess the learning "learning phase" indexes, which teachers/instructors want to apply to learning resources in a simpler and more consistent way.

Table 2 shows two learning resources used in the experiment, which were described about a learning topic of "Global Warming Issue". Subjects were 10 graduate and undergraduate students in department of engineering. Because the topic was well-known to the subjects, the results of pretest indicated that they had sufficient domain knowledge and they could be regarded as teachers/instructors.

**Results**

Table 3 shows the results of this experiment. The vertical axis means whether the system regarded each learning phase of each resource as resource indexes or not (System-Index or System-NoIndex for short). The horizontal axis means

</tr>
</tbody>
</table>
the subjects regarded each learning phase of each resource as resource indexes or not (Subjects-Index or Subjects-No Index for short). Each value in the table means the number of cases that fulfilled both indexing states. For example, there were ten cases where both the system and subjects regarded learning phases as indexes. We then performed Fisher’s exact probability test in Table 3. As a result, there was a significant relevancy between system-indexing and subjects-indexing (p=0.0042), and these orders were positively related with a correlation (r=0.40). It indicates that system-indexing agreed with subjects-indexing approximately.

**Conclusion**

In this paper, we have described a learning resource database that reorganizes learning resources on the Web with resource indexes. The paper has also proposed the local indexing and support system, which allows each teacher/instructor to simply and consistently index existing learning resources from his/her own point of view. In addition, we evaluated the local indexing support with the system. In this experiment, we compared system-indexing to subject-indexing, making sure that it is useful.

In the future, it is necessary to improve the reliability and simplicity of the local indexing. Especially, we would like to develop a system which extracts the structure/function of hypermedia automatically and which indexes the resource index more easily. We would also like to make it public.

Web Usability Criteria: the SCANMIC Model

Shahizan Hassan, Department of Management Science, Univ. of Strathclyde, Scotland; Feng Li, Department of Management Science, Univ. of Strathclyde, Scotland

Despite the fact that evaluation is very important during the web site development process and after a web site is being published, designers are facing problems in identifying the right criteria for the evaluation purposes. Although there are many guidelines and literatures on web design and evaluation, each of them varies in terms of quality, coverage, and suitability. Furthermore, not all criteria can be easily measured especially those that are subjective. The purpose of this paper is therefore to illustrate the process of identifying web usability criteria from the content analysis of current literature on web design and development. In addition, the results of the study are also presented including the completed list of the identified criteria that are grouped into 7 categories, screen design, content, accessibility, navigation, media use, interactivity and consistency. This paper ends with the discussion on main issues of the outcome of this study as well as its limitations.
Developing Infrastructure in Developing Countries: A Role for Faith-based Organizations in Technology Transfer in Kenya

Pamela B. Hassebroek
School of Public Policy, Georgia Institute of Technology, U.S.A.
E-mail: pamh@cc.gatech.edu

Abstract: Though developing nations encounter difficult obstacles to economic development, education institutions and telecommunications infrastructures as well as policies can provide ways to increased participation in, and benefits from, the world economy. With its significant social capital and international network, the Presbyterian Church of East Africa (PCEA), through the Presbyterian University in Kenya, may have an opportunity for contribution to Kenya’s developing economy. In this study we examine the state of Kenya’s economy alongside formerly underdeveloped countries that have benefited in the recent past by the globalization process. Are there similarities among the countries to suggest that Kenya could become another “Tiger” economy? In the absence of effective government leadership, can a non-governmental organization (NGO), such as the PCEA, use its social capital to promote infrastructure projects that result in economic growth for the country?

Globalization and Poverty

An urgent moral, political and economic issue today is poverty in the less-developed countries. Globalization promises these countries economic growth and improved quality of life for both rich and poor. New technologies that enable globalisation “promise not just big improvements in local efficiency, but also the further and potentially bigger gains that flow from an infinitely denser network of connections, electronic and otherwise, with the developed world.” (Economist 2000)

Globalization, as described by Friedman (Friedman 1999) and others, is a realistic model of the post-cold war system. This concept eliminates the idea of a “Third World” in the sense that anybody anywhere can contribute to the productivity of an economic enterprise. The new infrastructure provided by information and communication technologies and complemented by changes in government policies has enabled this global economy. Countries such as S. Korea, the Philippines and Ireland have recently been models for the gains that countries can make if they have the means to educate workers to participate in the global network. In today’s environment, many suggest that whole nations of people will fall by the wayside if access is not provided for those lagging behind. Economic growth is the answer to correct the marginalization; but growth is not an easy prospect for countries trampled by war, disease, malnutrition, illiteracy, drought, corruption and dire poverty.

Faith-based institutions and technology transfer

Faith-based institutions have been the deliverers of new technologies for centuries, most visibly in health care and education. Missionaries and clerics around the world have worked to alleviate suffering, bring literacy, and assist in disaster relief. Friedman’s model doesn’t exclude, just doesn’t mention the possibility of, contribution to globalization by faith-based organizations. Can a faith-based organization be effective in promoting the entrance of a developing nation-state such as Kenya into the new system of globalization through building of education/technology infrastructure?

There are many efforts in place where international support organizations are trying to understand and implement the best policies and practices in economic development. These not-for-profit organizations’ investments, e.g. the United Nations and the World Bank, are enormous. As providers of humanitarian aid they are bridging a gap that exists between those who can help themselves and programs provided by a government. Even in the U.S. where the GDP per capita is high, there are volunteers with the United Way, Goodwill
Industries, Habitat for Humanity and countless other initiatives that provide man-hours and funding to aid fellow citizens. Add the contributions of organizations operating internationally like the Red Cross, Rotary International and the Peace Corps, then local churches, synagogues and other religious-based organizations, to realize the vast array of groups helping others with both immediate needs and provision for the future.

Nation-states that are lagging in productivity have even more urgent priorities for their national budgets than does the U.S. But, an important link to economic development is universally thought to be education. In the recent past, priority has been given to primary education in developing countries. Now, there is a generation of students who have achieved both primary and secondary education levels and find that there are a pitiful few slots available in their countries’ higher education systems to accommodate their further educational needs. (Useem 1999) There is great demand for more and Kenya is no exception.

Along with the demand for higher education, Kenya is experiencing an exodus of professionals who have already earned university degrees. Research institutions and health facilities are losing major contributors who are emigrating to the U.S. and South Africa due to poor pay and lack of incentives from the government. Can faith-based organizations provide support to the universities in order to build the economy?

**Presbyterian University Development**

The Presbyterian University in Kenya began as an effort to offer local education to seminary students in training for the pastorate of PCEA congregations. Students have been traveling to Atlanta, Georgia in the U.S. to study since the early 1970s, an expensive, disruptive undertaking for those who made the commitment. And there are still far too few pastors to meet the needs for leadership given the explosion in PCEA congregation numbers. The provision of this education locally makes sound economic and cultural sense. The recent expansion to the degree program—pharmacy and communication—will educate even more students. But the addition of computer technology and its associated training, both to the infrastructure and to the curricula, is the area we see that needs to be incorporated before more buildings are constructed.

The Presbyterian University is supported cooperatively by the Presbyterian Church U.S.A., as well as educational institutions in the U.S. Princeton Theological Seminary along with the Interdenominational Theological Center in Atlanta are involved in providing funds as well as instructional support. We envision the further addition of the Georgia Institute of Technology and its vast talent in the area of computer, network, and Internet technologies. In order to become an effective, efficient higher education institution, this private effort must be balanced by government policies that are supportive to the requirements for an adequate telecommunications infrastructure system.

**Conclusion**

Evidence of education and telecommunications infrastructure within a country positively correlates with economic growth. To increase this infrastructure, there must be expertise for technology transfer. Education and health care have been the principal domains of religious organizations’ mission work in the past. Enlistment of the Presbyterian Church worldwide to assist in this development effort—to provide higher education and technology infrastructure—suggests a new frontier for faith-based organizations in the future.

Adopting an Instructional Pedagogy for Constructive On-line Learning

Stylianos Hatzipanagos, Chris Sadler, Mark Woodman, Maya Milankovic-Atkinson
Middlesex University, School of Computing Science, Trent Park, Bramley Road, London N14 4YZ,
United Kingdom

Abstract: The paper describes how an essentially instructional pedagogy was modified for use in
an on-line learning MSc programme which espoused a constructivist approach to study. We
adopted and adapted San Diego State University's I CARE approach in a distance learning
programme offered in Egypt and in Hong Kong. The benefits and problems of this approach are
explored, and issues raised of how on-line materials can be deployed as resources for conventional
face to face students.

Web-based instruction technologies have been adopted in the Higher Education community and are currently
redefining the boundaries between conventional and distance learning. The Global Campus project which was
established in May 1999 between the School of Computing Science of Middlesex University (MU) in London and
the Regional Information Technology and Software Engineering Centre in Cairo (RITSEC) is currently exploring
these boundaries. The goal was to provide an MSc programme in Business Information Technology in the distance
learning mode, in a form suitable for on-line study. The pedagogy adopted followed a constructivist approach
(Isackson 1999) from the design of learning materials to the support tools (asynchronous and synchronous) for
students to manage their study, and for interacting with each other and with tutors.

Adopted Materials Structure

The I CARE system (Hoffman & Ritchie) pioneered at San Diego State University, was adapted to provide an
infrastructure for the main body of web materials. It is a five-step instructional model, named to stand for
Introduction, Connect, Apply, Reflect and Extend.
The I CARE materials are split into sections (Hoffman & Ritchie 1998):
♦ The Introduction serves to place each unit in the context of the course as a whole, and should include clearly
stated objectives
♦ The Connect section is primarily for presenting new information
♦ The Apply section is the practice section of each unit
♦ The Reflect section gives students an opportunity to reflect on their newly acquired skills and knowledge.
♦ The Extend section has many possible functions: it can provide closure, prompt further exploration and
learning, assess students' skills and knowledge…

A departure from the original I CARE system was that the C was changed from 'Connect' to 'Content', as it was
thought that Content would have a more obvious meaning for students. Additionally a different, less linear flow was
adopted as it was felt that diversions from content should be allowed so that students could apply their new
knowledge immediately.

Typically the Content section presents a fairly linear development of the material with short 'in-line' exercises to
summarise or test understanding. Occasional hyperlinks to the Apply section (see Fig. 1) offer the opportunity to
move away from the narrative into activities with a wider, more exploratory scope. These may be computer-based,
such as programming or design exercises (see Fig. 2), or paper-based, such as examining an exemplary case study,
or web-based, such as visiting relevant web-sites. Their purpose may be to embed newly-gained knowledge or to
motivate the introduction of the next sub-topic. By contrast, hyperlinks to the Reflect section reveal questions
designed to reprise recently-learned material in a reflective or synoptic way. Many of these may look like the
descriptive components of typical examination questions, so they are useful revision aids. The Extend section
contains a short Review Quiz to assist tutors in monitoring student progress and may also contain additional material
provided by the author to allow keener students to explore beyond the confines of the syllabus. Figure 2 shows a
typical page for a module in the MSc BIT programme. It shows some of the buttons with text labels indicating their use.

Figure 1: Order of study in Global Campus 'I CARE' Model

WebCT was used to implement the I CARE model and for enhancing learner interaction by the use of its interactive facilities, but other components were also involved. This mixed approach involved use of complementary materials, e.g. CD-ROMs to substitute for on-line access. The CD-ROMs contain all the course material except for the activities, which the students have to complete online. The weekly pattern of learning involves student use of the learning materials, coupled with a classroom tutorial conducted at a local learning support centre (LSC) with locally employed tutors.

The Global Campus course components attempt the transition from a behaviourist to a constructivist approach in the design of web based learning materials and from tutor centred to student centred learning. The components that support this constructivist approach are:
1. The I CARE WebCT material with its non-linear, interactive structure which encourages discovery by the learners either individually or collectively.
2. The WebCT interactive facilities (synchronous/asynchronous communication tools-bulletin boards, virtual chat rooms and virtual whiteboards) which provide enhanced interaction, potential for negotiated learning and the sense of belonging to a learning community.

The Impact on Distance Learning Students

Global Campus students are well schooled (sic) in traditional learning methods dictated by the requirements which a physically-present lecturer may place on their time and effort. And traditionally, a lecturer might expect that it is relatively easy to gain and retain their students' attention, but more challenging to engage their cognitive and critical faculties. Removing the lecturer (as Distance Learning models presuppose) brings about a startling situation because
the attention-getting strategies become irrelevant and the need for cognitive and critical commitment more immediate and important. Distance learners must become active learners and they need to learn how to do this more-or-less straight away.

The initial response of many students was to print all the material so that they could read it offline. The project team attempted to accommodate this by providing a single file containing all the Content material which could be more efficiently printed. The other material (Apply, Reflect etc.) was not made available so that students would be driven back to the website (or CD-ROM) to complete their work. As the course progressed and students became more accustomed to the format, the desire for paper copies waned. The next step was to make two-way communications between staff and students, and amongst students as natural as raising your hand in class, or asking your buddy how the coursework is going.

In Global Campus the primary mechanism for this is through contributions to the bulletin boards and ‘feedback’ via electronic mail. This has not been as effective as had been hoped since students seem reluctant to commit their thoughts and enquiries to writing. To facilitate Computer Mediated Communication a number of steps have been taken:

(i) At the beginning of each course an induction programme is run by Middlesex staff at which:
   - Students are shown, step by step, how to log onto WebCT so that they will have the confidence and knowledge to work alone.
   - WebCT is introduced, in particular the electronic bulletin boards, chat rooms, quiz sections, calendar and print options.
   - At the end of the session, students are asked to email the feedback account to confirm that their accounts work.

(ii) All email feedback is made responsive by acknowledging emails and following up quickly.

(iii) Assignments explicitly involve an on-line element. Here students review and critique other students’ essays as one of the assignment deliverables.

(iv) The Middlesex lecturer conducts synchronous Chat sessions.

(v) The local LSC tutors are charged with an observational role and are encouraged to report back frequently.

Knowing the lecturer as a human being should help to lower the barrier. This could be achieved by arranging a face-to-face visit during the course or perhaps using introductory ‘friendly’ video clips embedded in the materials.

The Impact on ‘face-to-face’ Students

The face-to-face mode of study for MSc BIT modules running in the UK is now labelled as ‘resource-based’. Thus home students have the same materials as their remote peers. This has provided us with a control group, which can be used to judge the impact of change, both to the syllabus and the running of a module.

The active learning requirements placed on the distance learning students are in some ways enhanced and in other ways militated against in the case of face-to-face students. On the positive side, the lecturer is readily available as a human being who can be engaged with. Thus the chat rooms and other devices are more willingly used and feedback is easier for them to produce and for us to gather. On the negative side, the lecturer is tantalisingly available so that the impetus for active learning is attenuated and the route to passive learning is well signposted. This will only change when lecturers are able and willing to adopt more forcefully a learning support rather than a tuition role.

The Impact on Staff

The biggest initial transition for the lecturers is the requirement that information and attitudes that were once conveyed by gestures, jokes and off-the-cuff observations must now be painstakingly rendered into text or some other explicit visual format. Special attention needs to be given to:

(i) the lucid delineation of the learning outcomes of the unit.

(ii) a more precise (or at least realistic) view of the time and effort requirements of different pieces and types of work.

(iii) greater clarity about the nature and scope of assessment.

Perhaps the most profound effect of the developments that Global Campus has undertaken has been the embodiment of the curriculum as a tangible (at least electronically) resource. There is approximately 9 Mbytes of hypertext for each module and the precise learning intentions of the lecturer are explicit. Staff members need to come to terms with the requirement to maintain and update the material as a part of their normal pedagogic duties.
Conclusion and Future Developments

The paper describes the pedagogy adopted in the Global Campus project. Within a period of eighteen months the programme has been deployed in Cairo, Hong Kong and London and over two hundred students are currently learning to manage their learning with the support of local tutors. When the Global Campus version of the I CARE model is combined with WebCT for on-line use, students have available to them well-structured learning resources according to an explicit constructivist pedagogy and a set of tools to assist them to manage their learning.

Some areas where future developments might take the project include:

♦ Modifications to the ICARE format. The Content – Apply – Reflect format resembles a traditional ‘lecture’ format sufficiently closely that it was easy for authors to transform their materials. However, to give more emphasis to the active learning required of students, a constructivist model that would focus initially on the (active) learning tasks set in Apply and Reflect, with the Content being used as a starting point for student exploration may be better.

♦ More engaging, more interactive on-line learning aids, such as visualisations or simulations, require further designer and programming resources being made available to authors. To make this possible and successful the adaptive and communicative capabilities of the technology need to be harnessed to support a fully reflective learning environment.

♦ More use needs to be made of on-line learning aids if tutors are to be placed in a supportive rather than a leading role in student learning. For instance, formative feedback is still focussed around formal assessments and ways need to be found for tutors to engage with students in more informal contexts. This requires the active involvement of students of which our initial attempts, via chat rooms and intra-student assignment reviews, are only a beginning.

Abstract: In this paper we will present the characteristic features of a method for description and evaluation of learning environments which pursues to the improvement of the traditional questionnaire-based methods and to the integration of the varying points of view of design, support for learning and evaluation. This method that we call Integrated Pedagogical Profile (IPP) can be seen as an advancement of the profile of pedagogical dimensions presented by Thomas Reeves, but with some significant reconstructions. Our solution is based on the reconstruction of the dimensions and the creation of a fuzzy picture that can give an overall sight into the many aspects of learning environment, yet not giving a false impression of preciseness. This dynamic picture which integrates the mentioned points of view in interdisciplinary fashion is achieved by gathering the individual results and representing these by circles the opacity of which is related to the size of the sample, thus forming a general picture of the essential features.

Introduction

The aim of this work is to present a method for description and evaluation of learning environments which pursues to the improvement of the traditional questionnaire-based methods and to the integration of the varying points of view of design, support for learning and evaluation. This method can be seen as an advancement of the profile of pedagogical dimensions presented by Reeves (Reeves 1997), but with some significant reconstructions.

Currently the literature concerning constructivist approach to learning, learning environments or web-based learning environments entails various formulations for normative principles of learning, such as those of Jonassen, Salomon & Perkins or De Corte (Jonassen 1995; Salomon & Perkins 1996; De Corte 1995). What is lacking is the methodology for the evaluation of these principles. Usually the fundamental argument for the use of certain principles in the design of studies has referred to the purposefulness of the methods. However, the conceptual apparatus with which to evaluate what kind of learning environment fits the purpose in particular cases has been quite inadequate for practical work, because the understanding of the general concepts in such a level that enables accurate evaluation requires expertise in the field of educational science. In this work we will first discuss the problems of currently used methods and the theoretical grounds for our attempt to tackle these problems. This is followed by an in-depth example of our method.

Current Problems in Design and Evaluation

There are several reasons why the systematic evaluation of learning environments should be improved. Reeves lists four essential flaws in this area in his article “Evaluating What Really Matters in Computer-Based Education”. 1) Marketing the effectiveness of the technological innovations has surpassed the evaluation of their effectiveness 2) the quantitative evaluation of CBE has often been reduced to simplistic figures with extremely limited utility, such as the amount of money spent on hardware and software, the ratio of students to computers, or the amount of time students have access to CBE within a fixed period of time 3) the evaluations that have been previously conducted have usually been presented in the format of social science research reports which are not very accessible for wider audiences 4) the comparative studies have treated the instructional alternatives unproblematically as holistic
entities with meaningful differences (Reeves 1997). Hirsjärvi has expressed the weaknesses of questionnaires as a research method which concur with observations of Reeves. The studies based on questionnaires are considered typically superficial and theoretically modest. There are also some specific flaws, she spells out. First, there is no possibility to make sure how seriously the participants of the study have answered the questions. Second, it is not clear how apt the questions were from the point of view of the participants. The misunderstandings are hard to control. However, the questionnaires have real advantages, first and foremost their efficiency (Hirsjärvi 1997).

The problematics in this field can be summarized in the following manner. Qualitative methods and their methods of representation (such as social science research reports Reeves mentioned) are informative, but time-consuming. On the other hand quantitative methods, such as questionnaires, are user-friendly but superficial. Thus, our task has been to develop methods that would be efficient enough to be used in everyday educational practice, yet improving the informative value compared to the Likert-style questionnaires.

Theoretical Backgrounds

The points of view that we have attempted to integrate into our method can be characterised by the different functions of the method. First, the method and the mode of representation have descriptive function describing the qualities of learning environment by using bipolar scales. This idea has its origins in Osgood’s method which is known as the 'semantic differential' (Osgood 1957). Reeves uses analogous pedagogical dimensions in his profile (Reeves 1997), which we have attempted to develop further. Second, the method can be used as a Likert-style format of questioning and tries to capitalise its advantages while improving some of its defects. Third, the method can be used as a tool of explication in the design-process as well as in the learning-process. This function is derived from Donald Norman’s conception that intelligent activity is based on the external expression of thoughts (Norman 1993).

One theoretical point of view inherent in our model arises from the criticism of the comparative method mentioned by Reeves. Either the instructional alternatives have been treated as cohesive entities which are opposed against each other, or these paradigms have been broken down to essential features which are similarly in opposition. These kinds of comparisons are often presented in the context of justifying why the new paradigm should be adopted and the old abandoned. While these comparisons give some advice for evaluation of existing learning environments, they suffer from the values embedded in them—the new paradigm is seen as representing 'good' and the old paradigm as 'bad' or even 'evil'. This approach does have serious limitations and may also have serious practical consequences if applied carelessly.

When this kind of good/bad-distinction is present in the evaluation, it also leads to a situation where the 'good' qualities are actually treated as necessary conditions for optimal learning. Either all these conditions are met or the learning environment is less than optimal. This approach also easily advocates a normative picture of a learner who is continuously active, self-reliant, reflective, intentional, immersed etc., whatever the qualities in the particular list happen to be regardless of whether this kind of human being could even exist. Constructivism is in threat of becoming vulnerable to the same critique it has presented to the earlier tradition if it presents only one ideal for a learner, when the purpose has been just the opposite—to support different kinds of learners as well as possible. Following from these problems one methodological commitment in our work has been to find a more neutral stance which would enable assessing the different instructional alternatives according to the purpose of the learning-activity.

The problem of controlling misunderstandings in the Likert-style questionnaires that Hirsjärvi points out is partly caused by the singular nature of the assertions with which one is supposed to estimate one’s agreement. Ambiguity is an unavoidable feature of natural language which is epitomised when an expression is interpreted in isolation. However, even natural language is regular as the meaning of expressions is related to their context, or language-game in philosopher Ludwig Wittgenstein’s vocabulary. The more a person gets hints of the context of expression the more probable the correct interpretation becomes. (These issues have been previously discussed by the authors related to the problems of speech recognition (Hautakangas & Ranta 2000).) Thus the developed method should provide improved means for interpretation, if this flaw is to be decreased.

One characteristic problem in the design of web-based learning environments seems to be that one is attempting to create new practices at the same time with the tools for the practice with only limited help from
the general principles or ideals of learning. This means that the design process begins with an inevitably blurred vision of both the learning environment and its tools and the ways of learning that will emerge by using it. Thus, there is a need to support the explication and clarification of such vague idea. Norman says that the skill to use systematically the external modes of representing knowledge, such as writing, notes or visualization, is an important prerequisite for overcoming the limitations of intellectual activity.

- It helps an individual to join information obtained from different perspectives and to improve the cohesion and consistence of the conceptions and explanations.
- Writing and visualization of information is a process which contains many cognitive iterations.
- It helps to surpass the limitations of person's cognitive resources by releasing the capacities of memory into other use.
- The significance, coherence and general meaning of the explicated information is easier to evaluate than the internal ideas of the mind.
- Explication provides a kind of basis on to which one can build new or more structured thoughts and on which the creation of thoughts is easier.
- External representation gives other people a good opportunity to engage in the collaborative development of the idea or thought and the building of new thoughts. (Norman 1993)

Characteristics of the Integrated Pedagogical Profile

As said earlier, our method is based on the Osgood’s semantic differential which utilizes the bipolar adjectives. More specifically we attempt to make an advancement to the profile of pedagogical dimensions presented by Reeves. In this section we will concentrate on discussing one of the basic ideas of Reeves and give a detailed account on how our method is generated from this idea by taking one dimension as an example. Reeves is breaking down the general instructional alternatives to 14 pedagogical dimensions in his article. These are presented in the opposing ends of a scale. There is an example of one of the dimensions in the picture below. Our approach is to consider this as a partial definition of the concept 'teacher role' which defines the applicable range of the concept by using dichotomical limits as the ends of the scale.

![Teacher Role Scale](image)

Figure 1: An example of pedagogical dimension (Reeves 1997)

However, even if the concepts by which 'teacher role' is defined are presented in non-negative terms, which is one of the traditional requirements for scientific definitions (Niiniluoto 1986), the presentation has defects. The concepts in differing ends do not represent genuine opposites in the context of learning, which they should if the scale is supposed to cover the whole range of the phenomenon which is to be evaluated. Thus, the first step in the generation of our method is to rethink what the concepts representing the oppositions should be. First, the concept 'facilitative' does not represent an extreme case, which would rather be 'none', which is the case in pure self-study. The other end is a harder case. The concept should represent a situation where the teacher has a total control of the learner and his thoughts. One advocate for the concept would be 'totalitarian' which has also other connotations but for the time being it will suffice. After this we have a new scale.

![Teacher Role Scale](image)

Figure 2: A reconstructed scale for teacher role.

To consider this as a research method, one does have a concept which can be used to pose a question (e.g. "What is teacher role in learning-environment x?") and the scale with which teacher role can be positioned. This is
still a straightforward application of Osgood’s method which uses adjectives on the ends of the scale to capture the
differences (Osgood 1957). However, the next logical step would be to apply these basic ideas by operationalising
these concepts into empirical level. And one should notice, as Hirsjärvi points out, that the operational definitions
are not used to specify the entire meaning, but the method for measuring (Hirsjärvi 1997). An example of the
operationalisation into questionnaire-level could be:

“I was able to make  <-------------------------->  “The schedule of the course was fixed.”
my own schedule for
the course”

Also what lacks from the account of Reeves is the dimension of time. As learning is a process, the methods
of describing and evaluating learning in the learning environment have to include the dimension of time as well.
This means that the appropriate amount of support that the teacher is giving in the learning process can and often
does vary through time. This principle is traditionally described as ‘scaffolding’. One should notice that in the
learning-process time can also be seen as cyclical. A learner enters the learning environment many times, he is
each time a little more experienced in the goal-oriented activities he participates in.

Now, what are the advantages that are received from this kind of method? 1) It allows one to describe the
dimensions of learning environments more neutrally. It provides a support for evaluation of whether described
qualities of learning environment are purposeful in a particular context and to particular goals, without making the
scale itself biased. Thus, the instructional alternatives can be evaluated in different contexts. 2) The described
structure gives more information to support a correct interpretation of the assertions compared to the Likert-style
questions where the operationalisation has to lead to singular expressions. One can use the assertions in both ends
of the scale and the information that they represent the opposites to interpret the assertion as well as the internal
logical order of different questions. In addition, giving judgments is an activity that requires skill, and it may be
anticipated that when the methods are first used the judgments of novices may differ greatly. 3) In the design-
process the systematical use of dimensions pushes the designers to pass judgment on different aspects of the
learning environment. The profile gives a common ground for the discussion in the design-team. As the reasons
for individual judgments which can differ from designer to designer with different backgrounds are discussed
thoroughly using the explicated profile as a point of reference a shared understanding of the characteristics and
objectives of the learning environment is easier to reach. I.e. Nonakas & Takeuchi’s familiar idea of the tacit
knowledge of the participants getting explicated (Nonaka & Takeuchi 1995) may be achieved through the use of
the method. Thus, the design process becomes more transparent and structured, and the experience and created
best practices can be used as new prototypes or guidelines in future work.

The use of a systematic profile means also that different aspects of learning environment, such as usability
(Nielsen 1993), content, creation of new learning-practices etc., can be focused on in controlled fashion which
enables a better organization of the working-process. And as one reminds also that designing learning
environments is structurally a project, focusing on the essentialities is as important as it is in research. This is
highlighted in many works on project management and knowledge management by authors such as Goldratt or
Davenport & Prusak (Goldratt 1997; Davenport & Prusak 1998).

One should also note, that the tool itself is evolving. In our current project we have listed so far 49 concept-
pairs which are preliminarily grouped using Jonassen’s qualities of meaningful learning as general concepts or
categories under which the multitude of different concept-pairs representing different points of view are structured.
The use of this pattern brings out the dependencies and inconsistencies in this pattern, which, if treated as a
picture, is inevitably unsatisfying because the research itself involves the points of view of different disciplines.
The evolution of this pattern should, however, bring out information about the essential features that should be
taken into account in particular contexts.

Possible Critiques and Future Prospects

One obvious question that may arise from the critical reading of the described method is whether these 49
or more bipolar dimensions could exhaustively cover the whole phenomenon of learning in such manner that by
summing up the singular dimensions we could get a valid picture of the process of learning in its totality. Another
question is whether every single dimension should be regulated in order to reach an ultimate optimum of learning. The answer to these questions is no, and that there is no point in attempting to achieve such goals. As learning-process is tied to a particular context and situation one cannot hope to end up with general laws that could be applied in somewhat mechanical fashion. And it is not possible to evaluate whether there is a best practice of learning even if the context and objectives are known, rather, one can evaluate between better and worse practices that can be described and evaluated with support of other methods such as expert evaluation of the performance etc. Also, our goal is to find out what features turn out as most important factors in different contexts in order to guide the learning-processes to directions that have proved successful.

Related to this Reeves faces critique by using a method of visualisation where he makes a profile of the dimensions of learning environment by linking the different values together with a line, even if the phenomenon is not continuous and the categories are not exclusive. Thus, the method of visualisation is also an important aspect of the methodology. Our solution is based on the creation of a fuzzy picture that can give an overall sight into the many aspects of learning environment, yet not giving a false impression of preciseness. This picture is achieved by gathering the results of the questionnaires and representing these by circles the opacity of which is related to the size of the sample. By combining the results into one picture one gets a rough but informative picture of all answers. From this picture one can find the emerged clusters of answers which are darker and also pick out the exceptional cases (if considered meaningful) that can be easily distinguished from the general case.

![Teacher Role](image)

Figure 3: An imaginary example of the method (n = 30).

And as the results may be gathered as the time passes in the learning-process the visualisation can be presented by an animation which brings into focus the dynamic change in the results, i.e. the dynamic invariance which is a familiar concept already from the history of science (Routio 2000). This animation is analogous to the visualisation used in the weather forecasts.

Our challenge is to find out the valid scale which determines the opacity of an individual answer. This means that by research where we apply multiple methods we have to find the saturation point for the number of answers in order to set the darkest value of scale. Until that the visualisation can only be used as a relative scale which varies according to the number of answers.

Creating Constructivist Learning Environments Supported by Technology: Six Case Studies

Marilyn Heath Ed.D.
South Central Regional Technology in Education Consortium
@ Southwest Educational Development Laboratory
Austin, Texas,
USA
mheath@sedl.org

Abstract: Findings from these case studies are the result of a research and development study, Applying Technology to Restructuring and Learning (ATRL), carried out by the Southwest Educational Development Laboratory. This project was designed to provide descriptive models of constructivist learning environments supported by technology and used a grounded theory approach to discover what was truly going on in the areas under study (classrooms). The project, which focused particularly on schools with high populations of traditionally under-served students, involved an intervention study with a two-tiered design. Tier One was a collective case study of approximately 150 classroom teachers. Tier Two was composed of detailed case studies for six individual teachers. The exploration of their experiences, challenges, beliefs, practices, and thoughts during the process provide a "rich description" of the process of creating constructivist learning environments supported by technology. Contact the author for a copy of the full research report.

Background

Six schools were selected to participate in this study, one in each of four states in South Central United States and two within the state of Texas, one of them rural and one urban. Three broad questions guided this research study and created a framework for investigation and analysis: (1) What do constructivist learning environments look like in practice, particularly in classrooms with high populations of culturally and linguistically diverse students? Will a single model emerge? (2) How can teachers be assisted in developing constructivist learning environments supported by technology? What school context issues or teacher qualities influence this development and what role does professional development play in bringing about this development? (3) How does technology facilitate the development of a constructivist learning environment? How do teachers use technology and how does technology allow or promote a change in the way they teach?

Procedures

Data were collected for each of the 150 teachers in this study and selection of the six case study teachers was made through preliminary analyses of all the data collected during the first year of the study. From the analyses, ATRL staff identified five teachers who emerged as creating examples of constructivist learning environments supported by technology and whose experiences reflected a variety of responses to those goals. A sixth teacher's experiences contrasted to the others and served to exemplify what many teachers may face in their school or district -- limited resources, time, funds, and support. These teachers were also selected to represent a variety of student populations from diverse cultures, grade levels, and a variety in the amount of technology available in their classrooms. They represented different styles and approaches to creating constructivist classrooms. They also represented different stages of the change process, different cultural and geographical settings, and differing district policies regarding technology and the management of technology. The teachers talked about their background, understanding of their students, teaching philosophy, teaching strategies and the way that they learned to use technology and constructivist practices.
Models of technology assisted constructivist classrooms

Initially, ATRL researchers believed that all constructivist approaches could be captured and documented and that one model of a constructivist learning environment would emerge as a result of the same interventions. However, analysis of the observation data and interviews with six case study teachers indicated that there was no single model or prototype of a constructivist learning environment supported by technology. Instead, classrooms fell along a continuum described as: low, medium-low, medium-high and high constructivist models supported by technology. There appeared to be constructivist approaches that were replicable, but no single model that was replicable. Teachers seemed to select approaches that fit most closely with practices they had used in the past and combined them to create new instructional strategies. The variations in practice grew to create a wide range of classroom environments using technology. In general, the introduction of technology brought about significant changes in teacher and student roles as well as overall classroom management.

The case study teachers exhibited the following models of technology assisted constructivist classrooms:

1. The “Project-Based” model had small, collaborative groups of students studying a general topic. They collected information from multiple sources and created multimedia projects for sharing the results of their inquiry.

2. The “Collaborative-Learners” model allowed study of different aspects of a single topic. Students worked in teams to take advantage of activities and resources found at multiple learning stations. Students were in charge of how their group accomplished its tasks.

3. The “Student-Focused” model relied on understanding students and their individual learning styles. Lesson plans included opportunities for students to use art, music, drama, and other hands-on activities to supplement reading and writing activities.

4. The “Wishful-Thinker” model produced hope and several good ideas but few concrete results. There was little time to plan activities or implement them. Extra school-assigned responsibilities, lack of access to computers in the classroom, low technical and administrative support, and other external constraints impacted this model.

5. The “Learning-Centers” model focused on creating centers for a mix of subjects including language arts, social studies, science, art, and health, and computers. Students worked individually or collaborated with each other at the different learning centers.

6. The “Cross-Grade Collaboration” provided an opportunity for students to work with students at other grade levels for unique learning activities and specialized projects.

Findings/Summary

It appeared that confidence or comfort with technology was more important than technology expertise. Teachers who recognized the potential of technology’s instructional promise, despite their own limitations with technology, demonstrated greater success in creating technology-integrated classrooms. While teachers who had only one computer changed their practice, that change was minimal compared with the changes observed in classrooms with more than one computer.

With the presence of technology, teachers become cognizant of the need to change their instructional practice. For many of the project teachers, implementing technology became a catalyst for instructional change and once they made a decision to let students use technology, change appeared to flow from this decision. These teachers learned how and when to relinquish control so students could teach each other how to use the computer. Once control was loosened and teachers saw that students worked well with technology and that their work improved as a result, they began to loosen control in other areas, granting students’ greater autonomy in their work. This process was a gradual one but resulted in the locus of activity shifting from the teacher to the student. The student role, in turn, was transformed from a spectator to the protagonist in the learning process.

Abstract: This paper examines the results from the Teaching, Learning and Computing (TLC) survey (Becker, H.J. & Anderson, R.E, 1998) administered to the Applying Technology to Restructuring and Learning (ATRL) project participants. The TLC results were examined to shed light on the benefits of the ATRL professional development intervention and also to help inform the three research questions under consideration in this study: (1) What do constructivist learning environments supported by technology look like in practice? (2) How can teachers be assisted in developing constructivist learning environments supported by technology? (3) How does technology facilitate the development of a constructivist learning environment? A copy of the full research report can be obtained from mheath@sedl.org

Background of the study

The Applying Technology to Restructuring and Learning (ATRL) project was a five-year project funded by the US Department of Education, Office of Educational Research and Improvement and carried out by the Southwest Educational Development Laboratory’s Technology Assistance Program. The primary purposes of the project were to document how teachers and their teaching practices changed as they integrated technology into their classrooms and to document the role that technology played in that process. A major activity of this project was the design, development, and delivery of 72 hours of professional development that modeled constructivist learning environments supported by technology.

Six schools from across the five states of the Southwest Educational Development Laboratory region were selected to participate in this study. Site selection was based upon the following criteria: (1) High concentrations of economically disadvantaged populations based on the percentage of students qualifying for free and reduced lunch. (2) High concentrations of culturally and linguistically diverse students. (3) Rural and urban settings in the U.S./Mexico border region, Mississippi Delta region, and the Indian nations. (4) A commitment from administrators and 25 classroom teachers to support the creation of technology-rich learning environments that employed instructional approaches consistent with constructivist learning theory. Teachers either volunteered for participation or were recommended by their principals were some of several criteria were used for selecting the site schools.

Three broad questions guided the research study and created a framework for investigation and analysis: (1) What do constructivist learning environments look like in practice, particularly in classrooms with high populations of culturally and linguistically diverse students? Will a single model emerge? (2) How can teachers be assisted in developing constructivist learning environments supported by technology? What school context issues or teacher qualities influence this development and what role does professional development play in bringing about this development? (3) How does technology facilitate the development of a constructivist learning environment? How do teachers use technology and how does technology allow or promote a change in the way they teach?
The research component of the ATRL project was a two-tiered design. Tier one was a collective case study of the approximately 150 classrooms whose teachers participated in two years of the study and who attended 72 hours of professional development sessions developed and delivered by the ATRL project staff. The unit of study in tier one was the classroom. Data were collected for each of the 150 teachers in this study, including demographic data, classroom observations (using a highly structured observation protocol), sample lesson plans, teacher personal profiles, teacher self-assessments of computer skills, responses to professional development sessions, informal interviews, e-mail correspondence, and field notes. Analysis of this data helped inform how teachers changed their teaching practice and the role that technology played in that process. Tier two was a collection of six exemplary case studies selected from the 150 project teachers and whose practice exemplified learner-centered classrooms. Each teacher selected represented a different style and approach to both teaching and integrating technology as well as representing different stages of the change process that they have individually experienced across the two years of the project. An exploration of their experience, beliefs, practices, and thoughts during the process provides a “rich description” for understanding the process of creating constructivist learning environments supported by technology. Discussion of the case studies can be found in another paper: Creating Constructivist Learning Environments Supported by Technology: Six Case Studies included in the Ed-Media 2001 proceedings.

The Teaching, Learning, and Computing (TLC) survey (Becker, H.J. & Anderson, R.E, 1998) was one of the instruments used in tier one of the study. The TLC survey asked teachers to describe their best practices, teaching philosophies and uses of technology. The purpose of the survey was to compare ATRL project participants to a national sample of teachers and computer-using teachers. The TLC results were examined to shed light on the benefits of the ATRL professional development intervention and also to help inform the three research questions under consideration in this study.

In an earlier report, ATRL teachers were compared to a TLC national probability sample that contained 2251 teachers from all subjects (grades 4 - 12), 60% who were computer users in the class in which they felt they most often accomplished their teaching objectives (Becker, Ravitz, & Wong, 1999). In this earlier comparison, ATRL project teachers reported having access to technology at a higher rate than the national sample: computers in their classrooms (81.7% vs. 62.2%), access to a printer (98.1% vs. 77.8%), access to high speed internet from classroom (71.2% vs. 25.6%) and access to e-mail (97.1% vs. 51.9%).

For more accurate comparison purposes for this report, 104 TLC teachers were selected from the large national sample who taught in middle and elementary schools, in rural and town settings, and with low income and minority populations and who taught in those same states as the ATRL teachers. In future analyses we will also compare teachers who have received similar amounts of professional development but for this report we focus on teachers, who work in similar settings, not who received similar treatments. The ATRL group contained 102 teachers, 90% who were computer users in the class in which they felt they most often accomplished their objectives, and had just completed 72 hours of professional development. The amount of professional development that TLC teachers received was not determined.

Findings

Analysis of data to help inform research question one “What do constructivist learning environments supported by technology look like in practice?” revealed that there was no single model of a constructivist learning environment supported by technology. However, these learning environments appeared to share a number of common characteristics. When compared to baseline observation data, students in these classrooms had become more active, autonomous, and appeared to be highly engaged with the subject matter or learning content. Oftentimes they worked collaboratively with peers to solve a problem, presented findings or completed a project and used technology to accomplish their tasks. In such an environment the curriculum was structured in such a way to allow students greater flexibility and authority in terms of their own learning. The teacher, while an integral part of the classroom, acted more as a producer, rather than a director, setting up the learning situation and then allowing students to use the means necessary to arrive at a certain end.

Responses to the TLC survey told us about the types of and the frequency of computer use by ATRL teachers. Our earlier report, which compared ATRL teachers to the TLC national probability sample of teachers (not controlling on the variables mentioned above) showed that a far greater proportion of ATRL teachers increased their use of computers. Compared to five years ago, twice a greater percentage of ATRL teachers than the TLC national sample reported trying new software much more now (42.2% versus 21.7%). More than twice a greater proportion of ATRL teachers than the TLC teachers were using email 3-4 times a week (56.9% versus
24.7%). ATRL teachers were using computers more to much more for class preparation than the TLC teachers (90.1% versus 71.6%) and were also using computers for non-work activities more to much more (88% versus 69%).

Not only did ATRL teachers appear to report increased computer use; their objectives for use appear to be more consistent with a constructivist view of instruction. Using the smaller "comparison" sample from the study, Table 1 compares ATRL teachers to the comparison sample from the TLC study, using the controls, in their objectives for using computers with students. Percents are for teachers who said they used computers in the class in which they felt they most often accomplished their teaching objectives. As the data illustrate, ATRL project teachers listed the more constructivist objectives as being among the TOP 3 more often than the comparison group. Presenting information, working collaboratively, and communicating electronically were rated among the more constructivist objectives by the TLC’s authors.

Interestingly, while the N is low among the TLC teachers who taught in control conditions (low-income, minority, in region) when we further distinguish teachers who were identified for TLC using probability sampling, (contrasting these with the TLC teachers identified in the "purposive sample" of high technology schools and reform programs) we find that those in the purposive sample expressed considerably less constructivist compatible objectives, even compared to teachers from the TLC probability sample. This suggests those major reform and technology settings in these low-income and largely minority communities are substantially less constructivist than even the normal teaching. The evidence is that ATRL has taken a different path from other technology and reform efforts in these communities. Compared to the TLC "control" sample, that includes reform and technology use, ATRL teachers were substantially more likely to report a "top" objective of communicating electronically (16% vs. 2%), presenting information to an audience (23% vs. 10%), and learning to work collaboratively (36% vs. 16%).

To help inform research question two “How can teachers be assisted in developing constructivist learning environments supported by technology?” analysis of changes in teachers’ practice indicated that changes were based in part on the professional development sessions provided for them. Since the ATRL project provided 72 hours of professional development over two academic years of the project, the expectations were that project teachers would score higher than the national sample on many of the TLC items. Site reports and classroom observations showed that teachers were able to use the learner-centered and technology management strategies that were modeled in various professional development sessions. ATRL project teachers indicated that the constructivist approaches modeled in the professional development sessions helped them understand how they could manage their classrooms using some of the same strategies. Furthermore, responses to TLC items as shown in Table 2 indicate that professional/staff development influenced their teaching practice through changes of their understanding of learning and the use of technology.
responses indicate that the person who gave them the best ideas about teaching knew a lot about computers.

Results of the TLC analysis also helped to inform research question three “How does technology facilitate the development of a constructivist learning environment?” ATRL teachers indicated that they used computers in the class where they felt more successful. They also indicated that they allow students interest influence the choice of lesson topics and that computers play a substantial-major role to changes to students assignments.

Fifty seven percent of ATRL project teachers reported that computers played a substantial or major role in changing their teaching on the TLC survey, as compared with only twenty-eight percent of the comparison sample. Table 3 reports the comparison of ATRL teachers to the comparison sample in the various ways in which computers changed teaching practice: organization of space, organization of class activities, curriculum priorities, and teaching goals.

Discussion

Most ATRL teachers had little or no experience using technology with constructivist practices in their classroom prior to the ATRL professional development intervention. While many of the participant teachers initially expected technology-skills training in the professional development sessions, they instead received a
much richer technology curriculum-integration learning experience with meaningful authentic learning experiences and greater learner control. One of the goals for the professional development was to create activities that used limited numbers of computers rather than having a computer available for every person. The logic was that if teachers had to teach with a limited number of computers, it would be more meaningful for them to participate in sessions with limited computers. The object was to help teachers learn how to manage limited resources instead of becoming an “expert” in any single computer application. Each of the staff development sessions was supported by constructivist learning theory and took into account teachers’ understanding and beliefs about how students learn. Each session utilized inquiry, problem-based teaching and learning along with commonly available software found in classroom settings. Sessions also modeled instructional strategies or classroom management strategies that supported technology assisted constructivist learning environments.

Changes occurred as teachers became increasingly confident and comfortable using technology. There appeared to be a link between teachers’ comfort or confidence with technology and their use of technology with students. The computer skills self-assessment and the TLC survey indicated that participating teachers increased their use of technology with students. In baseline reporting, only 50 percent of teachers reported using the computer with students on a regular basis. By the end of year two, 75 percent reported regular computer use with students. Technology, when used with students, seemed to play a role in the creation of constructivist learning environments. Analysis of the computer skills self-assessment data, the TLC survey, field notes, teacher interviews, and informal observations indicated that when technology was used, it helped teachers shift practices toward more constructivist approaches. Indeed, such an observation is consistent with other research linking technology use and pedagogical practices (For example, Jonassen, Carr, and Hsu-Ping, 1998).

In general, observations also showed that successful technology integration and high technology use took place in those classrooms where there were four to six computers available for student use. On the other hand, the presence of four to six computers in a classroom was not a guarantee that technology use or constructivist practices took place. For example, one teacher found that six computers were too many to manage. She explained that it totally “disrupted” her classroom organization with students working on too many activities. She also found it difficult to handle technology issues while trying to carry out instruction. In her case, technology was forcing her to change her teaching practice in a way that was unexpected and undesirable. However, another teacher who had ten computers had previously been a computer teacher in a lab setting. He could successfully manage several computers and enjoyed having students working on multiple activities.

As they learned to use technology, teachers became conscious of themselves as learners, of what technology could offer them, and became more cognizant of best instructional practices using technology. Furthermore, as teachers became more comfortable with technology, they were more likely to let students use it. Once teachers allowed students to use technology and saw that many students had a certain amount of expertise they were more likely to cede control of technology to students. Once this control was loosened and teachers saw that students worked well with technology and that their work improved as a result, they began to loosen control in other areas, granting students’ greater autonomy in their work. This process was a gradual one but resulted in the locus of activity shifting from the teacher to the student. The teacher became less a repository of knowledge and more a general manager of classroom operations. The student role, in turn, was also transformed from a spectator to the protagonist in the learning process.

Summary

Technology adds yet another skill set that teachers must master. As Sandholtz et al. (1997) point out, “The addition of technology can exacerbate or enhance the already complex challenge of teaching” (p. 183). While the addition of technology did complicate many of the ATRL teachers’ lives, professional development activities that modeled ways to integrate technology helped teachers learn both new instructional strategies while learning and using technology. Supporting research (Brand
1998; Education Week, 1999) shows that technology curriculum-integration rather than technology skills training should be the primary focus of technology-centered staff development. A national survey of teacher’s use of digital content (Education Week, 1999) reveals that sixty five percent of teachers who received eleven hours or more of technology integration training say they feel “much better” prepared to use technology than they did twelve months ago. Unfortunately, in practice, only twenty nine percent of teachers receive six or more hours of curriculum-integration training.

Conclusions indicate that professional development for in-service teachers must be a top priority, especially professional development that emphasizes the effective integration of technology into the curriculum. The ATRL professional development intervention helped serve that need by providing a total of 72 hours of technology integration training over a two-year period. Instruction in those professional development sessions focused on and illustrated how technology supports educational objectives via instructional environments such as collaborative problem solving and cooperative learning activities. And most importantly, activities were designed that engaged teachers both intellectually and professionally.

Teaching Cognitively Complex Concepts: Content Representation for AudioGraph Lectures

Eva Heinrich, Chris Jesshope and Nic Walker
Institute of Information Sciences and Technology, Massey University, New Zealand
{E.Heinrich, C.R.Jesshope }@massey.ac.nz and nic.walker.1@uni.massey.ac.nz

Abstract: This paper investigates a solution to support the learning of cognitively complex concepts, through the recording, annotation and online delivery of multimedia lessons. Recording lessons for online delivery has the advantage of utilising all of the pedagogical skills of the lecturers and teachers involved. To facilitate the retrieval of appropriate teaching material, the lessons are annotated using a notation called the Flexible Structured Coding Language, FSCL, which facilitates a rich and precise description of these concepts, in a natural language-like format. Different streams of meta data are produced to describe the lesson’s properties, like cognitive type and media type. The approaches presented are set in the context of the IEEE draft standard on Learning Object Meta Data, LOM.

1 Introduction

The TILE project at Massey University is developing a “Technology Integrated Learning Environment” for the on-line delivery of education and training material, in a flexible and pedagogically effective manner. The architecture of this learning environment is described in another paper submitted to this conference (Gehne et al., 2000) and is not discussed in detail here. One component of this project however, is the provision of on-line lectures, which have been recorded by the educators in a multimedia format, using the AudioGraph tools (http://www.nzedsoft.com/). These tools have been developed over the last five years (Jesshope et al., 1998) and have been used extensively in the on-line delivery of both internal and extramural university teaching (Jesshope, 1999 and 2000a). There has also been an evaluation of the use of these tools by an independent researcher (Segal, 1997). The TILE project is concerned with the flexible and adaptive delivery of this media. We describe here, one approach to organising the learning material by annotating it with meta data, which will be queried, either explicitly by the student or implicitly through the knowledge that the system holds about a student, in order to optimise the student’s learning processes.

A characteristic of these online teaching resources is that they deal with the presentation of cognitively complex concepts and are not restricted to the transfer of simple procedural knowledge. The cognitive sciences have not yet provided the pedagogical task analysis necessary to structure such computer-based teaching resources (McArthur, 2000). We must therefore, rely on lecturers and teachers to deliver the teaching material for cognitively complex concepts. We can not, as is done for simple procedural knowledge, construct a lesson from single, basic components but, quite rightly, allow lecturers to record complete lessons. In order to provide a collection of teaching material, which is easily accessible to both learners and teachers and which is searchable and customisable, we need to provide effective mechanisms to discriminate the various components of these lessons.

The IEEE Learning Technology Standards Committee, working group P1484.12, has developed a draft standard for Learning Objects Meta data (LOM, 2000), specifying both its syntax and semantics for use in technology-supported learning. We use this standard as a framework for the discussion of mechanisms for content description and of the units of description, referred to as learning objects in the LOM standard. From there we follow on by presenting our own approaches to content description of learning objects. We conclude the paper with a description of further work.

2 Content Description Mechanisms

The LOM standard addresses a wide range of issues relating to technology-supported learning applications like security, privacy, commerce and evaluation. The purposes of the standard include: ‘to enable learners or
instructors to search, evaluate, acquire, and use learning objects', 'to enable sharing and exchanging of learning objects across any technology-supported learning system', 'to enable developing learning objects that can be combined and decomposed in meaningful ways', and 'to enable computer agents to automatically and dynamically compose personalised lessons for an individual learner'. The entries in the standard's base scheme for metadata relate to these objectives. For example:

- Interactivity type (entry number 5.1 in the base scheme) allows distinction between 'active' (information flows from learner to resource) and 'expositive' (information goes from resource to learner) documents.
- Learning resource type (5.2) describes the cognitive type of the resource, e.g., exercise, experiment or self-assessment. This is similar to the 'cognitive media roles' as defined by Ram et al (1998).
- Description (1.5), keywords (1.6), coverage (1.7), and classification (9 with various subheadings) all relate to the description of the content of the learning resource.

The LOM standard gives suggestions for the types of the data elements in the base scheme. The data values for entries describing the interactivity type should be taken from a set of restricted vocabulary ('active', 'expositive', 'mixed', 'undefined'). For the learning resource type an open vocabulary of single, descriptive terms is suggested (e.g., 'exercise', 'simulation', ...). The LOM standard refers to future work on a common representation of data and suggests, in the meantime, the use of formats such as XML to structure the data.

In the context of our TILE project we are interested in the detailed description of the content of a learning resource in a computer-accessible format. We now evaluate what the LOM standard and other approaches provide in terms of content description.

- The LOM standard gives us a framework for the description of very useful information in relationship to the content of the learning resource. Information like interactivity type, resource type, semantic density of information (5.4) or difficulty (5.8) facilitates the selection of appropriate material. Being keyword based, this type of information is easily accessible.
- One type of content description within the LOM standard is the classification approach (9) using taxonomies (9.2.2) or keywords (9.4). While this provides a high-level description of the content of a learning resource and facilitates a contextual relationship between resources, this does not provide a detailed description of content in the sense that we are interested in (which is the description of cognitive processes, interactions, and interdependencies).
- Another form of content description within the LOM standard is a textual description (description, 9.3), which, being free-form text, has all the power of a natural language to describe the contents. The drawback here is that the automated extraction of meaning from this textual description is not possible (Heinrich, 1999). A search for keywords only within textual descriptions leads to unsatisfactory results (Davenport, 1996) and the amount of background knowledge necessary to provide the right context for understanding natural language is prohibitive (Sowa, 2000).
- Ram et al. (1999) suggest the Procedural Mark-up Language, PML, which 'uses cognitive media roles to flexibly specify the knowledge structures, the underlying physical media, and the relationships between them'. Being based on XML, PML uses tags for the mark-up of information. Within the tag structure, the actual descriptions are given in free-form text format. This means, that for our purpose of content description, we face the same issues as with the LOM standard. Tag or keyword based information is easily accessible but not expressive enough; free-form text format is expressive enough to describe complex contents but not accessible enough for automated processing.

After this discussion on content description, we now want to address the issue of learning objects and in particular the application of content description to learning objects in the TILE project.

3 Learning Objects

The LOM standard defines a learning object as 'any entity, digital or non-digital, that can be used, re-used or referenced during technology-supported learning'. The base scheme of the standard gives the aggregation level (entry 1.9) of a learning object. It specifies that a learning object can vary in size from a single piece of raw media to a collection of HTML pages up to a complete course. The descriptions facilitated by the LOM standard are applied to the learning objects. There is no possibility to link a description to a specific position or section within a learning object.

In the PML approach by Ram et al. (1999), a PML document contains media tags, which are references to external files. These files can have various formats like video, audio or text. Via their media tags the external files are linked to knowledge nodes. As the authors write, they are working in domains, which are concerned
with the description of procedural knowledge. Therefore the external files will mostly display single objects (like a faucet, as in the example in the PML article) or simple procedures ('re-light the pilot flame'). The approach is to make the single multimedia objects very small and to link them into a hypertext network.

McArthur et al. (2000) write, in the context of interactive learning environments, that the focus will shift from teaching procedural knowledge to systems which can provide assistance in learning cognitively complex tasks. To explain such tasks we need a longer, more coherent explanation, not just single pictures and brief procedures. Hence our desire to capture complete lessons from the teachers and lecturers and to deliver this material within an appropriate framework that allows the searching for, or the adaptive presentation of, its component parts. This discrimination should be based on the semantic composition of these lessons. For if we cannot split the presentations into their atomic parts, we cannot combine them automatically into a pedagogically valuable whole, targeted to a specific learner with a particular learning style or ability. We therefore need to make use of the pedagogic skills of human teachers in capturing complete lessons and then provide a mechanism for describing the composition of the elements inside of these units.

If we look at these cognitively complex tasks it seems that the current approaches given by LOM and PML are not sufficient. PML requires splitting a multimedia presentation into very small parts, which can not provide a coherent argument to explain cognitively complex procedures. LOM allows large (and therefore possibly more comprehensive) learning objects but facilitates a description of these only at object level and not within the object.

4 Our Approach

Our approach to support the technology-supported learning of cognitively complex concepts is based on the following elements:

- Record complete lessons using the AudioGraph tools;
- Capture different streams of meta data and associate these both with and within the media elements;
- Describe the lesson content using the Flexible Structured Coding Language, FSCL (Heinrich and Kemp, 1999).

4.1 AudioGraph Lessons

The AudioGraph is a tool, which brings multimedia technology to the educators rather than having the educators direct the multimedia production through media experts. The direct nature and ease of use of the tools allow the educators to capture both procedural knowledge as well as cognitively complex concepts. The tools use synchronised images, text and handwriting with direct capture of sound bytes (voice). The presentations therefore, have the presence of lectures, or face-to-face communication, and hence the ability to capture whole lessons instead of combining single multimedia data elements on web pages. The process of recording a presentation is similar to that of presenting in a face-to-face mode, except that the user presents to the computer screen. Once the lessons have been captured, web sites with a simple hierarchical structure may be generated automatically. The lecturer may use simple static graphics, such as images or presentation slides, or may animate diagrams using vector or image-based graphics, to capture the more complex interactions within the material being presented, while the whole time, interleaving this with voice-based descriptions. Examples of AudioGraph material delivered using a fixed course structure that does not adapt to student progress or queries can be found at (http://www-ist.massey.ac.nz/~crjessho/comp-arch/). AudioGraph material, in fact, has all of the advantages of a video presentation but, unlike video, can be full screen and can be downloaded at modem speeds.

While the use of this material has been successful in university teaching (Jesshope, 2000b), feedback from students has shown the need for adaptive or selective presentation of the material. And here, AudioGraphs share the disadvantages of video media, namely the difficulty in indexing or semantically capturing the contents of a unit of presentation. Thus we need to link our meta data and content descriptions to specific positions or segments within the lessons. We want to be able to refer a learner to an exact segment of a lesson, which is relevant to the learner's current needs.

4.2 Streams of Meta Data

As suggested in the LOM standard, by PML or by Shikano et al. (1998) we want to capture meta data such as cognitive type or media type for our learning objects. Because our learning objects are lessons and we describe within these lessons our approach has to be different. As already indicated, when looked at from the outside, a lesson can be likened to a video document. If we look inside the lesson, we see that the information that is
presented by the lecturer uses different perceptual modalities. At one stage the voice of the lecturer will carry the
information, at another stage a graphic will explain a concept, at yet another point in the lecture, textual
information will be given. If we want to support different learning preferences regarding visual or auditory
information, we have to record the medium of delivery of information throughout the lesson. It is not enough to
specify the whole lesson as a video document.

The situation regarding cognitive types is similar. Each lesson will contain a sequence of cognitive elements,
arranged by the lecturer and influenced by their didactic style. Thus, in a lesson, a definition and then an
explanation might follow a teaching example. We must therefore mark the segments representing the different
cognitive types. This segmentation for cognitive types can be distinct from the segmentation for other aspects
like the media types. By describing each lesson by their different aspects, such as cognitive type, media type or
lecturer’s hints to the students, we arrive at parallel streams of meta data. Using these description streams we are
able to extract lesson segments according to the preferences of learners, like a segment giving an auditory
presentation of a particular example on a topic regarded as important by the lecturer.

4.3 Description of Lesson Content

As discussed earlier, approaches like the LOM standard describe the properties of and not the content of a
teaching resource. Where they allow the description of content, they do that in form of free-form text, which is
ever difficult to process for knowledge extraction. In the TILE project, we work on describing the content of our
lessons in a computer-accessible format. In the first instance we want to facilitate the retrieval of the material
presenting the appropriate contents, in longer term we want to explore the answering of learner questions based
on our content representation (see Heinrich and Kemp, 2000, for our initial ideas).

Besides the keyword approach, ontologies (see e.g. Decker et al., 1999) and topics maps (2000) are used to
describe domain knowledge in the context of multimedia documents. We follow a natural language like
description approach using FSCL (Heinrich et al., 1999) which gives us a number of advantages:

- FSCL descriptions are natural language like and can be understood by any human reader.
- The vocabulary of the FSCL language can be easily extended by the user.
- FSCL descriptions are based on a formal grammar and are therefore accessible in their structure using well
  understood parsing techniques.
- FSCL descriptions can be attached to segments of any multimedia document.
- FSCL facilitates both qualitative type description (as we need it for describing complex content) and
  quantitative type description (as needed for description of streams of meta information).

In searching for appropriate teaching material for the particular needs of a learner we can combine these FSCL
content descriptions with the streams of meta data discussed above.

5 Description Steps

In the current phase of our project we are working on the description of existing AudioGraph lessons. Using a
tool like Snapzpro (http://www.snapzpro.com) we are able to convert an AudioGraph lesson into a video
document and hence use an existing application, PAC (Heinrich et al., 1998), to apply FSCL descriptions to the
video.

As already described, our approach to description is based on streams of meta data and on content description.
To produce the streams of meta data we perform a quantitative style of coding. For each stream we define the
required vocabulary:

- Cognitive type: definition, explanation, example, proof, theory, exercise, solution, introduction, summary,
  revision, conclusion;
- Media type: visual-text, visual-pictorial, auditory-narrative, auditory-other;
- Lecturer’s hints: important, complimentary, exam-related.

For each stream we work through the lesson to produce the relevant descriptions. The way in which this coding
is performed differs. For cognitive types we code in an exhaustive, non-overlapping style. That means we have
to cover the whole timeline of the video with exactly one type. For media type we also code exhaustively but
allow overlapping. We describe each point of time in the video with a media type, but this time we are not
restricted to exactly one media type. We can create overlapping segments, for example, when an audio narrative
of the lecturer stretches across two segments of textual and pictorial information. The coding for lecturer’s hints
is non-exhaustive. These hints will be spread across the lesson and there is unlikely to be a hint at every point of
time in a lesson.
The description for content uses a qualitative type of coding. We construct description sentences, which can be attached freely to any lesson segment or point of time. The vocabulary for the content description is largely domain dependent. Over time we will be able to provide a generic core vocabulary which then will be extended by domain specific terms. We are working on a range of issues regarding the content description:

- What is the best approach to extract the content description, should it be based on the narrative, textual or pictorial information or probably a combination of all? Currently we transcribe the lecturer's narrative and base our description on that transcript.

- Working on the lecturer's narrative we have to distinguish carefully between content description and meta information. A statement like 'remember that in a recursive data structure there is no predefined size' contains two elements of information. The word 'remember' indicates a cognitive type information of revision, which we want to separate from the actual lesson content, which is the statement about the size of the recursive data structure.

- The current FSCL allows the formulation of statements like 'recursive data structures can be implemented using recursive calls to a procedural function'. Based on word categories such a statement can be parsed into its subject, verb and object components. To present the type of the cognitively complex content that we are working with, FSCL has to be extended, for example to recognise conditional statements.

At this stage the description process is a completely manual one, based on existing lessons. In the longer term we want to develop a procedure to facilitate the description. Included in this procedure should be guidelines for how to arrive at good content and meta information description. Parts of the description process should be automated, for example the AudioGraph document structure knows about media type and audio transcripts are optionally used as an aide memoire for recording speech. Eventually therefore the processes of recording an AudioGraph lesson and of describing it should be combined and partially automated in order to produce better quality descriptions and a considerable saving in time.

6 Conclusion

Using AudioGraph to record lessons gives us the advantage of a rapid and easy-to-use mechanism for the creation of learning material in cognitively complex areas. We think it is important to rely on the pedagogical abilities of lecturers and teachers to present learning material instead of trying to synthesise this material from single elements. We employ various description techniques to make our collections of lessons accessible. Two important aspects of our approach are that we attach descriptions to specific segments inside our lessons and that we describe the content of these lessons in a form amenable to computer analysis. Attaching descriptions to segments inside the lessons allows us to refer the learner to the appropriate section within a lesson instead of just referring the learner to the lesson as one learning object. Describing the lesson content, not just on a keyword basis but in a rich natural language like way, allows us to find the course material which exactly deals with the concepts the learner is trying to comprehend.

7 Status of the Project and Future Work

A specification and feasibility study for the TILE project client/server architecture has already been completed and is described elsewhere in this conference (possibly!). This architecture allows us to build up large collections of teaching material, which can be accessed and monitored quite easily by both on-line and off-line users (Gehne 2000). The work described in this paper will use student models, past history, student preferences and eventually direct questions, in order to present the student with the appropriate material contained within the TILE educational repository. We are currently working on creating content descriptions and streams of meta data using FSCL to facilitate this. One of the next projects steps will be to investigate how the FSCL description (including their segmentation information) can be integrated into the LOM framework.

Abstract: In this paper we look at learner-formulated questions in technology-supported learning applications. Traditionally, technology-supported learning applications request input from the learner. The learner's response is used to assess the knowledge of the learner, to define a navigation path through the material or to construct a learner model. With our work we want to add another form of interaction between learner and system, where the learner can pose questions to the system in similar fashion as to a human tutor. The paper discusses ways of dealing with these learner-formulated questions, question formats and existing approaches. It then introduces our approach for learner-formulated questions which is based on the Flexible Structured Coding Language, FSCL. We present two specific approaches, the syntax-based and the semantic-based approach. After a discussion of these approaches we conclude the paper with an outline of future work.

1 Introduction

This project is looking at learner-formulated questions in the context of online technology-supported learning applications. We focus on two main goals:

- Learners should have the possibility to pose questions to a technology-supported learning application.
- These questions should be formulated in the language of the learner.

Technology-supported learning applications traditionally have features in which the application is requesting input from the learner in the form of multiple choice tests or yes/no questions. The response of the learner is used to assess the knowledge of the learner, to define a navigation path through the material or to construct a learner model. We have no intention of replacing these features. Instead we want to add another form of interaction between learner and system, where the learner can pose questions to the system in similar fashion as to a human tutor. The paper discusses ways of dealing with these learner-formulated questions, question formats and existing approaches. It then introduces our approach for learner-formulated questions which is based on the Flexible Structured Coding Language, FSCL. We present two specific approaches, the syntax-based and the semantic-based approach. After a discussion of these approaches we conclude the paper with an outline of future work.

To achieve our goals we have to define a format in which the users can formulate questions. If we want to mirror the student–tutor situation we need to have a format which is 'natural' for the learner. Ideally we would use natural language which is our natural form of communication, is expressive and flexible, and is familiar to the learners.

Once we allow the learner to pose questions to the system in a 'human understandable' format, the system faces the task of responding to these questions. Before looking at the different possibilities for question formats we want to describe the various possibilities for interaction between learner, technology-supported learning application and human tutor:

- In a first scenario the learner formulates a question which is linked to a specific position in the teaching material. The question is then submitted directly to a human tutor. The tutor provides the answer which is stored together with the question for pursual by the learner and for future reference by other learners.
- In the second scenario again the learner formulates a question which is attached to a specific position in the teaching material. This time, the question is not directly transmitted to the human tutor. The computer system analyses the question first for syntactic and semantic characteristics. It compares the question against previously...
asked questions. If a semantically equivalent question and answer set is available, this set is returned to the user without intervention of the human tutor. If only a semantically close question is stored (or no related question at all), this question is passed on the human tutor. The tutor assesses the suitability of the semantically close question and answer set, edits where necessary and proceeds as in scenario one.

- The third alternative is parallel to the second scenario for posing the question and comparing against previously asked questions. Yet instead of passing an only semantically close or a new question to a human tutor, the system generates an answer. The question is matched against a knowledge repository, a suitable answer is generated and returned to the learner. In this scenario the question – answer dialog is performed without involvement of a human tutor.

The work we are describing in this paper addresses the second scenario. The approach we use for formulating the questions is compatible with a related content representation technique, which should allow us to move into the third scenario. In the next section we discuss related approaches to user querying before we introduce our techniques.

2 Review of Related Work

In the first scenario we have described, the questions are evaluated solely by the human tutor. The system assists the dialogue only by transmitting questions and answers between learner and tutor and by keeping a repository of previously asked and answered questions. The idea of collecting questions/answers and making them available to later users was employed in the context of a portal server for the first time in the medical prototype portal "Infomed-Austria" (Maurer et al., 1999, www.infomed-austria.at). In the context of technology-supported learning applications this approach has been implemented in GENTLE (Dietinger et al. 1998 and 1999, www.gentle-wbt.com), using natural language for questions and answers.

To move to scenarios two and three we need to have a "computer understandable" format for the questions. Searching through documents on a keyword basis is not semantically rich enough (Davenport, 1996). Beside its semantic restrictions, a keyword mechanism is not the desired type of interaction for our work as we attempt to mirror a human-to-human communication. Natural language processing faces a range of problems like lexical ambiguity, ambiguous sentence structures or context dependencies, which yet have to be overcome (Smeaton, 1997, Sowa, 2000).

The AskJeeves approach (Basch, 1999; www.askjeeves.com) allows the input of any natural language question. It uses a proprietary parsing technology to interpret user queries. The queries are matched against templates and a knowledge base containing millions of previously asked and answered questions. The answers to questions are produced by human editorial staff (Basch, 1999; Chowdhury, 1999). AskJeeves returns to the user previously asked questions with related meaning or keywords. Selecting one of these questions leads to web pages providing answers. The repertoire and understanding of AskJeeves is very impressive yet for our needs not specific enough. In contrast with the AskJeeves context we work within specific domains where we want to allow the users to enquire not mainly about terms but about cognitively complex concepts. The following two examples illustrate these points:

- What is the difference between MPEG and JPEG?
  AskJeeves focuses both on the domain specific keywords contained in the question and on question generic terms. It returns questions relating to 'MPEG' or 'JPEG' (regarding the understanding of these or other computer related terms; regarding the download of MPEG music files) and to comparisons (yet not for MPEG and JPEG but for internet shopping sites). In our context we need to provide a much more specific answer which directly relates to a comparison between MPEG and JPEG formats.

- Can JPEG files be converted into MPEG files?
  For this question AskJeeves gives some of the same answers as for the previous question (as links to downloads of music files). Additionally, it offers reference to conversion programs (relating to Macintosh and PC platforms). Again, we need to be more specific and want to provide different, more relevant answers to both example questions.

3 Learner-Formulated Questions Based on FSCL

As outlined above we want to provide a mechanism in which learners can pose questions to a computer system in a user-friendly, 'natural' way, similar to addressing a human tutor. We want the computer system to 'understand' these questions, to compare these questions to a database of previously asked and answered questions, and to respond with semantically equivalent or close question and answer sets. We base our approach
on the Flexible Structured Coding Language, FSCL (Heinrich et al., 1999). FSCL is natural language like, has a flexible, user-extendable vocabulary, which is arranged in categories, and a fixed grammar based on these categories. FSCL offers a subset of natural language, which is rich enough to express complex content and structured enough to be accessible to automated processing.

To develop a ‘natural language-like question system’ we first collected natural language questions and reviewed the grammatical structure of English language questions. We extracted the most important question structures and investigated how we could formalise these structures based on the FSCL coding language. We developed two parallel approaches, one syntax-based and one semantic-based. In the following sections we outline this work in more detail.

3.1 English Language Question Structures

We have analysed a set of 500 sample questions and studied books on English grammar (Wardhaugh, 1995, Klammer et al. 1992, Alexander, 1988). Within the space of this paper we can only very briefly describe the main question structures we have identified. For the discussion of these question structures we need to define some key terms:

- **Auxiliary verb**: a word used in conjunction with verbs (‘do’, ‘have’, ‘may’, ...).
- **Noun Phrase**: a word phrase of one or more nouns (or pronouns) which can contain adjectives and conjunctions (‘a good compression format like MPEG’).
- **Action Phrase**: one or more predicates where a predicate consists of a verb (including auxiliaries and adverbs) plus a noun phrase as its object (‘... is playing MPEG video’).
- **WhPhrase**: an interrogative word (‘who’, ‘where’, ‘what’, ...) phrase which can contain a noun phrase (‘how many compression formats ...’).
- **AdditionalClause**: a declarative sentence introduced by a conjunction (‘... before the application is playing the MPEG video’).

We now use these terms to describe some of the question structures (and give examples in Figure 1). Our first group of questions, the general yes/no questions, have two basic forms (the brackets denote an optional part):

\[(A) \quad \text{<auxiliary verb><nounPhrase><actionPhrase>[<additionalClause>]}\]
\[(B) \quad \text{<auxiliary verb><nounPhrase><object>[<additionalClause>]}\]

The second group of questions we want to introduce are ‘wh-questions’. These questions start with an interrogative word. They differ from a yes/no question by asking for missing information rather than simply requesting confirmation or denial of information supplied in the question. Some common formats of wh-questions are:

\[(C) \quad \text{<whPhrase><actionPhrase>[<additionalClause>]}\]
\[(D) \quad \text{<whPhrase><auxiliary verb><nounPhrase>[<additionalClause>]}\]
\[(E) \quad \text{<whPhrase><auxiliary verb><nounPhrase><actionPhrase>[<additionalClause>]}\]

We regard imperative declarative sentences as a third group of questions. While not strictly speaking questions these sentences are useful in our context as they elicit information:

\[(F) \quad \text{<verb><object>}\]

### 3.2 Principles of a FSCL-Based Question System

FSCL is built on a number of principles which we have adopted and partly modified for this work.

- **Vocabulary**: The FSCL vocabulary is fully defined by the FSCL user. Usually, words are taken from the specific application domain the user works in. The words have to be associated with the FSCL categories. They can be arranged in hierarchies to facilitate retrieval of description sentences and are stored in a database. The FSCL question system retains these core features with one exception. In the question system we distinguish between application domain-specific (as in the original FSCL) and question-specific vocabulary. Analysing our sample questions and the English language grammar we can identify a range of words which are question-specific, regardless of the application domain. Examples are the question words ‘where’, ‘what’ or ‘which’. As a consequence we predefine these words in the question system vocabulary.

- **Categories**: The categories are an important concept in FSCL as they allow the definition of a fixed grammar without pre-determining the vocabulary. We retain the category idea but add question specific categories for reasons as outlined in the vocabulary section.

- **Grammar**: Again we retain the FSCL approach of defining a LL(2)-type grammar based on the category identifiers as terminal symbols.
Semantic tree: FSCL description sentences are parsed and then stored in semantic tree format. This format is comparable to abstract syntax trees as found in literature on compiling techniques. The semantic trees don’t give the parse structure but the semantic structure of a sentence by displaying the subject–verb–object relationships within the sentence. The question system uses semantic trees to represent the question structures and the semantic trees are the basis for comparison of questions. The comparison of two semantic trees contains two interwoven processes. A comparison of the tree structures looks for the existence of the same sentence parts at equivalent positions in each tree. The actual words in these parts are compared for identity using features of the vocabulary definition like the word hierarchies.

3.3 Syntax-Based Approach

The syntax-based approach for our question system follows closely the grammar structures given in section 3.1. The main focus is to capture the syntax of these questions. The original FSCL categories have been retained and two new word categories, ‘W’—WhWord and ‘U’—Auxiliary, have been added. The new grammar builds on the original FSCL grammar. The original grammar was designed for declarative sentences and is now used for the additional clauses. New grammar rules are introduced to deal with the question specific structures (like question word phrases) and newly introduced elements (like action and noun phrases). The semantic tree for the syntax-based approach has nine levels. Figure 2 shows two questions in their semantic tree representation.

The syntax-based approach has the advantage that it allows the recognition of a wide range of simple and relatively complex question structures. The comparison of different questions is prepared. The semantic tree format identifies the role of every word in a question sentence. As in the original FSCL approach, two questions can be compared by comparing their tree structures and their words in equivalent tree levels and positions.

3.4 Semantic-Based Approach

The semantic-based approach focuses on the meaning of questions. We looked through our sample questions and grouped together questions which ask for the same or closely related concepts. These questions can have different syntactical structures while being semantically similar:

- ‘In terms of compression which of MPEG or JPEG is better?’
- ‘Why is MPEG better than JPEG?’

These questions can have equivalent syntactical structure but use different question-specific vocabulary to ask for semantically equivalent concepts:

- ‘How is MPEG similar to or different from JPEG?’
- ‘How does MPEG compare with JPEG?’
Using this approach we have identified twelve generic question types. For each question type semantically equivalent and close question variations have been defined. The question types cover the basic formats of yes/no, interrogative word and imperative statement questions as described in Section 3.1. Again we follow the principle idea behind FSCL of using word categories as the basis for the grammar definition, yet the original FSCL is not integrated as closely as in the syntax-based approach. Among the category definitions are three generic categories (for nouns, verbs and adjectives) to contain the domain vocabulary. The other categories represent the components of a question specific vocabulary. For example, the category 'whatWord' contains (at least at this stage in the project) only the word 'what'. Another interrogative word like 'which' finds its place in its own category 'whichWord'. This is different to the syntax-based approach where all interrogative words belong to just one category of 'WhWords', as they all take the same place regarding the syntax of a question. Another category in the semantic-based approach is 'greaterWord' which contains a collection of comparison words with similar meaning ('better than', 'greater than', 'better', 'better between'). As in the other approach, a LL(2) grammar is defined on the category identifiers. The semantic tree spans seven levels. Figure 3 gives examples of semantic trees for two of the generic question types.

The strength of the semantic-based approach lies in grouping questions of similar or close meaning. Questions within a group are translated into the same semantic tree structure which indicates their relatedness. The comparison of trees is simplified. Compared to the syntax-based approach the range of question structures covered and the power of expressing domain concepts is less at this stage.

3.5 Prototype Systems

We have implemented prototype systems for both approaches in Java. The prototypes contain the predefined question-specific vocabulary and they allow the users to enter their own domain specific vocabulary. Based on the vocabulary, the users can formulate questions. These questions are checked for syntax and, if syntactically correct, stored in semantic tree format in a database. Any new question is compared to other questions stored already in the database. The user is presented with the semantic tree format of the new questions and a listing of any relevant existing question.

4 Conclusion and Further Work

We have achieved the first steps towards learner-formulated questions in online technology-supported learning applications. Based on a review of sample questions and English language grammar we have identified the main question structures used. We then followed both syntactic and semantic approaches to formalise these question structures. These approaches are based on the Flexible Structured Coding Language, FSCL. We use question specific categories of words and generic categories, which can be filled by the user with vocabulary for their specific domains. Grammars are defined based on categories and allow parsing for the structure of the questions. Syntactically-correct questions are stored in semantic tree formats to facilitate the comparison of questions for
Figure 3: Semantic trees for example questions using semantic-based approach

semantic equivalence and closeness. The questions we deal with are natural language like. We have implemented prototype systems to allow for testing of our ideas.

The next step in our work will be to combine our syntax-based and semantic-based approaches. We want to be able to deal with the variety and complexity of question structures from the syntax-based approach and have the grouping of questions for semantic relatedness from the semantic-based approach. We then need to collect a substantial body of questions for testing our question structures and measures of relatedness. In the longer term we want to move towards the third scenario we have introduced where answers to questions can be deduced from domain-specific content representations using FSCL.

Abstract: In this paper, we analyse a so-called access to Best-Match learning resources in a WBT environment. We overview existing solutions and propose a new technical solution which extends the topic map functionality with a number of important features. This solution is based on a concept of so-called knowledge cards combined into a semantic network. The mechanism essentially utilizes such important property of semantic networks as a possibility to infer Learning Resources using semantic relationships.

1. Introduction

Traditionally, Web Based Training (WBT) (Gaines et al. 1996) system is supposed to maintain a training process available “anytime anywhere” by means of the World Wide Web technology. Nowadays, WBT attracts more and more attention as a tool for so-called “training on personal demand” which utilises different training scenarios than a classical WBT (Shaw et al. 1996). The following scenario covers a representative number of the training on personal demand applications. An employee needs a training on a particular subject to acquire additional knowledge, and is aware about a WBT server containing a relevant information. The employee access the server to find most relevant training material, to work through these material and to communicate with the subject experts and with other learners working on similar materials.

Implementation of the “learning on demand scenario” obviously requires a special tool for accessing best-match learning resources.

There are two well-known technical solutions which potentially my fulfil the requirements for accessing best-match learning resources: search engines and topic maps.

Currently, search engines are capable of performing very intelligent and customisable searches that retrieve the most relevant documents or parts of documents that fit a certain query. However, search function often cannot be applied for selecting best-match learning resource simply because query languages are not capable of defining such crucial thing as “learning goal”.

On the other hand, topic maps are used to present a comprehensive conceptual overview of learning resources provided by a particular WBT system. This approach allows browsing and searching on meta-level rather than browsing of individual documents. However, application of the topic map concept put a serious additional work load on authors who are responsible for providing comprehensive topic maps of learning resources in a WBT environment.

In this paper, we propose a new technical solution which extends the topic map functionality with a number of important features. This solution is based on a concept of so-called knowledge cards combined into a semantic network (Lambiotte et al. 1984). This concept has been implemented as a component of multipurpose WBT system called WBT-Master (http://coronet.iicm.edu/wbtmaster/know.htm).

2. Knowledge Cards

A Knowledge card is a description of particular concept (i.e. semantic entity). For example, a semantic entity “Database technology” may be seen as a knowledge card.
Practically speaking, each Knowledge Card may provide access to a number of associated Learning Resources. For example, a course on "Relational Data Model" may be associated with the Knowledge Card "Relational Data Model," some other Learning Resources may be associated with the same Knowledge Card.

Knowledge cards may be interrelated into a semantic network using different types of relationships: "is a part of," "is a kind of," "synonym for," etc. For example, the knowledge card "Relational Data Model" may be related as "is a part of" to the knowledge card "Database Technology." The knowledge card "World Wide Web" may be related as "is a kind of" to the knowledge card "Hypermedia Systems." The knowledge card "Training" may be related as "is a synonym for" to the knowledge card "Computer Supported Collaborative Training."

All possible semantic relationships are predefined in a special system thesaurus where the relationships are also provided with a numeric assessment of so-called inference probability. The inference probability is an assessment of "how much" a particular knowledge card is related to another knowledge card, and vice versa, in the semantic network. For instance, the inference probability between two knowledge cards can be set as 1.0/1.0 for the "is a synonym for" relationship.

Whenever an author contribute to the server with new material, he/she is supposed to associate it with one or more Knowledge Cards or create a new Knowledge card and place it into a proper position within the semantic network. Of course, it can be also done by a specially designated member of the server administration team (Knowledge engineer).

As a starting point, learners are not supposed to browse through countless learning resources. They are supposed, in a simplest case, to browse the semantic net consisting of previously defined Knowledge Cards.

3. Infer Procedure

The infer mechanism essentially utilizes the other important property of the semantic network (Nosek et al. 1990) - a possibility to infer Learning Resources using semantic relationships.

Whenever a user access a knowledge card, the system automatically infers all Learning Resources which are associated with this particular Knowledge Card and with Knowledge Cards related to this one.

For example, suppose that there were no resources associated with the knowledge card "Computer Science," but a number of other card (say, Databases, Programming, etc.) were defined as "is a part of" Computer Science. Accessing the "Computer Science" knowledge card will result in the resources inferred from other related cards.

4. Conclusion

Generally, first experiments with the Knowledge Card system demonstrate a rather good functionality and acceptance by users. User evaluation questionnaire and analysis of the server log files show that users definitely prefer a personal knowledge card to be an entry point to the whole system. Authors generally like the situation when they can simply contribute to the server without paying much attention to accessibility of the material. Note, the contribution is automatically associated with the author's personal knowledge card which, in turn, the server administration team.

Abstract: In the United States Department of Defense Education Activity (DoDEA) preK-12 school system, new instructional materials (e.g., textbooks) are adopted in each curriculum area every 6 years. As part of the adoption, vendors are required to provide an overview concerning the philosophy, goals, and organization of their materials, and to provide staff development. This type of program has required teachers to assemble at a site in Europe or the Pacific for five days of intensive training. Due to a limited number of participants and the high costs associated with travel and lodging, DoDEA decided to examine alternate ways to deliver the overview component of the training. The major focus of this paper is to describe the process DoDEA and three vendors used to develop what we call the online book walkthrough.

Introduction

Due to a limited number of participants and the high costs associated with travel and lodging, DoDEA decided to examine alternate ways to deliver training. It was decided that some of the training could be done more effectively and cost efficient as web-based instruction. We were the "someone" implementing the project. The web-page developers were the "someone" who would need to understand our requirements and build systems that met our expectations.

Imagine for a moment that you are working with developers who have various levels of expertise related to developing web-based training. In the past their success depended on their graphics ability, their HTML coding skills, or their knowledge of a web development package. Accessibility issues, users with limited web access, and issues of consistency in design might not have been major issues in their development projects.

During the initial planning stages, we assumed that the web-page developers had a basic understanding of how to design interactive learning modules and were knowledgeable of basic issues in human-computer interface (HCI) and accessibility. We soon learned this was not the case. Slow download times, old systems, lack of sophisticated graphic or sound cards, lack of Internet experience on the part of some our teachers, and the limited access to Internet connections in some of our schools were limitations with which the web-page developers were unaccustomed to deal. Two of the three web-page development teams found these constraints, especially those related to bandwidth and hardware limitations, difficult to deal with and design for. The third developer, whose background is in art, his primary medium being metal, found the constraints to be creative challenges.

Despite the differences in development experience and the organizations they worked in, all three developers possessed common elements. While they were experienced in web development, they had little or no knowledge of instructional design, nor much experience with accessibility issues. This lack of knowledge turned what we originally thought would be a fairly simple task that could be completed within 6 months into a rather involved effort that ran 14 months.
Assumptions In Our Thinking

As work on the online book walkthrough began, we became aware of flaws in our thinking based on our original assumptions:

- Because we were working with experienced web developers, we thought that they would understand basic computer interface design issues and accessibility considerations.
- Once provided with an analysis of the users and their environment, the developers would design systems to meet the users' needs.
- The quality of materials we intended to present to our users was based on higher expectations than those with which some of the developers were accustomed to dealing.

What We Got

As work continued, we received various drafts, which included among other things:

- Gross inconsistencies in design
- The use of non-standard HTML
- Graphics, animations, and sound files which either had no relevance to the content or added no meaning to the lessons.
- Systems designed in a purely linear fashion
- Dead links
- Confusion as to what were hot links and what were not
- Graphics without accompanying ALT text
- User requirements and standards that we provided were not taken into consideration
- Little or no testing had been done on some of the early modules

Current Status

The teachers have been given access to the book walkthroughs. They have been given surveys to complete containing questions related to ease of use and to their comfort level in using online training. Since this pilot project is still underway, information related to cost and to teacher feedback is in the collection phase.

Would we do it again?

Representatives of the vendors believed that their people knew what they were doing. As it turned out, although these representatives had many years in education and training, they had little or no knowledge on how to develop web-based instruction, but they were willing to learn.

This experience has brought benefits to DoDEA and to the vendors. We learned a lot about each other. Lessons learned were not a result of mandates by others, but rather the result of a better understanding and acceptance on the part of the developers regarding reasoning behind the design considerations. At this point we feel that, if "someone" (we) initiated a new project, "someone" (these developers) would understand our requirements and expectations for excellence.

Yes, we would do it again. To insist on a standard of quality and excellence is to provide our teachers with the level of excellence we believe they, as professionals, deserve. We feel that the time we spent and our perseverance was well worth it.
Understanding the Quality of Students’ Interactions through Computer Conferencing in Higher Education from the Social Constructivist Perspective

Abstract: This paper discusses the processes of interactions among learners in higher education through computer conferencing, and provides information regarding the quality of their learning experience. In order to investigate this phenomena, the social constructivist perspective with the metaphor of “persons-in-conversation” was undertaken as a conceptual framework. The attributes of computer conferencing and its relationship to social constructivism, point to interactions as essential processes through which negotiation of meaning and co-construction of knowledge occur. To address the scarcity of research using qualitative interpretive methods in computer conferencing, constructivism as a referent for the research method was used. The principles of grounded theory was employed in the analysis of computer transcripts resulting in the emergence of seven themes. In order to verify the hypothesis pertaining to the themes, additional questions were formulated and students’ end-of-semester evaluation was used. Analysis suggest that the activities occurring within the themes are dynamic interactive processes against which students’ conversation take place.

Purpose of the Study

This study aims to address the fundamental question: “What is the quality of interactions and the subsequent learning experience among learners in higher education in computer conferencing?” In order to investigate these qualities, the social constructivist perspective was undertaken such that the metaphor of “persons in conversation” (Ernest, 1995, p. 480) provided a framework for the study. Within this framework, the extent to which a community of learners is established is investigated within which, the nature of discourse within the community is analysed.

Motivation for the study

As a graduate student, the first author had the opportunity to take on-line courses that were supported with computer conferencing and the world wide web. This particular course under study was conducted wholly on-line. This was a new learning experience for her and she subsequently went on to assist the second author in moderating the on-line course. The second author is engaged in designing and facilitating on-line learning courses using social constructivism as a referent for her teaching in which the focus of the educational experience is on the web of interaction between the facilitator and her students and among students. The result of their exposure to on-line education led to their interest in research in this area of teaching and learning.
Significance

A review of recent literature shows that the principal issues where studies into computer conferencing has largely been conducted relate to application oriented issues (Mason, 1992), and evaluation into the quality of an online conference (Romiszowski and Mason, 1996; Gunawardena, Lowe and Anderson, 1997). These include investigations into the amount and patterns of participation showing the interrelationship (or threads) among messages submitted to a conference (Ahern, Peck and Laycock, 1992; Howell-Richardson and Mellar, 1996; Hillman, 1999), comparative patterns of participation among learners from varying backgrounds (Levin, Kim and Riel, 1990), and participation satisfaction regarding the medium of communication. Mason (1992), in reviewing methodological approaches used in evaluating CMC, reports that the majority of studies came out of a quantitative/positivist paradigm, using techniques such as survey questionnaires, interviews, empirical experimentation and computer-generated statistical manipulations which do not shed much light on the quality of learning taking place.

Recent researchers however, have begun to investigate into more specific aspects of students’ learning, including higher order learning (Fabro and Garrison, 1998), critical thinking (Bullen, 1998; Anderson and Garrison, 1995; Garrison, 1991; Newman, Webb and Cochrane, 1995) and social interchange among learners (Gunawardena and Zittle, 1997; Rourke, Anderson, Garrison and Archer, in press). These studies have exposed the small number of research, and the need to examine quality issues with regards to students’ on-line learning.

In relation to this, few studies have sought to analyse the transcripts of students’ on-line conferences for the purpose of investigating the quality of interactions and the quality of their learning experience using social constructivism as a referent for the investigation. This study follows initial studies carried out by Gunawardena, Lowe & Anderson (1997) and Kanuka & Anderson (1998) on professional development conferences with learners of roughly equal skills and knowledge in which they sought to analyse the processes of interaction among participants. This study seeks to investigate and understand the on-line construction of students’ knowledge in higher education, through an analysis of their conference transcripts, end-of-semester evaluation and further questions which were formulated from hypothesis generated from the analysis.

Conceptual Framework

Using social constructivism as a referent in investigating students’ educational experience, two interrelated elements are seen as essential to the investigation of the quality of the learning experiences: the establishment and presence of a community of learners, and the nature of discourse within the community. Within this framework, education is seen as a social learning experience (Garrison, 1993) in which negotiation of meaning and co-creation of knowledge occur. Operationally, we define interaction as the experience during which two or more parties engage in a collaborative effort to negotiate meaning and to form a unified knowledge. In the context of computer conferencing, interaction and communication are essential processes through which learning occurs. Kaye (1989) states that “conferencing is primarily about interaction” (p. 16).

The importance placed on interaction points to the fact that two kinds of knowledge creation take place in a shared learning experience such as that in computer conferencing. Knowledge is created at both the social - level of the community - and the individual who also creates his or her own understanding. “Social constructivism regards individual subjects and the realm of the social as interconnected” (Ernest, 1995, p. 479). This means that at all times, knowledge is both social and individual in a way that Tobin and Tippins (1993) describe as “a dialectical relationship existing between the individual’s contribution to knowledge and the social contribution” (p. 6). For Dewey (1938), education is based on the interaction of an individual’s internal and external conditions. This means that interaction and the situation during which one experiences the world cannot be separated because the context of interaction is provided by the situation. This idea of communication suggest the intersubjectivity between the individual, other people and the surrounding environment. As Vygotsky (1978, cited in McLsaac & Gunawardena, 1996) postulates, one’s social environment is a critical factor in one’s cognitive development. As such, knowledge should be seen as a matter of conversation and of social practice (Rorty, 1979 in Philips, 1997).

Following this conceptual framework, interaction and communication take precedence over individual learning in this on-line community of learners.
Research Design and Procedures

The research approach was underpinned by a constructivist theory of knowledge in which the aim of the inquiry is to investigate and understand the quality of the learning experience on-line. A constructivist epistemology views knowledge as a construct of individual's understanding (Guba and Lincoln, 1994). When individuals come together, such as in a learning environment, their construction undergoes continuous revision due to cognitive conflict which occurs as a result of different constructions among individuals. Through the hermeneutical/dialectic process, knowledge becomes more informed and sophisticated.

In view of this study which aims to investigate the processes of social negotiation and co-construction of meaning, this methodology is considered the most appropriate. It recognises individual’s construction of knowledge to be an interpretation and not a correspondence to an external reality (Von Glasersfeld, 1990).

This on-line unit is a postgraduate unit for science and mathematics teachers. Nine students undertook this unit, including the first author, and it was moderated by the course instructor who is the second author. The students come from Canada, Vanuatu, New Zealand and various parts of Australia; however, except for the student from Canada, all other participants were residing in Australia during the course of the unit.

The research questions, both original and emergent, formed the basis for the methods by which data were collected. The data were pieced together to answer research questions that evolved. Consequently, the research questions and research methods were emergent and self-reflexive. The research methods include transcript analysis using the principles of grounded theory, participants’ end of the semester evaluation, and open-ended questions which were formulated from the hypotheses generated from the transcript analysis.

Transcript Analysis: First, a critical review of a currently available interaction analysis model was conducted in which it found that Gunawardena, Lowe and Anderson’s (1997) model to be the most promising start for their concept of interaction is based on the principles of social constructivism. This model traces the construction of knowledge in social learning through five phases. Second, the researchers went through the conference transcript once in order to familiarise themselves with the manner of interaction among the students. Having observed the patterns of interaction among the students, the data was found to be incongruent with the categories from the model. Rather than impose the categories (from the model) onto the data at the early stages of analysis, the researchers felt that it would be more useful to let the categories emerge from the data. Literature on social constructivism and grounded theory were used to analyse emerging patterns, themes, phases, and concepts relating to the social construction of knowledge. From the transcript analysis, hypotheses were formed in which participants’ end of the semester evaluation was analysed to verify the hypotheses.

Open-ended questions: This instrument was used in order to further confirm or disconfirm the hypotheses formed through the transcript analysis. From the transcripts, it appeared that some phenomena pertain to all participants while others pertain to certain individuals. As such, two categories of questions were formulated, one relating to all participants, and the other, different questions relevant to the respective participants. From these questions, student’s perception regarding their learning experience was also investigated.

Findings and Implications

Analysis from the transcripts and end-of-semester evaluation point to the existence of seven themes pertaining to the ways students learn on-line. These themes represent dynamic activities occurring within them with each theme relating to the other interactively. In assuming the metaphor of “persons in conversation”, the transcripts represent students’ conversation with each other on-line; as conversations do not take place in separate phases, so too the themes which emerged from their conversation are not distinct and separate. The seven themes are: the learning environment, community of learners and the social presence of others, students’ background and prior knowledge, reflective thinking, peer-learning and students-centred learning, constructing knowledge, and the role of the facilitator. Within the social constructivist framework in which this study was conducted, these themes can be grouped further into two main categories: learning communities and discourse within the community.

In order to make meaning from students’ conversation and henceforth, their learning experience, the relationship between the themes in the respective categories can be understood from the perspective of theoretical codes (Glaser, 1978). Theoretical codes allow for themes to be organised so that the relationship between the themes can be clarified in order to understand the processes of students’ learning experience. Seen in this perspective, the initial role played by the facilitator appears to have set the learning environment that enabled a community of learners to be formed. Within the community, students’ background and prior knowledge became apparent, was
emphasised and played a key role in their discourse. Together, these form the total background against which students’ discourse took place. This environment in which interaction transpired is the learning community.

In relation to their discourse in the learning community as reflected in the Activity Room, students reflect on the readings in relation to their own experiences as well as their colleagues’ responses in relation to the readings. From their reflections, they then share their experiential knowledge and put forward their responses to the readings, and occasionally to their colleagues’, using different forms of communicative strategies. Thus, there was increase in peer-learning based on one another’s experiences and perspectives. It is worth noting that the learning community and the discourse within the community are not separate and distinct categories; the community both affects the discourse, and is affected by the discourse, creating a dialectical relationship.

Community of Learners. One of the second author’s intentions when she designed this unit was to develop a community of learners within which peer-learning and student-centred learning would occur. In view of this, she guided the first two weeks of discussion which enabled a community to be formed. Immediately following the second week, students’ interaction with one another could be seen to take place within the learning environment that she created. Later on, against this environment and through peer-learning, they established their own environment for conversation. The importance of the learning environment for the development of a community could be seen from this student’s end-of-semester evaluation, “The fact that we introduced ourselves and a little historical information set up a rapport between the group. This allowed me to feel more at ease, particularly as I don’t have a strong technological background.” Students’ personality as revealed in the self-introduction activity initiated by the facilitator, is important in helping students know who their colleagues are, and the way in which they will consequently communicate with one another. As this student said “I started the unit cautiously. I was testing the waters because I needed to know who my coursemates were as they would influence the way in which I contribute to the activity room.”

The importance of a community of learners is also seen to be significant to students’ interactions in the following ways: (a) It helped to create an equitable learning environment. Students do not feel threatened by one another’s ideas and are able to share their knowledge freely. (b) It enabled for social exchanges among students in addition to the more formal discussions. Through their social chats, students learn from one another. This was acknowledged by the facilitator when she said, “I really enjoyed the brief personal interactions...which makes me think that it is valuable enough to have it in the activity room and not as an e-mail. After all, this is part of the learning process, as it is not only in the information exchange[s] but also in the personal exchange[s]” (Activity No. 115). (c) Students do not feel themselves isolated in their learning experience, and regard one another’s experiences and ideas as resources towards their own learning.

However, while most students felt satisfied with the informal learning environment, there were others who felt that a more formal situation would be more suitable for learning. Thus, they do not view their colleagues’ social chats as sources of knowledge, but instead regard them as mere general chatter. One student indicated that her colleagues’ “responses became more of a general chat...they were too colloquial.”

Evidence of students collegial attitude towards one another can also be seen from the way in which they use the activity room for purposes beyond formal discussions. In addition to the social exchanges, they also share their classroom ideas, on-line resources, support each other in their learning difficulties especially those pertaining to technology, and encourage one another. The transcripts reveal that students who are learning on-line for the first time generally needed more support from their peers than those who are more experienced with this form of learning. However, they differ in their perception regarding the support they received from their peers.

Discourse within the community. Students’ conversation indicate that they are strategies which they used in order to communicate their ideas to one another depending on their intent and the context within which they are used. It is also true that the purpose of their conversation sometimes result in unintended outcomes, or lead to other forms of conversation. The transcripts reveal that three groups of students exist with regards to their on-line learning experiences, beliefs and attitudes in relation to the use of technology in the classrooms. These factors are seen to relate to the types of conversation and strategies they used in order to promote their ideas and opinions.

Students in group one are experienced teachers with more than 15 years of teaching experience. Generally, they are also experienced on-line learners with a positive attitude towards the use of computers in education. In their discourse, they often discuss the readings in relation to their prior experience as well as use them as justifications for their opinions. They are confident learners eager to put forth their arguments. The questions they posed to their colleagues are generally intended to obtain ideas and resources for their own classroom practices. They form the biggest cohort of students. Students in group two are both first-time on-line learners who are respectively naïve in matters pertaining to computers, and have no teaching experience. However, they are eager to learn from their colleagues and are open to new ideas. This can be seen from one of their transcripts, “...[I am] interested in capitalising on the use of educational software in enhancing learning and understanding and [I] hope to learn from...
all of you” (article no. 12). The consequence resulting from their lack of experience see them discussing the topics either from a personal perspective, or from a theoretical viewpoint. The questions they pose to their colleagues are often intended to deepen their understanding regarding the topics, and to clarify conflicts of understanding. In posing their questions, they also challenge the beliefs of their colleagues. Students in group three lack experience in computers and are sceptical regarding their practical use to improve teaching and learning. Regardless of the group in which students belong, they acknowledge that they learn something new from each others’ experiences.

The importance of students’ prior experiences establish their starting point with regards to their learning. Students’ starting point is significant as it reveals where their current knowledge and beliefs are at the beginning of the semester in relation to where they subsequently are at the end of the semester, and the kinds of interactions that occur in the activity room to create this change in understanding. It has been well documented in literature (Ernest, 1995; Tobin and Tippins, 1993; Von Glasersfeld, 1990) that students’ prior knowledge and beliefs act as both a motivation and constrain to their learning. When students are faced with a concept, model or theory, they bring their experiences to bear on this information; if the information falls within their existing frame of understanding and is adequate in the context in which they are created, the information is accepted as viable. However, if their prior experiences inform them that the piece of information is not likely to be workable, it is resisted. From their conversation, it appears that students’ cognition is more open to embrace new knowledge not currently held than it is to change incorporating the differences; this can be seen both from their resistance to change as well as from the scarcity of new knowledge which comes from a shift in their cognition.

In terms of discourse from a social constructivist standpoint, students generally created opinions rather than engage in active conversation and negotiation of meaning with one another. That is, they generally proposed their own different views rather than seek clarification or challenge one another’s views through active conversation. However, closer analysis of the transcripts show that tacit negotiation was continually occurring even when participants were apparently agreeing with one another (Gunawardena, Lowe and Anderson, 1997).

These findings in relation to the two categories suggest that: 1) a sense of community sets the learning environment that enables for the sharing of multiple experiences among students. These experiences in turn, act as a rich pool of resources towards students’ learning leading to their construction of new knowledge. 2) in order that students collaboratively build and integrate new knowledge into their existing framework, or change their existing framework, instructors should formulate ways in which to transform their tacit negotiations into more active interactions through negotiation and discussion among students.

*This research was conducted while Dr Maor was working at the Science and Mathematics Education Centre, Curtin University of Technology.

Abstract: This paper describes the design, development and evaluation of a website designed to ameliorate many of the problems encountered by beginning teachers. The site allows new teachers, and preservice teachers on school practice, to communicate with each other through a discussion board, and provides access to a range of resources including lesson plans, videos of exemplary teaching, annotated lists of useful websites and frequently asked questions. Such access may help to lessen the feelings of isolation and lack of support felt by many beginning teachers, and provide a link between the practical realities and constraints of the classroom and the more innovative, research-based methods and strategies teachers learn while at university.

Introduction

The beginning teacher experience can be as daunting in Australia as it can be in the rest of the world. One new teacher recounts the experience of her first teaching appointment in an outback high school:

I had an idea of what it was going to be like ... I just prepared for the worst. I had in the back of my mind ‘Well, OK it's not a very attractive place’. When I did fly over, I looked out and all I could see was the mud flats. I got off the plane and it was hot and it was red pindan, just red dirt, and you could see for miles. I just thought, ‘Oh this is awful’. I didn't like it. I thought ‘There ut no, there weren't any beaches. And there were signs everywhere that said ‘Beware of the Crocodiles’.

The school? The first day. It was pretty tough. It was sort of ‘Oh, I can’t stand this’. I almost chucked it in. I found the students had a lot of behaviour problems. Their first impression was that I was a student teacher. They didn't see me as a qualified teacher. They were very testy a lot of the times and I suppose being my first job, it was tough. I found that I didn't get too much support from the staff either. I was totally left in the dark. I didn't really have much support.

When I came here there was just nothing. I didn't have any resources. All the stuff that they did have at the school that was anything to do with maths, the stuff from the Ark. It was ancient yellow stuff, cobwebs and things, from the 60s and 70s that they had been using. I didn't know where to start. I didn't know what to do. As far as budgeting and costs and knowing what to buy, and no one else had any idea. It was up to me to decide. 'Well, you're the maths teacher, you need to decide what you need for your classes. What do you think the kids need?' So I was making phone calls down to Perth ... I needed some help ...
The sense of geographical isolation and professional isolation illustrated in this excerpt, are common phenomena for beginning teachers in Australian schools. Added to this is the paramount issue that all beginning teachers face—managing their classrooms. The anxiety can only increase when faced with the other issues of lesson preparation, motivation, assessment, social relationships with students, teachers and parents, pedagogical and content knowledge (Kent, 2000) and the current demands with the use of technology in teaching (Strudler, McKinney, & Jones, 1999).

Generally, on the completion of their teacher education courses, neophyte teachers display the modern beliefs and practices that those courses aim to achieve. But it is not surprising that the complex and difficult issues that beginning teachers are faced with cause many of them to retreat to the safe beliefs and practices that reflect traditional approaches (Raymond, 1997; Simmons, Emory, & Carter, 1999).

So how can teacher education courses develop and sustain modern beliefs and practices that are robust enough to cope with the critical realities of classroom teaching? One approach is to refine the curriculum in teacher education courses in ways that better reflect the contexts in which new teachers will find themselves. For example, Investigating Teaching Strategies in Mathematics Classrooms (Herrington, Sparrow, Herrington, & Oliver, 1997) and Learning about Teaching (Mousley, Sullivan & Mousley, 1996) are CD-ROM resource designed to situate preservice mathematics teachers in contexts that reflect real life instructional and assessment issues for teachers in K-12 classrooms. Another approach, which is the focus of this paper, is to provide a technology-based support mechanism for beginning teachers that is characterised by collegiality and reflection on practice (Peterson & Williams, 1998).

Mentoring programs and web-based teacher networks have been suggested as approaches in which beginning teachers can be supported through these concerns, where together with other novice and experienced teachers, they can reflect on their own developing beliefs and practices, and view and share the experiences of others (Weasmer & Woods, 2000).

The MEOW (Mathematics Education on the Web) website

MEOW (Mathematics Education on the Web) (http://www-scim.cowan.edu.au/MEOW) is a web-based approach developed to support beginning and preservice teachers of mathematics. When fully functional, the website will provide support for different groups of preservice and practising teachers. In particular, new teachers will be able to access the site to keep in contact with their former classmates and instructors, to share ideas and lesson plans with others around the world, and to access valuable resources.
On the website, resources and communication elements are accessible from a central interface which represents a well-equipped office (Figure 1). Teachers quickly learn where resources are located and can intuitively select the appropriate location in much the same way they access resources in a real office (Hedberg, Harper, Wright, & Farr, 1996).

Clicking on various elements of the interface—such as the telephone, the television, or the computer—gives access to different resources. Specifically, the site provides the following elements:

**Discussion board**: When teachers click on the notice board in the office interface, they connect to a discussion board where they can talk with their colleagues about problems or issues they are faced with in their mathematics teaching. They can present a description of something which might be worrying them, ask for suggestions on how to deal with a problem, or simply share ideas and thoughts with other teachers. Such a resource reduces the isolation felt by many new teachers, and gives them an alternative avenue of support to their workplace colleagues. Such support might also help to alleviate the anxiety reported by new teachers when they are directed to teach in a manner at odds with the methods taught in their teacher training courses.

**Lesson plans**: Clicking on any of the desk drawers gives access to a variety of lesson plans classified by year levels, by content and by processes. Teachers can click on any lesson by title and be given a description of how to use the activity with their students. Each lesson plan has an introduction, a description of the activity together with a list of any materials that are needed (some of these, such as 1cm grid paper, can be downloaded and printed from the website). For example, Figure 2 shows part of a lesson plan within the strand of pattern, suitable for Years 3-5. Ideas for extension activities are also provided with the lesson plans.
Lesson ideas

Cross the River [3-6]
Children play the game "Cross the River" and develop strategies to win. These are reported to other interested players.

Introduction
Show the children the game "Cross the River" and explain the rules. Children play in two teams of two.

Rules:
1. One team has the North Bank and one team the South Bank.
2. Each team has to place its counters by a number or numbers. More than one counter may be placed by a number (for example, all of them could be placed on 6).
3. Tunes are taken to throw the dice and add the scores. If a counter has been placed on that total then it is moved to safety across the river. Only one may be moved at a time from any total even though there may be more than one present.
4. When all of a team's counters are safely across the river the game stops.

Turns are taken to throw the first dice and add the scores. If a counter has been placed on that total then it is moved to safety across the river. Only one may be moved at a time from any total even though there may be more than one present.

Figure 2: A sample lesson plan from the Years 3-5 drawer

Contacts: Clicking on the telephone on the desk enables teachers to access contact details of their former instructors if they wish to contact them direct to discuss any issues they may have in their mathematics classrooms.

Web-based resources: Useful URLs: Clicking on the computer on the desk gives teachers access to web resources beyond the MEOW site (Figure 3). There is a wealth of resources available for teachers on the web (such as lesson plans, mathematical resources, factual information, etc.) and students and teachers are encouraged to add recommended sites to the list. Each URL link is annotated by the contributor giving reasons for its recommendation, and this helps to prevent the page from becoming simply a list of hyperlinks.

Figure 3: Teachers can access a wealth of resources on the web through the Useful URLs page

Useful URLs

http://www.eu/au/cnt/puzzles/puzzl.htm
Puzzle page from the Centre for Innovation in Mathematics Teaching.

http://www.worksheetfactory.com
Teresa suggested this site. Looks like an interesting resource for lesson plans.

http://www.graphpaper.com
This site allows you to create and print your own graph paper at the touch of a button. You will need either a PC or Virtual PC to make it work.

Cross the river.
Exemplary teaching: If teachers click on the television in the interface they are given lists of teaching and assessment strategies from which to choose, such as group work, problem solving, investigations and portfolios. Selecting any of these strategies allows them access to a streamed video of an experienced teacher demonstrating the strategy in a real classroom. Teachers can also view short videos of the teacher discussing the strengths and weaknesses of the strategy and also a student's perspective. There is also a description of the strategy in text format. For example in Figure 4 below, a short video can be accessed to demonstrate the use of role play in the classroom, and teachers can also watch videos of an interview with the teacher and a student from the class. A description of role play as a teaching strategy is also provided.

Figure 4: The exemplary teaching section includes short videos and interviews, with text descriptions

Common problems: The folder on the desk, when clicked, gives teachers access to many common problems faced by beginning and preservice teachers. This takes the form of a Frequently Asked Questions (FAQ) site, and the questions and suggested answers are taken from the discussion board and summarised for easy access.

Reflective support

The benefits provided by this resource for beginning teachers are numerous: they have immediate access to required information; they are able to collaborate in a virtual community and be relieved of the sense of isolation so often experienced; they can contribute to the database by posting successful lesson plans and other materials of their own; and they can share the information passed in the chat sessions without having to formally participate.

While the MEOW site provides a great deal of 'just-in-time' support, it is also designed to support beginning teachers in a more reflective way. Boud, Keogh and Walker (1985) define reflection as: 'those intellectual and affective activities in which individuals engage to explore their experiences in order to lead to new understandings and appreciations' (p. 19). These authors stress that such reflection must not occur solely at the unconscious level: 'It is only when we bring our ideas to our consciousness that we can evaluate them and begin to make choices about what we will or will not do' (p. 19). The site enables reflective practice by providing a variety of resources from which to gain alternative perspectives on any teaching task, and by providing exemplary performance and the modelling of processes, enabling students to reflectively compare their own performance to that of experts. Communication technologies also allow students to establish communication in the language of the culture, and to share stories and anecdotes of their experiences.
Preliminary evaluation

While the site has not yet been evaluated with beginning teachers, it has been evaluated formatively with a small group of eight target preservice teachers. The evaluation comprised observation of students using the site in small groups, a questionnaire and a focus group discussion. Students were asked to use the site and then to complete the questionnaire. At the conclusion of this session, all the students came together for a discussion of the issues.

The findings from the questionnaire were uniformly positive with students valuing as Very helpful or Helpful, the majority of support elements provided on the MEOW website. (Of the five respondents, only one response item fell outside these parameters.) In the focus group discussion, some problematic issues were raised, such as the uncertainty that schools would have reliable and ready access to the Internet. However, if such practical difficulties can be overcome, the students pointed out the value of cross-fertilisation of ideas between practising teachers, preservice teachers and university instructors. The students suggested that the video demonstrations of teaching and assessment strategies were particularly useful in providing practical demonstrations of the theory learned in their coursework during teacher training. Finally, the suggestion was also made that other discipline areas could use the site as a template and provide similar support (particularly useful for elementary school teachers).

It is proposed to conduct an interpretive, summative evaluation after the site has been fully developed and made available to beginning teachers. The investigation will focus on whether the site is used reflectively, the value of the lesson plans and other resources in strengthening teachers' mathematics pedagogy, and the value of the communication elements of the site in enhancing a sense of collegiality and reduction of isolation.

Conclusion

Achieving successful induction for teachers may result in reducing the current high attrition rates of beginning teachers and as other successful programs have found, may provide a positive influence on the beliefs and practices of their more experienced school colleagues (David, 2000).

The beginning teaching experience can be daunting. Adopting traditional methods of teaching and assessment from their own classroom experiences and discarding the methods advocated in teacher training courses may provide a safe and comfortable environment that enables one to survive the demanding pressures of the first year experience. A web-based resource such as MEOW has the potential to provide a bridge between the practical realities and constraints of the classroom and the more innovative, research-based methods and strategies that teachers experience at university. The website can provide a dynamic and reflective set of resources for new teachers, and importantly, provide the support that helps to overcome what can be immense geographical and professional boundaries.

Abstract: The long range goal of the investigators is to design and implement a computer network based intelligent system called a Distributed Adaptive Learning System (DALS) that measures the learning characteristics of individual learners and presents the information they seek in a form created dynamically to optimize their learning. A small scale version of a DALS utilizing only four learner characteristics and three methods of presenting information to the viewer will be constructed as a first step toward this goal. Features of a full-blown DALS will be incorporated into the model system. The three investigators bring the expertise and experience in the core disciplines needed to implement this simplified system; but to realize a full-blown DALS will require many additional expert collaborators. What is learned from this work will form the foundation for future research and development in Distributed Adaptive Learning.

Introduction
There are three components in every instance of human learning: what is to be learned, the learning venue and the learner. The authors define a generalization of this simple schema by labeling the three elements Knowledge - Agent - Learner respectively (this is our KAL model) and then broadening the meanings of the three terms to Knowledge Space, Agency and Learner Space. Because our target is network resident, technology facilitated learning, we envision the Knowledge Space as a sophisticated, intelligent database, the Agency as a collection of intelligent software agents that implements learning venues and the Learner Space as a set of Learner Filters each of which contains the learning characteristics of a single learner in the system. These elements are dynamic so each may change from the results of, or during, a learning episode.

Distributed Adaptive Learning System
The software system implementing this KAL learning model over a network is called a Distributive Adaptive Learning System (DALS). Design of a DALS raises a number of immediate questions: What characteristics/parameters affect human learning the most? How should ‘knowledge’ be organized to enhance or optimize learning? What are the best venues in which to learn? Addressing these and the myriad issues they bring up led the authors to design the general DALS reported here.

Knowledge Space
We employ concept hierarchies, called Knowledge Networks, to represent the content to be covered in a DALS learning episode. A pointer-free implementation of these Knowledge Networks is constructed by a three step approach (Lee,Y. & Geller,J., 96). The Knowledge Network is represented as a conceptual framework where agents are able to determine the level of abstraction for a given topic, interpret relationships between topics, monitor the learning process and evaluate learner progress. To respond to different learning preferences, different ways of presenting the same Knowledge Network are incorporated as Knowledge Views. These Knowledge Views are matched with the Learner Filter variable values and an appropriate view is presented to the learner.
Agency
Multiple agents collaborate to achieve adaptive learning. There are three types of agents: learner agent, presentation agent, knowledge agent. The learner agent monitors the learner’s learning patterns and ability to grasp a particular concept. The knowledge agent knows the content and its relation to other content. The knowledge agent determines what is presented to the learner. The presentation agent determines how the information is presented to the learner in each specific situation. All agents are considered to be equal partners with the learner so the complex interactions between humans and agents are mixed-initiative interactions (Allen, J.F., 99). The Agency provides the control structure for the DALS.

Learner Space
A basic tenet of the DALS development is that humans are genetically engineered “learning machines” with unique learning capabilities. Hence, aspiring to individualized learning must be grounded in an understanding of the factors that influence human learning. These factors are treated exhaustively in the literature. For example, Biner identifies demographic variables (Biner, P. et al., 95), Miller identifies field dependence/independence variables (Miller, G., 97) and Cox reports on learning styles (Cox, D. & Huglin, L., 00). In an attempt to create a learner centric, generic learning system, the investigators make the following assumptions:

1) There are a significant number of variables known to play a critical role in human learning
2) These variables can be identified and partially ordered according to their impact on learning
3) Some of these variables can be measured accurately and reliably
4) Individual learners can be characterized by a profile of these measurable variables
5) These variables have values with greater or lesser degrees of stability over time
6) A set of values of these variables implies a learning mode preference
7) Technology offers the opportunity to exploit these ideas to optimize individual learning

A DALS transmits information from/to the learner using filters to control the interaction between the learner and the system. Our filters, called Learner Filters and Knowledge Views, are implemented as plug-and-play components using knowledge base and multi-agent technologies. As a result of the interoperability, comparability and exchangeability of these components, the DALS can be dynamically reconfigured by selecting filter components specific to different knowledge domains and learning venues. Depending on the Learner Filter values, multi-agents select different Knowledge Views from the Knowledge Space to effect a learning episode.

Implementing a DALS
Using subject matter content from a Discrete Structures course, the authors plan to implement a simplified version of a DALS. The Learner Filters will be comprised of the four profile variables Thinking Style, Intrinsic Motivation, Academic Stress and Social Presence. Knowledge Networks will be constructed for the chosen subject matter, and Knowledge Views will be created for Guided, Discovery and Game Learning. Learner Filters for participants in the class will be used to select the Knowledge Views.

Abstract: In this paper we report on a course format where a group of in-service teachers works together with a group of computer science and mathematics majors via a computer conferencing system. Most of the time participants studied using the Internet but at the end produced and presented a seminar paper together in pairs. This type of a course has now been given twice which, interestingly, produced different outcomes. The teacher group did not turn out to be more discursive or more active in moderating. The teachers participated in a larger number of discussion topics while the students concentrated on those that were compulsory. However, an analysis of the discussion threads shows that both communities took equally part in most of the longer discussions which suggest that the course goal of sharing multiple perspectives was fulfilled. Computer conferencing was shown to alleviate the problems of participating and running the courses.

Introduction

The Finnish national educational strategy emphasizes the importance of teacher training and suggests more extensive ICT (Information and Communication Technology) training for them (Ministry of Education, 1997). After the basic ICT courses such as text processing, multimedia production and information seeking on the Internet, there should be possibilities to go further (Sinko & Lehtinen 1998). Typically, the responsibility is left to the university continuing education centers which arrange courses for interested teachers to apply more advanced technologies, such as conferencing systems.

We are interested in bringing together not only in-service teachers, but also make this community to collaborate with pre-service teachers and other university students interested in educational technology. There are many similar efforts worldwide. Norton and Sprague (1997) studied on-line collaborative lesson-writing between pairs of in-service and pre-service teachers. Brehm (1999) has outlined factors for this kind of activity which is also called telementoring. Casey (1999) advocates virtual international seminars for pre-service and in-service teachers together with graduate students. He even states that virtual seminars and global interconnectivity as "...the most significant innovation that I have experienced to improve the quality and depth of student involvement in seminars" (Casey 1999). All above report on benefits for those taking part, especially for those younger participants, namely pre-service teachers and students.

In this paper, we report on a slightly different possibility of introducing new Internet technology to in-service teachers. In our approach, the teachers are brought together with a community of young university students majoring mainly in computer science (some of them, however, are pre-service teachers to major in mathematics). In this way we hope to produce synergetic effects by combining the experience of the in-service teachers with the technological knowledge and enthusiasm of the computer science students. The particular course where this co-operation takes place is a common effort of the Department of Computer and Information Sciences and the Department of Teacher Education at the University of Tampere. Although part of the same university these departments are situated in two different cities, 100 kilometers apart, which lead us to utilize Web-based computer conferencing as an essential element of our course.
Background of the Study

The course under study ("Internet-based learning environments") is a voluntary second-year course for students majoring in computer science but is recommended to those interested in human-computer interaction and to those majoring to become mathematics teachers. This seminar type course has run every autumn since 1997. The course starts with lectures that take five weeks. During that time the selection of seminar topics is also carried out (week 3) and the pre-discussion on each topic on the Web commences (weeks 4-8). The final face-to-face seminar sessions take place during weeks 10-12.

We have reported elsewhere on our early experiences on this kind of "Web-extended" seminar course format (Hietala 1999). The benefits envisaged are as follows: more extensive and broader discussion of the topics, opportunities for the more shy students to participate, and time to get to know the other interested parties of the topic (community forming). The Web discussion has the same topics as the actual seminar presentations but the students are advised to carry out a free and more open-minded discussion than in the actual topic. Each discussion has two moderators (students giving the seminar paper) who are responsible for the starting, moderating and wrapping up the Web discussions (along the ways suggested by Bonk and Reynolds (1997)). In the seminar presentation the students are required to be a more focussed, maybe also illustrating their main ideas by demonstrating one or two Web-based learning environments. The moderating activity is taken into account in grading the students.

The Course with In-service Teachers

Here we report on two courses (autumns 1997 and 1999) where the course at our department was linked to the same course given concurrently (by the same lecturer) to a group of in-service teachers extending their information technology studies at the Department of Teacher Education. Now an idea arose to team up one in-service teacher with one student to prepare a seminar presentation together.

The benefits anticipated were the following. First, for the in-service teachers this new kind of a course might bring about a new "fresh" point of view to collaborate with a younger university student. Moreover, in the more technical topics and in the transfer of their presentation onto the Web (as an HTML document) the expertise of a more technically oriented student might be beneficial. On the other hand, the university students receive a discussion partner who is older and more mature and brings experience from the real school life. Furthermore, the opinions and work of the students might now lead to something more real than just another seminar paper for their university professor to read. On the whole, it was hypothesized that it would enrich the seminar discussions if we had voices in the participants from not only the community of Computer Sciences Department students but also from the Department of Teacher Education and especially those teachers who already had school work experience.

One problematic issue for all seminar students is typically how to select a seminar topic. On the latter course our participants were given the choice to suggest topics of their own, but this opportunity was not very much utilized. So the topics were mainly given by the lecturer. As a novelty of our geographically distributed seminar the selection of topics (one to moderate and present, two to be an opponent, or as we prefer to say, a designated commentator) took place within our conferencing system. We will come back to this in the next section. After obtaining a partner to their work they made contact, mostly by e-mail but sometimes also by telephone, and started the work. The first thing to do was to prepare and publish their initial thoughts on their subject - in other words, to start a discussion thread within the conferencing system.

The discussion period on the Web takes four weeks and after that the face-to-face seminar sessions commence. At the end of the course the in-service teachers are required to be present at the University to give their presentation together with their partner. Many participants reported this was the first time they actually saw their partner. As an experiment, one session in 1997, comprising two seminar presentations, was carried out using video-conferencing facilities, the pairs presenting being 100 kilometers away from each other.

The Conferencing System Used on the Course

Our conferencing software comes from the CoWoGLe (Conferencing on the Web for Group Learning) project that investigates the use of Web-based lightweight conferencing systems especially as part of university level course work (Hietala et al. 1997). The pedagogical goal of our use of the Web discussions on seminar
type courses is to guide the student discussion process into more argumentative and disciplined. One interesting feature that we hope to support this are the comment types in our conferencing system: our students were required to first decide the type of their comment and only after that write their comments. They are also requested to indicate the source of their comment. Comment types (also called as thinking types) encourage reflection-in-action (Duffy et al. 1998) because they make the student think about his/her contribution with relation to the other postings in the group (more on this kind of procedural facilitation see Hietala, 1998).

Another pedagogical strategy that our system supports is called post-before-read (Hiltz 1993): all students in a small group must state their own perspective to the initial start-up posting of the group moderator, and only after that they can see what others have written. This enhances the equal participation and maybe entices a broader set of issues to be covered in the subsequent discussions.

The Web technology could also help to manage a course in the problem of selecting a seminar topic mentioned earlier. Same number of students from these two groups was admitted to the course from the two locations. Remember they do not even meet each other at first. The conferencing system allowed them to select the topics they were interested at first-come-first-served basis starting the selection process exactly at the same time where ever they were located. We hoped that similar interests brought the pairs together. (Figure 1 shows the situation).

![Figure 1. Student selecting his/her topic for the seminar.](image)

Now, after having logged into the system, students would navigate to the list of seminar topics (on the left), they would click open the topic they were interested, and make a selection (on the right) of what roles were available there, that is, choose to be either a moderator, or a commentator. Within the conferencing system, we can also check that the two moderators come from these two different groups.

The Study

On these two courses under study there were 36 (1997) and 28 (1999) participants. The in-service teachers mainly taught at elementary level, although there were a few mathematics teachers at secondary level. Most of them were active in their schools in ICT and their major incentive for participating the schooling was to better utilize ICT in their daily work, not to earn grades as a graduate student. They had already 15-credit week training in ICT (especially geared for teachers) but these studies came from different universities so they background knowledge was not very homogeneous. Also the cities where they taught varied. Although most of their training for this 35 credit week ICT studies (of which our course was also part) took place in the city of Hämeenlinna (almost 100 kilometers from Tampere) some of them came from rather far (from Helsinki or even from Joensuu, 400 kilometers away!) This shows their dedication to this new type of training; however, it of course brought along problems in scheduling the seminar sessions.
The university undergraduates were mostly computer science majors, with 20% of them majoring to become mathematics teachers (i.e., were pre-service teachers). They had already one course on educational technology.

**Discussion Topics**

We can see in Table 1 that popular topics in the Web discussions were both broad and "up-to-date" ones while those technical or detailed did not receive so many postings. Issues that can be seen to interest either in-service teachers or computer science majors came to the top. The most popular threads contain already in their title words that already arouse interest, namely the words "critical" and "possible".

The "deep" discussion chains (up to level 12 and 8, respectively) suggest that our goal of aiming at sustained progressive discussions was met. Content analysis of these chains supports this observation.

**Table 1. The discussion topics**

**Discussion Activity in the Two Groups**

Let us next see how the discussion contributions of the two communities were distributed. As we can see in Figure 2 the discussion and moderating activity on both courses exceeded the compulsory (one comment per week in each of the three designated discussion groups) for all groups, but there were differences. Teachers were more active in the 1997 course while the student group produced clearly more contributions during the 1999 course. The student group turned out to take more actively care of their moderator roles.

The teacher group, however, was more active in the "Free commenting" i.e. in other topics than their compulsory moderator and discussant topics. This was true both years. For example, in 1997, teachers made on the average 6.61 contributions as free commentators while the students made 4.39 comments. This shows clearly that the teacher group wanted to obtain a wider view of the genre "Internet-based learning environments" and had contributions to offer in most of the topics. Students, on the other hand, concentrated on fewer topics (mostly those compulsory).

Let us analyze a little closer the longer discussions, i.e., those sub-discussions which contain five or more contributions. It turns out that 66% (1997) and 55% (1999) of them are balanced in that way that neither of the two communities dominates the discussion by having more than 70% of the discussion entries. In our opinion this suggests that one of our course goals - sharing multiple perspectives - actually did occur. Moreover, in these longer sub-discussions there were an equal number (29) that was started by a teacher or a student participant in 1997. In the year 1999 students started 23 (teachers 15) of these longer discussion chains. Although thus the year 1999 shows student dominance (see also Figure 2) we think that this gives evidence that both parties were rather equal in producing interesting contributions to the overall discussions.
Finally, both groups seemed to base their postings to personal experience: over 60% of the comments in either group were given the source type "My own opinion". The next popular source types "My own idea" and "Discussion with others" were used far more seldom. The source labels "From lecture", "From literature" or "From Mass Media" obtained the lowest usage. This shows that the content of the discussion was more of an exchange of experiences than elaboration of issues raised during lectures. Also, our Web discussion guidelines encouraged carrying out a free-form exchange of opinions related to the seminar topics.

Feedback from the Participants

Feedback was collected at the end of the two courses. It was mainly favorable, e.g., "The course was interesting because it was the first experience of studying using the Web ... In my opinion the separation between these two cities brought extra colour and feeling of reality." (student/1997)

Most of the critical comments focused on the seminar organization. Of course, teachers who came from far had more problems than the students did. After Web discussions the participants had also developed a better understanding of the topics and were "looking for more" in the face-to-face sessions.

"It was an OK course but I did not feel that the mixing up pairs with teachers and student was meaningful. Sure it worked relatively well but the teachers are working people and the arrangements would have been easier with a local pair. However it was interesting to get to know the conferencing system!" (teacher/1999)

All in all, the latter course seemed to arouse more critical comments on the collaboration, from both the students and the teachers. It is quite evident that there can be problems in communication with a person who is of different age, of different working background and from a different location.

Concluding Remarks

In our opinion, the approach described above turned out to be rather successful. According to our analyses, the quantity and quality of the seminar discussions benefited from having two communities being brought together. Especially the teachers' participation into a wider set of discussion topics and the fact that majority of the longer discussion threads were equally populated with both teacher and student participants suggests that our goal of both communities having the chance to learn from each other seems to have succeeded. Our analysis did not show dominance of one group in the discussions although more detailed content analysis is needed for definite results. In the feedback, however, we have at least one student who claims that his teacher pair was too authoritative and did not give him equal say in the seminar preparation.

Although the teachers reported problems not having enough time to participate especially in the seminar sessions the overall grades of both students and teachers were rather good. The Web pre-discussion
supported the actual seminar presentations, which turned out to be of good quality. Some of the participants even wanted the discussions to be alive for a longer period:

"Meeting an in-service teacher on the Web and elsewhere was something very useful for a computer science major and working with professionals gave us new ideas. The Web discussion period could have continued after the actual seminar presentations." (student/1997)

We recommend bringing in-service and pre-service teachers together with ICT oriented students in a manner described above. At our department, this collaboration between our students and in-service teachers has lead to another course of similar flavour. Namely, on a follow-up course where our students build an interactive Web learning environment we have a group of local in-service teachers as domain experts. They provide interesting topics for our students and act as advisors during the learning environment design and implementation process. The pupils in their classes can also serve as usability test subjects for these learning environments. In return, the final Web environments are installed permanently on our departmental Web site for their classes to use. Thus, the experiences of the two courses reported above did not diminish our enthusiasm for university and school synergy!

Socio-Cultural Factors Influencing Face-to-Face and Online Collaborative Knowledge Construction: Preliminary Findings from Survey Data

Cher M. Hill and Jan van Aalst
Faculty of Education, Simon Fraser University
Burnaby, B.C., CANADA, V5A 1S6
{chill, vanaalst}@sfu.ca, http://www.sfu.ca/~vanaalst/edmedia2.pdf

Introduction

We present preliminary data from a survey designed to probe issues we thought to be relevant to a successful implementation of Bereiter and Scardamalia’s (1996) theory of knowledge building and similar social constructivist approaches to teaching and learning. An important goal of research on knowledge building is to develop the practice of expertlike learning in school-based learning experiences. The survey consists of 30 questions, most of which ask students to indicate their level of agreement with a statement on a six-point Likert scale, also providing a verbal justification for their rating. The survey probes such issues as students’ epistemological beliefs, attitudes toward school activities (e.g., students’ perceptions about the relevance of what they learn to their immediate lives, their attitudes to and experience with working with computers, and metacognitive awareness. Some of the questions probed such issues particularly in the context of science education and language arts education. The survey draws from previously published work, including Schommer (1990) and Linn and Hsi (2000).

The motivation for this work was as follows. Lampert, Rittenhouse, and Crumbaugh (1996) found that the qualities, experiences, and beliefs that students bring with them into the classroom influence their ability to collaborative construct knowledge. Race (Catsambis, 1995), gender (Hsi & Hoadley, 1997), and status (Bianchini, 1997) have all been found to influence participation in classroom discussions, a vital aspect of collaborative knowledge construction. Furthermore, Chan (1999) reported that students’ beliefs about knowledge were related to their participation in a Knowledge Forum database. Because participation in face-to-face classroom discussions (Bianchini, 1997) and in online environments, as well as epistemological beliefs (Schommer 1990) are also related to student performance, it is imperative that researcher and teachers are aware of various socio-cultural factors that may influence knowledge building and similar educational practices.

The data set analyzed consists of the responses by 52 students in an experimental 8th grade combined English/Science program. Within this cross-curricular program, students from two separate classrooms jointly investigated various scientific and literary issues embedded in overriding themes through classroom activities and the Knowledge Forum database. The survey was given on the first day of school and again at the end of the single-semester program; only students who completed the survey on both occasions are included in the study. We examined statistical changes over the semester, as well as qualitative changes. These preliminary analyses allowed us to identify common beliefs and experiences inconsistent with knowledge building practices and to redirect the development of the classroom work in early stages of the project.

Preliminary Results and Conclusions

Pedagogical and Epistemological Beliefs

Some of the students’ pedagogical beliefs were consistent with knowledge building practices. The vast majority of the students subscribed to an incremental theory of intelligence and most students believed that both teachers and students are responsible for students’ education. The majority of the students believed that they were capable of self-instruction, given appropriate resources; on the pre-test, girls were less likely to endorse this statement than boys.
The vast majority of students believed that scientific knowledge is evolving as discoveries are made and new technologies are developed. However, few, if any students asserted that knowledge is socially constructed. While some students realized that information might be incorrect if it is out of date, the majority of students believed that information on the Internet and particularly in textbooks is trustworthy. It is expected that students' beliefs about the nature of knowledge may shift with further knowledge building experiences. There is some evidence to suggest that adult learners who participate in deep, collaborative knowledge building in online forums experience a shift towards more constructivist beliefs (Chan, 1999); however, it is unknown whether this finding can be generalized to younger populations.

**Pedagogical Practices**

Many of the learning strategies used by the students were inconsistent with knowledge building practices. The majority of the children reported using “fact-finding” strategies, stating that these methods were easier and allowed them to perform well on tests. Students disliked working on problems with no known solutions and this tendency increased over the semester. Students claimed that these problems were too challenging or a waste of time. Although the majority of students asserted that they revised their work, other measures of students revision do not support this finding. At the beginning of the semester most students claimed that they relied on external sources, such as teachers and tests, to evaluate their comprehension; however, by the end of the semester the majority of the students reported using metacognitive assessments to evaluate their understanding. As Scardamalia, Bereiter, and Lamon (1994) assert, students are adaptive and will use strategies that maximize performance while minimizing effort. While memorizing facts, rote problem solving, and avoiding progressive problem solving may pay off for students in traditional classrooms, students in collaborative knowledge construction environments must be encouraged to develop new learning strategies.

Students' self-reports of collaborative learning experiences were relatively low at the beginning of the semester, and did not increase by the end of the term. While applications such as Knowledge Forum can provide a platform for collaboration; teachers and students must understand the importance of collaboration in knowledge construction. Furthermore, assignments and evaluations need to be constructed that encourage interdependency and collaboration between students.

**Computers Access, Experience and Attitudes**

In general, students had positive attitudes toward the use of computers, had substantial experience with various computer applications, and the majority had regular access to computers and the Internet outside of school. However, our findings suggest gender differences in computer attitudes and experiences. These results are not surprising considering previous research findings in this area (see Volman, 1997). It has been suggested that online discourses are more democratic in nature (Hsi & Hoadley, 1997); however, students with less experience with technology may initially participate less in online discourses than other students. Simply introducing new hardware and software into the classroom is inadequate in addressing gender differences in computing and further steps must be taken to ensure equity.

Abstract: Well over a hundred course and learning management systems are available on the market today. So the time and energy an institution might invest in researching considerable. Unfortunately, many institutions seek out systems that are technically robust rather than ten has less to do with learning than management. The problem is that end-users, instructors and students, may be disinclined to use the system; all of the system's compelling administrative features will prove meaningless to them if the user interface makes learning cumbersome for students or if the system itself is so complicated that instructors develop strategies for avoidance. Because the success (or failure) of any learning management system is largely dependent upon the effective use instructors and students make of it, institutions would do well to consider—prior to system hunting, in fact—how they plan to train instructors and students to use the system and why they think such a system will benefit them in teaching and learning.

Introduction

This paper examines and illustrates pre-planning strategies for online learning programs that utilize course and learning management systems (CMSs and LMSs) and critiques the advantages and disadvantages of such systems according to certain basic criteria for effective, successful teaching and learning. It argues that teaching and learning concerns need to be at the forefront of system adoption decisions and system installations, especially in light of the cost—the educational cost of hampered teaching and learning, of course, but also the literal expense of the systems themselves. The Gartner Group suggests that institutions serving 10,000 users should expect to pay approximately $110,000 to install course and/or learning management systems and an additional $110,000 to use the systems (Aldrich, 2000).

Before the How and the Why

Well in advance of adopting an online course or learning management system, institutional administrators or program directors should take the time to assess faculty receptiveness to and facility with web-enhanced or online learning programs. This is a crucial preliminary step that is often missed—as is the step to assess students, though primarily for the kind of computer access they might have rather than their computer interest or competence levels. While a number of institutions perform market research to discern whether or not there is a genuine, fee-paying audience for the online education they might dispense, they engage in a good deal of guess work where faculty are concerned. Unfortunately, this "strategy" is far from atypical; offering the sun and the moon but proffering lumps of coal is the stuff of short-lived businesses and failed institutional programming everywhere. Internet-connected computers in every faculty member's office are merely a start, a good start, but hardly a means to an end. Most instructors and university professors are simply not ready to "set aside their roles as teachers and instead become designers of learning experiences, processes, and
environments” (Dunderstadt, 1999, p.7). And in order to get ready, most of them will need some very good reasons. Already overburdened with heavy course loads, faculty are not exactly thrilled about expending hundreds of hours discovering how a new course or learning management system works; many remain reluctant to use a time-consuming or cumbersome technology and require proof of its educational value.

A proactive approach can go a long way in avoiding the “cart before the horse” syndrome, which emphasizes the purchase and installation of learning management systems “without providing sufficient funding for the staff learning required to win a reasonable return on the huge investments being made” (McKenzie, 2001). While assessing a school’s need for course management software, one should also consider student requirements. Schools need to focus their efforts on uses of these systems that will be curriculum-rich, and not simply glitzy--what some call “powerpointlessness” (McKenzie, 2001).

**How, Part I: A Simple Plan**

The key to planning simply is planning introspectively. When people work with what they have and know, there aren’t as many variables. Of course, a person must have what he thinks he has, or she must know what she thinks she knows in order to develop a plan that is sincere and sensible. An introspective individual does not think “I have a computer, so I’ll start teaching online.” She wonders, instead, about her knowledge of the necessary technologies, about how much time it will take to become an adept user of these technologies, about her own comfort level with change and experimentation, especially where live human subjects (students) are involved. An introspective individual considers his basic capacity and fitness. He asks, “Am I up to the

In order to facilitate a basic capacity and fitness, colleges and universities need to have a training facility of sorts, a support system in place for their teaching faculty as they learn their way around this new approach to teaching. Some effective strategies are as follows:

1. Establish a plan for professional development. Administrators and professors should draw up a new set of guidelines for professional development that include the new course or learning management system. Junior faculty should receive credit towards tenure for their work with the system, while more senior faculty should also be in a position to derive credit towards promotion for their participation.
2. Organize study groups. Instructors should meet frequently to discuss their triumphs with and concerns about the new system. Such study groups are ideal for problem solving and for brainstorming. Many instructors come out of these meetings with a new enthusiasm for the educational benefits of learning management tools.
3. Establish curriculum development teams. Instructors in the same academic area can cooperate to develop their own standards-based study units to incorporate into the online course. “Even though the focus of these activities might be student learning and curriculum, participants are ‘learning by doing’ - another basic tenet of adult learning” (McKenzie, 2001).
4. Recruit technology coaches. Newcomers to course management systems can derive an enormous benefit from working with a more seasoned partner. Schools should identify faculty who have developed a high degree of facility with the system, and ask them to make themselves available to help their colleagues gain a degree of comfort and confidence with the system as well. In the absence of such faculty, e-learning services companies might be contacted to assist with the training.

The best approach to faculty training involves blending the above strategies to help convince faculty that the system works, and that help is there if they need it. Many teaching faculty prefer to learn on their own, and are far less threatened by advice from their peers than they might be by a high-tech workshop filled with “technosavvy” kids.

**Why, Part I: Remembering the Basics of Teaching and Learning**

Once the initial planning is completed, once an institution has discerned the general “will and skill” of its faculty to adopt and use new teaching and learning technologies and once it has established a support-system plan, administrators and program directors should understand that they are not likely to get their money’s worth
Effective tools should be able to reproduce and/or facilitate the teaching and learning experience of the typical college course. Thus it is vital to keep in mind the criteria of effective teaching and learning. Below is a chart detailing the course (CM) and learning management (LM) system features that can supplement, extend, and emulate the activities of teaching and learning.

<table>
<thead>
<tr>
<th>Activities</th>
<th>Effective Teaching</th>
<th>Effective Learning</th>
<th>Optimizing CM/LM System Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reading/Research</td>
<td>Instructors need to recognize and recommend adequate, if not excellent, course literature and resources.</td>
<td>Students need to be directed to adequate course literature and resources.</td>
<td>Systems with hypermedia-enabled library, database, annotation, categorization, and search features aid reading and research. Systems that display hypermedia clearly and make content easy to save and print are particularly effective.</td>
</tr>
<tr>
<td>Discussion</td>
<td>Instructors need to initiate and moderate class discussions.</td>
<td>Students need to discuss what they have learned with other students as well as their instructors.</td>
<td>Systems with asynchronous discussion forums, real-time AV and/or text chat, shared whiteboards, listservs, built-in email or email interfaces enhance, extend and capture discussion.</td>
</tr>
<tr>
<td>Lecture</td>
<td>Instructors need to disseminate their expertise on course subject matter in a timely, efficient manner.</td>
<td>Students need to access or avail themselves to expertise on course subject matter in a timely, efficient manner.</td>
<td>Systems accommodating hypermedia and streamed media can dispense video/audio lectures asynchronously or in real-time. Also web documents allow for immediate dissemination of and access to lecture notes and transcripts.</td>
</tr>
<tr>
<td>Assignments</td>
<td>Instructors need to announce, distribute, and acquire a variety of course assignments—to and from individuals and groups.</td>
<td>Students need to know about, access and submit course assignments.</td>
<td>Systems with hypermedia-enabled pages allow for immediate dissemination of and access to assignments; systems that simplify announcing assignments with features such as calendars, bulletin boards, and email alerts are particularly useful—as are systems that simplify or automate the assignment submission and review process. Also advantageous are systems that facilitate and track group work or group-produced assignments.</td>
</tr>
<tr>
<td>Examinations</td>
<td>Instructors need to assess student knowledge and abilities; they need to announce, distribute, and acquire course examinations—to and from individuals and groups.</td>
<td>Students need to know about, access and submit course examinations.</td>
<td>Systems with hypermedia-enabled test, survey, and test bank features allow for a wide range of test types; one that allow for restrictions (such as time limits) and programmable actions (such as randomized testing, automated grading, and alternate coursework based on score) can optimize the use of exams in teaching and learning.</td>
</tr>
<tr>
<td>Labs/Practicums</td>
<td>Instructors need to supervise or gauge student skills or techniques in certain contexts at specific times.</td>
<td>Students need to practice and demonstrate skills or techniques they have learned in certain contexts at specific times.</td>
<td>Systems that offer real-time functions, such as AV or text chat, and interactive simulations, such as VRML and Shockwave media, can enhance or extend a traditional course features that are generally face-to-face or physical activities requiring and interactivity. Some developments in VR (virtual reality) programming look especially promising.</td>
</tr>
<tr>
<td>Relevance/Timeliness</td>
<td>Instructors need to demonstrate the significance or relevance of concepts and theories.</td>
<td>Students need real-world examples; they need to appreciate the relevance of concepts and theories.</td>
<td>Systems that support a means of listing, displaying, linking to, or categorizing (by chronology, subject, author, etc.) relevant and timely events and news in a variety of media formats underscores the importance of course concepts and theories.</td>
</tr>
<tr>
<td>Consultation</td>
<td>Instructors need to meet with students privately to discuss individual concerns.</td>
<td>Students need the opportunity to meet with instructors privately to discuss their concerns.</td>
<td>Systems with an email interface or built-in email system, AV or text chat, or discussion forum allow for public, private, and group consultation.</td>
</tr>
</tbody>
</table>
### Activities

<table>
<thead>
<tr>
<th>Feedback/Grading</th>
<th>Effective Teaching</th>
<th>Effective Learning</th>
<th>Optimizing CM/LM System Features</th>
</tr>
</thead>
<tbody>
<tr>
<td>Instructors need to acquire feedback on their teaching from students as well as disseminate feedback on assignments, examinations, labs, and courses.</td>
<td>Students need prompt, clear feedback on assignments, examinations, labs, and courses.</td>
<td>Systems that include tests systems that automatically grade quizzes or organize survey data are particularly helpful, as are tools that include online grade books that store, calculate, and display grades for instructors and students. File transfer systems, email interfaces or built-in email systems also enhance the ease by which content can be assessed and returned.</td>
<td></td>
</tr>
</tbody>
</table>

| Record/Review | Instructors need to keep careful records of their work and their students’ work. | Students need the opportunity to/facility for recording, studying and reviewing course content. | Tools that keep and display careful records and can graphically represent, extrapolate, export, archive, and/or recycle contents are advantageous. Also advantageous is the ease with which web content can be excerpted, downloaded, copied, and printed. |

---

**Note:** The teaching and learning activities in this chart are loosely based on Neil Rudenstein’s (1996) observations about the Web’s potential in his special address at the Harvard Conference on the Internet and Society; also, a special thanks to Gail Darden (2001) at Eduprise, Inc. for her assistance in developing this table.

---

### Why, Part II: Analyzing the Systems and Selling the Analysis

Online learning tends to be more self-directed than classroom learning, thus any system adopted must be easily adaptable to the style of the individual user, capable of producing “fast results.” Neither instructors nor students want to be faced with hours of pointless searching in order to figure out how to use a new tool or how to find their documents. In light of the expense involved in setting up an institution with a new course or learning management system, a thorough examination of what that product offers is definitely in order.

Keeping in mind the criteria of effective teaching and learning, and how these criteria are represented by available learning systems, one must perform a thorough exploration of tool features in order to satisfy the basic needs of instructors and students.

### Course Tools

<table>
<thead>
<tr>
<th>Content hub</th>
<th>Announcements</th>
<th>Index/Homepage</th>
<th>Calendar</th>
<th>Syllabus generator</th>
<th>Built-in HTML editor</th>
<th>Auto-linking (text)</th>
<th>Auto-embedding (media)</th>
<th>Context-sensitive help</th>
<th>Content search</th>
<th>Content upload</th>
</tr>
</thead>
</table>

### Collaboration Tools

| Discussion Forum | --better optimized by search, compile, time/date stamp, attachment, archive, moderator, and anonymous post features. | Email | --built-in or email interface systems | Real-time chat | --better optimized by archive, multiple room, private messaging, AV, browsers, and whiteboard features. |

### Assessment Tools

| Multiple question types | Hypermedia support | Automated grading | Automated and pre-programmable feedback | Test bank creation | Randomized testing | Surveying and statistical extrapolation | Offline testing | Regarding, grade changes | Restrictions (timed, password protected, multiple attempts, availability) | Online grade book |

### Student/Management Tools

| Grade viewing | Student websites | Content bookmarking | Enrollment functions, including batch and individual uploads | Student tracking | Webpage tracking | Read and unread message or submission alerts | Annotation capability | Change profile | Link to offline content or CD-ROM |

---

*Note:* The CM/LM system categories and features described in this chart are based upon a working document created by Jane Harris (2000) at Eduprise, Inc.
Examining CM/LM system features in light of how those features may augment teaching and learning will go a long way in assisting institutional decisions about which system is best for the institution. Indeed, a course or learning management system is not necessarily useful or cost-effective if what it does best is exchange data with the university system's back-end (such as Datatel, PeopleSoft, etc). Indeed, if it doesn't facilitate the data exchanging that instructors and students engage in on a daily basis, there won't be much to send, in the end, to the back-end. Finally, instructors are not easily sold on a product that puts the work of the university (teaching and learning) at risk in the name of a more efficient administrative data flow. They will, however, buy into a system that streamlines their efforts, maximizing their teaching while augmenting and enhancing student learning.

How, Part II: Revising the Plan

Regardless of the system ultimately adopted by an institution, a new set of instructor competencies will result from its implementation. Except for the case of the absolute beginner, some of these skills will already be present, i.e. the ability to open a program, the ability to work with word processing software, etc. Others will be new and specific to the chosen system—whether one needs to know how to develop online tests depends upon whether the system in place possesses a testing feature, for example.

In many cases, however, instructors will not make use of all the tools available in any one system. Certainly the instructor who does not wish to utilize an online discussion forum has no need to learn how to use one properly. Likewise, the instructor who does not intend to insert links into his online text has no need to be familiar with HTML. Developing a set of training goals or competencies can be complicated by the needs of the instructors, so they are worth careful consideration. Ultimately administrators and program directors will have to decide to what extent the training plans can be customized, and then integrate those goals and competencies into the simple or first-stage plan. In addition to professional development mentors, study groups, curriculum development teams, technology coaches, another useful approach to faculty training involves a sort of “show-and-tell” session, in which new users are introduced to those more familiar to the system. The more seasoned users can then show off their work, and discuss teaching approaches and system features that have proven to be particularly effective for them. Individual instructors can then determine, based on their own pedagogical approach, which features will be the most useful to them, and subsequently avail themselves of the training necessary to gain a level of comfort with these features.

Conclusion

Educational administrators and program directors have a great deal of information to sift through when investigating course and learning management systems. It is, however, in their best interest to take care in the process, and avoid “jumping on” the first or next “great thing” that comes along. Additionally, what might appear to be the best system to the administrator, may have so many bells and whistles that it is too cumbersome for faculty and students to use—what results are creative avoidance strategies—both on the part of the students and the instructors. While many teachers wish there were magic elves who could put their online courses together for them, or even a lowly graduate assistant who would be willing to spend a few hours a week typing material, all but a lucky few will be spared; most will end up doing this work themselves. It therefore behooves administrators and directors to keep in mind the level of “user-friendliness” in any course management system being considered. In addition, administrators should be aware that many instructors will balk at using online course materials if they do not stand to gain any recognition or reward for the time taken to learn how to work with the system and to prepare their materials for online dissemination.

Moreover, administrators should be talking to teaching faculty well before any system comes under consideration. Faculty want to have a say in which system is ultimately chosen, and may well balk at using one that, though glitzy and shiny, is impossible to use and is pedagogically unsound. Teaching faculty must also have ample opportunities to learn how to use the system. At the University of South Carolina, for example, we have found that many faculty hesitate to attend large, campus-wide Blackboard workshops, preferring instead to attend smaller, intra-departmental training sessions that are tailored to their specific instructional preferences.
In these smaller settings, faculty are able to work with faculty who teach in areas closer to their own, and whose ideas they can more easily adopt and adapt to suit their own needs.

Abstract: Despite the fact that moving information around in the networked economy is generally accepted as being easy, it is still surprisingly difficult to move an individual's structured knowledge across time and place in ways that are useful with the context of the educational institution. Using a developmental portfolio to assist students in demonstrating evidence of their learning over time—from course to course, semester to semester, and on into their teaching career—makes pedagogical sense. However, this rarely takes place because of the challenge of negotiating compatibility of media formats or software applications, conflicts and redundancies in curriculum and instructional strategies of faculty. With the creation of the Digital Backpack, lessons and other student-related artifacts can be ported to a classroom setting. Student teachers who become employed have at their disposal, a set of tools that allows them to be a better teacher.

The Digital Backpack: Issues in the Development and Implementation of a Digital Portfolio

One of the roots of the word "portfolio" is "port," the same Latin root that gives us "portable." But the professional development portfolios of pre-service teachers, which at their best are the tools students use to structure and refine knowledge during the course of their education, have become anything but "portable." In fact, they seldom are carried away from the institution that requires students to produce them.

It has been estimated that if you collected all the portfolios produced in one year from all the teachers who are certified by colleges and universities in the area of St. Louis, Missouri, in the United States—or about 750 people, the pile would reach the height of the Gateway Arch, a 630-foot monument. At the University of Missouri–St. Louis (UM-St. Louis), these documents need to be assessed by faculty, and this means physically moving them to a room where faculty do the assessments. The idea of "portability" ceases to have much to do with an individual’s evidence of knowledge and has everything to do with carting these documents from place to place.

Despite the fact that moving information around in the "networked economy" is generally accepted as being easy, it is still surprisingly difficult to move evidence of an individual’s knowledge across time and place in ways that are useful within the context of an educational institution. Using a developmental portfolio to assist students in
structuring evidence of their learning over time — from course to course, semester to semester, and on into their teaching career — makes pedagogical sense. However, this rarely takes place because of the challenge of negotiating compatibility of media formats or software applications, conflicts and redundancies in curriculum and instructional strategies of faculty.

The State of Missouri requires students to create and submit portfolios for certification. UM-St. Louis requires portfolios from every student in order to complete certification. The student portfolios contain artifacts — papers, lesson plans, videos, photographs, recordings, etc. — for the 10 teaching areas: (1) Subject Matter, (2) Human Development and Learning, (3) Individualization and Diversity, (4) Curriculum/Performance Standards, (5) Instructional Strategies (6) Motivation and Management, (7) Communication Skills, (8) Assessment, (9) Reflective Practitioner, and (10) Relationships. Students are expected to provide evidence that demonstrates the extent to which they have met each of the standards. The materials presented in the portfolio are produced in the education classes and arts and sciences classes taken by students during their course of study. Students are expected to save the materials for presentation in the portfolio. Each of the standards has three levels of competence: (1) developing, (2) passing, and (3) exceeds expectations.

The process at UM-St. Louis is that three faculty assess the portfolios according to ten state mandated criteria. A number score is given each criterion and comments are made. This creates three pieces of paper. The scores from these are averaged and the comments noted. Each student is notified of the average scores they received for each criterion and a summary of the faculty comments is attached. The work that goes into entering scores and copying comments is currently in serious need of automation. While some states may have more sophisticated systems for scoring, the fact remains that digital portfolios and digitized scoring could provide a more efficient and improved method for working with portfolios.

Many of the current digital portfolio applications by universities focus on a visual presentation of the portfolio as opposed to a presentation of the portfolio's content. Energy is spent on making attractive web pages to contain the artifacts or links to the artifacts. These presentations focus on the software used to design the web page, and the visual presentation itself. Too often, they are nothing more than a, "how to make the web page portfolio." The implementation of the Digital Portfolio or Digital Backpack at UM--St. Louis is driven by the need to present the content of the evidence of the student’s learning.

The Technology and Learning Center at the College of Education at UM--St. Louis has been experimenting with several object oriented document management applications and courseware applications since November 1999. Figure 1 contains a snapshot of our prototype portfolio structure based on Missouri standards.

The current design of the Digital Backpack at the University calls for use of Xerox Corporation’s DocuShare product. Using only a web browser, users can save, access, organize and manage documents and attach information to documents (e.g., reflections, observations). The system is easy to use and resembles familiar file management environments, like Windows Explorer and Mac Finder. The staff at the Technology and Learning Center at UM--St. Louis believes that DocuShare is the best platform for the digital portfolio design because it is fully customizable, has a relatively open architecture on which we can easily build and is entirely native to the Web. The basic functionality of DocuShare allows users to upload and download files, organize them into collections, and search -- all through a browser.
The next stage of development of the software will include a portfolio structure creator tool that enables the university to designate the portfolio structure for any group of users. Included will be the ability to generate the new portfolio structure for each user automatically, create user accounts automatically from the university’s databases, and allow pre-service teachers to select, seal (make “read only”) and submit a portfolio to a review group.

While placing artifacts in the Digital Backpack is relatively easy, a need exists to have students place all artifacts produced while studying to be a teacher in the Digital Backpack. Students complete many assignments in a digital format that can be easily included. However, many faculty make assignments without reference to digitization and without reference to placement in the student’s portfolio. Thus, the situation that currently exists is a “mad dash” by students to complete their portfolios in the last year, as opposed to an orderly accumulation of digital artifacts. By working with the sixty-five full-time faculty and more than one hundred part-time faculty, the Technology and Learning Center is proposing to help faculty members integrate technology into their classes more fully, thereby creating a process whereby students have a wealth of artifacts to choose among for their final portfolio presentation for certification.

An additional setting. Student teachers who become employed have at their disposal, a set of tools that allows them instantly to be a better advantage of the Digital Backpack is its portability to the classroom once student teachers have found a job. They can use materials with which they have familiarity. This heightens the potential for their being more comfortable in that first often difficult year of teaching. As the teach, these teachers can add to their portfolios. The Digital Backpack thus allows for continuity from their university learning experience to their professional teaching experience.

The potential for use of the Digital Backpack is being implemented and explored at UM–St. Louis. The overarching principle of a backpack is that it contains the evidence necessary for demonstrating competence, evaluating work, teaching and sharing information. It has the potential to be a powerful tool that integrates the activities of the student, the university faculty and the school. With an easy-to-use document management system, the Digital Backpack also has the potential to assist in making a long-term connection between the student and the university.
MAMBO - Experiences from developing, implementing, and evaluating a multimedia-enhanced distant education learning system

Dipl. Ing. Tobias Hofmann, Dipl. Des. Thore Schmidt-Tjarksen
Bauhaus University Weimar, CoGVis/MMC
Bauhausstr. 11, D99423 Weimar, Germany
tobias.hofmann@medien.uni-weimar.de, tjarksen@igroup.org

Abstract: During the course of the MAMBO-Project at the Bauhaus University in Weimar, Germany, a multimedia-enhanced distant education course in the field of water and environment has been developed. This included the creation of multimedia elements, restructuring of existing content, development and implementation of a XML-based content management system prototype for cross-media publishing and development of an internet technology based learning environment. The resulting course has been evaluated by an independent team of psychologists.

Introduction

Between January 1998 and June 2000, it has been the authors' job to implement one conventional paper based courses for distant vocational training in the field of water and environment offered in Weimar into a multimedia-enhanced environment for research purposes, and to perform an evaluation on the final product.

The aim of our work was to show if and how the use of multimedia elements in such an environment could add quality to the learning process. Furthermore, we wanted to find out how the production of suitable course material could be achieved and imbedded in an average German university environment.

Fields of work

The project work can be separated into the three parts of implementation:

1. Structuring and formatting of text: The paper-based material, originally being composed in different releases of MS Word, and containing text, 200 figures, and 80 equations, had to be reorganised. Handling and publication of such large amounts of non-reusable content has been described in previous work [Hofmann99], where we explain the reasons for developing a for our purposes “ideal” workflow using SGML/XML and a CMS.

2. Creation of multimedia elements: We redrew all 200 figures to get the best results for printouts as for viewing on the screen [Shneiderman98, p. 336-342]. We built different parts of a sewage plant in 3D Studio Max. Out of those files we created roughly 30 animations, 20 VRML-files, 20 figures, icons, and a video film of 18 minutes length. As an add-on, we created a software for process simulation of a waste water treatment plant.

3. Integration of old and new: The conventional material and the new multimedia material was integrated in one interface. We decided to use a web browser as front-end, to be independent from the hardware platform and the operating system. In the test case the students had to be enabled to work at their local computer at home with an Apache web server and Netscape Communicator. This allows them to access the content from a CD-ROM in several manners (such as the original sequential paper based version, a different, hypermeshed multimedia version, or a screen or print version of a PDF-file), but also to use several administrative functions like a history, notes, or search.

Multimedia Production

The production of each sort of multimedia element is different in itself, but might also be different for other environments with other constraints. The common factor for all elements is the complex process of their production involving different groups of experts. A standardised workflow has to be developed. The modelling of strongly computer-related objects like for newly created 3D-objects can not be created and presented on the traditional way (paper based). A benefit of 3D-objects is the re-using of different elements out of one model.
(pictures, animation VRML). This requires modularisation and standardisation, as those elements are based on different models of computing [Regenbrecht00, p. 19].

Therefore, the general phases in the workflow of this example can be separated in building, animation, and export. Different groups of experts have to work together.

Getting deeper into the example, in order to create an animation, the author (or teacher) stands for the didactical goal and by what content to achieve that goal. In a next step, detailed information has to be developed by somebody allowing a modeller to create a 3D-model fitting the needs of the teacher, the animation, the VRML to be exported, and the graphical display of all. In a parallel process, the story has to be given to a writer, who translates it into text which can be read out loud by a speaker and be recorded. This recording is used as a basis on which to create an animation by either the modeller or someone else, then the text is spoken again by a professional speaker. After doing some sound editing, the sound file and the animation pass to someone who packs them together and compressing picture and sound as needed. Controlling mechanisms between the single steps have to ensure the quality of the final product.

Consequences

Experiences from our work have shown, that even though different processes have been laid out at the beginning and followed rather closely by most members, a limit of practicability is reached rather soon. In a distributed environment like ours, it would be very desirable to have a distributed framework taking care of the connections between different files, description of content in metadata, and securing transactions with the ability to roll back to an earlier state. It would further be desirable to have such a framework implemented in a manner, which allows non experts to adapt its functionality to their needs without having to rewrite the whole thing. On the other hand we are aware of the dangers resulting from such an ease of use in changing such mechanisms.

On another level, teachers and authors have to get acquainted with the new possibilities and chances, but also the pitfalls coming along with new media. By what we know from the field of psychology and didactic, there is still research being done on how to best use multimedia for learning [http://www.vgk.de/research.html]. Experiences gained from that will be adapted by teachers and authors in the future, to create and use teaching material better suited for both their own and their students need. This again asks for tools to allow the authors to concentrate on their work of providing and structuring information instead of becoming computer experts.

Benefit

The results from the evaluation of our course material show that the application of developed structuring rules to existing text material leads to a text hierarchy which the students found to be easier to navigate in [Schubert01, Appendix A]. Newly created multimedia elements were accepted as an important source of knowledge (illustrative, informative) and therefore very helpful, especially in the beginning of studies. Students did not want to do without them, nominated them explicitly as an added value of MAMBO and recommended additional animations.

On the course production side, the workflow of creating new course material has been adapted as a result of our work. The higher quality and easier reusability of figures due to following documented and standardised creation processes are noted as benefits from this adaptation. Currently, all existing material is transformed and restructured to allow for automated processing and easy platform independent publishing.

The Learning Software Awards Competition

Brad Hokanson, Univ. of Minnesota, USA; Simon Hooper, Univ. of Minnesota, USA

The University of Minnesota has sponsored a second competition to recognize the design of innovative educational software. The competition was open to professional and not-for-profit educational software designers in such areas as higher education, K-12 education and commercial training. Winners of the second competition were announced in late April. Finals judges were Dr. John Bransford of Vanderbilt University, Dr. Brent Wilson of the University of Denver, and Dr. Peg Robyler of the University of West Georgia. Over a hundred other individuals have served as preliminary judges.

One of the competition's goals is to establish a bank of exemplary educational software that can be examined by designers and students of educational software design. We propose to present the results of the competition at the conference and show the winners.

The presentation will present some of the exemplary work in the field; discuss how technology can successfully be used in the classroom; and why it is worthwhile to take the time and take the risk. Observations of the judging and competition process will be presented as well as future plans for the competition as an annually recurring event. Video of the award ceremony and judges interviews will be available. Winners of the competition will be demonstrated and observations from the process and the pool of winners will be presented.
Media and Cognition: An Imaginary Journey

Brad Hokanson, Univ. of Minnesota, USA;

There are three broad steps or evolutions in current educational theory as it relates to computers and cognition. These three descriptions of computers in education and cognition include: that computers and technology act as a delivery mechanisms which transmit information without regard to or changing the content. The second understanding is one which recognizes technology as a generative mechanism, one which acts as a 'tool', as one uses a pencil, just faster. And finally, there is an understanding that technology and computers can exist as media in and of themselves, a place for creation, shaping our thoughts and the nature of the results of our exploration.

Let us build on our own learning, through our own imaginations, as a means to investigate the idea of media and cognition.

Imagine your own educational experience. Picture in your mind's eye the best teacher you had throughout your educational experience. Was that teacher solely concerned with the information delivered? Did that teacher vary substantially in method with other teachers you have experienced? Now picture the worst teacher you have had; probably that teacher focused or spent inordinate amounts of time and effort in getting the facts straight and covering the content.

This is a presentation on the concepts concerning media and its use in thought; cognition and media. It is an exploration of our use of new media and technology as a means to thought, and by that nature, involves other means beyond the verbal presentation of a paper; it involves visual referrals to supporting quotations and directed imaginations to the participants own history of cognitive development. Viewers in the poster session will be asked to answer a series of questions about their own thought patterns and educational history; these responses will build the poster presentation and the data for the paper.
TRIANGLE: A Multi-Media test-bed for examining incidental learning, motivation and the Tamagotchi-Effect within a Game-Show like Computer Based Learning Module

Abstract: At first sight, "TRIANGLE" appears to be just another piece of learning software but it is much more than this, it is an experimental test-bed for examining motivational factors in computer based training. Such a multi-media application derives its power of attraction from the quality of the interface design and the multi-medial content. Used as a trial on a defined target group of K12-students this learning module returns results on three basic effects; motivation, incidental learning and what we term a "Tamagotchi-Effect" within a Game-Show-Setting. Depending on how much an avatar has learned, it can answer questions for the player in the Game-Show. The avatar serves as a personal "Tamagotchi". Mathematics was chosen because it is rarely the favorite subject of K12-students at the age of 14-16, therefore it is ideal for testing motivational factors.

1. Introduction

A large variety of institutions are currently supporting Web Based Training (WBT) and Computer Supported Learning (CSL) as the future solution for gaining knowledge and becoming "fit" for the growing requirements of jobs in any field (cf. Rozell & Gardner, 2000). Even governments themselves and the European Union seem to see the future of education systems in promoting computer based training as an alternative to the common learning techniques used today (cf. Holzinger, 2000a, [W01]).

Coming up with a vast amount of ideas and concepts, most programmers of educational software appear not to have tested their products beyond interface usability aspects. With "TRIANGLE" [W02] we bring a specialized learning module, implementing some ideas and motivational techniques of the state of the art multimedia development. While appearing, at first sight, to be just another piece of educational software, the purpose is to provide a test-bed for examining some new principles and ideas.

The module was originally based on the work for the masters thesis of two students of Graz University of Technology, where they developed and implemented a Game-Show-like web based training environment named "VRFriends". Details and both theses are available on [W03]. The basic idea of "VRFriends" is to learn by playing a quiz show. A virtual partner reacts on the players input, for example with anger, if all the answers are wrong, or happiness if the player wins (cf. Holzinger & Maurer, 1999). When analyzing the pros and cons of this concept, we detected the necessity of testing this learning module within its own target group (K12-students).

2. Concept of "TRIANGLE"

The concept of "TRIANGLE" is to provide a motivating computer game, where players need to gain knowledge in order to win. But more than that, even if the player is not willing to learn, nevertheless he may do so by playing the Game-Show and remembering the answers to given questions. In order to test the efficiency of the methods of incidental learning and to measure degrees of motivation, there are some demands on the learning module:
Linearity and time limits: Test-persons must be forced to play the whole module without having too great scope in controlling the game flow, also, there must be a time limit for the whole game.

Diversity: To identify oneself with the avatars in the game, the player must have the option to choose among a diversity of characters.

Attractiveness: Multi-medial attractiveness is of extremely high importance. The game "must rock", has to "be cool" in order to motivate. This is the most difficult part, because it also sets focus on hardware requirements (cf. Holzinger, 2000d), which would not commonly be the purpose of learning software (see fig.1).

Measurability: The module itself has to provide values of some kind, which can be measured and - more important - compared among different test-persons.

![Fig.1 The “Game-Show”](image)

3. Technological Background

3.1. Hardware Aspects and Software Considerations

When sending questionnaires to the schools which offered to be test partner in this project, we realized that the different hardware status is a great problem in creating a homogeneous testing environment. So we decided to limit the groups of test-persons (K12-students) to 10 and let them "play" on notebooks with headsets, in order to minimize disturbing influences and to have equal conditions for every group in any school.

While "VR-Friends" was strictly web based, we wanted "TRIANGLE" to be a state of the art multimedia, which raised the requirements for a web based module to a very high bandwidth. As the motivational aspects had precedence over public availability, and the amount of time invested in programming should not exceed the cost of testing and research of retrieved data, we decided to use a standard multimedia authoring tool. Our choice was the "Director 8" from Macromedia (cf. Endres-Niggemeyer, 2000). Additionally this software is made for publishing in internet [W05]. The current version can easily be converted to an internet application, by making use of the "Shockwave" plug-in, which comes with most common internet browsers.

3.2. Open Architecture

Another requirement which we kept from "VR Friends" is an open architecture, which allows anybody to modify contents and examples of the learning module. In the current version this is realized by using a very simple
hypertext format for the learning material and Game-Show questions, including multi-medial content organized in a strict directory and name system.

4. Theoretical Background

A big problem in successful learning is keeping the motivation for continued learning. This problem is most crucial if the material to be learnt is difficult to understand or even worse, the learners do not have much personal interest in the material but have to learn it for some "external" reason. In learning as such we have on the one hand intentional learning - used in traditional computer assisted learning systems - on the other we have incidental learning (cf. Holzinger & Maurer, 1999).

4.1. Why incidental learning is important

In traditional classroom learning as well as in traditional computer assisted learning sessions intentional learning dominates. But not all learning is intentional, a fact often overlooked. Game-Shows are an ideal example. Also the concept of avatars and agents (Wang, 1997; Lieberman, 1998). Many people are of the opinion that unless learning is planned, setting out to learn some specific, one really hasn't learned anything. Worse, many people believe that unless learning opportunities are offered by some institution, the learning is either of lower quality or, possibly, not learning at all. According to Lankard (1995) incidental learning serendipitously increases particular knowledge, skills, or understanding. Incidental learning, then, includes such things as learning from mistakes, learning by doing, learning through networking, learning from a series of interpersonal experiments. It is clearly obvious that incidental learning is particularly powerful for children. And certainly nobody would deny that children up to the age of six are learning quite a lot - their mother tongue for instance. But at the age of six incidental learning looses its importance and is replaced by a "sit down, listen and repeat" approach (Anderson, 1985). Standard research experiments in these fields include examples such as Anderson and Bower (1972), where one group of the testing persons was informed that afterwards there would be a memory test, and the other group was not. The intentional group recalled only 48.9 % of sentences while the incidental group recalled with 56.1 %, significantly more. Interviews later on showed that the intentional learners performed less well because many of them were busy employing poor memorization strategies. Many students are hampered in intentional learning situations by their mistaken ideas about memory and memorization strategies.

4.2. Motivation

According to Brehm & Self (1989) intensity of motivation is reflected by changes in the sympathetic nervous system. Increasing motivation is dependent on increasing arousal, which - as a psychological concept - refers to the degree of alertness, awareness, vigilance, or wakefulness (Robbins, 1997). It varies from very low values (coma or sleep) to very high values (panic or extreme anxiety), however the relationship between arousal and intensity of motivation is not linear. This relationship is called the Yerkes-Dodson-Law, first described by Yerkes and Dodson (1908), which points out that there is an optimal level of arousal for the most effective learning behaviour (Holzinger, 2000b). The chance of the VR-Friends concept is to keep arousal of the students as often as possible in optimal areas to get best learning performance. Berlyne (1965) pointed out, that one of the most important sources of arousal are stimulation, meaningfulness, and for VR-Friends particularly relevant, the novelty of situations, and the surprises that come with them. A further interesting cognitive factor is described by Brehm & Self (1989): Motivational arousal may be a function of the extent to which the learner assumes personal responsibility for the outcomes of behaviour. That is directly connected with something we call the "Tamagotchi-Effect":

4.3. Tamagotchi-Effect

Since Tamagotchis [W04] became a worldwide success in 1997, experts have been wondering why these Tamagotchis have been successful in such an unexpected way. It would be very interesting if these virtual beings could be used for other, possibly, more useful things. As a result an idea emerged to develop a completely new learning software that could considerably improve the quality of learning with computers by using such effects. This approach was called "VR-Friends" and should represent some sort of virtual learning-companion based on the Internet. VR-Friends differ in three ways from original Tamagotchis. They are kept happy if their owners answer questions correctly, they are implemented in software, not in hardware and they live on the web.
5. Implementation

5.1. Incidental Learning

One of the main theses to be tested with "TRIANGLE" is the efficiency of incidental learning. The primary knowledge imparted in the game is mathematical (the content is specialized on the triangle, hence the name). But an equal amount of additional knowledge is involved. In the training phase these two areas of knowledge are not kept separate, although internally there is a strict distinction between mathematical knowledge and additional facts, meaning that the avatar also gains only mathematical knowledge, if the player only retrieves pages with primary content.

5.2. The Tamagotchi Effect

The virtual companion is implemented as a sequence of pre-rendered video files. In the training phase, the avatar rests on the lower right side of the screen, reading in a book, looking around, talking to the player and reacting to screen changes (see Fig.1). This is implemented by an event driven system. At every event occurrence a video sequence is added to a animation queue. For greater diversity there are up to three different video sequences for the same event. This avoids repetitions and makes the avatar more "alive". In the Game-Show the chosen avatar is one of three candidates playing. Depending on the correctness of the answer it is delighted or sad.

But the most important fact about the Tamagotchi is the ability to learn with the player and to help in the Game-Show. This is implemented in a very simple, but effective manner. A routine calculates the time required for reading the whole page, based on the number of words, after about 70% of this time passed without a change to another page, the avatar "learns" this part of the material. Depending on how much the avatar has learned, it can answer questions for the player in the Game-Show. So it is up to the player, the avatar itself is his "Tamagotchi".

5.3. Motivational Factors

A multi-media application like "TRIANGLE" derives its power of attraction from the quality of the interface design and the multi-medial content. On the other hand, the interface itself has to be quite functional, as it serves as a replacement for common learning environments. While learning, the player deals with a text area ("the book"), a multimedia content window ("the blackboard") and some navigational elements. The virtual companion also has a very prominent place on the screen and is always present and in motion. The training phase could bore some students, so the avatar (the learning partner) comes up with witty comments, creating a moment of motivation to continue learning in order to see all the funny comments. The primary motivational element is the Game-Show. Here the player can show what he has learned and win points by answering correct questions. So the training appears to be only preparation for the Game-Show, while really being the main purpose of the whole module. In addition to the multi-medial components of the interface, animated jingles introduce the player to the phases of the game. Music is not a carrying element throughout the program, nevertheless it fills the game show with ambience.

5.4. Open Architecture

An open architecture for the content data structure was a basic requirement. "TRIANGLE" is planned as a prototype of learning software, which provides multi-medial fun and edutainment capabilities while being open to everyone who likes to impart any kind of knowledge to students. Therefore a very simple hypertext format was developed. There are two types of hypertext: content and examples, both in plain text format and divided in sections initiated by defined tags. The examples contain the question title, the question, the correct answer and the maximum points. Content consists of a head, any numbered tags and the information itself. In the text hyperlinks can be set by formatting a word in a certain structure. The target of a hyperlink is simply the filename of another text file, similar to HTML. In addition multimedia content can be provided by tags pointing at bitmaps or video files in the corresponding directories, and also the witty comments of the avatar are defined in the content hypertext files. Considering this simple data structure one can see that it would be easy to provide a simple content editor for anyone who likes to adapt the module for his learning material.
6. Experimental Setting

6.1. Target Group

The target group for testing our module were K12-students. There were a couple of reasons for this choice. The students were aged between 14 and 16 and they already had some experience in using computers. The mathematics curriculum is independent of the school type, which made it possible to test the module without the necessity of producing various versions with different contents. Mathematics was chosen because it is rarely the favorite subject of students at this age, therefore it is ideal for testing motivational factors (cf. Boaler, 2000).

6.2. Classroom settings

Groups of ten students were placed in a classroom each equipped with a notebook computer. The first questionnaire collected data about motivation, mood, readiness etc. Then the students played the learning module in a time limited (20 minutes) training process, in which the students were allowed two attempts to win the Game-Show with a maximum of points. During the game the module collected data about the user behavior. A further test of motivation showed the students’ enjoyment when playing the game (and learning). Finally a questionnaire collected general data.

6.3. Data Provided by Module

The module itself collected a variety of data, some for reasons of user interface testing, others required for motivation tests. The program saved the data in an external file, which was easily transferred to a statistical program (SPSS). The collected data contained: the chosen avatar, the number of correctly answered questions (divided into mathematical and additional knowledge), the intensity of content study (by measuring time in relation to the amount of text on a page), the number of hyperlinks followed, pictures watched etc. Most of this data were used to control questionnaire results.

7. Results

The first questionnaire measured the motivation according to the AMS-Scale (Gjesme & Nygaard, 1970). The first 15 items determining the performance of motivation (expectation and success). The remaining items measuring the unsuccessfulness and fear. Thus, the first questionnaire showed the level of motivation before starting “TRIANGLE”. Our program delivered the values during the game by storing all links used in log-files. The second questionnaire set, after playing with “TRIANGLE”, delivered a standard of comparison to the first test. Finally, a special test showed the adjustment in attitude to mathematics in school.

7.1. Thesis 1: Incidental Learning

The results of the case study showed that additional factual knowledge provided by hyperlinks was also memorized. Supported by carefully selected multimedia elements to serve as “anchor points” the learner builds a network of facts - a mind map of the knowledge contained in hypertext. Since there was very little probability that the students were acquainted with the material before their participation the correctly answered questions serve as prove for the success of incidental learning.

7.2. Thesis 2: Tamagotchi Effect

Although the students enjoyed the interaction with the virtual partner in the program, no positive effect was measured in the case study. There were no significant differences in the motivation and success of the two groups using different versions of “TRIANGLE”. The overall motivation was very high and the avatar or it’s absence did not influence on the groups enjoyment. The original concept of the “VR-friends” could not be carried out. Due to the low level artificial intelligence, time and technical limitations the personal interaction was weaker as planned. By further experimentation more versions should be used.
7.3. Thesis 3: Motivation

The case study showed a high level of basic motivation among the students using “TRIANGLE”. Whether, due to real interest in the program or the novelty of something new is difficult to judge: most students enjoyed the game show. Several students reacted emotionally to success and failure, showing that they were really “in the game”. These motivational factors can be used to intensity previously learned material. Multimedia elements received a higher level of acceptance than the classical education methods. An advantage of this multi medial software was proved by the correlation between the number of correct answers and the media elements participated in.

Abstract: One of the hottest topics in recent information systems and computer science is metadata. Learning Object Metadata (LOM) seems to be a very powerful mechanism to represent metadata, because of the great variety of LOM Objects. This is one of the reason why the LOM Standard is cited in a lot of projects in the field of eLearning Systems. We came to the conclusion that this multi media learning (MML) related technology could enhance conventional learning systems. Some applications have many possibilities to interpret and use the information of the Learning Object Metadata base schema. One of the disadvantages of the very complex metadata-structure is the fact, that it is going to be difficult or confusing to determine the relevant elements for a satisfying result. Therefore a Learning System based on the LOM standard is expected to provide an intuitive user interface that supports the user in getting good results. This article describes why metadata is needed, discusses the development from Dublin Core, Gateway to Educational Materials (GEM) and Warwick-Framework to the IEEE LOM and presents four examples of successful implemented systems.

1. Introduction

1.1. What is metadata?

Metadata is commonly described as being "Data about data", which provides a means by which the multimedia’s semantics can be described in a structured fashion for use by various applications. More technically Metadata is standardized information to describe digital information resources (cf. Dorner, 2000). Metadata created only for use by a single application goes against Searchability, Extensibility, Reusability and Scalability. Required is a standard that everyone conforms to for the exchange and use of media. But even this may not be enough, especially for interoperability issues e.g. spoken language independency.

1.2. Why is educational metadata needed?

Traditional search techniques are user-directed, manual and often time-consuming tasks. The reason for creating metadata, from the perspective of the provider of learning material, is to improve the possibilities of document retrieval (especially the search precision) as well as to support control and management of collections. But there is still another problem remaining: Digital documents with their abundance of different formats and control measures might not always be usable directly by everyone. The format might be unreadable, the content can be encrypted, even prohibited or only permitted after payment. The document might be large, difficult or time consuming to access etc. Especially if multimedia documents are used in education like audio and video, metadata is extremely helpful in managing the multimedia learning content. A solution for all those cases could be metadata which supports the users
decision process. Such metadata, necessary to describe educational material homogenous, could be e.g. language, title, catalogue numbers, date, format etc, and in the case of audio and video a time-based documentation of the audio/video image content on a layered basis depending on the documentation focus.

As these multimedia objects typically get larger and larger, a manual metadata documentation becomes very expensive and is not practical anymore. In these cases content management systems (CMS) can support automatic extraction of metadata with audio/video analysis processes that e.g. separate clips into scenes or extract relevant key-frames (cf. Kleinberger, Schrepfer, Holzinger, Müller 2000).

1.3. Why are standards needed?

Metadata is information about an object and as the number of objects increases, the lack of information or metadata about objects has produced a critical and fundamental constraint on our ability to discover, manage and use objects. Only standards might address this problem by defining a structure for interoperable descriptions of learning objects. According to Wantz & Miller (1998) there are four remarkable efforts concerning education via the Web:

1.4. Dublin Core

Emerging from the field of digital cataloguing the Dublin Core defines a small, core set of metadata attributes for describing features of generic Web resources [W01, W02]. This core set of metadata is given in the following XML-notation which can be a possible physical representation of the Dublin Core metadata attributes:

```xml
<?xml version="1.0"?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
    xmlns:dc = "http://purl.org/dc/elements/1.1/">
    <rdf:Description about="http://purl.org/dc/about/index.htm">
        <dc:title>Dublin Core Metadata Initiative - About the Organization and Process</dc:title>
        <dc:description>A description of the Dublin Core Metadata Initiative process.</dc:description>
        <dc:date>1999-04-06</dc:date>
        <dc:format>text/html</dc:format>
        <dc:language>en</dc:language>
        <dc:contributor>The Dublin Core Metadata Initiative</dc:contributor>
    </rdf:Description>
</rdf:RDF>
```

Forsberg & Dannstedt (2000) encountered problems when applying Dublin Core due to the fact that these problems are a consequence of trying to describe information resources without taking into account the context in which the learners create and consume information.

1.5. Gateway to Educational Materials (GEM)

The GEM-Project, as a project of U.S. Department of Education and the Educational Resources Information Center on Information Technology (ERIC/IT), has extended the Dublin Core with metadata to support the description of lessons, curriculum units and special educational resources [W03]. The Dublin Core Element Set (DC) became the base referent for GEM elements. The following GEM metadata example from Sutton (1998) shows the integration of scheme and type information in HTML 4.0 meta tags:

```html
<META NAME="DC:subject.level01" SCHEME="GEM" CONTENT="Science"/>
<META NAME="DC:subject.level02" SCHEME="GEM" CONTENT="Biological sciences"/>
<META NAME="DC:subject.level03" SCHEME="GEM" CONTENT="Life sciences"/>
<META NAME="DC:subject.level03" SCHEME="GEM" CONTENT="Technology"/>
```
1.6. Warwick-Framework

Based on the Warwick Workshop 1996 in the UK, the so called Warwick-Framework provides an architecture for the interchange of distinct metadata packages and allows to combine good extensibility to provide elaborated schemes to certain communities with a simple interoperable Dublin Core description of form and content of the objects. Feature overkill is avoided. It provides the possibility to describe either on an item or on a collection level. The Dublin Core could be a good incentive to authors and publishers to deliver a minimum of metadata with their documents [W04], (cf. Lagoze et.al, 1996).

1.7. IEEE Learning Object Metadata (LOM)

The IEEE Learning Technology Standards Committee (LTSC, [W05]) working group IEEE P1484.12 (Learning Object Metadata Working Group, Chair: Wayne Hodgins) has developed a standard conceptual model.

The IEEE conceptual model for meta-data definitions is a hierarchy (see fig.1). At the top of this hierarchy is the so called "root" element. This root element contains many sub-elements. If a sub-element itself contains additional sub-elements it is called a "branch." Sub-elements that do not contain any sub-elements are called "leaves." This entire hierarchical model is called the "tree structure" of a document [W06].

![Fig.1: The IEEE LOM Hierarchy](image)

2. LOM – Scope, purpose and working draft

2.1. Scope

This proposed standard will specify the syntax and semantics of Learning Object Metadata, defined as attributes required to fully/adequately describe a Learning Object. Learning Objects are defined here as any entity, digital or non-digital, which can be used, re-used or referenced during technology supported learning. Examples of technology supported learning include computer-based training (CBT), web-based training (WBT), or intelligent computer-aided instruction systems in Medicine (cf. Holzinger et.al., 2000). Examples of Learning Objects include multimedia content, instructional content, learning objectives, instructional software and software tools, and persons, organizations, or events referenced during technology supported learning.

The Learning Object Metadata standards will focus on the minimal set of attributes needed to allow these Learning Objects to be managed, located, and evaluated. The standards will accommodate the ability for locally extending the basic fields and entity types, and the fields can have a status of obligatory (must be present) or optional (may be absent). Relevant attributes of Learning Objects to be described include type of object, author, owner, terms of

---

Page 774
distribution, and format. Where applicable, Learning Object Metadata may also include pedagogical attributes such as: teaching or interaction style, grade level, mastery level, and prerequisites.

It is possible for any given Learning Object to have more than one set of Learning Object Metadata. The proposed standard will support security, privacy, commerce, and evaluation, but only to the extent that metadata fields will be provided for specifying descriptive tokens related to these areas; the standard will not concern itself with how these features are implemented. The working group is expecting that these standards will conform to, integrate with, or reference existing open standards and existing work in related areas. For example core attributes of Learning Objects will be coordinated with or may simply defer to the efforts to standardize content objects in general [W07].

2.2. Purposes

According to the WG the main purposes of the LOM are to enable [W06]:
- learners/teachers to search, evaluate, acquire, and utilize Learning Objects,
- the sharing and exchange of Learning Objects across any technology supported learning system,
- the development of learning objects in units that can be combined and decomposed in meaningful ways,
- computer agents to automatically and dynamically compose personalized lessons for an individual learner,
- education, training and learning organizations, both government, public and private, to express educational content and performance standards in a standardized format that is independent of the content itself,
- a strong and growing economy for Learning Objects that supports and sustains all forms of distribution; non-profit, not-for-profit and for profit,
- the documentation and recognition of the completion of existing or new learning & performance objectives associated with Learning Objects.
- and least but not last to compliment the direct work on standards that are focused on enabling multiple Learning Objects to work together within a open distributed learning environment.

To provide researchers with standards that support the collection and sharing of comparable data concerning the applicability and effectiveness of Learning Objects. To define a standard that is simple yet extensible to multiple domains and jurisdictions so as to be most easily and broadly adopted and applied. To support necessary security and authentication for the distribution and use of Learning Objects.

3. Examples of LOM-based Systems

3.1. ABITS - An Agent Based Intelligent Tutoring System for Distance Learning

ABITS (An Agent Based Intelligent Tutoring System for Distance Learning) is an Intelligent Tutoring Framework highly re-usable and suitable to several knowledge domains, and has been realized in the context of the InTraSys ESPRIT project. It is able to support a Web-based Course Delivery Platform with a set of "intelligent" functions providing both student modeling and automatic curriculum generation. Such functions found their effectiveness on a set of rules for knowledge indexing based on Metadata and Conceptual Graphs following the IEEE Learning Object Metadata (LOM) standard. Moreover, in order to ensure the maximal flexibility, ABITS is organized as a Multi Agent System (MAS) composed by pools of three different kind of agents (evaluation, pedagogical and affective agents). Each agent is able to solve in autonomous way a specific task and they work together in order to improve the WBT learning effectiveness adapting the didactic materials to user skills and preferences [W08].

3.2. GESTALT (Getting Educational Systems Talking Across Leading-Edge Technologies)

For GESTALT (Getting Educational Systems Talking Across Leading-Edge Technologies), the emphasis is on delivery of learning within a managed process as part of the core business of the educational or training organization. This entails tight-knit integration between the learning delivery and the central management of the institution, with reliable flow-through of data on student tracking etc. The GESTALT project is then coming at this problem from a systems perspective, the goal being to achieve organization-wide integration of existing and future systems within the institution and linking the promotion of on-line learning opportunities with the CORBA-based brokerage service. The broker would service queries from potential learners across a wide range of delivering organizations and a central value-added function of the broker is that it quality assures these offerings and the institutions behind them. As can be seen from the above descriptions, these two projects have a very different view.
of the role of on-line learning, but nevertheless they have co-operated (along with IMS and others) on the definition of the IEEE Learning Object Metadata. It is hoped that this will strengthen the LOM specification, enabling it to meet a wide set of requirements across user communities.

Other areas of development within GESTALT have included a European-focused implementation of the IEEE Public & Private Information (PAPI) specification from the Learner Model Working Group and the definition of a Unit Object Model for describing student progress between the Learning Environment and the Administration MIS. Aligning European R&D activity with the wider standards formation work has had clear benefits in terms of developing a common language for describing systems, components and functionality and generally encouraging the cross-fertilization of ideas around the globe [W09].

3.3. ARIADNE (Alliance of Remote Instructional Authoring and Distribution Networks for Europe)

The ARIADNE Project has been active both within the IEEE LTSC and in the formation of the Learning Technology Working Group under CEN/ISSS. The project Manager, Eddy Forte, is also the chair of the PROMETHEUS forum. The European Commission (DG III, DG XIII) and CEN have been instrumental in the formation of PROMETHEUS, a forum for exchanging ideas and driving consensus amongst actors in this area within Europe. In the international arena, ARIADNE has been a major contributor to the IEEE LOM work. The actual project has developed a range of tools for the delivery and support of on-line learning which are made available free-of-charge to the ARIADNE user community. Many both within and external to the project have authored content which is described using metadata and made available to tutors via the ARIADNE Knowledge Pool Sites. The ARIADNE distribution model seems based on co-operation between, and free access for, the academic community who will develop their own content and tools which will be freely exchanged. As such, the system model is very flexible as tutors simply select the tools they wish to use [W10].

3.4. The L3 project

The L3 project (L3 stands for Life Long Learning, cf. [W11]) is a project founded by the German government with the goal to create a technical and organizational infrastructure for a lifelong further education. The solution approach emphasizes two different points: On the one hand the creation of an educational infrastructure which uses new media efficiently and can be used by all interested people, independently of there education or social position. On the other hand the development of organizational structured and economic business models with which the developed infrastructure can be operated at a medium term.

The central component of the educational infrastructure is a multimedia repository (cf. Kleinberger, Holzinger 2001) which manages online educational content, especially multimedia content like audio and video. The educational multimedia content consists of learning objects which can be structured hierarchically in courses and lessons. The actual relationship between the learning objects is defined in a course structure which is represented in XML. Metadata for the learning objects is represented in an XML notation of the LOM definition 2.2 with appropriate document type definitions. Media objects are references out of the LOM metadata objects to physical media objects stored also in the multimedia repository.

Because the multimedia repository is designed in layered building blocks with different services for its functions, it can easily be embedded in educational environments like the lifelong learning environment build up in decentralized service centers and learning centers

4. Conclusion

There are some standardization initiatives for metadata in teaching and learning objects. Learning Object Metadata (LOM) seems to be the most powerful and most extensive mechanism to represent metadata, because of the great variety of the LOM Objects. There are some implementations which are using LOM already, but we weren't able to find an implemented System based on the LOM standard which contains an intuitive user interface for the definition and search for metadata. The other side of the very complex metadata-structure is the fact, that it is going to be difficult or confusing to determine the relevant elements for a satisfying result. Of course the decision to remove some of the Objects would be a difficult one, because of the danger to loose the functionality and flexibility of the current model. Exactly this seems to be the biggest advantage of LOM due to it's hierarchical and extensible approach.

Abstract: Web-base learning environments are strongly driven by information revolution and the Internet, but they have a number of common deficiencies, such as slow access, no adaptivity to individual student, limitation by bandwidth, and so on. This paper outlines the benefits of mobile agents technology, and describes its application in web-based learning environment to improve learning process. Mobile agents technology is being used in the implementation of the TILE adaptation mechanism, which the TILE project aims to provide an integrated system for the management, authoring, delivery and monitoring of education at a distance.

1. Introduction

Intelligent Agents are one of the "hot" topics in Information Systems Research and Development at the moment. The last ten years have seen a marked interest in agent-oriented technology and a distinct trend has evolved to the research and development work on intelligent agents. This trend relates to the diversification in the types of agents being investigated and most popular types include user interface agents, information agents, multi agent system, mobile agent and so on.

The educational systems, especially the web-based learning environments, are becoming mainstream applications on the Internet. But these environments face some common deficiencies, which need to be resolved. Intelligent agents, and in particular, mobile agents, have huge potential to address those deficiencies. A number of research projects have been initiated to apply agent technology in web-based learning environments. But most of these research projects have used intelligent interface agents, which are usually static. In this paper, we shall demonstrate how mobile agents can address the problems that limit the potential web-base learning environment development.

2. Challenges for web-base learning environments

The information revolution has induced the boom of knowledge economy. This strong trend is supported by the updating technologically skilled workforce, which is achieved by lifelong learning, education in the workplace and distance education. Those are the prime factors driving the web-base education.

Institutions with long-standing involvement in distance education, such as the Open University in United Kingdom, are incorporating web-based elements in their instruction. Although Web-based course materials have advantages over conventional textbooks and lecture notes, they have a number of common deficiencies, such as access to course materials is slow; courseware does not adapt to individual students; the real time interaction between student and system is hard to achieve because of the connection unreliability and bandwidth limitations.

A number of attempts have been made to attack some of these problems, but solution to one problem often impedes solutions of the remaining problems. For example, InterBook (Brusilovsky et al., 1996) supports adaptivity and authoring, but all adaptation and page generation takes place at the central server, risking access delays. QuestWriter (Bogley et al., 1996) supports authoring, and has built-in client-side and servers side interactivity, but does not adapt presentations to individual students; the real time interaction between student and system is hard to achieve because of the connection unreliability and bandwidth limitations.

The Adele agent basically belongs to an intelligent interface agent, which still concentrates on providing helps to students.
In general sense, a web-based learning environment should interact with the students, adapt to the needs of individual students, support interaction with teachers and other students, and be user-friendly to the authors. The emerging mobile agents technology is not only capable to facilitate these benefits but also attempts to address the problems mentioned above.

3. Motivation for using mobile agents

Although it is possible to propose an alternative, based on an existing technology, to almost every mobile agent-based function (Chess et al., 1995), in certain cases mobile agents have significant advantages over conventional approaches at the design, implementation and execution stages. The motivation for using mobile agents stems from following anticipated benefits:

- **Efficiency and reduction of network traffic**: Mobile agents consume fewer network resources since they move the computation to the data rather than the data to the computation. Also mobile agents can package up a conversation and ship it to a destination host, where the interactions can take place locally, so network traffic is reduced (figure 1).
- **Asynchronous autonomous interaction**: Tasks can be encoded into mobile agents and then dispatched. The mobile agent can operate asynchronously and independent of the sending program.
- **Interaction with real-time entities**: Real-time entities require immediate responses to changes in their environment. Controlling these entities from across a potentially large network will incur significant latencies. Mobile agents offer an alternative to save network latency.
- **Local processing of data**: Dealing with vast volumes of data when the data is stored at remote locations, the processing of data over the network is inefficient. Mobile agents allow the processing to be performed locally, instead of transmitting the data over a network.

![Client-server paradigm vs. Mobile Agent approach](image)

**Figure 1.** Client-server paradigm vs. Mobile Agent approach.

- **Support for heterogeneous environments**: Both the computers and networks on which a mobile agent system is built are heterogeneous in character. As mobile agent systems are generally computer and network independent, they support transparent operation.
- **Convenient development paradigm**: The design and construction of distributed systems can be made easier by the use of mobile agents. Mobile agents are inherently distributed in nature and hence are natural candidates for such systems.
4. Application of mobile agents technology in web-base learning environment

After examining the benefits of mobile agents, and considering the limitations of web-based learning environments, it becomes clear how mobile agents technology addresses those limitations very naturally. We discuss below how mobile agents can improve web-based learning environment.

**Figure 2. Scenario of mobile agent working**

- In a web-base learning environment, as shown in figure 2, mobile agents can be used to pre-fetch the domain content that will be requested shortly by the student, and report student’s performance to the central server. This pre-fetch process is based on real-time analysis of the student’s behavior, and calculation of the probability of a request. Each student behavior, as they work through the web-based learning system, can be monitored and recorded by an intelligent interface agent, which runs on the student computer. Depending on the state of the network, an immediate request or a reservation can be fulfilled by the mobile agent. In this way, end-to-end quality of the service can be improved for the delivery of distributed multimedia material, such as that represented by distance education. This agents technology avoids unnecessary networking delays, cope the bandwidth limitation and adapt the representations to students, based on the student performance.

**Figure 3. Scenario of mobile agent moving around distributes systems**

- In terms of mobile users, portable-computing devices such as laptops, palmtops, and electronic books will access web-based learning environments. These devices have unreliable, low-bandwidth, high-latency telephone or wireless network connections. Mobile agents will be essential tool for allowing such access.
Mobile agents offer application developers a new programming paradigm with higher-level abstraction and unified "process" and "object". In terms of scalability of system and easy authoring, these features of mobile agents offer a flexible and effective philosophy on learning environment development, design, and scalability.

In the future, web-based learning environments can share resources through different systems, as shown in figure 3. Both the computers and networks on which web-based systems are built are also heterogeneous in character. As mobile agent systems are generally computer and network independent, they support distributed systems and resources sharing.

On another note, web-based learning environments are ideal test beds for mobile agents technology. Till now, electronic commerce has been treated as the only important target for mobile agents technology. Money is involved, so security is a key factor for agent technology. There are three types of security: agent-agent security, host-agent security, and agent-host security. Existing techniques can be successfully applied to protect agents from malicious agents, and hosts from malicious agents, but it is currently very hard to protect the agents from malicious hosts due to the possibility of the host changing the programming code of agent for some vested interests. This factor is one of main obstacle affecting mobile agents applications in the real world. However, in education sector, the agent-host security is not as important as in electronic commerce. This makes the web-based learning environments as the most suitable test bed for mobile agents technology.

Mobile agents technology is being applied in the TILE project. Following section gives brief introduction of TILE before describing the application of mobile agents.

6. Application of mobile agents for student adaptivity in TILE

The Technology Integrated Learning Environment project (TILE) aims to provide an integrated system for the management, authoring, delivery and monitoring of education at a distance. Its architecture gives a modular framework for the inclusion of a range of tools to achieve the project's goals. TILE can be compared to a computer aided software engineering (CASE) tool but for the development of on-line education. It supports the planning of syllabi and courseware, the tracking of development by staff, the reuse of course-ware modules and (if necessary) any auditing of royalties. Finally and perhaps most importantly it provides a means by which the educational web sites are built. One of the main aims of the TILE is to provide adaptive learning environment to the students. The adaptation in the system requires consideration of following criteria (Kinshuk et al., 1999):
(a) adaptation with respect to current domain competence level of the learner;
(b) suitability with respect to domain content; and
(c) adaptation with respect to the context in which the information is being presented.

![Figure 4. Adaptation mechanism in TILE environment](image)
The fulfillment of these criteria requires the development of student model that captures the interactions of student with the system to extract information about student's competence level for various domain concepts and tasks represented in the system. TILE environment benefits from the collaborative learning on the web by having two separate student models:

1. **Individual student model**, which serves an individual student and contains the detailed information about particular student's domain competence level, preferences, interaction information and other relevant details; and

2. **Group student model**, which generalises various attributes over a number of students and attempts to classify students in various categories (for various attributes).

This two-step modelling enables the system to provide adaptation at different granularity, and also refines default assumption of the system towards new students.

The learning process in the TILE environment also benefits from the client-server approach, which has been extended to the adaptation process. Consequently, the student model is divided into host and client bases. The host base contains the group student model, and partial individual student model, whereas client base contains only individual student model. This approach serves a number of purposes. First of all, it allows the system to be much more flexible, particularly in the web-based environment, where connectivity between host and client is not always guaranteed, and the quality of the connection often suffers from traffic congestion. The client side student model facilitates adaptivity even in offline mode, whereas host side student model allows adaptivity based on new information available from the domain experts and better adaptation procedures resulting from group student model. Figure 4 shows the schemata of the adaptation mechanism in the TILE environment.

Mobile agents technology is being used in the implementation of the TILE adaptation mechanism. Figure 5 describes the implementation of mobile agents technology in the adaptation mechanism.

![Diagram](image)

**Figure 5.** Implementation of mobile agents technology in adaptation mechanism.

As seen in figure 5, a mobile agent interacts with client side inference engine to pick up data, which relies on individual student model at client side. Then mobile agent moves to the host (or server) side. At host side, mobile agent performs all the processes needed, such as updating the partial individual student model based on summary of client side student model (based on the data brought by mobile agent), interacting with group student model to determine if that student model also needs to be updated. After mobile agent finishes all actions at host side, it gathers all the information it needs, and returns to the client side. Then it updates the client side individual student model. This mobile agent approach works even in the intermittent connectivity between client and host because mobile agent can be dispatched when the connection is available and then the agent works autonomously without requiring continuous connection.
7. Conclusion

There is a strong case in favour of the use of mobile agents in many Internet applications. Moreover, there is a clear evolutionary path that will take us from current technology to widespread use of mobile agents within the next few years. Once few technical challenges are met and few pioneering web-based applications start using mobile agents technology, we believe, the use of mobile agents will expand rapidly. TILE project is one such step in that direction.

A number if research issues are still to be resolved. For example, besides building mobile agent, we also have to provide environment for mobile agent. Although some mobile agent systems, such as Bee-gent, come with wrappers, they are still quite limited. But we hope, mobile agents technology will open a new interesting research area in the web-base education, where traditional approaches are proving fruitless due to severe limitations imposed by the existing technology.

Abstract: A framework for designing intelligent assistance in discovery learning environment is proposed. The process of discovery learning is analyzed and the required functions for intelligent assistance are discussed. A flexible simulator which fits any types of discovery learning is necessary. The problem solvers which perform fundamental tasks of discovery are also needed: Hypothesis generator and experiment designer. We especially focus on the other important function: Evaluator of the effectiveness of counterexamples. Counterexamples have much clue for learning, but a learner often feels difficulty in utilizing them. We, therefore, propose the method of evaluating counterexamples from two educational viewpoints: (1) Does it suggest the occurrence of error clearly? (Visibility), and (2) Does it suggest the cause of error? (Suggestiveness). Some case studies are presented to illustrate these functions. Then, the whole framework is described.

Keywords: discovery learning, microworld, intelligent assistance, counterexample

1. Introduction

Microworld has been getting important as an educational tool to support learning by doing. It provides computer simulation of restricted environment, in which a learner can manipulate the existing objects directly and see the result of her/his action intuitively. A learner explores the world and tries to discover the knowledge and laws in the learning domain. Such a situation is educationally quite good because it promotes a learner's initiative, motivation and interest. Here, discovery learning becomes a central issue.

Discovery learning, however, is not so easy. It needs several skills in 'discovery task,' e.g., how to generate a hypothesis, how to design an experiment to test it. A learner without these skills often comes into an impasse or objectless action, so appropriate assistance is necessary.

One way is to provide some auxiliary tools which makes cognitive process of discovery explicit. For example, in generating hypothesis or in designing experiments, it is quite difficult to find out what are the essential elements of the domain. So, to provide a list of basic variables will be helpful. Hypothesis Editor and Monitoring Tool [Joolingen 1999] are the typical examples.

Another way is to provide more 'intelligent' assistance. It gives a learner some advice concerning the contents of the discovery task, e.g., to suggest a reasonable hypothesis based on the data in hand, to judge the reasonability of the experiment to test the hypothesis. Electric Studio [Shoda 1999] is an example, of which domain is the diagnosis of electric circuit.

For designing the intelligent assistance (which is of our main interest), it needs the problem solvers in discovery task. Especially, hypothesis generator and experiment designer are the essential. The former generates all reasonable hypotheses based on the data in hand, and the latter generates all reasonable experiments to test the hypotheses. They are often depend on the learning domain.

Few discovery learning environments, however, have been developed with such intelligent assistance. It is because there occurs two difficulties in designing such an environment. The one is domain dependency of the problem solvers, but it could be alleviated by modularizing them to interact with other components through abstracted data. SimQuest, the authoring system for discovery learning environment, has the libraries of such components [Joolingen 1997].

The other difficulty is more serious. That is, 'too kind' adviser deprives a learner of her/his initiative, which is the essential merit of discovery learning. (It may teaches her/him what to do next.) Explanations from the adviser must be minimum not to demotivate her/him. In discovery learning environment, it is preferable that the phenomena in microworld themselves make a learner be aware of what to learn.

Such an 'educational' phenomenon often appears as counterexample, which is the phenomenon a learner didn't predict. It impresses on her/him the necessity of learning by suggesting the error in her/his action. Thus, the 'learning from mistakes' is promoted [Perkinson 2000].

A Counterexample, however, must be carefully used in discovery learning. A learner often ignores the anomalous data as the error in measurement, or excludes it out of range of the hypothesis [Chinn 1993]. Even when she/he accepts the counterexample, without any help, she/he cannot reach the correct hypothesis and comes into impasse [Fukuoka 1994, Nakajima 1997].

Therefore, when using counterexamples in microworld, it is necessary to evaluate their educational effective-
ness and to decide whether they are shown to a learner or not. (Inappropriate counterexamples confuse a learner.)

We have studied this kind of 'management' by using Error-Based Simulation (EBS), which simulates a learner's erroneous equation of motion in mechanics [Hirashima 1998, Horiguchi 1998, 1999, 2000]. As a counterexample, EBS must be evaluated from the following viewpoints: (1) Does objects' erroneous motion in EBS make a learner be aware of the occurrence of error? (Visibility), and (2) Does objects' erroneous motion in EBS suggest the cause of error? (Suggestiveness) We have designed such mechanism and developed the EBS management system, of which usefulness has verified through experiments.

In this paper, we propose a framework for designing discovery learning environment with intelligent assistance, especially focusing on the counterexample management. It is done by generalizing our methodology in EBS research project. First, two types of discovery learning is described. Secondly, the required functions for intelligent assistance is discussed. Thirdly, two viewpoints for managing counterexamples are introduced and how to evaluate their effectiveness is also discussed. Some examples are presented for illustration. Lastly, the whole framework is described.

2. Requirements for Intelligent Assistance in Discovery Learning

2.1 Two types of discovery learning

In discovery learning environment, a learner often encounters counterexamples. Figure 1a. illustrates a typical case (type-A). After observing a few phenomena in microworld, a learner constructs a 'theory' which is assumed to rule the phenomena and to explain the phenomena. Then, she/he makes an experiment to test her/his theory, which yields a new instance of phenomenon. If her/his theory is wrong, the new instance contradicts it, to become a trigger of reconsidering the theory, i.e., counterexample.

In this case, it is assumed that a learner predicts the world of phenomenon ruled by her/his theory, which is compared with the one ruled by 'correct' theory. Most of simulation-based learning environments provide one simulator only which simulates the latter world, because the former already exists in a learner's head.

In some cases, however, the world ruled by a learner's wrong theory needs to be simulated explicitly. For example, when a learner attempts to make an object in microworld move as she/he plans, she/he writes some kind of command sequence, i.e., program. If the program includes some bugs, the object moves in contradiction to her/his prediction. In this case, the world ruled by a learner's wrong theory (eq. program) must be simulated because she/he doesn't predict it, while the correct (planned) world is in her/his head. This is illustrated in Figure 1b (type-B). 'Turtle' world [Papert 1980] is a typical case of this.

Another example of this type is EBS-simulator [Hirashima 1998], which simulates a learner's erroneous equation of motion in mechanics. It is assumed that a learner can correctly predict the motion of objects, but fails to construct correct equation. The world ruled by her/his erroneous equation is simulated and compared with the correctly predicted world.

The difference between these two types of discovery learning mainly comes from the difficulty in formulating a theory. For example, when a learner supposes a proportional relation between two observed variables, it may not be so difficult to formulate it by using linear function. Yet, when she/he predicts an object moves circularly by centripetal force, it will be more difficult to formulate the equation of circular motion. Thus, in the case of complicated formulation, a learner often fails to write her/his theory (eq. prediction) down as the formula. Such a formulation includes several processes and knowledge, so some bugs can easily steal in.

It must be noted that the boundary between these two types often becomes ambiguous. (Suppose that a simple program to control 'Turtle' gradually gets complicated.) It is difficult to know which type of discovery learning is ongoing only from the observation of a learner's action. Therefore, it is necessary to design the flexible simulator which can simulate both correct and erroneous formula of theory. One example is Logo interpreter for 'Turtle' world. EBS-simulator for mechanical world is another example. Both of them allow a learner's formula (Logo program or equation of motion) with some range of semantic (not syntax) error.

2.2 Functions for intelligent assistance

The cause of errors in type-A discovery learning is supposed that a learner doesn't have sufficient data...
(instance of phenomenon) to make the correct theory, or that she/he mistakes the important data in hand. Therefore, the assistance needed is to suggest the additional experiment which yields counterexample to her/his theory, or to teach how to construct the adequate hypothesis to explain all data in hand.

The cause of errors in type-B discovery learning is, as described above, the difficulty of formulation of theory. The assistance which guides a learner to construct a formula will be helpful.

For providing intelligent assistance in a discovery learning environment, therefore, the following functions are necessary:

**Function-1: A problem solver for 'discovery task'**
The function which generates all reasonable hypotheses from the given data. It judges the reasonability of a learner's hypothesis based on the data in her/his hand.
It also generates all reasonable actions (i.e. experiments) to verify the given hypothesis, and judges the reasonability of a learner's action based on her/his hypothesis.
In other words, the function as a problem solver for 'discovery task.' (It knows all the 'correct' theory and principle in microworld.)

**Function-2: A problem solver for 'formulation task'**
The function which generates all formulas of theory in microworld. It knows all the principle which rules the objects' behavior in microworld, and builds them up to the formula.
It also diagnoses a learner's formulation process, and checks the misconceptions within.
In other words, the function as a problem solver for 'formulation task.'

In addition to the functions above, a discovery learning environment needs another important function. A flexible simulator plays an essential role here. When a learner's action/formula yields counterexample, the difference between its result and her/his prediction is very important. It must be clear and meaningful. Even when the action is 'theoretically' reasonable, or even when the formula makes an object's unpredictable motion, if its result isn't clearly different from a learner's prediction, it is not 'practically' (eq. 'educationally') effective. Therefore, the following function is necessary:

**Function-3: An evaluator of counterexample's effectiveness**
The function which evaluates the effectiveness of the difference between the result of a learner's action/formula and her/his prediction. It is performed as follows: The flexible simulator simulates a learner's wrong hypothesis/formula. It also simulates the correct theory/formula. Then, the both results are compared and the difference is educationally evaluated.

2.3 Two viewpoints to evaluate counterexamples

Apparently, it is necessary to prepare some kind of criteria with which the difference of two results is evaluated. 'Visibility' is the key issue in considering this. Because all a learner can observe in microworld is the objects' behaviors (i.e. phenomena), her/his erroneous idea must be visualized in them. There are two viewpoints:

**Viewpoint-1: Awareness of the occurrence of error**
In this viewpoint, it is made sure that two simulated results are clearly different. It is measured by comparing the specific (often physical) variables of these phenomena in microworld by using the criteria, which defines what kind of difference of the variables is 'visible' to a learner.
This suggests a learner's hypothesis/formula contains some erroneous idea, to motivate her/him for reconsidering.

**Viewpoint-2: Awareness of the cause of error**
In this viewpoint, it is made sure that the difference of two simulated results points out the cause of error, besides its occurrence. It suggests a learner how to correct her/his erroneous idea. The criteria is necessary, which defines what kind of difference of the variable in microworld suggests what kind of error in problem-solving.

The former viewpoint is concerned only with the phenomena themselves in microworld. Some observable (often physical) variables are selected and checked whether they have clearly visible difference between the two results. The ability of human perception should be carefully considered to define the 'visibility.' (It may be useful to provide some kind of 'visual tool' which aids a learner to observe the variables.)
This viewpoint is comparatively simple, but often useful to give a learner good motivation for reconsidering.

The latter viewpoint is more complicated. It is concerned not only with the phenomena themselves but also with the problem-solving process. The difference between the two results must be 'suggestive' of the cause of a learner's error. (Here, to be 'visible' is a necessary condition.) Some kind of rules are necessary, which link the phenomena in microworld to the misconceptions in problem-solving. The criteria should be defined based on the task analysis of the domain.

The phenomena which are 'visible' but not 'suggestive,' sometimes mislead a learner because it doesn't reflect her/his problem-solving process. This viewpoint becomes necessary in such cases.
We call both 'visibility' and 'suggestiveness' in above two viewpoints 'visibility' sensu lato. In defining the
criteria for Function-3, 'visibility' plays an important role. It is much concerned with the problem-solving process of Function-1 and Function-2, so these three functions (and the flexible simulator) must cooperate with each other.

In the next chapter, we present some examples which illustrate how the criteria are defined and how the effectiveness of counterexamples are evaluated. Then, we propose a general framework of designing the discovery learning environment with intelligent assistance discussed above.

3. Examples: designing the evaluator of counterexamples' effectiveness

In this chapter, we describe how to provide intelligent assistance when a learner encounters counterexamples. It is illustrated by using a series of case studies in managing Error-Based Simulation (EBS) [Hirashima 1997, Horiguchi 1999, Horiguchi 2000]. EBS simulates a learner's erroneous equation of motion in mechanics. Objects' unnatural motion in EBS often differs from their correct motion predicted by a learner, which motivates her/him for reconsidering her/his erroneous equation.

The difference, however, is not usually 'visible' to a learner, or sometimes misleads her/him. Therefore, it is necessary to evaluate the effectiveness of EBS as a counterexample. We've designed such mechanism and developed the EBS management system. Thus, what we discuss here is type-B discovery learning, and is mainly concerned with Function-3 described in chapter 2.

3.1 EBS management from viewpoint-1 [Hirashima 1998]

In the earlier stages of our research, EBS was mainly managed from the viewpoint-1. In motion simulation of physical objects, the most specific variable is their velocity and acceleration. So, using these variables, we defined the following criteria for evaluation of the difference.

**Criterion for Error-Visualization-1 (CEV-1):**

In EBS, an object's velocity must qualitatively differ from its correct velocity, i.e., their qualitative values must be different.

**Criterion for Error-Visualization-2 (CEV-2):**

In EBS, the rate of change of an object's velocity must qualitatively differ from the one of its correct velocity, i.e., their qualitative values must be different. The rate of change of velocity usually means acceleration, but sometimes means the derivative by non-time parameter.

These criteria are derived from the fact that human ability of vision is sensitive to rather the qualitative properties of motion than the quantitative ones. CEV-1 is preferred to CEV-2 because the velocity is easier to perceive than its derivative. The reasonability of them were verified through cognitive experiments [Horiguchi 1998].

By using these criteria, the effectiveness of EBS is evaluated as follows: When an erroneous equation is constructed by a learner, it is simulated by EBS-simulator. The correct equation is also simulated, and it is checked whether the difference between the two simulations satisfy CEV-1 and/or CEV-2. The module which performs this process is implemented by using qualitative reasoning techniques, and called EBS-manager [Hirashima 1998].

For example, consider the problem in Figure 2a. When a learner constructs Equation-B, the EBS which simulates the equation is judged 'effective,' because the block's velocity and acceleration in the EBS are qualitatively different from the ones in correct simulation. (It satisfies both CEV-1 and CEV-2.)

When a learner constructs Equation-C, matters are more complicated. The EBS which simulates the equation satisfies neither of CEV's by itself, because the block's velocity and acceleration in it are not qualitatively but only quantitatively different from the ones in correct simulation. EBS-manager, in such a case, searches some 'modification' of the EBS which makes qualitative difference. In this case, perturbing the angle of slope $\theta$ works well. When $\theta$ increases, the block's velocity decreases according to Equation-C, while it increases according to the correct equation. This satisfies CEV-2, so such an EBS is generated and used as a counterexample. The snapshots of the EBS management system are shown in Figure 2b.

3.2 EBS management from viewpoint-2 [Horiguchi 2000]

The merit of viewpoint-1 is its simplicity. It does not depend on the problem-solving process but only on the resulting phenomena, so it is comparatively easy to design the evaluator of counterexamples' effectiveness. The counterexamples evaluated from viewpoint-1, however, don't always provide a learner useful information to correct her/his error, and sometimes mislead her/him. This comes from the lack of consideration of the problem-solving process. Therefore, our recent researches are paying more attention to the viewpoint-2 for managing EBS.

Apparently, the problem solver which can construct the correct equation is necessary. (It means the Function-2 in chapter 2.) We developed it by modelling the formulation process of equation in mechanics. The model
The intelligent adviser will adjust these modules and user interface (which should be also modularized). The one plate. This modular model allows the system designer to utilize the existing tools and simulators of each domain.

4. Framework for Discovery Learning Environment and Concluding Remarks

The functions which are required for intelligent assistance in discovery learning environment were discussed. They are: the problem solver for discovery task, the problem solver for formulation task, the flexible simulator, and the evaluator of the simulations' effectiveness. (The last needs some criteria for evaluation.)

The identified cause of error must be visualized and suggested by EBS. The last set of rules we need is the one which describes what kind of motion in EBS suggests what kind of misconception in problem solving. The fundamental idea is quite simple. When a human observes an object moving, she/he feels its 'motive force' working. We apply this fact to the difference of motion. For example, assume that a learner observes a block moving to the left with deceleration when she/he predicted it moves to the left with acceleration. She/he will feel that the force which acts to the left is missing, or that the force which acts to the right is extra. The same thinking is possible about the relative motion of two objects. The rules are formulated as shown in Table 3 and 4. They are called Criteria for Cause-of-Error Visualization (CCEVs), which link the motion in EBS to the cause of error suggested.

For example, consider the problem in Figure 3. When a learner constructs the equation in Figure 3a (the direction of friction μN is erroneous), the 'unmodified' EBS becomes as shown in Figure 3b, in which the string shrinks. According to the CCEV in Table 4, however, this motion suggests the error about tension, which is not the cause of error. The EBS manager, therefore, searches the 'modification' which makes EBS suggest the real cause of error. It finds the perturbation of the mass of block m2 works well. When the mass m2 increases, the block's velocity increases according to the erroneous equation, while it decreases according to the correct equation. This satisfies the CCEV in Table 3, and such an EBS correctly suggests the error about friction μN (Figure 3c).

4. Framework for Discovery Learning Environment and Concluding Remarks

The functions which are required for intelligent assistance in discovery learning environment were discussed. They are: the problem solver for discovery task, the problem solver for formulation task, the flexible simulator, and the evaluator of the simulations' effectiveness. (The last needs some criteria for evaluation.)

The more 'intelligently' each function is designed, the more highly it depends on the learning domain. So, it is preferred modularizing them as independent components to designing them according to some common template. This modular model allows the system designer to utilize the existing tools and simulators of each domain. The intelligent adviser will adjust these modules and user interface (which should be also modularized). The one key issue is to abstract the variables each module uses for efficient interaction, and the other is to enrich the component libraries.

We are now developing the authoring system for intelligent discovery learning environment of such an architecture.

A Computer Tool for Writing Japanese as a Foreign Language

Chris Houser
Kinjo Gakuin University
Omori 2-1723 Moriyama-ku Nagoya 463-8521 Japan
chris@houser.cc

Abstract: Because few materials teach how to write in Japanese as a Foreign Language (JFL), students must write as much as possible, and learn largely by trial and error. But the complexity of the Japanese writing system, and the awkwardness of the method traditionally used to type Japanese, combine to make writing JFL truly daunting. This paper proposes a new method to write JFL. A computer program combines information from several bilingual dictionaries and creates a concise display showing the JFL student all they need to select quickly and easily from menus of Japanese homonyms and synonyms. Informal experiments suggest that this program helps JFL students to write accurately and with three times the speed of previous methods.

Background

Students of Japanese as a Foreign Language (JFL) are perhaps most challenged when they write Japanese. One reason is a lack of materials teaching writing. This is surprising: A stroll through any large bookstore in Japan finds dozens of texts and CDs; a web search finds hundreds of sites, all teaching JFL. But these materials concentrate on listening, speaking, and reading. Very little material addresses writing. Most students must learn to write by trial and error, so they need to write as much as possible.

A second reason JFL students are challenged when writing is that the Japanese themselves have difficulty typing Japanese. Again, this is surprising to Europeans, because European languages are relatively easily input. One need only spell a European word (on a keyboard) to type it:

Figure I: Typing English (left), Japanese (middle) and JFL (right)

In (Fig. 1) E denotes a European word; for concreteness, let's say an English word. Such a word can be entered into a Personal Computer (PC) by typing its spelling, and the typing is straightforward because all the needed characters are displayed on PC keyboards.

In contrast, to write in Japanese, one must be able to input some 6000 different characters. How can Japanese enter this wide range of characters using only the 100 or so keys on a keyboard? Indirectly: Japanese type pronouncing a word, and then the computer looks up the typed pronunciation in a dictionary, and displays the written characters. For example, typing shikou produces the characters shi, meaning thought.

The problem: homonyms. The pronunciation shikou is actually shared among several unrelated words. When a Japanese types shikou, the computer in fact finds multiple writings in its dictionary, and displays them in a menu. So a Japanese typist inputs a few letters, then examines the resulting menu, and picks the desired word (Fig. 1 Middle). This process seems laborious to Europeans. “Blind typing” is impossible, since Japanese must constantly attend to the computer screen.

For a student of JFL, unfamiliar with Japanese vocabulary, typing is even more complex (Fig. 1 Right). Of course, a computerized dictionary can accelerate the added first step, mapping English to equivalent Japanese words. But the third step, choosing among homonyms, can be especially difficult when the student can't recognize some of the menu entries. A typical homonym menu can bewilder

Previous Work

Of the various software that search dictionaries for Japanese homonyms, perhaps the most commonly used is NISAME 97 (Microsoft 1997), which Microsoft distributes with recent versions of Windows and Office. This program includes definitions of some of the homonyms as an aid to choosing the sought word. But these are of little help to JFL students, because (1) only a small fraction of the homonyms have definitions, and (2) the definitions themselves are written in Japanese and so are not easily understood by JFL students.
Bi-lingual dictionary software (MindDate 2001, Basis 2000) and web sites (Altavista 2001, Breen 2001, Rudick 2001) translate single words and noun groups between English and Japanese. While more convenient than paper dictionaries, these are all quite awkward to use while writing. Typically, a student need first look up an English word, finding several Japanese entries in an English-Japanese (E2J) dictionary. For example, "thought" has 92 entries in WWWJDICT (Breen 2001). Then, in order to choose the most appropriate of these entries, the student must look up each entry in a J2E dictionary to confirm their (English) meaning. Some of those 92 entries turn out to be only tangentially related: one translates back into English as "false science; science out of line with the world of thought." Such blind-alley dictionary searching can be tedious.

Text editors designed for JFL writing (Rosenthal 1999, NJStar 2000) include similar bilingual dictionary software, but are no more convenient than standalone and web dictionaries. Students need a new alternative, one that collects information from various dictionaries and presents it in an easily understood form.

A Tool for Writing JFL

This paper proposes a computer tool called Writing JFL, a tool that combines the data from multiple bilingual dictionaries and then concisely displays all the information JFL learner needs to correctly type Japanese. For example, when a student knows the Japanese pronunciation, but not necessarily the writing of a word, she can type the pronunciation and then, as usual, choose from a list of homonyms sharing that pronunciation. What is unusual is that the homonyms are presented along with their (English) definitions, taken from a J2E dictionary (Fig. 2 Left):

```
Shikou (waiting upon (someone) (vs)
志向 intention; aim
思考 thought
指向上 (object oriented); directional (microphone)
執行 execution (vs); giving alms; carrying out
高級 supreme; supremacy
試行 making an attempt (vs)
延命 tooth tartar
```

```
考えんかんかえる to consider.
思考 shikou thought; idea
思考 thought; thinking; thought; ideas; intention
思考 shikou thought
熟考じゅっこう careful consideration; deliberation
見解けんかい opinions; point of view
意見けんかい opinions; view
```

Figure 2: Screens in Writing JFL. Left: Written forms for typed Japanese reading. Right: Translations of typed English word.

Selecting from this menu is easy even for JFL students. [The (vs) notation indicates a specific verbal usage, giving further clues to the words' nuances and grammar.]

As another example, when a student can't recall even the Japanese pronunciation, she can type an English word, and see a menu of (nearly) equivalent Japanese words (Fig. 2 Right). Each Japanese word is presented with its Japanese pronunciation and English definition. For the JFL student, this display tells them everything they need to choose between these near synonyms. It is a natural display. Yet no prior software created such a display. The key point is that this display is generated by first looking up the given English word in an E2J dictionary, and then looking up each of the resulting Japanese entries in a J2E dictionary, to confirm its English meaning. This program simply automates the manual strategy JFL students have long used with computer and even paper dictionaries. At it results in a radical change in the way JFL texts are input (Fig. 3):

```
E dictionaries pick
```

Figure 3: Writing JFL.

We implemented this program, using EDICT (Breen 2000) as our J2E dictionary, and GENE95 (Kurumi 1995) as our E2J dictionary. Informal trials with three adult JFL students suggest that this program allows students to write accurate Japanese three times faster than with prior methods. When compared with previous tools for JFL writing, this system was preferred unanimously.

Abstract: Rapid technological development in the last decade makes it easier than ever to use technologies as collaborative learning tools. Computer video conferencing as a computer-supported collaborative learning (CSCL) technology brings learners closer to real-world environments and it provides increasing opportunities for learners to share experiences across time and space. This paper reports on how multipoint desktop video conferencing (MDVC) is used in preservice teacher education programs in Singapore. Our summative research findings reveal that student teachers reacted positively to the scaffolding provided by peers and supervisors via video conferencing. MDVC apparently opened up a new avenue for collegial learning, and student teachers do not have to rely only on the expertise found in their own schools.

Introduction

During the evolution of computer-supported collaborative learning technologies, researchers have increasingly embraced Vygotsky's sociocultural theory (Vygotsky, 1986) in evaluating and understanding electronic learning environments (Bonk & Cunningham, 1998). Vygotsky's sociocultural theory postulates that individual mental functioning is inherently situated in social interactional, cultural, institutional and historical contexts, and learning occurs through social interactions with peers, mentors and experts. Researchers holding sociocultural views have begun to concentrate their investigations on the role of social interactions and dialogues, scaffold instructions and collaboration in computer conferencing environments (Iseke-Barnes, 1996). Focuses are shifting from discussions on tool features and procedures to the theoretical rationale or justification for using technologies, and to studies on how technologies can augment and redefine the academic learning environment (Koschmann, Myers, Feltovich & Barrows, 1994).

Reflective practice is a widely accepted concept in teacher education. It is generally agreed that active and critical examination of one's thoughts and teaching will help one to make sense of the complexities of teaching and improve one's teaching. Reflection as defined by Dewey (1933) is "turning a subject over in the mind and giving it serious and consecutive consideration," and it enables us "to act in a deliberate and intentional fashion". Schon (1983) developed Dewey's concept of reflection by emphasizing the context and time in which reflection takes place. According to him, reflection may be "reflection on action" and "reflection in action". "Reflection on action" refers to the thinking about the lesson before as well as after the lesson. "Reflection in action" refers to the thinking that occurs during the act of teaching. The assumption is that by thinking about our actions and reactions as we are teaching we can improve our teaching. Loughran (1997) developed a conceptual framework that may help preservice teachers reframe their experiences. Reflection may take place in three stages, (1) during the
Reflection is an essential component for bringing understanding to the complex nature of classrooms (Zeichner & Liston, 1996). As suggested by various researchers (Richardson, 1989; Schon, 1983; Zeichner & Liston, 1987), reflection should not take place in isolation, rather teachers should constantly strive to make sense of their practice and the student learning with other teachers. This paper reports on how multipoint desktop video conferencing (MDVC) is used to facilitate reflective practice of student teachers during their teaching practice. Learning theorists claim that when learning is situated in meaningful contexts requiring collaborative processing, learners tend to remember the information better (Brown, 1989; Cognition and Technology Group at Vanderbilt, 1991). We hope to find unique opportunities in MDVC for student teachers to share ideas, experiences and teaching resources in real time with an audience wider than the schools where they teach.

Launch of the Teaching Practice Discourse and Computer Communications Technology Project

The Teaching Practice Discourse and Computer Communications Technology Project of National Institute of Education, Singapore, is a project funded by the Ministry of Education of Singapore, and it was launched in May 1999. The project builds on a previous research effort that investigates the discourses between student teachers and their university supervisors (Sharpe, et al., 1994). The early research found that there was a preponderance of low-level factual discourse in student teacher-supervisor conferences, and that conferences were relatively short. It concluded that ways and means needed to be found to increase both the quantity and quality of student teachers and supervisor discourse.

The appearance of multipoint desktop video conferencing (MDVC) technology brings hope that this new communication technology may help to break down barriers of time and space that prevent the quantity and quality of professional sharing. Desktop video conferencing allows users at different locations to see and hear each other using ordinary desktop computers fitted with cameras, microphones, speakers and necessary hardware and software. Desktop video conferencing may be point-to-point, meaning persons talking to each other from two separate desktop computers, and it may be multi-point, that is several persons conference from several desktop computers. For the purpose of our project, we needed a system that could link student teachers across schools and the choice had to be multi-point.

Fortunately, by the time our project was initiated, all the Singapore schools had been provided with Asynchronous Digital Subscriber Line (ADSL) gateway access into SingaporeONE, an ATM network suitable for Wideband Internet applications. SingaporeONE offers low cost user access into a system already designed to distribute video-on-demand (VOD) multimedia services and with sufficient bandwidth capable of hosting a multi-channel MDVC server. The project takes advantage of the existing infrastructure in the schools and uses CU-SeeMe for video conferencing.

The First Phase of the Project (May 1999 – May 2000)

During the first phase of the project, we concentrated on exploring the feasibility of using MDVC for student teachers to have real time discussion. Student teachers doing teaching practice in different schools used MDVC to conference with their peers in other schools and their university supervisors (Sharp, et. al., 2000). Conferences were carried out on a weekly basis among student teachers and their university supervisors. Each conference group consisted of up to five student teachers from different schools and one supervisor. The participants shared ideas and experiences on aspects of their teaching with their peers and their university supervisors in real time.

Three cohorts of 59 student teachers used MDVC during the first phase. Summative evaluations showed that MDVC benefited the users in a number of ways. First, it provided an avenue for student teachers to share ideas, problems and solutions. It enabled them to discuss any matters relating to their teaching practice at the time needed and to receive immediate feedback from peers and supervisors. This is particularly important when student teachers experience varying degrees of isolation from their university supervisors and peers. MDVC also provided a channel for student teachers to obtain peer support and encouragement so that there was a reduction in stress for some of them. More importantly,
MDVC broke down communication barriers between student teachers and supervisors. As a result, they felt more comfortable to share ideas and discuss problems with their supervisors.

Student teachers reacted positively to scaffolding provided by peers and supervisors via MDVC. It appears that MDVC opens up a new avenue for collegial learning, and student teachers do not have to rely only on the expertise found in their own schools. Peer and mentor support helps to reduce student teachers' frustration and isolation. It stimulates more interchanges among peer learners and between learners and supervisors. There was a definite feeling amongst all the participating student teachers that they knew each other and the university supervisor much better than they would otherwise. As a student teacher put it, "I look forward to MDVC sessions because I know I will get encouragement and support from fellow trainees and the lecturer chairing the session". It appeared that MDVC actually enhanced trust, perhaps, by a process of decontextualizing conferencing by providing an alternative social frame (Goffman, 1974).

The Second Phase of the Project (July 2000 - present)

During the second phase of the project, we explored the possibilities of using video streaming in MDVC. During the seven-week teaching practice (3 July to 25 August 2000), 28 student teachers were each allocated one of the three teaching competencies for video taping: (1) lesson introduction, (2) questioning and explaining, and (3) small group teaching. A checklist covering a number of teaching behaviors associated with each competency was provided to help student teachers in planning and was explained in detail by one of the researchers. Of the four weeks MDVC, three were used to cover each of the three competencies and one was used for overall reflection.

All the schools involved were provided with a digital video camera, tripod and digital video capture card. Six of these cameras were able to record digital video to tape whilst simultaneously capturing digital still photographs to a memory card, while the other two captured directly to a memory card in MPEG1 format. Both allowed uploading of digital video to a PC and subsequent transfer to the university by the File Transfer Protocol (FTP) method in either MPEG1 or AVI digital video format. Both the school technical assistants and student teachers were trained in how to use the cameras and tripods, the capture cards and FTP. They were also shown where to position the camera in the classroom.

Each student teacher arranged with a fellow trainee or their school’s technical assistant to make one three-minute digital video clip of their classroom teaching using the digital video camera. They were allowed to re-shoot the video if they were unhappy with it. The video clips were then transferred electronically by the school technical assistants to the university using the File Transfer Protocol (FTP). At the university, the video clips were edited and placed in a password-protected area of the project WebPage. Video streaming was chosen over conventional file downloading mainly for the reason of confidentiality. Using video streaming meant that no permanent file would be left on the school computers and no video streams may be copied. The school technical assistants were instructed to delete the clips from their own hard disks once they had been transferred to the university.

The student teachers were instructed to view the video clips prior to the scheduled MDVC conference the following day. At one of the conferences, however, the supervisor chairing the session found that four out of five student teachers had not watched the clips for various reasons. The student teachers were then instructed to leave the conference and to return in 20 minutes after viewing the video clips. This unexpected situation turned out to be helpful for us in understanding the feasibility for such a use of technology. All the student teachers reported easy downloading and convenience of viewing the video clips. It took only around one minute to download one three-minute video clip. They responded extremely positively towards such a new experience and welcomed the opportunities provided in sharing of their peers’ teaching using the learning environment of MDVC and the Web.

As we were able to stream videos successfully both before and during the MDVC sessions, most student teachers watched video clips of participants in their own group, and some managed to watch clips from other groups (Figure 1). In addition, we tried to incorporate in the Whiteboard in the MDVC sessions. The student teachers were asked to take at least one still video photograph per week of aspects of their school, including their pupils' work and one of the MDVC conferences was devoted to the sharing of these photographs, using the application sharing feature of the CU-SeeMe.
Despite the technical problems encountered initially, the feedback collected so far was generally positive. The student teachers appreciated the opportunities of sharing ideas with their peers. Typical comments were “Eager to hear from what other trainees have to comment on my teaching”. “Informative, reflective, corrective”. “Received positive comments that build up my confidence”. “Peers normally give very non-threatening and constructive feedback. It’s very comforting”. However, a few student teachers felt that there was not enough critical comments, for example: “full of praise, good but doesn’t help me improve on my bad points as some comments are withheld”. All indicated that it was a good learning experience and most would probably agree with the student who commented that it was a “good learning experience; helps in better and more critical analysis development”.

Viewing their own teaching clips obviously facilitated the student teachers to reflect. As one student teacher put it, “it was definitely beneficial as I was able to evaluate and reflect on how I could improve myself”. Another one said it was “helpful in pinpointing my own mistakes”. Still another one could actually see how I teach and learn the mistakes that I made”.

From February 2001, we entered the final stage of Phase Two. While continuing to video stream in videoconferences, we incorporated the facility of file sharing of CU-SeeMe (Whiteboard) in our conferences. We shared lesson plans and web pages during the conferences. We intend to conduct in-depth analysis at the completion of this cohort’s teaching practice. Such analysis will help us learn as much as possible about its pedagogic value and the kinds of administrative support required (Winn & Jackson, 1999).

Discussion

Our experience has demonstrated that it is technically feasible to use multipoint desktop video conferencing to facilitate student teachers’ reflective practice and it is possible to combine multipoint desktop video conferencing with digital video streaming. Although we have not experienced one hundred percent reliability, we can predict that such reliability is not too far away.

MDVC helped create a platform for the kind of ‘reflective practicum’ propounded by Schon (1987) and later refined by Darling-Hammond (1994). The student teachers were provided with opportunities to “learn by teaching, learn by doing and learn through collaboration” (Darling-Hammond, 1994). The MDVC enabled our student teachers to take part in a ‘distributive community of practice’ with participants who shared a common concern of learning how to teach. By participating in videoconferences, student teachers were provided with opportunities to participate in reflective conversations with their university supervisors and peers.

Our summative evaluations to date show that MDVC benefits the users in a number of ways. In our student teachers’ opinion, a major advantage of MDVC over face-to-face conferences is that MDVC reduces the “physical barriers” and it makes it easier “to bring up issues because you feel a safety in distance”. It appears that MDVC represents a less formal medium compared to the formally arranged face-to-face supervisor visits. MDVC provides an avenue for student teachers to share ideas, problems and solutions. It enables them to discuss any matters relating to their teaching practice at the time needed and to receive immediate feedback from peers and supervisors. This is particularly important when
student teachers experience varying degrees of isolation from their university supervisors and peers. MDVC also provides a channel for them to obtain peer support and encouragement so that there is a reduction in stress for some of them. As a result, they feel more comfortable to share ideas and discuss problems with their supervisors. Timely feedback, questions, and reconceptualizations from both supervisors and peers further fueled these learning activities because of the relevance of the discussions to teaching.

But did the platform and the opportunities that it provided actually result in improvements in discourse and reflectivity? At this stage, we only have feedback from the student participants and our own experiences to go by, although we intend to collect a range of ‘harder’ evidence during the main study which began in late February 2001. It is clear from the feedback that the student teachers felt that watching themselves and their peers teach and being able to discuss this had been beneficial. As chairpersons, we thought we detected a growing confidence and willingness to join in discussions as the weeks went by. All participants joined in the discussions and there was never a shortage of anecdotes and ideas to share. We felt that the shyness and unwillingness to criticize that some of the participants noted was more a feature of the earlier conferences. In our judgement, it was due in part to the student teachers never before having had to engage in professional discussion of each other’s teaching. As a result they lacked the requisite critical and justificatory discourse skills. The video clips and conferences provided them with practice in this important professional skill but, we feel, that we still have a great deal to learn in this respect.

Abstract: This paper presents the Finnish information strategy for education and research 2000-2004 and the principles for its implementation in Finnish educational institutions. The paper concentrates on describing national projects for building virtual learning environments for students from primary schools to higher education. Also the Finnish strategy for teachers' in-service training is presented. The ministry of education requires that all educational institutions devise their own information strategies, depicting their vision for the use of ICT in education and steps taken to implement the vision. This is a key factor for the successful development of ICT use in education and for building virtual learning environments.

Introduction

The first national information strategy in Finland steered the national information society development from 1995 to 1999. In spring 1999 the Finnish Ministry of Education put in place the next information strategy for years 2000-2004, along with an organization for implementing the strategy (Table 1). The basis for this national strategy was an extensive evaluation of the use of ICT in education in Finland. The evaluation covered all levels of education, from kindergartens to elderly people (Sinko & Lehtinen, 1999).

Table 1. The organization for implementing the Finnish information strategy in the field of education and research.

The government has annually earmarked about €45.5 million for the implementation of this information strategy. Local authorities and municipalities are also investing in the implementation of the strategy because they share the responsibility for funding the educational system.

The nine projects listed in Table 1 have been set up to implement the strategy. The focus in this paper is on four of these projects, namely the training of teaching staff, virtual school, virtual polytechnic and virtual university.

Descriptions of all the projects can be found in the Ministry of Education publications: "Education, Training and Research in Information Society, a National Strategy for 2000-2004" (1999) and "Information Strategy for Education and Research, 2000-2004 Implementation Plan" (2000). This paper is largely based on these publications but information has been updated concerning recent work carried out in the projects.
Training of Teaching Personnel - OPE.FI

From the perspective of equal opportunity, teachers are the key to the implementation of our national strategy for education, since their skills in and attitudes towards using ICT in education influence the possibilities of youngsters and adult learners to become familiar with technology as a part of their studies.

Developing ICT uses in educational institutions requires an accepted, shared vision and understanding of the role and uses of educational technology. One central aim in this subproject is to encourage all institutions, from primary to higher education, to develop their own strategies for using ICT in education. As a part of this process, the curriculum should be evaluated and updated to meet the requirements of the information society. All educational institutions should devise their strategies by the end of 2002. The teacher training departments in universities are required to formulate their information strategies even earlier, by the end of 2001.

The teacher training project has developed a three-step model for providing teachers with the necessary skills, as well as for estimating the need for teachers' in-service courses (content, duration, the number of teachers to be trained). The three-step model has been designed to be independent of the level of education at which the teachers work (Table 2). The model has been developed by a group of experts on teacher training and on the educational use of ICT, and it is based on our experience that the first step towards developing professional skills in the educational use of ICT is to acquire some technical skills. After the teachers feel relatively comfortable with the technology, more emphasis can be put on new notions of learning and teaching.

Table 2. The three-step training model of Finnish teachers (adopted from Koli and Kylämä, 2000)

The aim is that the first step (basic skills) is organized and funded by teachers' employers and the next two steps are funded by the government and organized by the continuing professional education centers at Finnish universities. The training is organized in ICT and web-based learning environments. The emphasis in training is on teacher teams and school communities, not individual teachers. By this we want to encourage cooperation between teachers and a new kind of working culture in schools.

The teachers' in-service training process based on the three-step OPE.FI model should be completed by the end of 2004. In 2001 and 2002 special emphasis will be put on assisting the information strategy processes, and the teacher teams will also develop these strategies as a part of their training.
Virtual School

The virtual school develops new solutions which guarantee flexibility, equality and diversity in education and training in primary, secondary, upper-secondary and vocational schools. The virtual school project is co-coordinated by the National Board of Education. The aim is to develop and provide learning materials and courses of high pedagogical quality. In addition to opportunities for distance education, the virtual school offers materials for use in classroom settings. Distance education courses are being developed especially for upper secondary and vocational schools.

The core of the virtual school is its own user interface, portal. The portal offers study modules, courses and other learning materials, as well as tools for communication, networking and tutoring. The portal is also used to disseminate good practices. The portal is developed as a tool for both students and teachers. One important aspect in the development of portal services has been to assist schools in devising their information strategies. The National Board of Education has also published a book and several articles in educational journals to support the strategy processes. Educational authorities, training providers and schools are developing the educational portal; some services are being developed regionally. The private sector can join in the development work, especially the production of learning materials.

Schools are also supported financially in the acquisition of hardware and software and in the creation of networks. Schools can get funding from the National Board of Education only if they have a strategy for the use of ICT in education. The technical situation in educational institutions is presented in Table 1 (Networking in Finnish schools 1996-1999). According to the preliminary results of a survey made in September 2000, which has not yet been published, the percentage has reached 100 % at all levels.

Table 3. Internet connections and number of pupils/PC in Finnish schools (year 1999)

The aim is that by year 2005 every school has an information strategy, every teacher uses the educational portal and new forms of co-operation exist between the private and public sectors.

Virtual Higher Education

In Finland polytechnics and universities provide higher education. Polytechnics offer professional education (degree programs of 3.5 - 4 years). The polytechnics were established in 1991. There are 29 polytechnics and 20 universities in Finland. There are two projects for developing virtual learning environments in higher education: the virtual polytechnic and the virtual university. Even though separate project groups carry out these projects, they share many features, and are therefore presented together here.

The Finnish virtual university and polytechnic are based on existing educational institutions: students have to be enrolled in one of the regular universities or polytechnics if they aim at a degree. The virtual higher education projects do, however, accommodate the lifelong learning perspective in the form of a virtual open university and polytechnic and continuing professional education.

All Finnish universities have joined in the virtual university consortium and agreed to develop virtual learning environments for their students. Similarly, all polytechnics are participating in the virtual polytechnic project. The Ministry of Education funds a development unit for both projects.
Our aim is that by the end of year 2004 there will be a virtual university and a virtual polytechnic offering high quality education, also internationally. The virtual university and polytechnic are being built on a network in which universities, polytechnics, companies and research institutes are jointly developing virtual learning environments. This co-operation will diversify teaching and strengthen research networks. The emphasis is on the educational use of technology in teaching and learning and a combination of face-to-face teaching and distance learning assignments. The Finnish virtual university and polytechnic are not based purely on distance education. Therefore the emphasis is not only on producing digital learning materials for use in a distance education setting but also on strengthening teachers' capability to plan learning processes which take partly place in a web-based environment.

Figure 1. Areas of development in virtual higher education

The funding of the virtual university started in January 2001. The scope of development is presented in Figure 3. The Ministry of Education finances the development of virtual courses, supportive services and course development in each university. It also funds several co-operative projects between universities, including a network for all Finnish open universities and some regional networks between universities. There are also networks in different subject areas: educational sciences, law, psychology, social sciences, literature, cognitive sciences, communication studies, studies in futures research, music, mathematics, chemistry, computer sciences etc. The virtual polytechnic is also planning to set up content development networks in several areas.

There are also a number of projects in support of virtual university development, such as a project for planning, guiding and assessing studies in the virtual university, a national program for training university teachers in educational use of ICT (according to the OPE.FI model) and a network for educational technology units in all universities. The information strategy process in universities and polytechnics is supported and encouraged to contribute to long-term planning and to determining development priorities. Building the virtual university and polytechnic is not only a technical question but above all a pedagogical one. Therefore both projects are strongly networked at all levels to enhance the exchange of good educational practices.

Both the virtual university and the virtual polytechnic are building an educational portal. Some of the services required can be developed jointly. The virtual polytechnic project aims at having their portal in operation by the end of 2001. By the end of 2002 each student will have studied at least one course on-line and by the end of 2005 at least one student will have graduated with a virtual degree.

Co-operation required

Developing virtual learning environments for educational system as a whole also requires solving some common issues together. The standardization of educational technology and copyright issues are considered the most urgent
areas of cooperation between the three virtual learning environments. We have started a standardization process with a view to compatible technologies and tools. The process is open to all parties interested in developing compatible solutions. We also hope that the standardization process will be a good starting point for co-operation and networking between the private and public actors.

Copyright issues are also being addressed with a view to sharing model contracts in projects developing content for virtual learning environments by the end of 2001.

The Development of On-line Educational Institutes: Malaysian Secondary School Experience

Hanafizan Hussain, Multimedia Univ., Malaysia; Zarina Abdul Rahman, Universiti Tenaga Nasional, Malaysia; Jamilin Jais, Universiti Tenaga Nasional, Malaysia; Kalaichelvan G. M. Kannan, Universiti Putra Malaysia, Malaysia

The development of an open learning environment that can deliver education and training anytime, anywhere, is now not only feasible but also achievable. Using current and emerging information and communication technologies it is now possible to build the fully on-line institute even in schools. This is further boosted by the introduction of Multimedia Super Corridor - Smart School flagship in Malaysia. This study will attempt to describe both technological solutions and an organizational culture capable of supporting such an educational institute to embrace change and proliferate in an information age. This study asks questions of, if technology is the key to participating in the Information age, what and how much technology is required and will be investigated. It has been suggested that the appropriate cultural climate; information and knowledge systems in a flexible format; and an Interactive Learning System capable of delivery are three key elements that will constitute the on-line institute.
Retrieval System of On-Line Kanji Dictionary with Learning Functions

Koji Iida, Waseda, Japan; Kazuto Yamada, Waseda, Japan; Shinichi Fujita, Waseda, Japan; Seinosuke Narita, Waseda, Japan

In this paper, the authors have attempted to develop a useful system in retrieving Kanji. It will be terribly difficult for non-Japanese people to master Kanji because Kanji characters are over 2000 and their shapes have much complexity. Especially it will be hard to retrieve Kanji with a conventional dictionary. Even if the user does not know any of Reading, the total number of Strokes, Radical, this system allows people to look up Kanji characters easily by only selecting its simple peculiarity like the number of vertical lines, a number of horizontal lines and four parameters. This system works effectively by just only mouse click when someone encounters an unfamiliar Kanji character. This system consists of the client and the server. The database of this system is updated when the user retrieves a certain Kanji. For that update, this on-line dictionary will become more useful.
Childrens' Attitude toward Internet

Takashi Ikuta, Niigata University, Japan; Toshiyuki Kihara, Osaka City University, Japan

The purpose of this study is to clarify the characteristics of the attitude towards the Internet with the comparison of an attitude toward the old medium. We use the picture-projection technique to measure attitudes toward media, that is, watching a movie, reading a newspaper, reading a comic book, reading a book, watching TV at home, talking with friends and using multimedia and the Internet. Two schools children, one used to the Internet and the other who has not used computers, were used as subjects. Forty-five short sentences describing a communication situation were prepared, and children were asked to match these sentences to the pictures. The results show significant differences of attitude toward the Internet between two schools children. We find characteristics of the attitude toward the Internet is the possibility and awareness of the expansion of communication, on all-powerful feeling and the feeling of necessity.
A Survey of Current Computer Skill Standards and Implications for Teacher Education

Abstract: Many national and provincial initiatives are underway to specify the technology skills that students must demonstrate at each grade level. The Government of the Province of Alberta in Canada has mandated the implementation of a new curriculum beginning in September 2000 called the Information and Communication Technology Program of Studies. This curriculum is infused within core courses and specifies what students are "expected to know, be able to do, and be like with respect to technology" (Alberta Learning, 2000). Since teachers are required to implement this new curriculum, school jurisdictions are turning to professional development strategies and hiring standards to meet this goal. This paper summarizes the results of a telephone survey administered to all public school jurisdictions in the Province of Alberta with a 100% response rate. We examined the computer skills that school jurisdictions require of newly hired and currently employed teachers and discuss the implications of standards.

Background

Various government authorities have recognized that Information and Communications Technology (ICT) has a major impact on our economy. The Alberta Science and Research Authority (1998) acknowledges that ICT is "the world's strongest, fastest growing economic sector" and the Government of Canada (2000) recognizes that "Canada can benefit by becoming a world leader in the development and use of advanced information and communications technologies." Furthermore, the U.S. Department of Education (2000) has realized that technology is transforming the American economy. As a result, these authorities are pursuing initiatives to incorporate technology into K-12 schools not only to prepare students for this new economy, but also because they see the "potential for technology to transform the teaching and learning experience" (U.S. Department of Education).

One initiative making an impact in the K-12 school system in Alberta is the integration of technology into the classroom. Beginning in September of 2000, Alberta Learning has mandated a new curriculum called the Information and Communication Technology (ICT) Program of Studies, which is to be infused within core courses and specifies what students are "expected to know, be able to do, and be like with respect to technology" (Alberta Learning, 2000). Since trained teachers are required to carry out this new curriculum, school administrators are turning to professional development strategies and hiring standards are being revised to meet this goal. This study examines the computer skill requirements of newly hired teachers reports any plans by school jurisdictions to implement changes in policy.
The Study

Purpose

The developments in technology over the past few years have influenced expectations by governments, school jurisdictions, teachers, parents, and students. Schools are being asked to prepare students to use technology in the 21st century. Since teachers are vital to an integration plan, they have been under pressure to learn and incorporate technology skills into their teaching. The purpose of this study is to become familiar with the current status of computer skills required for teachers being hired by school jurisdictions in Alberta, so the Faculty of Education at the University of Alberta can try to improve the match between the needed skills identified by the respondents of this study and the curriculum being offered. Whether school jurisdictions planned to change their computing skill requirements in the immediate future is investigated including what those changes might be.

Method

In January 2000, a letter explaining the purpose of the study was sent to the superintendents of each of the public, separate, and francophone school jurisdictions in Alberta with an attached interview guide. The superintendents were asked to nominate an appropriate person for participation in a 10-minute telephone interview. The designated respondents were then sent a copy of the contact letter along with the interview guide to provide them with an opportunity to review and prepare their responses. From February to April, participants were contacted by telephone to obtain informed consent for their voluntary participation in the structured telephone interview. A 100% response rate was obtained from the 60 representatives, one from each school jurisdiction. They included 17 superintendents, 22 assistant superintendents, 12 technology coordinators, 5 human resources representatives, and 4 other individuals who were nominated by the superintendent.

Limitations

Two limitations were identified during the study. First, participants’ interpretation of requirements differed. While some considered only written policy to be a requirement, others had definitions of requirements that consisted of only expectations. To address this issue, the categories, “no, but expected” and “no, but ask in interview” were included in the coding of responses. The second limitation involved the sample of participants. Because participants differed in job position, they are likely to have different perspectives on hiring policy and/or different degrees of familiarity with applicant profiles. Furthermore, participants are likely to have different degrees of experience with technology, which would influence their interpretation of technology preparedness. No correction, however, could be made for this limitation.

Findings

Current Computer Skill Requirements for Newly Hired Teachers

The respondents were asked whether their jurisdiction had mandatory computer skill requirements for newly hired teachers. Seven respondents indicated that they did have such requirements, but three of these said they were minimal. One respondent stated: “Well, it’s kind of an odd situation. We do have – we would have requirements. Unfortunately, they don’t come with them, and so we have to hire and then train on their own. Many of them don’t come with it.” The other 53 respondents indicated that their jurisdiction did not require computer skills from their newly hired teachers. Of these respondents, 20 reported that while computer skills were not required, prospective teachers were asked if they had these skills during the interview. One respondent best summarized this: “We do, however, ask questions with regard to their level of competency in dealing with technology, and it is more or less a subjective as opposed to objective list of criteria.” Twenty-two respondents indicated that while computer skills were not required, they were expected and were seen as an important asset. One typical respondent in this group said: “I think there is a general level of expectation related to that. For example, we would not place advertisement in any Alberta newspaper for a teaching vacancy that did not include some reference to our need to hire people with these skills.” While it is important to note that the vast majority of respondents indicated that computer skills were viewed as very important, a few indicated that other skills and knowledge were more important than computer skills. One such respondent stated: “With an elementary generalist, computer skills is not a requirement and it would not be
the decision-maker as to whether we hire or not. There would be many other things that would be more important to us in that hiring decision."

**Expected Changes in Computer Skill Requirements for Newly Hired Teachers**

We asked the respondents, who indicated their jurisdiction did not require computer skills from prospective teachers, whether their jurisdiction planned on introducing such a requirement. While five respondents said their school jurisdiction planned to implement such requirements, one did not know if they were being pursued and 28 responded that there were no plans to employ requirements. The jurisdictions that planned to introduce requirements were not at a stage where they could describe their proposal, but one respondent summarized the general tone that they were going to "step up the volume, so to speak," in what they would require from new teachers and computer skill requirements. The respondents, who said there were no plans for requirements, raised specific issues about requirements. These issues are well represented by the following quotations: 1) "The only time we would ask for specific skills with regard to technology would be when we're looking for teachers who are going to be teaching in the CTS area - especially in that area," 2) "I think the question that our board is asking is - the resources that we put into technology - are they making a difference for student learning?" and 3) "I still believe strongly that give me a teacher with a good attitude and I can teach them the rest, so no, I would not choose a candidate who has high computer skills over a candidate who demonstrates a very positive attitude."

Nineteen respondents indicated that they would like to implement such standards, but identified some reason why they could not do so. The majority of these respondents indicated they would experience trouble finding applicants with these skills:

"We'd like to [implement requirements]. It would be pretty darn hard to do so. ... I'll tell you, though, that if we have got an applicant who has got that kind of knowledge - that instructional knowledge in how to use multimedia tools and such - digital cameras, scanners, you name it - they would certainly have a definite edge in employment over anyone else. At this stage, we could not require that, and, you know, demand a certificate, for example, or even coursework in that area, because we certainly wouldn't get the applicants."

Another respondent, however, felt applicants met their expectations: "In general, we are finding that the majority of teachers coming to us now have the skills we need in terms of basic computer use and are comfortable with it." In this case, the respondent indicated that her/his jurisdiction was interested in basic skills such as being able to use e-mail and word processing.

**What Kinds of Computer Skills are Required or Expected?**

We asked the respondents to identify what kinds of computer skills they required or expected their teachers to have. Fifty-five of the 60 respondents answered this question and each respondent could give multiple answers. Of the 55 respondents, 50 identified "basic skills" as required. Basic skills were generally defined as being able to utilize word processors, spreadsheets, databases, presentation software, and the Internet. Twenty-eight respondents indicated that knowledge of technology integration into the curriculum was also required and five identified subject-specific skills. One respondent described the challenge in specifying skills: "I guess part of the difficulty is you are trying to draw a line in the sand in the middle of a sandstorm because the line is going to keep moving."

The issue of what kind of computer skills teachers should have was one of the areas that created the most divergence in answers. All 28 of the respondents, who included technology integration in their list of skills, also indicated they understood that to do this their teachers would need a command of basic computer skills; however, 22 respondents did not indicate that their teachers needed more than basic computer skills. Many of those who said teachers needed to be able to integrate technology into the curriculum felt very strongly about this point. One respondent said, "we're really looking for people who can build this bridge between technological expertise and helping kids learn better, more effectively, more quickly than previously." Another respondent from a jurisdiction that requires computing skills outlined their teacher performance expectation that
"the teacher utilizes computer technology successfully to assist in the delivery, enrichment, remediation, and monitoring of student learning. This would include content presentation, delivery and research applications, enrichment and remediation where appropriate, word processing, information management and record keeping, and electronic network usage. The extent to which technology is utilized will vary depending on the age of the students and the availability of hardware and software."

The respondent went on to state that hardware and software were "very available" in that jurisdiction. A different respondent was quite specific that

"particularly for new people who are entering the field of teaching, I think it is not unrealistic to expect that they have complete familiarity with technology and are able to have a comfort level — certainly how they integrate it into the instructional process, I think is part of the training that they go through in university and in the actual experience that they receive in the schools, but I think they should have a general familiarity with operating systems, programs, etc., and should be comfortable with technology as opposed to afraid of it."

It must be noted that a few respondents were much less positive about the need for teachers to have computer skills. A statement from one respondent summarized this view: "My whole point is that the verdict is still out has technology really improved learning for students? ... We spent all this money and that on the technology, and do we really see better teaching and better learning that's going on? I don't know. I hope so."

Issues and Implications for Policy and Practice

A number of issues emerged from this study that have implications for both policy and practice. These issues will provide a foundation for future discussion about the implementation of standards and inform school administrators about the current state of hiring policy in the province of Alberta.

Preservice Teacher Education

Extent of Preparation

Several respondents suggested that it is not unrealistic to expect that universities should be graduating students who have "complete familiarity with technology and how to integrate it" within the curriculum. While this perception is shared among many of the respondents, there is a difference in opinion as to whether universities are fulfilling this role. The responses vary from the view that "many applicants do not come with requirements so we have to hire and train them" to those who believe "universities have skill requirements for graduates which are going to essentially allow us to put something down on paper saying this is what you need to teach here." Those respondents who were more critical of the extent to which universities prepared teachers to use technology indicated that the "courses being offered were not keying in on curriculum integration." Regardless of the expectation of the extent of technology preparation at universities, respondents often reported that "the more [graduates] have when they come, the less we have to train and the better we feel that they would be," and, furthermore, "it would save [jurisdictions] a fairly large cost in terms of professional development."

A few jurisdictions are taking advantage of student teachers and new teachers who are placed in the school. One respondent said "we have used student teachers on practicum to actually come out and act as peer tutors with some of our teachers to upgrade their technical skills," and another said, "of course, we expect [new teachers] to be [more skilled] and hopefully they are, so they are the ones who can turn around and help the older teachers." Not all respondents, however, were happy with the level of knowledge student teachers had with regard to integration of technology into the curriculum. One respondent summarized this concern, "we had student teachers out here and I talked about integration of technology into the curriculum and they said — they were on their last practicum — and they said 'we don't know anything about that.' I said, 'oh, that's interesting.' So, then I guess my thought is as superintendent is well, now we even have to train those coming out of university."
Hiring Standards

Written Policy vs. “De facto” Requirements

Any discussion of ICT curriculum and requirements for students must eventually lead to dialogue about the implementation of that curriculum with reference to requirements for teachers. Our study found that some school jurisdictions have their requirements for teachers written into public policy, whereas others instead held “de facto” requirements. In the latter case, although policy requirements were not implemented, there may still be implications for teachers who do not meet expectations. One respondent, who said computer skills are not required at this point in time, summarizes the de facto requirement: “What we’re trying to do is provide opportunities for the teachers to forcing the teachers to do so, but with the understanding that more and more administrators are looking for those skills, so if they don’t upgrade then their opportunity for placement or

Whether requirements are written in policy or not, it is important for school administrators to get “a clear sense of [their] own expectations for technology-using educators if [they] are to prepare future teachers for appropriate use of technology in their classrooms” (Gillingham & Topper, 1999). The benefit of using written policy to communicate those expectations would be the consistency of those requirements across a school jurisdiction. Most respondents made note that the hiring process is now site-based as opposed to centralized and the implementation and/or enforcement of requirements for teachers are often at the discretion of the principal. For example, one respondent asked, “Is there a sense of understanding that many of the inservice requirements and the hiring practices have moved to school sites?” Written policy would also communicate those expectations explicitly to universities offering teacher education programs, so that preservice teachers can be better prepared for their placements after graduation.

In contrast, the implementation of policy requirements may have a negative effect on the needs of the teachers learning technology. For example, schools may have different needs and obstacles to meeting requirements. One respondent summarized this point: “We looked at our own unique needs for our teachers ... So, I think any school that has technology, and all do, have different provisions for their teachers to access information and support.”

The Need for Standards

There is much debate about whether there should be standards for computer use for students and teachers. In Alberta, where this study was undertaken, the government has mandated the ICT Program of Studies for students. Almost universally, respondents acknowledged that this was one of the major reasons (in some cases, it was the only reason mentioned) for their jurisdiction introducing technology skill requirements or expectations for their teachers. No one complained that the ICT Program of Studies had been implemented. Some commented that the government had taken too long implementing these standards or had mismanaged their introduction:

“I would say the implementation of technology in the classroom would be the single most bungled educational initiative in Alberta if not the world over the last 20 years, and I think it’s only now we’re figuring out what this is really about. This can work for us and work well with enough resources if we continue to focus on the connection between technology and learning.”

Consensus seemed to be that standards for students had been mandated and their schools were complying. However, questions seemed to emerge around issue of teacher standards: Should all teachers have ICT skills? What level of skills was necessary? Should teachers learn how to integrate technology in their teaching? Should older teachers be “grandfathered” and only new teachers be required to meet certain standards? Without a mandated standard for teachers, jurisdictions are answering each of these questions differently.

Technology standards for teachers have been created (ISTE Accreditation and Standards Committee, 1996) and in areas like California (Swofford, 1999) standards have been mandated for new teachers only. It may be that the solution to many of the questions raised above may entail the mandatory implementation of standards in the province for both new and existing teachers.
Conclusion

The eventual success or failure of any computing initiative is shaped by the individual teacher (Collis, 1996). To preserve financial investments in technology infrastructure and to prepare students for the new economy of the 21st century, school administrators must look to teacher training and technology standards. Since administrators and teachers are entering new territory with respect to technology implementation, it became apparent that many respondents were eager to know what other school jurisdictions were doing with respect to professional development and hiring standards. This is evidenced by the 100% response rate that was obtained. Many participants provided additional supportive comments about the pursuit of research in this area. For example, one respondent said, “Well, may I say right off the top that I’m really pleased this is being done, because this is an area that you are taking this initiative.” Further research is recommended in this area to begin to address some of the specific themes and questions identified by this study.

Abstract: A human-centred approach to the use and development of computerised information systems (IS) is needed to complement the prevalent technocentric way of designing and utilising the applications of IS. The human-centred approach emphasises the need to understand the computer and the human being as an entity the design of which should be based on knowledge of human behaviour both during the development and the use of IS. This paper describes two interrelated studies in which the human-centred idea is concretised by examined the nature of university students’ argumentative e-mail discussions, and the IS designers’ conceptions of the human being in the context of information systems development.

Introduction

The change towards an information society has been effectively implemented throughout the industrialised world with the aid of information technology (IT) during the past decade. An information society can be defined as a global network built on IT. The nature and qualities of this network are conditioned to a great extent by the information systems (IS) which are developed to connect IT and human beings. An essential task in an information society is to develop technological innovations, applications of information technology, in particular (Webster 1995). Thus, while information systems pervade almost all aspects of human life, they also mediate and condition human action in many ways. In this new situation it is important to clarify how information systems are integrated to human action. The foci of research should, thus, be on both the use and development of information systems.

An essential task of information systems development (ISD) - a process consisting of requirements analysis, logical, physical, and program design, as well as implementation (Friedman & Cornford 1989, p. 178) - is to provide tools for human beings to exploit the technological infrastructure for various purposes. The process of ISD and its outcomes change human action in many ways. However, the focus in ISD has traditionally been on technological questions. Technocentrism and technological determinism are common ways of thinking within research in the field of IS (Jones 1991), and also flourish among IS professionals (Iomäki 1999). The importance of taking human characteristics into account in the development process has not been fully recognised (Kirby et. al 1995). The cognitive quality of information systems, for instance, has seldom been developed (Zucchermaglio 1993). In addition, current ISD lacks appropriate techniques for analysing human activity in certain contexts (Maguire & Graham 1998). It is evident that the properties of future information systems should meet, not only technical requirements, but also various kinds of human cognitive, emotional and social characteristics. In particular, human needs such as work satisfaction, self-efficacy, and need to learn should be paid attention to. For this reason, expertise concerning human characteristics and behaviour is necessary in information systems development.

Recent studies have shown that the use of contemporary information and communication systems has increased and enriched students’ interaction (Ruberg et. al 1996), and developed university students’ argumentation skills (Marttunen 1997). Thus, these new technologies are well-suited in higher education whose essential goal is to promote students’ higher-order thinking skills. However, not enough attention has been paid to the learning of students’ argumentation, and communication skills at any levels of education (Laurinen & Marttunen 1998).
This article describes two studies which are included in a larger project (User's Cognitive Resources evoking Technology project, UCRET) concerning human-centred use and development of information systems (see Isomäki et al. in press). The focus in these two studies is on both the use and development of information systems. One study clarifies learning and the nature of students' argumentative discussions in a networked environment. Another study clarifies information systems' professionals' conception of the human being. The unifying theme of these two studies is the constructivistic approach to human learning and knowledge construction.

Constructivist Theory

According to constructivist theory, learning is regarded as vigorous cognitive activity in which people interpret their observations and knowledge on the basis of their previous knowledge and experiences. Individual constructivism, which is to a large extent based on the thoughts of Immanuel Kant and Jean Piaget, regards learning as an individual process and pays attention especially to the description of the cognitive structures and mental models of an individual (Phillips 1997). Individual constructivists also stress the importance of individual students' sensory-motor and conceptual activity during the learning process (Cobb 1994). Socio-constructivism (Vygotsky 1982), in contrast, regards learning mainly as a social process which is mediated, in particular, by human language. Socio-constructivism stresses especially the social, interactive and collaborative processes of learning (see Tynjälä 1999). Learning occurs when individuals construct knowledge and understanding by engaging in social discussions and activities concerning shared problems and tasks (Driver et al. 1994).

From the pedagogical point of view it is essential in constructivism is that in the learning process the learner is seen as an active subject who constantly defines and shapes his/her learning environment, by finding, for example, new paths in learning materials. An essential idea in constructivism is also that the learner's previous knowledge forms the basis for new learning. This means that existing structures of knowledge are elaborated, completed, and re-structured by combining new information with previous knowledge structures (Resnick 1989). Constructivism also stresses the importance of the situation in which learning occurs since learning is regarded as contextually bound and culturally mediated in nature (Lave & Wenger 1991). Finally, constructivism stresses the importance of social interaction in the learning process. Interaction, for example, in a multimedia or e-mail-environment makes it possible for a group to build new knowledge through the efficient delivery of information, discussion, negotiation, and argumentation.

Jonassen et al. (1993) emphasise that information technology and open learning systems support advanced knowledge acquisition by providing environments and thinking tools that include constructivistic conceptions of learning. Open learning systems, for example, can be characterised as need-driven, learner-initiated and conceptually and intellectually engaging in nature. Technology-based environments such as communication-based environments, simulations, hypermedia environments, and other multimedia-based learning software, engage the learner in tasks that facilitate knowledge construction. An example of such tasks could be an engagement in argumentative discussions in which new knowledge and understanding of issues are constructed by critically examining other students' points of view on the issues handled. Thus, it is important to clarify how modern information and communication technology can be applied in the development of such instructional methods that promote the cognitive skills that are essential in terms of the construction and selection of new knowledge.

In the study concerning IS experts' conceptions of the human being (Isomäki 1999) constructivism is applied in order to understand IS professionals' conception of the human being inherent in information systems development. During the process of ISD professionals are elaborating, supplementing and re-structuring their view of the user of the system (cf. Resnick 1989). This means that IS professionals' conception of the human being forms a basis for their understanding of the users of the system that they are building (Uljens 1991). This kind of knowledge creation occurs in reflective action, which involves constant contemplation of one's knowledge, beliefs and values with respect to the object of thought and action (Schön 1983). As Mathiassen (1998) points out, in modern communities of practice IS professionals co-operate in conformity with reflective action. In this way IS professionals experience and learn the knowledge, beliefs, norms and values that are valid in particular communities of practice (Brown & Duguid 1991; Lave & Wenger 1991). It is essential in reflective action to form an understanding of a design according to the situation at hand, and not to take one's previously formed view for granted (Schön 1983). With respect to the humanisation of IS this means that within the interactive and uncertain situations inherent in the development process the emphasis of investigation should be on IS professionals' reflections concerning the human being. Thus, it is essential to clarify the information systems professionals' conception of the human being.
Towards Humanised Information Systems

The aim of the UCRET project is to produce research knowledge which promotes human-centred information systems development. Traditionally, the human-centred view of ISD is understood as an approach often referred to as the tool perspective. Within the tool perspective attention is predominantly focussed on the computer, and the user of the computer is often forgotten (Nurminen 1986, p. 90). In this paper, a human-centred view in ISD means that the computer and the human being are seen as an entity in which it is essential to know how people behave when they use computers. That is to say, understanding human behaviour is the starting point and focus of reflection during systems development. This is a fundamental characteristic of the humanisation of IS which refers to application development aiming at adjusting information systems to human action.

The human being is the most important facet of an IS, and therefore, knowledge about human behaviour is needed as a basis for developing computerised information systems that esteem humans as thinking, feeling, social and cultural creatures with their own will. Firstly, it is necessary to know how people use information systems in order to accomplish tasks characteristic of human behaviour. Relevant questions are, for example, how do people interact with each other, how do they solve problems, and how do they construct knowledge with using computers. Secondly, it is important to know how the human being is taken into account within the information systems development processes. Important questions are, for example, how IS designers conceptualize human action, and what kind of conceptual structures of humanity are included in the theoretical models of IS methodologies. Human-centred information systems development can be understood as a cycle in which knowledge of the use of the systems is utilised in ISD, resulting in more humanised information systems which are again used and further examined. By utilising these principles in contemporary ISD it would be also possible to create more human-centred development procedures for information systems development.

The two studies described in this paper support the idea of the humanisation of computerised information systems in different ways. Information about learning of argumentation, and communication skills in computerised environments may be utilised in efforts to take human characteristics into account in ISD. For example, information about how the use of a communication system promotes argumentation and problem-solving skills can be utilised when designing and investigating new communication systems. Information about the argumentative structure of e-mail messages may support the development of such applications that help users to gain well-grounded decisions in situations involving conflicting interests. An example of this kind of application could be an extension to an electronic commerce application that helps the customer and vendor to agree on disagreements about purchases. In addition, applications whose design is based on knowledge of human problem solving or argumentation patterns could facilitate interaction between users and IS designers during the process of information systems development. Moreover, information about IS designers' ways of conceptualising humans as users of information systems may be utilised in analysing the educational needs of information systems specialists. This is significant in regard to innovative applications of modern information technology supporting human action in diverse situations. In order to evolve, the application of modern information technology is increasingly dependent on knowledge of human behaviour. The following sections demonstrate the main research results achieved in the two studies of the UCRET project.

Quality of E-mail and Face-to-Face Argumentation During University Studies

The study examines the quality of university students' (n = 27) argumentative e-mail (n = 11) and face-to-face (n = 16) discussions. The discussions were based on argumentative writings. Free debate and role play were used as working methods in organising the discussions. During free debate the students defended their personal opinions while in the role play, half of the students were given a point of view that they had to support, and the other half were given an opposing standpoint. The data in the study consist of 326 student e-mail messages, and transcribed face-to-face discussions (7 x 1.5 hours).

The results showed that the e-mail students mainly took a neutral position in relation to a fellow student's standpoint while the face-to-face students, in contrast, mostly expressed agreement. The amount of disagreement was about the same in both environments. The e-mail students, however, grounded their disagreement and put forward elaborative agreement more often than the face-to-face students. These results suggest that the e-mail students presented higher quality argumentation than the face-to-face students. One explanation for the face-to-face students' worse performance is that oral face-to-face discussion is a social situation in which particular social rules must be obeyed. These rules include the giving of emotional support to others and the endeavour to maintain group cohesion during the discussions, as happened in this study. The students showed this support especially during role play by making short non-grounded disagreeing comments against those belonging to the group who had the opposing role, and by producing short
non-elaborated agreeing comments to those belonging to their own side in the role play. The written e-mail discussion situation does not include as distinct social rules as the face-to-face situation. This gives the e-mail students better opportunities to put forward more carefully grounded and more elaborated opinions than face-to-face students. Furthermore, the results indicated that the proportion of grounded disagreement was higher in role play than in free debate among both the e-mail and face-to-face students. Thus, it can be preliminarily concluded that role play as a working method motivates students to engage in argumentative discussions more successfully than does free debate. The details of the study are presented in Marttunen and Laurinen (in press).

Information Systems Designers’ Conception of the Human Being

The aim of the study is to clarify the Finnish information systems (IS) experts’ conception of the human being as a user of computer-based information systems. The question is explored from a phenomenographical point of view. Within this approach essential features of awareness signify that certain structures of awareness are implied by certain ways of understanding. This means that an individual is simultaneously aware of certain aspects of a situation or a phenomenon, and this awareness of certain aspects logically implies a tacit awareness of other aspects. In addition, certain aspects become focal whereas other aspects recede into the background. The simultaneous nature of the different aspects of awareness are denoted by what- and how-aspects - a special case of the notion of intentionality (Marton & Booth 1997). The thematic interviews of the study were based on the results of a pilot study. The themes of the interviews were focussed on human issues from the different viewpoints of the phases or situations of information systems development (ISD). The subjects of the study comprised 20 information systems experts from seven different enterprises representing the major fields of Finnish information industry.

The results indicate that the IS experts’ focus of thought often is on the situational features of ISD and that human issues are omitted. The IS experts tend to conceptualize users through the intentions of the situation in question rather than by connecting characteristics typical of the human being to the user. For example, the human being is conceptualised in terms of business, information technology, job titles and work tasks. Some of the experts reflect on their work in relation to the user but contemplate the human characteristics through themselves. The descriptions connected directly to users centralise around an emotionalist view of the human being: users are seen as emotionally reacting creatures often afraid of computers. In addition, emotionally shaded enthusiasm is regarded as a desired basis of motivation for cooperation and learning. In some cases the conceptions with focus on the users also denote that users are ignorant concerning information systems and that they use information systems in a simple manner. The study suggests, first, that human action or characteristics are not always taken as a design premise in contemporary ISD, and second, that IS experts do not possess holistic knowledge about human behaviour. In this sense the results are in accordance with Swanson’s (1988, pp. 43–51) definitions of the mechanistic and the utilitarian approaches to information systems development. According to the results of this study, however, the reflective comprehension (Swanson 1988, p. 53) way of thinking is not common among the contemporary IS professionals. The more detailed description of the preliminary results is presented in Isomäki (1999).

Conclusion

The research results of this paper showed that the learning environments based on the use of information and communication technology are effective when the aim is to promote the construction of new knowledge. This is indicated by the results showing that students’ argumentation skills developed when an e-mail learning environment was utilised in teaching. The results of another study indicated that IS experts tend to conceptualize users through the contextual features of information systems development rather than by connecting characteristics typical of the human being to the user. For example, the human being is conceptualised in terms of business, information technology, job titles and work tasks. Some of the experts reflect on their work in relation to the user but contemplate the human characteristics through themselves. The descriptions that are connected directly to users centralise around an emotionalist view of the human being. On the basis of the results it seems evident that human action or characteristics are not always taken as a design premise in contemporary ISD. Furthermore, IS experts see humans in terms of their emotional characteristics.

The results described in this paper have shed some light on the topical questions concerning the humanisation of information systems. The results of the project have clarified the role and learning potential of the human being in a computerised environment and the ways in which the human characteristics are seen in regard to the development of information systems. However, another essential aspect of the humanisation of IS concerns the question of how to
References

Integrate the research results gained from both the use and development of information systems in order to promote more humanised ways of developing information systems. This question stills awaits future research.
This paper describe a prototype that makes it possible to run WWW applications in wireless networks. Web technology in conjunction with today mobile devices (laptops, notebooks, personal digital assistants) and the emerging wireless technologies offer the potential for access to data and applications by mobile workers. Now the limited bandwidth, high latency, high cost and poor reliability of today wireless networks inhibit supporting web applications over this type of networks. The WirelessWeb prototype reduce the response time by intercepting the HTTP data stream and performing various optimisations including: file caching, protocol reduction, and elimination of the redundant HTTP header transmission. This paper describe these possible optimisations and some experimental results.
Incorporating Computer Assisted Learning into the Teaching of Cultural Studies: The Virtual Shopping Mall Case Study

Annamarie Jagose, English Department with Cultural Studies, Univ. of Melbourne, Australia; Somaiya Naidu, Department of Teaching, Learning, and Research Support, Univ. of Melbourne, Australia; Lee Wallace, Women's Studies Department, Univ. of Auckland, New Zealand

The Virtual Shopping Mall introduces first-year students to the critical study of consumerism and commodity culture via a web-based learning environment that interpellates and motivates student learning through the strategic adoption of the architectures of computer games. Using hybridized learning and game protocols, the Virtual Shopping Mall provides a thematically coherent environment - the mall - to afford situated learning. This paper describes the development of the project, locating it within the research fields relating to game-based and situated learning. It describes each of the four components of the module - Sales Pitch, Just Looking, Quiz Zone and Retail Therapy - and the ludic motivations and critical competencies they are designed to elicit. This paper describes the three-pronged evaluation strategy put in place to test the pedagogic hypotheses of the pilot module and ensure effective redesign as necessary.
Cyber-based Service Learning: Community Projects in Africa

Peggy James, Political Science Department, University of Wisconsin-Parkside, USA
james@uwp.edu

Abstract: Results from a pilot project on cyber-based service learning in Nigeria are reported. Students worked on three projects with Nigerian organizations through electronic media. US students learned the applied aspects of working within a developing country and the different twists that conceptually similar problems might have in a developing country context. Community organizations received valuable help from students who were more connected to the internet and other materials than was available in Nigeria. Future community engagement projects are planned for Nigeria and Moldova.

Electronically mediated learning has become relatively commonplace at the university level, as asynchronous learning has enabled distance education not only for single courses, but in the establishment of virtual universities. Some of the original enthusiasm has waned, however, as universities became aware that asynchronous learning might not be an effective replacement for interactive learning or hands on applications. It has become evident that in some cases technology needs to be appropriately placed within a larger learning experience, and that teaching pedagogies be expanded to included different modes of learning. What has also become obvious is that technology is not an equalizer: there are significant areas of the globe that cannot benefit from uniform levels of electronically mediated education. Even within more developed countries, we find entire groups of people who are marginalized from technology’s ‘democratization of information’.

The University of Wisconsin-Parkside has begun a project to introduce cross-cultural, electronically mediated learning experiences that allow students to not only interact with other students on a learning topic, but also to engage in virtual community engagement, where participants can actually participate, electronically, on community projects in other countries using expertise from their home country. A test project has been successfully implemented with Nigerian organizations, and new courses involving womens’ organizations in Moldova, and a German University are being offered in upcoming semesters.

The first course, Community Projects in Africa, involved students in the United States in three projects undertaken by Nigerian organizations. Initial communication was initiated through pictures sent over email, and introductions. Traditional media (video and tapes) were provided by the Nigerian organizations to give students an introduction to the Nigerian social context. Projects included an AIDS conflict resolution in central Nigeria, peer health education programs in Oriade, and the negotiation of an environmental contract between local governments and Shell Oil in Port Harcourt. Students communicated directly with community workers on these projects through email and internet connections. The product of the course was a complete project analysis and recommendation done by the students and transmitted to organizations, after a site critique was provided to the students.

To the more electronically sophisticated participant, this may seem like a simple exercise. In reality it was nothing short of miraculous. The organizations worked with only one computer at times, and were working under conditions of variable electricity and unstable political situations. Normally, these would be the marginalized sectors mentioned earlier. However, it is imperative that the electronic connections to these locales be appropriate to the level of technological, social, and economic development of the participating country. Too often, developing countries are left out of this learning opportunity because it is simply too difficult. While the courses might be offered through traditional email participation, compressed video is an ideal format for the exchange, so that participants can ‘see’ the others in the virtual classroom, even though it may be thousands of miles away. It must be emphasized that the project works within easily available technology- we are not proposing the creation of a virtual reality site- such an endeavour is beyond the scope of the participating institutions.

The results were very encouraging. Students participated in virtual learning, obtaining international experience, while maintaining a local opportunity to practice what they are learning. One of the most
pedagogically interesting results was that students stated they had, for the first time, a real understanding of what it means to be a developing country. Even though they understood the concept theoretically, when in practice they experienced the consequences of no electricity, political difficulties, and a marginal phone system they truly understood what it might be like to work productively in the community under these circumstances. The concept of development came through the learning object, rather than through a content oriented lecture. Faculty also benefit through the offering of courses with this multinational contingent in mind, thus providing a motivation to 'internationalize' the course, and also make it more culturally sensitive. There are pedagogical issues at work here, also, since the faculty member must exercise more flexibility in the course (communications are sporadic and non reliable) and be able to encourage independent learning for the students, as well as a sense of community both between the two countries and within the class at home. The experience resulted in a tight knit learning group, which some faculty may need to become accustomed to.

Acknowledgements

The author would like to thank the Institute for Global Studies at the University of Wisconsin-Parkside for funding the project, and cites the invaluable contributions of Dr. Lillian Trager, Judy Asouni, Lola Dare, and Miriam Osoun.
"To DIE for!" - Declarative, Interrogative and Experiential Learning of (Geo)Science on the Web

Patrick James, Univ. of Adelaide, Australia

This project outlines a program including the development, delivery and evaluation over the last four years of online learning programmes to senior science and geoscience undergraduates within a larger Faculty and University Online development project. Lotus Domino was initially used as the software database engine to compile, manage, store and present the course materials. As an example, for one geoscience subject nearly 500 web pages have been compiled and delivered online to the students. Evaluations of this teaching and learning program indicate its overall acceptance and improvement in course delivery to students due to increased flexibility.
Towards Universal Access to Web-based Learning

Abstract: Universal access to the Web as a learning resource may be facilitated by the use of an adaptive Web based learner support system. This paper describes how modifications to the CAIN system can achieve this aim by matching the cognitive load imposed by Web text pages with the working memory capacities of users.

People who are disabled often experience social isolation, as do many elderly people because their friends die or their family members move away. There is therefore considerable value in the development of software that helps to provide such people with new interests in addition to supporting their access to friends and relatives (Katz & Aspden 1997).

The World Wide Web (Web) appears to offer a vast repository of educationally useful information that would be useful in supporting the development of new interests and further learning for people who are elderly or disabled. However, the Web's disorganized nature reduces its effectiveness as a learning tool and as a tool that enables people to pursue new interests. Therefore, further research is needed to develop the means to transform the available material into coherent information able to support learning or research activities (Eklund & Ziegler 1996; Marshall 1995).

The Computer Aided Information Navigation project (CAIN) (Lamas, Jerrams-Smith, Gouveia & Heathcote 2000) is an example of a Web-based Adaptive Learner Support System. As such, it provides adaptive navigation support in order to increase the Web's value as a learning tool (and one that enables people to pursue new interests). CAIN's approach is reactive as it seeks to provide a way of dealing with the vast amount of useful information currently available on the Web rather than trying to improve the Web's infrastructure.

CAIN provides direct guidance navigation support by enabling the user to follow a context specific ranked sequence of selected Web pages without ever needing to perform any search or follow any link if they do not wish to. This approach does not seek to prevent goal-oriented exploration but rather to provide a reliable path or guideline to help users to retain their focus.

CAIN includes heuristics that use information about the user (stored in a user model) and about each of the Web pages (stored in a Web model). This enables the selection and ranking of the most suitable Web pages for each individual user.

Although CAIN provides adaptivity to suit the needs of different users, it needs to be extended in order to meet the specific needs of a much wider range of users and to enable universal access. Our current work therefore entails consideration of the various physical and cognitive attributes of users that affect their learning via the Web. Consequently, CAIN's user modeler will be modified so that the user model will take account of the individual's physical and cognitive attributes. In addition, changes must be made to the way in which the Web is modeled by CAIN.

Cognitive factors which are likely to be influential during learning include working memory capacity and motivation. Of these, working memory capacity appears to be important for learning (Baddeley 1997). In addition, our investigations indicate that it is also likely to be one of the cognitive attributes that can be supported by adaptive learner support systems such as CAIN. We suggest this for the following reasons. First, working memory capacity can be tested in a reliable manner. An existing procedure for testing users'
working memory span is quick, easy to administer, reliable and well-1980). Very minor extensions to CAIN's user modeler will enable such information to be added to the user model.

ques for rating the suitability of Web resources for use by individuals of differing working memory capacity. Currently, all ratings are added to the Web model of CAIN by experts. It is necessary to automate this process as much as possible. We are therefore developing software to carry out automated rating of Web

(Gathercole & Baddeley 1993) suggest that the load on working memory capacity. This is because syntactic analysis loads the central executive component of working memory. An empirical study (King and Just 1991) categorized participants as working memory span. It was found that the comprehension performance of low span participants was particularly poor when they were required to read syntactically complex sentences. It is proposed that an t to examine the interaction between working memory span and the syntactic complexity of Web text pages. Automation of rating the syntactic complexity of a page will be arser.

use of passive verbs and of negatives, especially the use of double negatives. Finally, we intend to carry out an empirical study which wil hence learning from pages of differing complexity as measured by Fog indices such as the Gunning Fog index (Gunning & Kallan 1994). The Gunning Fog index rates text complexity on the bas as the proportion of words of greater than three syllables and the average sentence length. If Fog indices do indeed predict which pages will be more valuable for subjects who have lower working memory capacity, ly straightforward to write the software to provide a Fog index rating for each page.

comprehensibility of text. These combinations will be tested empirically and compared with working

A Rich Learning Environment Is Yet To Come: An Action Evaluation on a National eLearning Project for Elementary Education in Taiwan

Huecyhing Janice Jih
Department of Educational Technology
Tamkang University
No. 151, In-chun Rd., Tamshui, Taipei, Taiwan 251
jih@mail.tku.edu.tw? jih@kimo.com

Abstract: Over 250 teachers and principles from eighty elementary and middle schools, representing twenty-five executive districts, selected to serve as Change Agents of a national web project named K-12 Gas Station. Their major tasks are to design, produce, and implement web-based courseware on the "...". Besides the expense on the hardware and courseware in the project, there have literally been over twenty thousand seminars/workshops on computer-based education funded each week for in-service teachers at all levels K-12. The actual effectiveness or impact of such diligence is now generally considered suspect. The action evaluation of this project revealed that the whole project should make a sharp turn. The author, a consultant of this national project, has made complete and precise suggestions on the revision of the project. This paper is a condensed report of this research.

The National eLearning Project

Bringing rich learning environment to students in grades K-12 is a high priority for the Ministry of Education in Taiwan. If we are going to bring quality e-learning materials to all students, produce technology literate citizens, and meet the national education goal to be first in the world in academic achievement, we must provide teachers and pupils with rich content for all subject matters in grades K-12. To reach certain apex-level goal, the Ministry of Education has to deal with the major problems of low availability of computer hardware, insufficient courseware and incompetent humanware.

Taiwan educators have invested in the technology of internet-based classrooms. The Ministry of Education at Taiwan has granted 25 million US dollars for courseware and at least one billion US dollars for island-wide wired campus infrastructure at 1997-2000 fiscal years. Over 250 teachers and principles from eighty elementary and middle schools, representing twenty-five executive districts, selected to serve as Change Agents of the "K-12 Gas Station" (a virtual Learning Resources Center at http://content.edu.tw; Fig. 1). Their major tasks are to design,
produce, and implement web-based courseware on the “Learning Resources Center Project” (http://content.edu.tw). The incentives provided to those Change Agents were: (a) grants ranging from $40,000-60,000 for courseware development per year; (b) free-of-charge training workshops; (c) opportunities to lead regional workshops; (d) all-expenses paid trips to present materials/workshops developed at regional and national professional conferences; and (e) stipend for better performer. All Change Agents met every other month during the school year to discuss issues. They share ideas, results, and frustrations via the e-mail and TANET. The project was overseen by a nine-professor steering committee and managed by a leadership team of seven government officers. The overarching goal of this project was to make a quality and quantity learning environment for K-12 schools in Taiwan. Besides the expense on the hardware and courseware in the project, there have literally been over twenty thousand seminars/workshops on computer-based education funded each week for in-service teachers at all levels K-12. The actual effectiveness or impact of such diligence is now generally considered suspect (e.g., Wu et al, 2000).

Action Evaluation of the Project

All participants function as reflective practitioners together, reflecting and examining the goals, values and activities. These interactions are done continuously during the project. The researchers serves as the counselor and engages in the project from the beginning, articulating and negotiating their goals, their values, and their proposed action plans. The action research described in this paper was performed as a counseling project for an eighteen-month research grant funded by the Ministry of Education to the researcher.

Information used to write this paper was collected from the following sources: (a) Review of documents: The researcher reviewed each school’s proposal as well as the evaluation result for each. (b) Semi-structured focus-group: These interviews conducted by the researcher at the sites. Each interview lasted approximately two hours. In some cases, follow-up phone calls and e-mail were made to gather additional information. (c) Informal observations of workshop and training programs. The researcher made short, informal observations trainees participating in training activities. (d) peer-evaluation questionnaires: The questionnaire collected island-wide responses of 119 teachers concerning their instructional practices with computers, barriers of computer usage, needs for computer-based resources, educational background, and computer as well as curriculum in-service training. (e) e-mail communication and web-forum, and (f) the self-reflections of the researcher as a member of the steering committee. Besides these, Formal meetings and informal discussions with the MOE staff. These meetings and discussions were held between Feb. 2000 and Dec. 2000 and covered aspects of website planning. After all the site visits were completed, researchers conducted several meetings with MOE staffs to clarify revision as well as implementation issues.

Data from communications and interviews with participants strongly suggested that the whole project should make a sharp turn. Discussion among these change agents covered the important issues of vision, quality of web site, learnability of courseware and capabilities of teachers. The primary results described below are reported in terms of four aspects of the project because the researcher feels that an exhaustive evaluation report is beyond the scope of this manuscript. The following are some major points emerging from these meta-analyses:

Vague Vision

The vision of the virtual Learning Resources center is far way from the crystal clear visibility. The education administrators, the computing education professionals and teachers as primary users brought different vision and expectations into the change agent team. At the first year, ‘just put anything on the web’ become the major misconception of the project (http://content.edu.tw). The reason why they treat it that way was that none of the change agent has ever had experience on web before. Unfortunately, the ambiguity lasted for three years. Until today, they still try to figure out the major goal of the project.

Wimp Website

A teacher views their professional responsibility as a process of continual, reflective inquiry and the exchange of ideas with their peers leading to the development of a shared community base. They value various opportunities to share their expertise with other teachers beyond the classroom or the school. Partnerships with community members, collaborations with colleagues, and engagement with and any educational activities do expand teachers’ understanding of teaching practice in ways that are sometimes unavailable in school. Therefore, more availability of learning community access should be provided in order to encourage teachers’ opportunities in terms of professional development. Nevertheless, the K-12 Gas Station with a WIMP (windows, icon, menu, and pointing device)
interface is a ‘wimp’ system. On the one hand, the de-centralized infrastructure of the web servers is quite manpower demanding. On the other hand, the simplified features and structures (e.g., there is no database server for users to share their work) of the website could not meet the needs of ‘sharing’ information for virtual communities.

Incompetent Involvement

Although it cost a huge amount of budget, however the result turns out not so appealing. Several key persons of the Change Agents stated that they feel incapable about their involvement in the project and that the whole project is “just waste of time and money.” Why? Because they never have been designed or produced any web-courseware before this national project taking off. Some change agents considered themselves as digitizer—who specializes in scanning photos and/or digitizes video clips. Some of them even could not find one single subject matter teachers in their schools. Anyone who can make (or locate somebody else do) better image processing works become the superstar of the whole group. Nevertheless, none of them is familiar with or heard the instructional design or systemic development of courseware.

Teachers, as well as administrators, parents, and community professionals, have a vital role to play in educational reform of K-12 in Taiwan. They need the following professional development supports: need a transformation model rather than a transmission model, need pedagogical strategies, need appropriate infrastructure and computer resources, and need to model strategies, give guidance and feedback, allow for revision (Krajcik, 2000). However, certain support is absent from teacher training programs and the national project. Only few teachers might integrate the e-materials into their teaching and learning processes. Yet, K-12 teachers have had few opportunities either to increase their domain content background or to have many of the many good learning materials that have been shown to improve student interest and achievement in all area of subjects. Researchers and practitioners proclaimed that, for technology innovation to occur, teachers must feel that they are a part of the reform. However, the major role of teacher should and must be a user of the learning environment, not a one-man team developer.

Rare Resources

The leading characters in any gas station should be the gasoline itself. Consequently, rich learning resources in terms of raw materials, lesson plans, teaching guides, worksheets, activity books, references, and cooperative projects should be provided on the K-12 Gas Station. However, the major characters on the station are scanned pages or reprint pages of textbooks along with their teaching guides as well as published materials available for each teacher (Fig. 2). The real needs for learning resources is under development.

**Fig. 2 The Snap Shot of Resource Pages in the K-12 Gas Station**
Misjudged Needs

Educational administrators have too often placed computers in each school and teacher's classroom with innocent expectation that technology would and should emerge into classroom activities. However, the truth is teachers always didn't ask for computers nor internet and would not or should not have any specific plans for using those current or future technologies. Fewer than one fifth subjects (20.2%) reported having using computers in their own classroom. Over one third (37.0%) subjects view computers as a "Game station." Approximately one half (47.1%) subjects rank computers as a major factor for short-sight of pupils.

Compact Curricula

One non-technology problem is scheduling. Over one forth (28.6%) subjects proclaimed that the compact curriculum is a crucial barrier for computer usage. Elementary teachers have many different subjects to cover and so many pupils to teach and guide. It is beyond all reason for most teachers to integrate computer technology into daily school works.

Inconvenient Instrument

The availability of computer is far from satisfaction in Taiwan's classrooms. Among those 119 subjects, 47 persons (39.5%) and 59 teachers (49.6%) complaint that there is no computer nor projector in their classrooms. Moreover, computers and internet often break down. Therefore, the difficult accession to technology becomes a major excuse for teachers not using computers into their teaching practices.

Conclusion

The real voyage of discovery consists not in seeking new landscapes, but in having new eyes. — by Marcel Proust

Learning is an active process and should call into play our fully imaginative and creative capabilities so that subject itself becomes a delight to learners of all ages. It is only when we make explicit use of new natures of learning technology that the "new" learning media would add multiple value to human learning of any subject. Many challenges to effective design remain in quality 'rich' learning environments. What recommended by Jonassen's group (1998) should be a good start for the reform of the on-going project. For instance, (a) authentic problem context or project space, (b) authentic tasks and activities, community of learners, (c) cases, examples or simulations that help explain the problem, (d) cognitive and collaborative knowledge-building tools, (e) cognitive apprenticeships, (d) rich information resources, (e) student options/choice and (f) assessment/standards (rubrics). The researcher has made complete and precise suggestions (Tab. 1) on the revision of the project by the end of this century.

A comprehensive reform of the structure and function of the web-based learning resources center, ways of e-course design and development, and the teacher training programs is underway. This reform has been characterized as "quality oriented, deep, total solution, and serious." It is systemic, requiring that all components of the learning environments be partners in change. It is occurring at the national level, in the county level, in schools, and in individual classrooms. We look forward to the fruitful results of the follow-up reform.

Acknowledgements
The research project described in this paper was performed as a pilot study for a research grant funded by the National Science Council to Jih. The opinions expressed herein do not necessarily reflect the position or policy of the MOE and the Tamkang University, and no official endorsement by any group should be inferred. The researchers are grateful to thank the Change Agent teachers of twenty-two Elementary Schools for their participation and cooperation with this study. Special thanks to Dr. C. C. Chen, Mr. C. F. Liou, Ms. S. M. Han, Ms. Y. C. Lin, Ms. S. C. Chang, Ms. S. C. Wu and Dr. C. S. Chang, for their theoretical and empirical ideas in the initial efforts to launch this research. For comments on a previous version of this manuscript, special thanks go to Ms. S. C. Wu. For assistance in running the research, I thank Ms. S. C. Wu, Ms. Y. T. Chu, and Ms. S. F. Chang, the promising graduate students with the Educational Technology, Tamkang University.

Abstract: A Web-based learning community is far beyond putting learning materials into a Web site. It can be seen as a complex virtual organization with enormous work involved with people, cyber-environment, and facilities. There is an inevitable choice to use various agents to assist or replace human to a certain extent for the work in a virtual learning community. There is a strong need for the development of the designated architecture for integrating and using various agents. This research is focused on developing an open agent architecture that can easily integrate developed agents to a learning system and flexibly modify the agents with permission. This paper describes the design ideas of such desired architecture, demonstrates how the architecture system works, and explains three agents in a Web-based learning system, University21.

Introduction

With advances in the Internet and multimedia technologies, development of Web-based learning communities for K12, high education, lifelong learning of citizen has become a hot topic. However, establishing a Web-based learning community is far beyond putting learning materials into a Web site (Donath, 1997, Jones, 1997, Maynatt, 1997). A learning community is in fact a complex virtual organization (Ma, Huang, and Shin, 1999, Ma and Huang, 1999, Ma, Huang, and Kunii, 2000) involved with people, facilities, and cyber-environment. Tremendous work and manpower for maintaining, upgrading, and managing facilities and cyber-environment are required. Teaching/learning activities also require lots of assistance to release human from difficult and/or tedious work so as to achieve teaching/learning efficiency. With rapid developments of software agent technologies, it becomes a good choice to use various software agents (Johnson, 1998, Mengelle, et al., 1998) to assist or replace human for work in a virtual learning community. To efficiently conduct teaching, learning and management activities, many agents are required. In a virtual learning community, agents are mainly classified into three categories, personal agents, facility agents, and cyber-environment agents. Personal agents assist people for personal activities. Facility agents automatically provide monitoring, maintenance and upgrading of tools, systems, and resources. Cyber-environment agents are resided in virtual office, virtual private room, virtual course room, etc. for supporting teaching/learning related activities. Tab. 1 gives a list of only partial agents on demand in a virtual learning community system. Facing so many agents needed, it is natural to encounter a problem, that is, how to integrate developed agents to the virtual learning community system. It seems an architecture that allows easily and flexibly integrate developed agents is preferred. This motivates us to design and develop a so-called open agent architecture. Agents developed by different parties can be easily and flexibly integrated to a virtual learning community system via the open agent architecture. This paper is focused on describing the design principles of such desired architecture, demonstrates how the architecture system works, and describes some agents in University21 (Ma, Huang, and Kunii, 2000). Finally, conclusions are drawn and future work is addressed.
I glum

The Design Principles

The open agent architecture is designed under the following emphases. (1) It should make system developers easy to integrate agents developed by other parties; (2) It should make agent developers flexible to upgrade or modify agents; (3) It should make agents transparent to users for use. It is necessary to point out that to be platform independent, the agent programs are written in Java language. The open agent architecture has the following three characteristics and can work in two modes: the centralized or the distributed

Ease
It means that a virtual learning system can easily integrate an agent. In a centralized system, the system only needs to download the agent programs and unpack the agent programs, adds the agent name to the agent list, adds the agent IP address to the agent routing table, allocates a certain resource for the agent, and starts the agent server when the agent is requested by a user. In a distributed system, the system only needs a privilege to start/stop the agent server (Schmidt, 1998) and redirect users to a site where the agent programs reside and the agent server runs since agent programs are distributed in the local machine and resources are managed locally too.

Flexibility
It means that an agent can be flexibly added, removed, and modified with permission. In a centralized system, an agent can be flexibly registered or deregistered. Agent programs are uploaded or upgraded by the agent developer with permission. In a distributed system, an agent is only registered or unregistered with the agent name and address where the agent programs are resided. Uploading programs is not necessary. The agent developer can modify or upgrade the agent programs in his/her local site. The open architecture system is only given a privilege to start/stop the agent server in the remote site. When an agent is to be deregistered or upgraded, the system stops the agent server, deletes the agent name from the agent list, and removes the agent IP address from the agent routing table.

Transparency
It means that all registered agents are dynamically shown in the agent list with attached information like agent name, agent ID, server status, and program type. Whether an agent is available or not, whether an agent server is running or not, and whether an agent is being used or not, all those information is available to users. The server starts to run when a user makes a request of using the agent if the server is not running. The client program is automatically downloaded to the user site. If it is a Java applet, it automatically runs on the Web browser in the user side. Otherwise, the user runs Java application program with a simple command like make run.

The open agent architecture system is designed under the above emphases with features of ease, flexibility, and transparency. Fig. 1 gives a system architecture that consists of four basic layers: client, agent, platform and external layers.

Table 1: A list of partial agents on demand in a virtual learning system

The open agent architecture is designed under the following emphases. (1) It should make system developers easy to integrate agents developed by other parties; (2) It should make agent developers flexible to upgrade or modify agents; (3) It should make agents transparent to users for use. It is necessary to point out that to be platform independent, the agent programs are written in Java language. The open agent architecture has the following three characteristics and can work in two modes: the centralized or the distributed

Ease
It means that a virtual learning system can easily integrate an agent. In a centralized system, the system only needs to download the agent programs and unpack the agent programs, adds the agent name to the agent list, adds the agent IP address to the agent routing table, allocates a certain resource for the agent, and starts the agent server when the agent is requested by a user. In a distributed system, the system only needs a privilege to start/stop the agent server (Schmidt, 1998) and redirect users to a site where the agent programs reside and the agent server runs since agent programs are distributed in the local machine and resources are managed locally too.

Flexibility
It means that an agent can be flexibly added, removed, and modified with permission. In a centralized system, an agent can be flexibly registered or deregistered. Agent programs are uploaded or upgraded by the agent developer with permission. In a distributed system, an agent is only registered or unregistered with the agent name and address where the agent programs are resided. Uploading programs is not necessary. The agent developer can modify or upgrade the agent programs in his/her local site. The open architecture system is only given a privilege to start/stop the agent server in the remote site. When an agent is to be deregistered or upgraded, the system stops the agent server, deletes the agent name from the agent list, and removes the agent IP address from the agent routing table.

Transparency
It means that all registered agents are dynamically shown in the agent list with attached information like agent name, agent ID, server status, and program type. Whether an agent is available or not, whether an agent server is running or not, and whether an agent is being used or not, all those information is available to users. The server starts to run when a user makes a request of using the agent if the server is not running. The client program is automatically downloaded to the user site. If it is a Java applet, it automatically runs on the Web browser in the user side. Otherwise, the user runs Java application program with a simple command like make run.

The open agent architecture system is designed under the above emphases with features of ease, flexibility, and transparency. Fig. 1 gives a system architecture that consists of four basic layers: client, agent, platform and external layers.

- In the client layer, TCP protocol is used for client-to-client communications via the agent server. The agent server is running and then waiting for connections from its clients. After the connections are established, communications among the clients are conducted through the TCP protocol.
In the agent layer, socket connection is used in a centralized system while IIOP (Internet Inter-ORB Protocol) (Schmidt, 1998) which runs atop the TCP transport protocol is used in a distributed system for communications among agents via the messenger.

In the platform layer, the function modules of the open agent architecture are provided. This layer is further divided into two parts: system components and external system connection components. The system components consist of agent manager, agent data holder, and messenger. The external system connection components provide various proxy servers corresponding protocols that are ready for connection to external devices or systems. The request of using an external device or system is analyzed by the connection adaptor and the inquiry agent is connected to the corresponding proxy server.

In the external layer, it places devices and/or systems that agents may require to connect, such as HTTP Server, Mail Server, FTP server, the Internet, database, search engine, etc.

**Figure 1: A basic composition of the open agent architecture**

**The Function Modules**

How an agent is functioning in the client layer is relied on the agent (agent server and client programs) rather than the open architecture system. The most core functions of the open architecture system are provided in the platform layer. In this section, we will discuss each function module below.

**Agent Manager**

Agent management is a function module of operating an agent life cycle on the open agent architecture platform. It mainly provides functions like agent registration, upgrading, deregistration, running an agent server, connection of agent clients to the agent server, and front-end functions to the agent data holder.

To register a developed agent to the open agent architecture platform, an agent developer accesses a web page and clicks the *register* button, and then an agent registration page is popped up. The developer inputs necessary agent related information, such as agent name, agent IP address, agent program package name, agent working mode, and server execution command. For working in the centralized mode, the agent program package (*.jar file) is uploaded, unpacked and placed to the host where the agent manager is resided. At the same time, agent related information is sent to the agent data holder by calling method `addAgent()`. For example, an agent name is added to the agent list and agent IP address is added to the agent routing table in the agent data holder. A space allocation request is also sent to the database via the agent data holder. The process of agent registration is shown in Fig. 2.
For working in the distributed mode, uploading of the agent programs is not necessary since all agent programs are distributed and run on the agent developer's local JVM machine. Only information about the agent, such as agent name, agent IP address, server execution command, etc., is registered. After an agent is registered, it is ready for use. When a user would like to use an agent, the user goes to a specified web page and clicks an agent icon (or an agent name from a list of agents), after that, the agent client program is automatically downloaded to the user's local machine and run on the local JVM (Java virtual machine). The client program requests a connection to the agent server and the agent server receives the request and accepts the connection. The connection between the server and the client is thus established.

Similarly, to deregister or modify an agent from the open agent architecture platform, an agent developer accesses a web page and clicks deregister or modify button. The developer has to input his/her user ID and password. If the permission is granted, he/she can enter information related to the agent to be deregistered or modified, the agent manager will perform the process of removing the agent, such as, disconnecting all clients, removing agent programs, deleting the agent related information from the agent list and the routing table, and releasing allocated space by calling deleteAgent() or modifyAgent() from the agent manager.

**Agent Data Holder**

The agent data holder mainly manages information and data of agents like agent name, agent description, agent type, agent's access path, and etc. The following methods are public to the external modules.

- Void addAgent()
- Void deleteAgent()
- Void modifyAgent()
- String getAgentName()
- String getAgentPath()
- Void getAgentInfo()

Calling those methods is either from the agent register program in the agent manager or from the messenger when an agent requests to communicate with another agent. There is an interface between the agent data holder and the database. Data related to an agent is stored in the database. The agent list table and the agent routing table as shown in Fig. 3 are updated during the agent life cycle operations and client connections.

**Figure 3: The agent routing table and the client table**
Messenger

Messenger is a mediator among agents. It enables the communications between two agents. When receiving a request of connecting to another agent from an agent, the messenger analyzes the request with attached information and retrieves the requested agent information from the agent routing table via the agent data holder by calling `getAgent()` method as shown in Fig. 4. When receiving the retrieving result from the agent data holder, the messenger connects the inquiry agent to the requested agent by calling `connectToAgent()` method if the request agent exists, otherwise it returns a “not found” message to the inquiring agent if the requested agent does not exist.

![Figure 4: The role of the messenger](image)

Connection Adaptor

In fact, the connection adaptor behaves like a protocol handler that dispatches the request from an agent and decides which type of communication protocol to be used between the inquiry agent and the requested external device or system. After that, the connection adaptor connects the agent to the requested device or system via a proxy server corresponding to the communication protocol to be used.

Agents in University2l

University2l (Ma, Huang, and Kunii, 2000) is a virtual university system that is aimed at supporting all teaching, learning and administrating activities via the Internet. It requires many agents to assist teachers, students, and administration staff for the teaching, learning and administration work involved in University2l. After developing many agents written in Java by different people or parties, we face a problem of integrating developed agents into University2l system. The open agent architecture as the agent system platform in University2l solves our problem. Currently, three most often used agents, scheduling agent (Ito and Shintani, 1997), friend-making agent, and web-course maintenance agent, are integrated into University2l, respectively. The scheduling agent is used for personal scheduling, meeting scheduling, team work scheduling, and tele-lecturing scheduling. A user can request to use the agent from his/her private office, a virtual courseroom, or a virtual collaboration room. Friend making agent plays an important role in a virtual university system since users feel lonely when they are teaching/studying in such virtual environment and the friend making agent can help them find friends to chat, discuss, and even collaborate with. To achieve effective and efficient teaching/learning, friends are indispensable. A user can use the friend making agent from his/her private office. Web-course maintenance agent helps teachers to periodically check and update their teaching materials. With more and more Web-based teaching materials, checking and updating them become difficult and tedious. However, it is an important work. The web-course maintenance agent relieves teachers from such difficult and tedious work. A teacher can use the agent from a virtual courseroom. Both scheduling agent and friend making agent are multi-agent systems and web-course maintenance agent is a single agent system. For the multi-agent systems, communications among agents are conducted via the messenger on the platform layer of the open agent architecture. It is necessary to point out that University2l is currently a centralized system. Integrating three agents to University2l follows a centralized fashion. The programs of three agents are uploaded, unpacked, and resided in University2l’s server machine as we discussed above. The agent server programs are run in University2l host and the client program is automatically downloaded to and runs on the user’s local Java virtual machine when a user requests to use the associated agent by clicking a hyperlink in a web page. The integrated agents are transparent to all users in University2l. Users are not aware where agent programs are. What they do just interact with GUI of each agent. They can input their preference, make requests, be consulted with, and get reporting results as well as communicate with an agent through the GUI of the agent.
Conclusions and Future Work

To be platform independent, the open agent architecture is implemented in Java language. For those agents developed in Java language are expected to be easily and flexibly integrated into a virtual learning community system via the open agent architecture platform. As a virtual learning system, University21 has the open agent architecture embedded. Three agents are integrated into University21 via the open agent architecture platform. It proves the our design efforts of the open agent architecture: making the system easy to integrate developed agents, making agent developers flexible to modify their agents, and making agent related information transparent to users. The agent architecture is just like a door of a virtual learning community system that is open to developed agents and allows them to easily and flexibly join and work for human in the teaching/learning community.

It is necessary to emphasize that the open agent architecture is applicable not only in Web-based learning community system but also any Web-based virtual systems such as virtual trading/shopping center system, home agent system, a virtual company, and a virtual city where various agents are used. However, this research is just at its infant stage, there is lot of remain work to be done. We will mainly focus on implementing a distributed open agent architecture, handling agent synchronization problem, and making agent manager intelligent.

Acknowledgments

The author thanks Mr. Masao Nonaka and Ms. Sanae Wada for their partial implementation work.

Abstract: Web-based instruction provides a new medium for the presentation of instructional activities. The medium has the capability of addressing individual preferences and styles of learning through its structure and the use of multiple forms of media. Through careful design and adherence to the objectives of instruction and to learners' needs, web-based instruction can provide a successful environment for a variety of learners. Factors in the web-based environment, such as visualization, as well as individual student characteristics, such as goal orientation, achievement, and perception, must be taken into account, so the design of web-based instruction enhances the educational opportunities of the learners. This study examines learner characteristics that impact engineering students' use of a web-based instructional environment as well as their achievement.

Research Framework

Web-based instruction is a form of hypermedia that is delivered through the World Wide Web [WWW]. Web-based instruction provides a new medium for the presentation of instructional activities that has the capability of addressing individual preferences and styles of learning through its structure and the use of multiple forms of media. Web-based instruction can be developed to closely augment the structure of a learner's memory and place the learner in control of instruction. In the development of web-based instruction, the designer must realize that the instructional media are merely vehicles for the exchange of ideas. There is a need for sound pedagogy and meaningful and stimulating learning experiences that focus on the needs of the learner in order to improve education (Reeves, 1996). The understanding of principles about how individual learners organize and retrieve knowledge and develop personal schema is vital to the design of web-based instruction.

Due to the shift from behavioral to cognitive perspectives, researchers have become increasingly interested in the manner in which learners process information (Ausburn & Ausburn, 1978). Cognitivists define education as not the mere transmission of facts, but the construction of robust mental models (Ormrod, 1995). As a cognitive tool, the WWW can be utilized for knowledge construction instead of reproduction, the design of knowledge, and meaningful learning (Reeves, 1996). Therefore, it is important to determine how individuals learn in order to determine how web-based instruction can reach its potential in educational settings.

The designers of web-based instruction can capitalize on its characteristics as a form of hypermedia instruction to meet the needs of individual learners. First of all, the environment can be designed to take advantage of the structure of the learners' mind. Web-based instruction is a potential learning tool with the capability for extending and augmenting the mind of a learner (Marmolin, 1991). The environment can serve as an information processor, guiding or scaffolding students through cognitive strategies to enhance the organization of their knowledge structures. Web-based instruction has the capability to move the act of learning from hearing and seeing to doing and understanding. Secondly, web-based instruction can capitalize on a learner's motivation for learning, the individual's goal orientation, and their verbal or visual learning preference. By adapting to individual learning styles during the design phase of web-based instruction, individual needs in the learning situation are met.
In order to aid students in the visualization of information, web-based instruction can be designed using multiple forms of media, such as animations, graphics, and text. These multiple forms of media provide the learners with rich and realistic contexts for multichannel learning. The navigational scheme of the environment can be designed so the interface is user-friendly, simple, and the interconnectedness of ideas is clear (Cockburn & Jones, 1996; McLellan, 1992). Learners’ goal orientation, whether task goal orientation, relative ability orientation (performance-approach or performance-avoid), or extrinsic goal orientation, affects the learners’ focus while exploring the information provided in the environment. These classifications impact the students’ performance in the class and their navigational pattern within the environment. Finally, students’ perceptions of web-based instruction ultimately impact its value and use.

In web-based instruction, the design should not be transferred just from one medium to another, but the experience should be redefined with the capabilities of the new medium utilized. Instructional designers must capitalize on the new opportunities that the web provides to learners—to access information from remote locations, to interact with the instruction, to access the instruction at their own pace, to visualize the instruction, and to see the complex relationships in the instruction (Alexander, 1995; Owston, 1997). The design of web-based instruction should not focus on the technology but on the goals of the lesson, the needs of the learner, and the nature of the task involved (Rieber, 1994). "The World Wide Web can appropriately be considered the largest and most diverse hypermedia system in existence" (Eveland & Dunwoody, 1998); however, little research has been published regarding the uses and effects of learning from a web-based environment. Therefore, there is a need for more sound research about the impact of the WWW on learning.

Research Questions

In order to validate the design and utilization of a web-based instructional environment such as ThermoNet, several research questions were explored. These questions focused on the design features that best enable students of thermodynamics to succeed in a web-based instructional environment. The questions this study attempted to answer were: (1) Which student characteristics affect student achievement to the greatest degree? Characteristics to consider are students’ goal orientation, modal learning preference, and access time., (2) Which student characteristics affect the amount of time students engage in ThermoNet to the greatest degree? Characteristics to consider are students’ goal orientation and modal learning preference. Additionally, how does students’ academic achievement affect the amount of time students engage in ThermoNet?, (3) How are students’ perceptions of ThermoNet affected by their characteristics? Characteristics to consider are students’ goal orientation, modal learning preference, access time, and achievement., (4) What are the benefits of utilizing the web both as an instructional and a research medium?

Design of Study

Sample

The participants of the study (113) were volunteers taking the course ME 326: Thermodynamics in the School of Engineering at the University of Texas at Austin. The course is an introductory level course based on thermodynamics that is required for all engineering majors who are focusing on mechanical engineering; therefore, students within the course had a wide range of abilities. Typical of engineering courses, there was a male dominance with only 17% of the population consisting of females. The average age of a student enrolled in the course was 21.2 with ages ranging from 18-35. The breakdown of the ethnic background of the students included: 45% Anglo-Saxon, 28% Asian, 12% Hispanic, and 6% African-American. The remaining 9% chose not to disclose their ethnic background.

The amount of computer access and expertise for the sample population was plentiful. Out of the students polled, 82% of the students had computers at home while 18% did not. A large percentage of the students (38%) had also used advanced applications, such as programming and web publishing. The majority of students felt that they were fairly competent in using computers.

Treatment
The web-based instructional site used for the study is entitled ThermoNet. The underlying goal of ThermoNet was to be the most versatile and interactive source of thermodynamics on the Internet. Since the time of its creation, ThermoNet has evolved into a more comprehensive source of information to supplement regular classroom instruction for the course ME 326: Thermodynamics.

Due to the potential benefits of a web-based instructional environment, it was deemed unethical to pursue research with a group of students who had no access or less than desirable access to the treatment condition; therefore, ThermoNet was accessible by all of the students involved in the study, and no control group was used. Since ThermoNet was conceptualized as a supplement to traditional classroom instruction, groups of students who utilized the web site to varying degrees naturally occurred.

ThermoNet was designed as an instructional web site for many reasons. It was originally envisioned as a site for students to not only find supplementary materials to the textbook, but also to particularly focus on the elements of communication that utilize the unique attributes of the web. Those elements of communication included the use of graphics, interactivity, access to subject matter, and access to real-world applications. The goal of the developers was to create a highly graphic site since thermodynamics is not a naturally graphic topic. The developers used interactivity as a key component of ThermoNet. The objective was to present concepts succinctly and then enable the student to interact with the web site to reinforce the concept. Finally, the developers created real-world applications within ThermoNet. Through graphics and video clips, more real-world applications could be portrayed in an instructional web site than in a conventional text. In summary, the developers attempted to capitalize on material that could be communicated through the web and was not readily accessible by a student of thermodynamics.

Variables

Independent Variables

There are four independent variables used in the study: (1) goal orientation, (2) verbalizer-visualizer classification, (3) academic achievement, and (4) access time. Students' goal orientation was measured by an adaptation of the Patterns of Adaptive Learning Survey (PALS, Midgley et al., 1997). PALS was designed to measure four separate constructs: task goal orientation, performance-approach goal orientation, performance-avoid goal orientation, and extrinsic goal orientation. The Cronbach's alphas for this scale were reported from .69 to .76 (Midgley et al., 1997) and greater than .70 (Midgley et al., 1998). The students were classified as either a verbalizer or visualizer according to the Verbalizer-Visualizer Questionnaire [VVQ] (Richardson, 1977). The VVQ was found to have adequate internal consistency reliability, .70 and .59 for verbal and visual items respectively (Kirby et al., 1988). Students' knowledge about the concepts of ThermoNet was assessed through a posttest. The posttest was the students' final exam that was developed by the professors participating in the study. Students' access time was calculated by subtracting the time students entered ThermoNet from the time they exited the site. The server tracked the students' usage for two months--from mid-semester until the end of the semester.

Dependent Variables

There are three dependent variables used in the study: (1) academic achievement, (2) access time, and (3) perception of ThermoNet. Both academic achievement and access time were briefly described in the Independent Variables section. In order to determine the utility of ThermoNet and the impact of a web-based instructional environment on students, a Perception Survey was given to the subjects in the study. The content of the survey covered the following categories: Achievement and Design. The coefficient alphas for the Perception Survey subcategories were .91 for the achievement category and .89 for the design category with an overall alpha of .92.

Qualitative Data

Each student who participated in the study filled out a detailed questionnaire. This questionnaire was solicited in order to gain further information regarding the students' perceptions regarding learning thermodynamics and their perception of the potential usefulness of computer-based learning resources. In order to get further insights into the general use and evaluation of ThermoNet, qualitative interviews were administered to individuals in the study. Interviewees were a diverse selection from the sample population. Students were selected for the interviews using purposeful sampling: theory based sampling and maximum variation sampling (Patton, 1990). The purpose of the interview was to probe the reasons behind students' time spent engaged in ThermoNet, their preferred learning style, their favorite features of ThermoNet, and what aspects of ThermoNet they believed could be enhanced in the future.
Procedures and Analysis

Each of the 3 classes of Thermodynamics was asked to participate in the study. Prior to conducting the study, the contents and features of ThermoNet were demonstrated to students in their discussion groups. Because the web-based instructional environment was a supplement to the students’ typical instruction, the subjects accessed the site during their personal study time. The time that students used ThermoNet was a unique aspect of the study since the data were gathered from the server. The demographic questionnaire, Perception Survey, VVQ, and adaptation of the PALS were administered during discussion groups that were conducted by the teaching assistants. The academic achievement test was administered during the regular final exam time by the professor of the course.

In order to answer research question one (Which student characteristics affect student achievement to the greatest degree? Characteristics to consider are students’ goal orientation, modal learning preference, and access time.), a stepwise regression was calculated to determine if student characteristics and access time predicted the academic achievement. All of the students who participated in the study, whether or not they actually accessed ThermoNet, were included in the regression analysis. All of the students were used since insight could be gained from knowing whether or not students of certain characteristics accessed the site or not.

In order to answer research question two, (Which student characteristics affect the amount of time students engage in ThermoNet to the greatest degree? Characteristics to consider are students’ goal orientation and modal learning preference. Additionally, how does students’ academic achievement affect the amount of time students engage in ThermoNet?), a stepwise regression and an ANOVA were performed. First, the regression was used to determine if student characteristics predict access time. All of the students who participated in the study, whether or not they actually accessed ThermoNet, were used in the regression analysis. Second, an ANOVA test comparing the access time among two achievement groups was conducted. The top and bottom quarter in terms of achievement, was the independent variable.

In order to answer research question three (How are students’ perception of ThermoNet affected by their characteristics? Characteristics to consider are students’ goal orientation, modal learning preference, access time, and achievement.), a stepwise regression was calculated to determine how the student characteristics, access time, and achievement predicted the students’ perception of ThermoNet.

In order to answer research question four (What are the students’ perceptions of the benefits of utilizing the web both as an instructional and a research medium?), questionnaires were administered to all of the students and open-ended interviews were conducted with students of differing achievement levels and with students labeled as visualizers and verbalizers to gain insight into the students’ backgrounds and perceptions of ThermoNet.

The ultimate goal in analyzing the preceding research questions was to determine the impact of learner characteristics on students’ achievement in thermodynamics and their perception of a web-based instructional environment. With this goal in mind as well as the limitations of the study, the quantitative questions were analyzed using the statistical procedures, regression analysis and ANOVA. The results of these statistical analyses were triangulated with the qualitative interview data.

Results and Discussion

The present study gives many insights into the students’ characteristics, and how these characteristics impact the students’ achievement, their use of ThermoNet, and their perceptions of a web-based instructional environment. While some of these results seem counterintuitive, they reveal how specific student characteristics need to be taken into account during the design and development of web-based instruction.

One of the main goals of the study was to determine the effect of students’ goal orientation, learning preference, and access time on their achievement. The stepwise regression analysis showed that the best predictors of achievement were performance-avoid goal orientation (t=-2.976, p<.05) and performance-approach goal orientation (t=2.293, p<.05). These two variables predicted almost 11% of the variance in the students’ final exam grades. Students with a performance-avoid goal orientation were more likely to have a lower achievement level. On the other hand, students with a performance-approach goal orientation were more likely to have a higher achievement level. Students with a performance-approach goal orientation focus on demonstrating and proving competence. They tend to be competitive in a scholastic setting and this competition often leads to the acquisition of a higher achievement level. On the other hand, students with a performance-avoid goal orientation tend to be low achievers. Typically focused on avoiding the display of lack of competence, these students tend to feign more intellectual ability than they actually possess. They often try to avoid challenging tasks and display decreased performance (Elliott & Dweck, 1988; Miller et al, 1993).

888
Page 838
The results suggest that the web-based instructional environment had no impact on the students' achievement since time spent engaged in ThermoNet was not a predictor of achievement. In order to gain additional information about achievement, students who did log on to ThermoNet were divided into two groups according to the amount of time spent on ThermoNet. Table 1 reveals the descriptive statistics for the two groups of individuals who used ThermoNet. The descriptive statistics revealed that students who used ThermoNet less actually had a higher achievement score than students who used ThermoNet for more than 90 minutes. Therefore, an analysis of variance for the two groups was conducted which revealed that the difference between the two groups was not statistically significant although the large difference in number of students in each group was a limitation.

In order to determine how students' perceptions of ThermoNet impacted their achievement, a stepwise regression analysis was computed. The regression analysis showed that the best predictors of students' perception of ThermoNet's impact on achievement were performance-avoid goal orientation (t=3.655, p<.05) and extrinsic goal orientation (t=-2.622, p<.05). These two classifications predicted almost 27% of the variance in the students' perception.

A regression analysis was also conducted to determine the predictors of students' perceptions on the design of ThermoNet. The regression analysis showed that the best predictors of students' perception of ThermoNet's impact on achievement was the final exam grade, verbalizer, and performance-avoid goal orientation. These three classifications predicted over 27% of the variance in the design portion of the ThermoNet Perception Survey.

The results of the questionnaire indicated that students often have difficulty applying general theory to specific cases and formulating solutions from problem descriptions. They also insinuated having difficulty knowing where to find correct property data for example problems. Students suggested they were lacking a physical "feel" for the subject matter. Overall, the students implied that they were satisfied with the course. They were content with the
depth of knowledge, the time spent on specific sections of the course, and the tests covering the information. In order to extend the information gathered through the instruments specified in the study, eleven students voluntarily participated in an interview. Several themes emerged from the analysis of the interviews. These themes included: lack of time, focus of content, preferred mode of learning, and future enhancements.

Many developers believe that when they develop effective instruction, adoption of its use will follow in time; however, this might be a false assumption. The “if you build it, they will come” mentality is not a true statement when working with students who are already pressed for time and are given the option of whether or not to use the instructional medium. Present day students grew up using video games and have a “point-and-click” mentality. This is a trend and designers must tailor their approach to designing instruction to fit the natural background of the students. Therefore, in order to have students access a web-based instructional environment, incentives or requirements must be built into the design. These incentives should be determined during the outset of the development of the site so that the objectives of the web-based instruction can be designed around this idea. Otherwise, if there is no required connection between the web-based environment and what students are expected to learn, there will be little traffic on the site as was evident in this study.

Although the effectiveness of web-based instruction is still unknown for the majority of contexts, the present study attempted to find some research evidence for the support of web-based instruction. The findings of this study provide insight into the type of individuals who use and benefit from web-based instruction and how these characteristics predict their perceptions of a web-based instructional environment. While some of the findings were inconsistent with hypothesized results, the study as a whole gives insight to instructional designers about the capabilities of the WWW for instruction and how web-based instruction should be designed to promote learning.

An Intelligent Agent for the Promotion of Learner Independence

Ray Jones, John Cook and Fiona French
Learning Technology Research Institute
University of North London
Holloway Road, London N7 8DB, UK
r.jones@unl.ac.uk

Abstract: There is a current trend, in Higher Education, towards a student-centred approach to teaching and learning that will better prepare a student for the role of lifelong learner in the future. This approach sees the teacher becoming a facilitator in the learning process, rather than the transmitter of knowledge and the student taking more responsibility for their learning.

In order to promote this type of learner independence we propose a type of intelligent agent that we term an Automated Learning Assistant (ALA). The ALA is a system that attempts to mimic some of the teacher's facilitation behaviour by providing support for the student in the tasks associated with learning, rather than providing direct help in a particular knowledge domain. That is, the ALA knows about the process involved in taking a particular course of study but not about its content.

Introduction

The ALA is an automated system that can provide personalised help in the way that a learner approaches their study of a course. The ALA performs tasks and provides help that would otherwise be undertaken by a tutor and as such, we characterise the ALA as a form of Intelligent Agent (IA). Lieberman defines an IA thus:

An intelligent agent is any program that can be considered by the user to be acting as an assistant or helper, rather than as a tool in the manner of a conventional direct-manipulation interface. An agent should as well display some, but perhaps not all, of the characteristics that are associated with human intelligence: learning, inference, adaptability, independence, creativity, etc. (Lieberman, 1997).

Unlike the use of IA in Intelligent Tutoring Systems (e.g. Ramirez Urusti, 2000 and Cook, 2000) the purpose here is not to provide help from within the learning domain. Rather, its role is to advise the student on how they should be engaging with a course of study and to prompt them if they appear to be problems.

ALA Functions

Among the functions that an ALA would perform are:

1. Remind the learner of due dates and deadlines (for the submission of assessed work, for example).
2. Remind the learner of work not done or resources not accessed.
3. Help in finding resources for a task and management of those resources.
4. Managing a repository of personal notes and other work.
5. Submission of coursework from the repository.
6. A function that allows learners to contact others who are working on similar tasks to facilitate cooperative working.

Furthermore, it is the intention that the functionality described should not need to be designed for individual courses but that courses are designed such that a generic ALA could access the online resources of any course and provide assistance to any learner on that course.

Technical Architecture

In order to provide similar functionality across a number of courses, those courses need to be designed utilising an open architecture, such as, proposed by the IMS Project (Graves, 1999). Here, the online resources for a
course are described in a standard format that can be easily accessed, programmatically. The purpose of this type of initiative is to make the components of a course more easily re-usable and to bring some standardisation to managed learning environments. However, by extending the information (or metadata) about the course in a similar open way, an intelligent agent could extract appropriate data from the course structure that would be of timely use to the learner. The language of choice in these matters is XML as this provides a vendor independent representation of a data source that can be relatively easily manipulated using standard software tools.

Interface

One of the most important aspects of the ALA system is the user interface. Unless the user can adequately engage with the system and therefore take advantage of its facilities then its utility is severely compromised.

One approach would be to utilise a ‘portal’ approach with the various sections of the portal mapping onto the functions of the ALA. Here the ‘agent’ effectively disappears into the interface itself. An alternative would be to attach the agent functionality as a kind of toolbox that is attached to the online course (one can envisage this being drop-down menus or toolbars). Here the agent functionality is explicit and a separate part of the interface.

A second version of the explicit agent would be the use of an avatar or virtual helper. There are good reasons to suppose that such an avatar might be useful, particularly for learners who are not used to the agent functionality. While they might not provide much more in the way of functionality, they can provide a useful ‘hand-holding’ function for new users, who later might abandon the avatar for a simpler interface (Sumner and Taylor, 1997).

This suggests that a customisable interface might work best, with the user being able to select from a number of options depending on their preference or familiarity with the system.

Data Architecture and Agent Logic

As mentioned before the data representation of the resources would utilise IMS-style structured data that would incorporate references to physical resources but also data regarding the timing of assessment, how resources are related to particular tasks or topics, etc. Additionally, data structures would be designed that would record the activity of the learner, for example, work that had been completed and resources that had been accessed. These structures would be accessed by the agent logic to provide the agent functionality to the learner.

Conclusion

The aim of this work is to design an intelligent system that will provide real help to the learner in the way they organise themselves for study. It is also the intention to draw on existing or emerging standards (e.g. IMS) in order to make the system compatible with courseware delivery systems and to make it generic in order that the same system could operate on similarly structured courses.

Abstract: We developed the VR program to be used to learn the periodic table in chemistry education. It is discussed how to develop the VR periodic table and what to learn through that. The VR program is developed using the 3D Webmaster program of Superscape. The students can receive the feedback according their action on the VR world. There are some chemical knowledge such as chemical elements, atomic radius, electron affinity, and ionization energy etc. The students could study interestingly and cooperatively the periodic table.

Introduction

As the computer is popularized in individual and society, it is using a many of area. In particular, there are many materials to learn a science knowledge using multimedia through computer. Many of them are web-based learning materials, which are developed by Java or Flash. Since the technology of the representation, storage, computation and communication in computer make progress, the environment of education is also developed.

Virtual Reality (VR) referred to 'immersive Virtual Reality.' In immersive VR, the user becomes fully immersed in an artificial, three-dimensional world that is completely generated by a computer (Steuer, 1992). It is also possible to define VR in terms of human experience, 'a real or simulated environment in which a perceiver experiences telepresence,' where telepresence can be described as the 'experience of presence in an environment by means of a communication medium.' (Riva, 1999). A key feature of VR is real-time interactivity, in that the computer is able to detect student input and instantaneously modify the virtual world (Seth 1999, Wylmarie, Robert 1999).

It is reported that using the VR simulation in chemistry education can increase student engagement in class, promote understanding of basic chemical principles, and augment laboratory experience (Christine 1996).

In this research, we develop the VR periodic table to grow up the attendance and interest of students in learning chemistry.

VR Periodic Table

The 3D models and objects are presented in the VR periodic table that is developed by 3D-Webmaster of Superscape, therefore the students easily recognize that. There are 4 push buttons on the left-down side in the screen (fig 1). Each of them is the electron affinity, ionization energy, atomic radius and reset. When the students push electron affinity button (fig 2), they can see the periodicity of electron affinity immediately. The knowledge of main
elements is also displayed as pushing those elements in periodic table and the discoverer, character, structure are presented on the other frame.

![Periodicity of the electron affinity](image1)

Figure 2. Periodicity of the electron affinity

![Periodicity of the ionization energy](image2)

Figure 3. Periodicity of the ionization energy

**What To Learn**

Students in the level of middle or high school could learn chemical knowledge such as chemical elements, atomic radius, electron affinity, and ionization energy etc. through VR periodic table. Moreover, since the 3D models or objects are used in learning of chemical concepts, the students can feel the interest, and learn independently or cooperatively in learning situation.

Image Interpretation Of Digitized Signatures

Thirumagal Jothi, Avinashilingam Univ., India; Anusha Dhanraj, Avinashilingam Univ., India; Meena C, Avinashilingam Univ., India

Image database of signatures are maintained and the process undertaken in this project is that new signature is being compared with the existing signature. If the signature is mismatched then using a new module called Experts module is being used for the interpretation of signature images. This project provides various menus for image acquiring, where the image is acquired through image sensors like scanners or digital cameras. An acquired image needs preprocessing like maintaining Levels, Color Balance, Brightness and Contrast, Equalize, Threshold, Variations and Cropping for better performance of images. Most vital part of the program is to remove unwanted dots and scratches, which is done throughout a menu known as SPOTING (which is technically known as Rubber Stamping/Cloning). All the images are converted to gray scale mode using Desaturate method before comparison. Comparison is done pixel by pixel. A separate module for image comparison is provided with two windows. One window is provided for displaying a newly acquired image. In another window the corresponding signature image from the database is displayed. After comparison the expert feeds his analysis and relevant information to provide better results.
Web-Based Instruction; A Paradox and Enigma in Instructional Paradigms and Design Principles

Michael G. Kadlebowski
Northern Illinois University
906 Aspen Drive
Lombard, IL 60148-4254
mgkski@juno.com

Abstract: If we look at the delivery of information and learning via web-based instructional systems we find some similarities to traditional learning, however we find more differences than similarities. We find that many web-based instructional systems do indeed make use of stimulants such as movies, sounds, and graphics. We also find that the best web-based instructional sites provide a reference library of sorts, to assist the student in their understanding of the material elements of the particular course. These reference libraries are usually hyperlinks to other educational or related web sites, which the student can use as a resource to further enhance their understanding of the materials. Some hyperlinks use video and animation to gain and hold the attention of the student, while others are merely “page turner” type of information sites.

But what of the interaction that takes place in the traditional classroom? What becomes of the theoretical arguments that an experienced educator would foster, stimulate, and encourage among the students and/or the educator? What becomes of the personality, fervor, and strength of conviction that normally results as a benefit of these stimuli? What becomes of the vocal intonations, inflections, and the facial expressions exhibited by the student? Are these qualities lost in web-based instruction? Can a chat session accomplish and achieve the finer points of theoretical argument without having the face-to-face stimulants and reactions that are readily apparent in a traditional classroom?

This paper will present the argument that on the basis of initial statistical information that in some cases web-based instruction is not succeeding, and in fact experiences substantially higher attrition rates than traditional classroom instruction, with all other variables being equal.

Thesis Objective

The hypothesis of this paper is to present to the reader an argument as to whether existing instructional paradigms and design principles, philosophies, pedagogy, and practices require revision to effectively teach web-based instruction. Due to the length restrictions of this paper the reader is advised that not all paradigm’s, philosophies, and practices are included, and those that are evaluated as to their usefulness in web-based instruction are very limited in scope, definition, and explanation. In all probability you will find that this paper will ask more questions than it answers, but in doing so will hopefully stimulate each of us to critically view and analyze the effectiveness of the current and prevailing practices employed in web-based instruction.

Background
As early as 1973 Daniel Bell, and later in 1980, the futurist Alvin Toffler identified several massive changes that our society has undergone: from the agrarian age to the industrial age, and now the information age. These futurists predicted a complete change in our societal values, and the reforms that would be necessary to accommodate the change from an industrialized to an information based society. In many cases, these futurists were correct in their predictions, and our society today is indeed mired in the process of adjusting itself to accommodate this new age of information and technology.

In looking at our educational systems and the population of students that these systems serve we find quite a vast array of scope and difference among students. Demands upon and within the educational sectors are changing. For higher education, demographics and workforce changes are fundamentally altering the student population. In 1995, 44 percent of all college students were over 25 years old, 54 percent were working, 56 percent were female, and 43 percent were attending college part time. In 1997, more than 76 million American adults – 40 percent of the adult population – participated in one or more adult education activities, up from 32 percent in 1991 (National Center for Education Statistics).

Today a students’ lifestyle and objectives are also very different than those students of yesteryear. It is not at all uncommon to find that today a typical student may be a single parent, who may be working two or more jobs to make ends meet in order to provide for their family. This same person may want to pursue a higher education, but may be unable to do so as a result of time commitments and constraints that are usually and traditionally required in institutions of higher learning. Additionally we find that many students do not have specific available time blocks, which they can reserve or allocate to a particular course or educational unit of instruction on a regular basis.

More students than ever before engage in learning programs that offer courses at nights or weekends. Some educational institutions even offer courses on Sundays – which in some religions could be considered sacrilegious! Schools have realized that in order to sustain themselves and to remain competitive they must adjust their offerings to accommodate this diverse and ever growing population of students.

As a result of newfound technological advancements in the fields of computer technology, education, and instructional technology, we find that web-based instruction is becoming somewhat commonplace in what would be considered traditional higher educational settings. Many schools now conduct a minimum of some type of web-based instruction. Additionally an entire new industry of web-based instruction has risen to compete with the universities in this endeavor.

In those otherwise traditional institutions where the implementation of web-based instruction has been implemented, the school is assisting the non-traditional student in the meeting of their educational goals and objectives. The school is also meeting its own social obligation to educate even the most non-traditional of students. With the movement toward web-based instruction well underway, the question and thesis of this paper, is whether prevailing instructional and design practices are suitable to effectively support the non-traditional student in their use of web-based instruction.

**Instructional Paradigms & Theory**

A paradigm as defined in Webster's Encyclopedic Unabridged Dictionary of the English Language is an example serving as a model and/or a set of forms all of which contain a particular element...based on a single stem or theme. Therefore in extrapolating and interpolating the term instructional paradigm we could state that the definition would be a set of forms or examples of educational theory and practice based upon particular elements. You could in a broader sense regard this as the practice or pedagogy of instruction and/or design.

Probably the most noteworthy expert on instructional design paradigms is Robert M. Gagne, who authored the *Principles of Instructional Design*. Gagne bases his paradigms on the belief that instructional design efforts must meet intellectually convincing standards of quality and that such standards need to be based on scientific research and theory in the field of human learning. Gagne takes into consideration learning outcomes, including intellectual skills, cognitive strategies, verbal information, attitudes, and motor skills. He also considers the knowledge, skills, and abilities of learners and how the differences among learners affect instructional planning and design.
Behaviorism was a term coined by the American psychologist John Broadus Watson (1878-1958) in his paper, "Psychology as the Behaviorist Sees It." It is a theory of animal and human behavior holding that actions can be explained entirely as responses to stimuli, without accounting for the profound influences of interpretation on introspection. Thus an educator who believes in behaviorism would tend to attribute learning as a reaction to an event or action that would stimulate the student, but would be provided by the educator. To the behaviorist, teaching is essentially a matter of arranging contingencies of reinforcement so as to produce and maintain prescribed behaviors.

Constructivism is quite an opposite paradigm of behaviorism as described and defined above. Jerome Brunner first proposed the concept of constructivism in the mid-1960's and builds on earlier ideas of Jean Piaget. Basically, the theory of constructivism holds that the learner rather than the educator develops or constructs knowledge and that opportunities created for such construction are more important than instruction that which originates from the educator. This is certainly not to state that there is not educator guidance or involvement, but that the student essentially will have a very strong voice in the selection and completion of tasks that will aid her in their learning approach to the given subject matter.

Web-Based Instruction

If we look at the delivery of information and learning via web-based instructional systems we find some similarities to traditional learning, however we find more differences than similarities. We find that many web-based instructional systems do indeed make use of stimulants such as movies, sounds, and graphics. We also find that the best web-based instructional sites provide a reference library of sorts, to assist the student in their understanding of the material elements of the particular course. These reference libraries are usually hyper links to other educational or related web sites, which the student can use as a resource to further enhance their understanding of the materials. Some hyperlinks use video and animation to gain and hold the attention of the student, while others are merely "page turner" type of information sites.

But what of the interaction that takes place in the traditional classroom? What becomes of the theoretical arguments that an experienced educator would foster, stimulate, and encourage among the students and/or the educator? What becomes of the personality, fervor, and strength of conviction that normally results as a benefit of these stimuli? What becomes of the vocal intonations, inflections, and the facial expressions exhibited by the student? Are these qualities lost in web-based instruction? Can a chat session accomplish and achieve the finer points of theoretical argument without having the face-to-face stimulants and reactions that are readily apparent in a traditional classroom?

The correct response to these questions is that it depends upon the design of the course and the process of delivery that is used. If a web-based course is designed along the lines of the Gagne theory of instructional design, it could certainly achieve and accomplish its' objective. However while the elements of design are crucial and critical, so is the interaction of the students with both each other, as well as the educator. Regardless of how well web-based instruction is designed, if it is designed solely as a stand-alone product without any human interface or interaction it will, at the very least, not meet its' learning objectives or in the worst case, the ultimate goal to educate. Most students need interaction and human intervention so as to gain and experience the sociological elements of instruction.

The focus of a recent study by West Texas A & M University on the attrition rates for 15 graduate business courses offered on campus as well via a web-based instructional method reveals some interesting statistical patterns. During a three-year period beginning in 1997, it was convincingly found that MBA courses delivered via web-based instruction experienced a substantially greater attrition rate than did the same courses taught by the same professors in a traditional setting. The only variables between the two settings were the students and the delivery medium. The overall combined attrition rate for the web-based courses was a resounding 50% greater than the on campus courses, with several web-based courses experiencing an attrition rate of greater than 100% of those taught using traditional methods on campus! Some of the explanations of the higher attrition rates offered by the authors of the study include but are not limited to the following factors:

- Students were not able to adjust to the self-paced approach.
The rigor of the study was greater than anticipated.

Lack of student and faculty experience with web-based instruction.

Of particular concern and note is that courses in the various business disciplines that rely upon mathematics appear to be especially ill suited to web-based instruction. As an example, a Statistical Methods course on campus experienced a 13% attrition rate, while its' web-based equivalent experienced an attrition rate of 43%, or greater than 3.3 times the attrition rate of the on campus course. A Quantitative Analysis in Business web-based course experienced an attrition rate of 33% as compared to the same on campus course which experienced an attrition rate of 17%, or about half that of the web-based course. These differences in attrition rates should not and cannot be ignored.

In a survey of online teachers and learners recently prepared for the Project Steering Committee of the VET (Vocational Education Teachers) Teachers and Online Learning Project the report author indicates that there are several themes running through the comments that are cautionary. These include the need to ensure that the instructional design is correct, and that motivation concerns, as well as the difficulty and confusion of on-line users is taken into consideration during the design process.

Could it be that our quest to satisfy the masses and provide an educational forum for such a diverse audience is somewhat poorly designed or ill conceived? Could it be that the lack of human intervention or contact is a contributor to the causes of frustration and ultimately to the significantly higher attrition rates of web-based instruction?

In my own teaching experience in web-based instruction, I have found that even on the best graphically designed web site, the student needs and will actually seek out interaction with another student or the educator. This human intervention and interaction is crucially required of many students, but not all. Some students are perfectly content viewing and reading information from a computer monitor and learning in this way. But the two fundamental design questions remain: what is the objective of the particular course, and what is the desired instructional outcome? If these two questions do not include the learning of social interaction among culturally diverse students, have we not failed to meet our social obligation to educate?

To illustrate further I have discussed web-based instruction with Professor Margaret West, Ph.D. of Northern Illinois University. In any course in which Dr. West provides web-based instruction she insists on face-to-face class meetings at various points throughout the semester. This allows the students to interact not only with each other but also to be mindful of the humanness of the educator. It allows the educator also to view the humanness of the student, who may be shy, or intimidated by either the web-based instruction, or the human interaction with fellow students. In any event this human interaction provides a further development of the educational endeavor, and allows for the student to learn the intricacies of the social environment of learning. In a written response to my inquiry as to the necessity of these activities, Dr. West responded as follows:

"In the past, I taught the course entirely online with just a face-to-face kick off and a face-to-face debrief. Feedback from students in the debriefs indicated that they were seeking more external support for avoiding procrastination in the course. They also wanted opportunities to meet with their partner for the partner consulting activity. With that feedback, I decided to add a face-to-face meeting approximately once a month. The goal of the face-to-face meetings is to provide a "check-in" on course assignments so the student paces the assignments throughout the semester, and to provide an opportunity to meet with their partner."

In having the opportunity to bring to fruition a mix of the traditional class room environment along with a constructivist educational attitude, I believe that the student will learn a great deal more as a result of human intervention and interaction than when merely left alone at the web site to learn. The fact of the matter
is that much of web-based instruction includes the ability of the student to engage in forum discussions with other students, and at predetermined times with an educator leading the course of discussion. Additionally in many web-based instructional settings the student can and does frequently send e-mails to the educator or other students. Fundamentally however, these interactions are not human interactions at all. These keystrokes are merely a very weak substitute for the actual human interactions that would readily take place in a traditional classroom setting and provide only for the instantaneous delivery of inquiries and work product.

Certainly there are numerous other theories of instruction that could possibly demonstrate arguments on either side of this thesis. As an example, lets briefly consider problem-centered learning, within the element of web-based instruction. One of the most noteworthy educators of our times, Dr. Thomas M. Duffy of Indiana University and Unext.com is a strong proponent of problem centered learning in a web-based environment.

While I certainly do not possess neither the education, the credentials, nor the experience to argue this point with Dr. Duffy, I believe that I can respectfully suggest at a minimum that problem centered learning on the web, may not be suitable to every student. Once again, without human intervention and the social implications and benefits that this type of interaction provides to the student, the student may eventually find themselves lost in their ability to intellectually and emotionally engage in the most simple of arguments or discussions.

Aside from the normal fears that some students have relative to their ability to function within a personal computer environment, what other fears may exist if we enroll this student in a web-based course to which she may possess little or no knowledge, and then “throw her to the wolves” using a problem centered scenario? I fully realize that even in a problem centered scenario there are on-line resources available to the student including chat forums, additional reference materials, and even periodic and timely assistance and feedback by the educator. However, without having any academic knowledge of the subject matter, coupled with these other fears within a problem centered scenario, with little or no in-person intervention available would appear to be a situation that would have a high likelihood of failing to meet the learning objectives of that particular course of study. Even if specific learning objectives were met and determined to be successful, have we not failed to provide the student the type of human interaction and socialization that may assist them overall in their particular vocation? Why would we want to place a student in the position of potentially passing a course of web-based instruction, but not learn the art and beauty of social interaction and behavior coupled with intellectual stimulation and constructive argument?

On the positive side most web-based instruction does provide discussion forums, discussion groups, and e-mail capability. Collectively these various venues enhance the students’ ability to write philosophically and intellectually. Using these forums will indeed enhance the educational benefit of web-based instruction, but not necessarily to the same extent that web-based instruction coupled with human interaction could or does.

Conclusion

The solution to the issue of designing an effective web-based instructional model lies in the answer to the following question. In which ways can web-based instruction bring both the best instructional process to the student, as well as bring about the convergence of a stimulating and encouraging environment of learning while also meeting learning objectives within a social environment? Is a shift in design and practice paradigms necessary, or are we what we are experiencing merely a juxtaposition and congruency of the instructional design principles of Gagne, coupled with the principles and practices of either the behaviorist and constructivism approaches to learning?

Is or will it ever be possible for us as a society to provide the same type of interaction that takes place in classrooms via web-based instruction? If so, will we loose any of our abilities as educators, or will web-based instruction create more clearly defined challenges and obstacles to the educational process? Will web-based instruction be able to take advantage of alleviating distances between the masses while still being in a position to provide a quality education, or will web-based instruction fall by the way side as merely a technology fad that was temporary at best?
With only limited research or empirical data and/or analysis available on this topic or of the effectiveness of web-based instruction to accomplish learning objectives, we can all pontificate and engage in this type of hyperbole. However with the emergence of preliminary research as referenced earlier, there are strong indications that web-based instruction may not be achieving its educational goals. What may be necessary is that a combination of the tried, tested, and scientific principles of instructional design and educational pedagogy must be employed in order for web-based instruction to succeed. Unequivocally, under no circumstances should proven instructional principles be sacrificed in order to serve the masses more efficiently.

In order for web-based instruction to succeed with the same or exceedingly difficult goal of increasing the benefit of the educational experience to the student, a new type of web-based design and instructional practices, principles, and pedagogy will emerge. A new type of instructional delivery system will continue to emerge and evolve as a result of technology advances and convergence in the way of high-speed video conferencing, tele-immersion, and real time conversations using a readily available and affordable high capacity bandwidth.

A new type of educator will also emerge. This will be an educator who has had the successful experience of teaching in a traditional classroom setting but is able to take advantage of the technology to bring forth a better delivery method of instruction within a web-based instructional setting. This will be an educator who believes that personal intervention within a web-based environment is not only necessary for the student, but also for the educator and indeed will provide a valued sociological benefit to both.

Is web-based instruction a suitable alternative for all subjects, for all students, and/or for all institutions? The unequivocal response to this rhetorical question is of course not. Each of us possesses certain behaviors, skills and attributes, which allows us to learn. We are as different in these processes as the night is from the day. Web-based instructional methods are only a single source utilized to expedite instruction. Some students will continue to use the services of a traditional institution, coupled with web-based instruction, while other students will be more suited to the rigors of a traditional classroom situation.

Will we require making a committed and concerted effort in a paradigm shift in order for web-based instruction to succeed? I am not certain that a complete shift in tried, and tested philosophies, paradigms, and methods is as necessary as is the return to the fundamental approach to education which is to recognize the uniqueness and differences in learning style’s and learning patterns that distinguishes us as human beings, students, and individuals. Only with the acceptance of these learning differences can we as instructional designers, and educators utilize the technology resources to reach the masses. Only with this recognition of differences will we be in a position to challenge and to establish new paradigms of instructional design philosophy. Only with the recognition of these differences will we establish and possibly redefine the instructional philosophies and practices, which currently exist within a web-based learning environment.

Time, experience, technology and the dedication of educators and students to attempt new methods of delivery and instruction will be one of the bases of foundations for any new or re-configured paradigms and/or instructional practices that may come into existence in the future. The evaluation of these success and/or failed attempts coupled with only the passage of time will eventually allow us to effectively evaluate the changes necessary to determine if a shift in educational paradigms, philosophies, dogma and practices are required to suit the information age, and more specifically web-based instruction.

It is imperative and essential that the reader understand that I am not as a professional just another contrarian opposed to web-based instruction. If web-based instruction is to be utilized as yet another delivery mechanism for instruction, it must be designed in accordance with instructional technology principles that take the humanness of both the student and the educator into full consideration. Ultimately if the human factor is incorporated into web-based instruction we as a society will have successfully merged technology with the human elements of communication to ideally suit a generation of students raised upon tried and proven principles of education, coupled with the use and the excitement of technological resources.

In any event, we as educators are very fortunate indeed to be involved on the “cutting edge” of a distance learning evolution and revolution! What an exciting opportunity for each of us to participate in the development and establishment of a new paradigm ideally suited to this new and ever changing technology as well as meeting the needs of the student and society. What an exciting time to be involved in the educational process and in the future development of intellectual stimulation, inquiry, and argument using advanced technology!

Abstract: For the first time at teacher education sector in Finland the Vocational Teacher Education College in Hämeenlinna offered basic pedagogical studies (10 credits) in the net-based environment. This pilot project and development work created new possibilities for teacher education by producing and representing new, creative and innovative but at the same time clearly functional solutions and alternatives.

New developments

Hämeenlinna Vocational Teacher Education College (VTEC) at Hämeenlinna Polytechnic is coordinating a 3-year-project designed for vocational adult education centers in Finland. Altogether over 700 teachers are developing their own work and functions of the adult education center by studying 35 credits in this project.

Purpose

The purpose of this action research is to design, develop and realize a 10 credit course in basic pedagogical studies in a network based learning environment during the year 2000-2001. In the research, attention is also paid to the Information Strategy Program for Education and Research of the Ministry of Education for 2000-2004.

The action research is linked to a beginning post-graduate qualitative research focusing on these 10 credits of basic studies in this project. The results of the studies will be reflected to the goals of vocational teacher education. The research design is emphasized in the mutual development together with the students (Heikkinen, Huttunen & Moilanen 1999; Hart & Bond 1995.) The cyclical process of this action research is brought about by the development work. The purpose of participatory action research is to produce knowledge and action, which is useful for the acting group, and which empowers people on a deeper level through the processes of constructing and using knowledge. The knowledge and experience of those involved in the research is respected and valued in participatory action research according to the emancipatory interest of knowledge. (Reason 1998.)

The point of developing adult education centers becomes important in connection with these studies. Network based learning gives the opportunity to study simultaneously with learning at work and students get personal experiences of e-learning, so that these instructional designs could become more popular in adult education centers.

Framework: Basic Pedagogical Studies 10 credits

These studies are designed according to the Hämeenlinna VTEC's mutual agreement with Helsinki University, Faculty of Education. The studies are divided into three modules. The pedagogical planning of these modules is...
based on the latest research in open and distant learning environments and pedagogy in web-based learning (Matikainen & Manninen 2000; Kiviniemi 2000; Pyykkö & Ropo 2000; Aarnio 1999 and Enqvist 1999). The main challenge was to design functional solutions and select the tools, which enabled reflective learning processes through e-learning in WebCT learning environment.

Each module was based on the constructivist view of learning (Rauste-von Wright & von Wright 1994). The pedagogical implications were developing metacognitive skills, emphasizing understanding, situational and problem based learning, and different ways of producing knowledge (Tynjälä 1999). Because all these students already work as teachers, they were frequently asked to give feedback about this course to enrich and facilitate the development of virtual learning.

Results

In the first module, Basis of Education (4 credits), the students conducted their studies by course discussions, group discussions, reading circles, discussion summaries, research presentations and an individual brief essay through web-based learning. The learning process was supported by systematic follow-up, personal and group instruction and tutoring together with instant encouraging and directive feedback. In the beginning of the first module there were 45 students in six teams. Six of them changed from network based alternative to writing essays after the first month. Only 15 students completed their tasks on schedule. Rest of the tasks have been handed in later for assessment.

In the second module, Society and Education (3 credits), the students perform their tasks in new teams. The success of the study is based on interdependence among team members (see Lave 1995; Lave & Wenger 1991). Students were encouraged to find new ways to present their assignments in the digital portfolio. The assessment was based on the individual digital portfolio. The 23 enrolled students formed six study teams. Nine students finished the module on schedule and a few weeks after the course most of the students had completed the tasks.

The third module, Teacher's Work in Change (3 credits), finished at the end of March this year. The learning process was directing the course design towards transformational learning (Mezirow, 1995; Kauppi 1998), context creation, setting up own targets, acquiring profound knowledge, critical thinking, self-evaluation, reflection and shared expertise (see Hakkarainen, Lonka & Lipponen 1999). The students were challenged to invent their own individual learning path for this module. So the process was also linked to each institution's development projects for personnel. The module ended at digital portfolio presentations and team discussions about them. There were altogether 15 students at this module and all of them completed their tasks in time.

Conclusion

For several years Hämeenlinna VTEC has offered web-based instruction and tutoring to support students' learning processes. This was the first time that basic pedagogical studies were offered in the net-based environment at any of the vocational teacher education colleges in Finland. This pilot project and development work created new possibilities. The feedback and information will be thoroughly and systematically analyzed to further develop this way of studying. The basic pedagogical studies, 10 credits, will hopefully later be available in international market through the Finnish Virtual Polytechnic. Thus there could be international cooperation and networking in the future.

From the perspective of vocational adult education centers, the students became familiar with net-based studies. They are equipped with skills and experience to plan, implement and tutor web-based studies as teachers in their different vocational fields. This will be a challenge to the institutions in the future as well.

The impact of these studies is obvious. As a leading unit of vocational teacher education in Finland, Hämeenlinna VTEC has great challenges in the complex and changing working life of the future and this project and action research produced and represented new, creative and innovative but at the same time clearly functional solutions and alternatives. Open and distant learning environments are the future and on our part we are making it come true.
Feedback in Virtual Learning Environments

Marja Kallonen-Rönkö
Educational Technology Centre, University of Joensuu,
P.O. Box 111
80101 Joensuu, Finland
marja.kallonen-ronkko@joensuu.fi

The use of virtual learning environments is expanding rapidly in all areas of education including the instruction in the universities. A lot has been written about the university students' and teachers' experiences in virtual (on-line) environments. However, it's still hard to base on the user's experiences the answers to questions like this: which characteristics in environments are beneficial for learning and which are not?

This research tries to develop methods for answering this question and for utilizing the answers. Methods are developed for gathering feedback from students and teachers working in different learning environments in universities. During and after the courses the students and the teachers send feedback via e-mail, discussion groups and digital questionnaires. This feedback is processed both statistically and with other methods. The results of the feedback system are utilized in different groups who are working with on-line environments, evaluation of instruction in universities or developing Finland's virtual university e.g. the virtual environment for counselling and evaluation. The feedback system will be developed further in cooperation with these user groups.
Organizing web based discourse

Abstract: We present a system that makes it a simple task to create web pages that provide explanations based on images or diagrams. The result approaches the dynamic presentations teachers are used to do with the help of a blackboard or overhead projection system. This naturally leads to the question of what constitutes a good explanation. We will show that some intelligent adaptive properties have to be included into the system in order to tailor the explanations to the needs of individual learners. The Easy-Web-Explainer is used to create pedagogic resources to be inserted in a curriculum.

I - Introduction: Explanation presentation versus explanation generation.

Most of the literature associated with Computed Intelligent Assisted Education (Wenger 1987) has concerned itself with the automatic generation of explanations from first principles (sometimes embedded in a micro-world) or from more or less structured knowledge bases. The work presented here takes another, complementary point of view. Given some knowledge available in one or several alternative forms, the objective is to adapt the presentation to learners needs and preferences. For many subject domains the state of the art in Artificial Intelligence limits the kinds of reasoning that can be simulated, or if not, the amount of required coding work is prohibitive. Without trying to reinstate CAL with its rather inflexible ways of driving a learning session, we show here that there is ample room for works to improve the way more or less rigidly structured information can best be presented to learners.

The proper temporal sequencing and spatial layout of information is considered here as a major factor in facilitating the understanding of complex information, even though their importance can vary from individual to individual (Luger 94). The usefulness of carefully exhibiting the structure of a reasoning can be linked to diverse sources. Clearly, some learners can be helped by information displays that alleviate demands on short term memory. For instance, in it has been argued that a proper indentation of solution steps in Mathematics and Physics problems significantly facilitates problem solving (Ramsey 83). In the Dynaboard project (Kaltenbach & Frasson 89), the case has been made for laying out a reasoning spatially in such a way that important properties of the reasoning, such as symmetry, would appear more clearly. Also, it has been found that spatial layouts of formal reasoning facilitate processes of abstraction and the discovery of useful analogies. The main idea underlying Dynaboard was to provide computer facilities that could significantly support the editing and reading of complex mathematical proofs displayed as demonstration graphs. It was shown that of necessity, in order not to surcharge the graphic layout of a proof, the graphic objects, such as arrows, had to carry ambiguous meaning. However, this defect could be eliminated by providing ways of dynamically refining the interpretation of a graphic object at the time of reading. The nesting of information levels and the spatial metaphor were subsequently introduced in order to achieve a good compromise between computer screen area usage and the need to display spatially rather complex and large information structures (Kaltenbach, Robillard & Frasson 91). The Easy-Web-Explainer system presented in the following aims to generalize these effects in the context of the web, by making the structuring and re-structuring of information units rather simple and natural.

The current system proposes a generic structure that can be used in the context of many teaching disciplines (from concrete, such as how to operate some kind of equipment to perform a task, to abstract such as understanding a proof in Mathematics) that can be helped by embedding pictures and diagrams in a discourse. The next section
shows how the current system is used by a learner. The following one describes the authoring processes. Finally, based on the limited experimentation so far, it is shown how the advantages of a greater exploitation of student modeling could improve the system.

II - The Easy-Web-Explainer system

1 - The explainer explained

Our objective in creating an explainer system is essentially to help learners structure information sequences into meaningful units that can be inserted in ever increasing contexts. These units are traversed in forward mode by the learner as many times as necessary before proceeding to the next unit.

Figure 1: Starting an explanation associating text and diagram.

Figures 1 presents the basic structure of the explainer for a single level of explanation. This is a framed web page in which the top frame contains the title of an explanation in Mathematical Analysis. For students to follow the successive steps of the explanation they must click successively on the white hand in the left panel. The red hand in the panel on the right points to a part of the diagram for which a text explanation is given in the bottom panel. The bottom frame explanations are web pages and so can contain multimedia components in addition to text. In particular the text can be spoken so that learners do not have to alternate their gaze between the bottom text and the diagram. An explanation proceeds by pointing successively at various points of the diagram (called here “focal points” or “foci”). The left panel in Figure 1 lists the successive steps of an explanation. Each step can contain several foci. The steps are designed as a compromise between two extremes; on the first hand each explanation step should constitute a meaningful unit and on the other hand each step should be reasonably brief. If in the design of an
2 - Creating an explanation with the Easy-Web-Explainer

The Easy-Web-Explainer software is presented here by roughly following the successive stages of the creation of an explanation. When the application is started the user gains access to the main panel presented in window “Control Panel” shown in Figure 2. Explanations are structured according to the file and directory hierarchy of Microsoft Windows. An explanation corresponds to one directory and explanations can in principle be nested to any arbitrary level since an explanation (directory) may contain several explanations (sub-directories). The “New Explanation” button opens a files/directories browser that enables the explanation author to position a new explanation in the current explanation hierarchy. The system distinguishes between two types of inserted new explanation; an explanation that gets inserted in the sequence of already existing explanations and an explanation that comes as a refinement of an existing explanation step. This second case is used to provide a deeper or alternative explanation to an existing explanation step. In either case the new explanation is positioned by simple clicks on Windows Explorer types of structures. Hyperlink management is automatic; buttons and links are inserted or created on existing explanation pages and the new explanation to reflect the new organization. As a result of this operation a directory is created at the proper place in the directory hierarchy with a name requested from the user and a generic framework of an explanation is created as HTML pages in that directory.

By clicking on the button “Open” the user gets a directory selection box to select an existing explanation. With a click on button “Steps” the user can then see a list of current explanation steps (Window “Get Explanation Steps in Figure 2). This window can be used to go directly to view or edit an explanation step as described in the next paragraph. The captions for the successive explanation steps can be edited (replacing the default numbering system). Currently the suppression or addition of an explanation step not at the end of the existing sequence of steps is possible but awkward, requiring a form of successive copy and paste operations to create a new sequence from the old one. The automation of this process is under way. More generally a graphic editor for explanation sequences in the form of graphs (as in Figure 4) should be developed.

To Edit or create a new explanation step the user clicks on button “Edit/Fill a Step”. This brings forth a window “Get Foci” as seen in Figure 2. The explanation step number is displayed on the top right text field and is incremented automatically with each new explanation step. This window enables the user to enter the name of a Gif or Jpeg file to be used in the explanation (here “FPanel.jpg”). Though it is possible to vary this image with each new focal point, usually the same image is used throughout an explanation step. The graphic files have to be prepared outside of the current Easy-Web-Explainer with adequate graphic software. Currently the user has just to place these files in the directory of the current explanation. To get the graphic to display in the right window panel, the user clicks again on button “Fill a Step” of the control panel. At this point the user is ready to enter the information relative to the focal points of interest (foci) for this graphic. In the current version of Easy-Web-Explainer is necessary to calibrate the graphic in order to insure that the focal points defined in it will be reflected exactly in the Netscape Navigator browser. Then it suffices to click on a point of the image to get the coordinates. To enter a particular focal point, the user clicks on button “New Focus”, then clicks on a particular point of the diagram. This writes the coordinates of the point as the last item in the focus point list on the XY text field. Of course the information already entered can be edited. The window “Get Foci” in Figure 2, show the focal points associated with a presentation of the user interface of a car radio/cassette player. The user has clicked on the first focal point...
explanation, the explanation author cannot get a good compromise, this is a sign that the explanation should be presented with more levels. The current implementation provides for two levels of explanation. Ideally, as we shall ails in the third part of this paper, the way of structuring the information to be displayed by the

In Figures 1, not much textual (possib
the traversal of the successive focal points of an explanation step rather fast. The idea is to try to approximate the dynamics and tempo of explanations provided by human teachers so as to facilitate in the learner’s mind the chunking of significant knowledge units. When checked the box just above the list of explanation steps will automatically chain one explanation step after the other, meaning that by default no explanation is repeated. However by clicking on any radio button of the explanation step sequence, the learner can go to the start of any explanation step. If the checkbox is unchecked the explanation step proceeds until a statement indicating the end of the step is indicated. If the learner does not click on the next step, then the explanation is repeated.

2 - Creating an explanation with the Easy-Web-Explainer

The Easy-Web-Explainer software is presented here by roughly following the successive stages of the creation of an explanation. When the application is started the user gains access to the main panel presented in window “Control Panel” shown in Figure 2. Explanations are structured according to the file and directory hierarchy of Microsoft Windows. An explanation corresponds to one directory and explanations can in principle be nested to any arbitrary level since an explanation (directory) may contain several explanations (sub-directories). The “New Explanation” button opens a files/directories browser that enables the explanation author to position a new explanation in the current explanation hierarchy. The system distinguishes between two types of inserted new explanation; an explanation that gets inserted in the sequence of already existing explanations and an explanations that comes as a refinement of an existing explanation step. This second case is used to provide a deeper or alternative explanation to an existing explanation step. In either case the new explanation is positioned by simple clicks on Windows Explorer types of structures. Hyperlink management is automatic; buttons and links are inserted or created on existing explanation pages and the new explanation to reflect the new organization. As a result of this operation a directory is created at the proper place in the directory hierarchy with a name requested from the user and a generic framework of an explanation is created as HTML pages in that directory.

By clicking on the button “Open” the user gets a directory selection box to select an existing explanation. With a click on button “Steps” the user can then see a list of current explanation steps (Window “Get Explanation Steps in Figure 2). This window can be used to go directly to view or edit an explanation step as described in the next paragraph. The captions for the successive explanation steps can be edited (replacing the default numbering system). Currently the suppression or addition of an explanation step not at the end of the existing sequence of steps is possible but awkward, requiring a form of successive copy and paste operations to create a new sequence from the old one. The automation of this process is under way. More generally a graphic editor for explanation sequences in the form of graphs (as in Figure 4) should be developed.

To Edit or create a new explanation step the user clicks on button “Edit/Fill a Step”. This brings forth a window “Get Foci” as seen in Figure 2. The explanation step number is displayed on the top right text field and is incremented automatically with each new explanation step. This window enables the user to enter the name of a Gif or Jpeg file to be used in the explanation (here “FPANEL.jpg”). Though it is possible to vary this image with each new focal point, usually the same image is used throughout an explanation step. The graphic files have to be prepared outside of the current Easy-Web-Explainer with adequate graphic software. Currently the user has just to place these files in the directory of the current explanation. To get the graphic to display in the right window panel, the user clicks again on button “Fill a Step” of the control panel. At this point the user is ready to enter the information relative to the focal points of interest (foci) for this graphic. In the current version of Easy-Web-Explainer is necessary to calibrate the graphic in order to insure that the focal points defined in it will be reflected exactly in the Netscape Navigator browser. Then it suffices to click on a point of the image to get the coordinates. To enter a particular focal point, the user clicks on button “New Focus”, then clicks on a particular point of the diagram. This writes the coordinates of the point as the last item in the focus point list on the XY text field. Of course the information already entered can be edited. The window “Get Foci” in Figure 2, show the focal points associated with a presentation of the user interface of a car radio/cassette player. The user has clicked on the first focal point
this shows the pointing hand at coordinates (90, 50) on the image of the radio. This has also resulted in the automatic opening of the window “Explanation

Figure 2:

The “Select pointer” button allows the user to select a particular form of pointer to point to be displayed over the graphic. Currently there are two pointer types available, a hand and arrows with different orientation angles. More choices will be available in the future, in particular a tool to highlight particular areas of a diagram or image. Eventually, users should be able to use highlights of their own design. It is also projected to make it possible to handle several highlights at the same time, or several highlights in automatic succession (i.e. without intervention by the user).

On terminating an explanation step the user needs to save the information by clicking on button “Save/Update”. It is easy to add more focal points to an explanation step. As mentioned before, rearranging the sequence of focal points is more complex and should be attended to in the next version of the software. Figure 3 shows the focal point corresponding to Figure 2, as seen by a learner.
- Experimentation and proposed extensions

The Easy Web-course to taught at Université Paris-Sud (France). Following some preliminary testing with a Faculty, it was considered that the dynamic explanations contributed positively to student’s understanding of difficult points.

However it has been found that the system could manage better the transitions between the successive levels o in addition to the introduction of a sophisticated preference system in which the learner can prescribe the way in ted, the system is designed to record the past navigation choices the learner has made and learn from that information the best way to proceed in the future.

Figure presents a diagram of how the various levels of an explanation are arranged at present. Four levels

Figure : Nesting of explanations
The elements of hypertext concept in some monographs published between Hypertext '87 -conference and the launch of World Wide Web: in progress -report

Juha Kämäräinen, Department of Information Studies Univ. of Oulu, Finland

Concepts of hypertext introduced in several textbooks published after Hypertext '87 -conference and before introduction of WWW are analyzed by using grounded theory methodology to build models of dimensions of hypertext concepts. The hypertext concepts are mostly based either on orientations of text or database. E.g. the concept of network obtains different interpretations according to the basic orientation.

By focusing on monographs instead of articles or compiled works it is aimed to find out what kind of conceptual environments the authors prefer and how they situate hypertext into them if the form allows authors to develop broader approaches. The interval used here is chosen to concentrate one's attention to the period, during which the interest in hypertext was increasing rapidly but a particular technical environment was not dominating.

The study is intended to create a basis for re-conceptualizing the hypertext authoring activities and can be relevant in developing authoring skills.
Using Computers in the Programming of Qualifying Teachers of Arabic in the Faculties of Education in Egypt

Dr. Abdelrahman Kamel Abdelrahman Mahmoud
Department of Curricula and Methodology
Cairo University Faculty of Education in Fayoum
Egypt
abdelrahman@internetfayoum.net

Abstract: In Egypt, the teacher of Arabic does not study computer in the syllabus of his preparation in Faculties of Education. Moreover, he does not use it in studying any of the syllabi till he graduate as a teacher.

This research attempts to pointing out the importance of using computer in qualifying the teacher of Arabic and showing some primary aspects of the relationship of Arabic language to computer.

This issue seems to have been lost between the extreme simplification of technicians from one side, and the sharp overlook of linguistics from the other side; the issue is inevitably difficult and interrelated so that simple solutions or tricks will not do. It is also so important and vital to the extent that its importance is in the first priorities of preparing our Arabic societies for the information society where the labour of information, its industries and services will prevail.

Behind this research is on invitation to modernize the outlook of the Arabic language as a whole. It is a demand that corresponds to the duality of computer and English language, and many other languages such as Russian, French and German. Such a demand needed a full revision of all the sides of the linguistic system, where the mechanic system impose on the topic it handles a degree of accuracy and completion without which it can not be subjected to the logic or the machine. Maybe in our approach to this problem on this level an indication of how the computer may compensate for our linguistic backward: theoretically, regulationaly and implementationally.

Using computer in preparing the teacher of Arabic is based on showing the relationship of Arabic to computer; this requires the subjection of accurate science handling.

The attempt at adjusting the linguistic theorizing of Arabic and handling in mechanically is the aspect that helps to reveal the position of super theoretical knowledge on the side of scientific maturity of applied sciences.(16), (19)

The present research is an attempt at showing the duality of culture which prevails over our Arab societies; such duality is one of the main reasons of the deformity of our cultural and scientific view, and the deformity of our intellectual and educational product.

Introduction

In Egypt, the teacher of Arabic does not study computer in the syllabus of his preparation in Faculties of Education. Moreover, he does not use it in studying any of the syllabi till he graduate as a teacher.

This research attempts to pointing out the importance of using computer in qualifying the teacher of Arabic and showing some primary aspects of the relationship of Arabic language to computer.

This issue seems to have been lost between the extreme simplification of technicians from one side, and the sharp overlook of linguistics from the other side; the issue is inevitably difficult and interrelated so that simple solutions or tricks will not do. It is also so important and vital to the extent that its importance is in the first priorities of preparing our Arabic societies for the information society where the labour of information, its industries and services will prevail.

Behind this research is on invitation to modernize the outlook of the Arabic language as a whole. It is a demand that corresponds to the duality of computer and English language, and many other languages such as Russian, French and German.
Such a demand needed a full revision of all the sides of the linguistic system, where the mechanic system impose on the topic it handles a degree of accuracy and completion without which it can not be subjected to the logic or the machine. Maybe in our approach to this problem on this level an indication of how the computer may compensate for our linguistic backward: theoretically, regulationally and implementationally.

The English basis imposed technical restrictions on the mechanic handling of most languages. Such limits reach the utmost with the broadening of the field of linguistic variety between these languages and that of the basics i.e. English. English and Arabic represent from the point of view of computers two extremes; this, in turn, led to the emergence of many technical obstacles in arabizing computers which made of language another barriers added to another group of barriers separating the Arab user from that new comer which emerged and grew in a various linguistic milieu.

Language is the container of thought. The structure and system of language impose a certain pattern of method of thought on its users; this is known as linguistic determinism. Change in any language requires an important change in the nature of language which the society uses for the existence of a mental revolution necessitates the existence of a linguistic on first.(17:205), (15), (18), (13)

Computer illiteracy in our Arab societies does not only require the availability of Arabic programmed language but also the existence of practical means to use Arabic language itself to converse with the computer.

Using computer in preparing the teacher of Arabic is based on showing the relationship of Arabic to computer; this requires the subjection of accurate science handling.

The attempt at adjusting the linguistic theorizing of Arabic and handling in mechanically is the aspect that helps to reveal the position of super theoretical knowledge on the side of scientific maturity of applied sciences.(16), (19)

The present research is an attempt at showing the duality of culture which prevails over our Arab societies; such duality is one of the main reasons of the deformity of our cultural and scientific view, and the deformity of our intellectual and educational product.

Previous Studies:

There are various previous studies which pointed out the importance of using computer in teaching generally. (8), (9), (11), (6), (7)

The impact of teaching expertise on educational software selection: An examination of the strategies used by teachers and novices in their approach to software selection

Expertise in teaching has been associated with a comprehensive knowledge base, well organized schemas resulting from a deep understanding of the problem, to concrete situations, and the ability to recognize features of the problem central to the solution (Borko & Livingston, 1989; Leinhardt and Greeno, 1986; Sabers, Cushing, &amp; Berliner, 1991.) The introduction of computer technology to the classroom has added, for some teachers, an unfamiliar dimension to the classroom environment, a dimension in which their problem solving expertise may not be as effective. This study examines the impact of computer technology on teachers' approaches to the problem of evaluating educational software packages for instructional merit. Sixteen teachers and 14 novices evaluated two educational software packages for educational merit. Two of the teachers had expertise in educational technology. The remaining teachers and the novices had no formal training in using educational technology. Participants' "think-aloud" responses were recorded, by audio and video tape, as they evaluated the software, and their responses to a brief interview and survey were collected. Teachers generated a greater percentage of technical and pedagogical statements, but did not differ significantly from Novices in their attention to specific Pedagogical variables. A qualitative analysis revealed that teachers and novices had different approaches to the problem solving task directed in part by schemas they held for effective instruction. Further, the technology-trained teachers appeared to have greater access to their schemas for effective instruction than those teachers for whom the computer was an unfamiliar environment. These findings suggest that technology training may need to be an integral part of teacher education programs.

Computer skills for pre-service teachers: Perceptions and implications for curriculum development
The purpose of this study was to examine the national profile of necessary technology skills for teachers and the perceptions of school administrators, cooperating teachers, and student teachers regarding specific technology skills needed by pre-service teachers. A survey of literature provided a national profile through standards adopted by the National Council for Accreditation of Teacher Education. The perceptual data, compiled from a survey instrument developed for this study, were self-reported and limited to administrators, cooperating teachers, and student teachers currently participating in a teacher education program in rural northwestern Pennsylvania. Descriptive data analysis, including survey mean scores data and standard deviation were utilized to determine existing technology use and the profiles of perceptions from target populations. Mean rank analysis was applied utilizing the Kruskal-Wallis procedure to identify significant differences among sample populations. The results showed that perceptions of necessary specific technology skills vary significantly among populations. Also, notable variance was found within target populations, however, a number of technology skills were clearly identified as priorities for pre-service teachers. The data revealed that word processing skills have the highest priority among groups. Other high priority skills included use of e-mail, accessing the internet, utilizing CD ROMs, and knowledge of computer terminology. Low priority skills included knowledge of programming languages, MS DOS, web page design, Ethernet function, and reformatting hard drives. The blend of priorities identified in this study and the perceptions of experts in the field of technology in education, grounded in the general standards advocated by NCATE, should be the basis of technology curriculum for pre-service teachers in northwestern Pennsylvania. The results of this study were consistent with literature and research that suggests technology curriculum in teacher education should be developed with a wide variety of populations in order to best reflect the needs of pre-service teachers and society.

The effects of a self-paced modular computer-training program on in-service teachers' attitudes and sense of computer self-efficacy

The issue of technology integration for schools can no longer wait as business, government, and education call for students to be prepared to use the tools of the 21st century. Pre-service teachers are presently receiving some training with the publication of the National Council for Accreditation of Teacher Education standards for technological literacy. In-service teachers are also being called to meet the needs of the 21st century student, but, lacking the teacher preparation training in technology and having honed successful classroom strategies without the use of technology, they are finding the acquisition of these skills more difficult. As professional development programs begin to address the needs of the in-service teacher, the issues of attitudes toward computers and computer self-efficacy must be considered. Successful training programs must address the special needs of in-service teachers, a population of adult learners with little experience or exposure to the digital world. Investigated in this study were the effects of a self-paced modular computer-training program on teacher attitudes and computer self-efficacy. Forty-two in-service teachers at St. Paul's Episcopal School participated in a four-module self-paced computer-training program that included modules covering an introduction to computers, Windows 95, word processing, and telecommunications. Two computer attitudes instruments were used: Delcourt and Kinzie's 1993 Attitudes Toward Computer Technologies scale which measured comfort/anxiety and perceived usefulness constructs and Shaft and Sharman's 1995 Attitudes Toward Computers Instrument which measured a global computer attitude construct. These attitude measures were administered at the beginning of the self-paced computer-training program and again at the completion of the last module. The Compeau and Higgins' 1995 Computer Self-Efficacy measure was administered upon completion of each module for the purpose of assessing the impact of each module on the participants' sense of computer self-efficacy. Results indicate that participation in a training program that meets the needs of the in-service teacher and includes self-pacing, independent and collaborative learning opportunities, and the presence of support personnel positively impacts the attitudes of comfort with computers and perceived usefulness of computers as well as a global attitude toward computers. The participants' sense of computer self-efficacy is also impacted positively. In-service teachers who feel positive toward and efficacious with computers are more likely to feel comfortable bringing the tools of technology to their classrooms and their students.

A comparison of paper-based, computer-based, and voice-mail study media in relationship to student achievement in information systems courses

The problem investigated in this study was the use of paper-based, computer-based, and voice-mail-based study media and their relationship to student achievement in information systems courses. Providing information on the usefulness of study media to schools, businesses, and textbook publishers to assist them in decision making was central to this study. This study may be useful to professionals interested in the larger framework of comparing study media and test performance. This research also examines the relationship between student achievement and a particular study medium when compared with number of questions studied, amount of study time used, age, income, gender, distance from campus, grade-point average, full-time employment, part-time student classification, previous computer skills, and access to a computer. An experiment was conducted using a quasi-experimental posttest-only control group design. Statistical procedures were used to pretest the data to
determine randomness of the groups. Two information systems courses were used to test each study medium. An introductory business course in information systems and an advanced course in which all students would have computer experience were used to test each study medium. This experiment was conducted at a public university. The majority of the students were part-time students who were employed full-time. The university does not have residential students. Quiz, midterm examination, and final examination grades were used as the measure of student performance to determine if there was a significant relationship between study medium and student achievement. The hypothesis that there is a significant relationship between study medium and student achievement was not rejected.

Utilization of computer technology by teachers at Carl Schurz High School, a Chicago public school (Illinois)

This case study investigated computer use by teachers at Schurz High School and identified the factors affecting their use. Current and desired computer skills were also evaluated to make appropriate recommendations regarding inservice training to help increase the use of computers among faculty at Schurz. Descriptive data was gathered on Schurz by interviews, sign-up sheets, software documentation, and reports and pertained to demographics, academic probation, technology plan, school improvement plan, staff development, funding, computer inventory, computer labs, vocational educational programs, and technology support. A survey was used to gather descriptive information on how computers were used in classrooms and interactive labs. Survey items were designed and revised to gather data relevant to seven research questions. The population for this study involved the 133 classroom teachers on staff at Schurz High school during the first semester of the 1998–99 school year. One hundred usable surveys represented a response rate of 75%. The respondents represented 12 departments in the school, including business/computer education, math, physical education, English, special education, technical, foreign language, science, music, social studies, art, and English as a Secondary Language. The major findings of this study show that the vast majority of teachers used a computer for personal or school use; almost all teachers with 1–10 years of teaching used a computer; teachers with 31–35 years of teaching represented the largest group of noncomputer users; the highest percentage of use for both computers and the Internet was for preparing instructional materials; the lowest percentage of use of computers and the Internet was for instructional use for students; teachers used word processing the most for preparing instructional materials, for instructing students in the classrooms, and in the interactive labs; the second greatest computer use was for web searching; and few teachers used software other than word processing in their classrooms. The factors that affected computer use included the direct relation between use of computers and number of computers in the classroom; lack of computer projection devices in the classrooms; lack of duty-free time to prepare lessons including technology; other educational commitments; and insufficient teacher training, support, and follow-up.

Secondly, there are various previous studies which pointed out the importance of using computer in teaching Arabic in particular such as the following:

1. Analysis of heritage for determining the date of its emergence and its source; the Iliade as a myth was analysed by computer; it was found that it is composed of 15694 lines of verse, 112000 words and it was ascertained that Homer is its poet. Also the plays of Shakespeare have been analysed to ensure that he is the writer.(10)

2. Thematic identification of the degree of influence of men –of- letters on others. The most well known uses of computer in that field is that study which was performed to know how far the poet Shelly was influenced by his predecessor Milton. The statistic comparsion of Shelly’s famous poem “Prometheus unbound” and Milton’s “Paradise Lost” the sphere of common lexicon and the relative distribution of the ranges of the two poets using of them. A comparison of the sentences of both poems -which included the most common lexicon- was performed to give a quantitative criterion of Shelley’s being influenced by his predecessor.(10)

3. A comparative discourse analysis of output produced by learners of German in a chatroom and a face-to-face discussion group, and its potential implications for foreign language instruction.

The purpose of this research project is to contrast written German discourse as it was produced by 63 learners of German as a foreign language in 4<sup>th</sup> semester German in a synchronous computer-mediated communication environment, i.e. in a chatroom, with the oral discourse produced by 63 learners of German in a small group face-to-face discussion groups. This study uses a variety of measurements to better describe and define the language produced in chatrooms and face-to-face discussion groups. First, the level of participation is measured by coding the data with communication-units, or c-units. The final statistical analysis indicated that the different levels of participation in the chatroom and the face-to-face discussions were significantly different. Second, this study
hypothesizes that the output produced in real-time synchronous computer-mediated communication constitutes a new type of orality in a virtual world, a hybrid between spoken and written discourse. Communication in a chatroom environment allows students to write as they would speak. The written output produced in a chatroom during this experiment shows features of oral language. The term "virtual orality" describes this type of orality in a virtual space. "Virtual orality" is derived from Walter Ong's "secondary orality," which delineates an orality that is produced by speakers in our society who have the awareness and consciousness of literacy, i.e., they live in a society that is knowledgeable of and influenced by writing. In the third part of this study, the Type-Token Ratio is used to measure the variety of different words in relation to the total number of words produced. In an effort to determine the language level of the students, this study uses a scale of language stages as they are described by Erwin Tschirner, followed by an analysis of verb morphology, and attributive and predicative adjectives. The last chapter asks if and how computer-mediated communication can be productively employed in a foreign language teaching environment. Tentative recommendations about the use of real-time computer-mediated communication and face-to-face discussion groups for instructors conclude this study.

4. Reading instruction of first-grade students within a whole learning reading program using CD-ROM versus traditional print storybooks

This researcher investigated the use of technology within a whole learning reading program to determine whether statistically significant differences in reading achievement develop between instruction using traditional text in a classroom setting and electronic print in the form of books on CD-ROM used in a computer lab setting. Participants were 92 first-grade students from a large, semi-rural elementary school in Orange County, New York. All of the subjects received instruction under both control and treatment conditions. Subjects scores on a district-wide fall reading matrix were used as pre-treatment observations to determine equality of groups. Three days following a sequence of instruction led by the teacher were conducted using traditional and electronic print books. Three books were completed under each method/medium. The books on CD were selected from Level B in the Scholastic Beginning Literacy System WiggleWorks. The same books used on CD were used in traditional print. Post testing was conducted individually after instruction on each book. Assessment included a 20 item word list, a 70-80 word passage (both taken from the text of the book used), 5 factual comprehension questions, and a retelling. Information on or about the computer's effectiveness as a source of language development through pre-literacy experiences to increase sight word vocabulary and in improving comprehension were addressed. The study served to evaluate the effectiveness of books on CD as a delivery mode for whole learning instruction in reading. Results indicate that the use of books on CD are particularly

5- Synchronous computer-mediated communication in the intermediate foreign language class: A sociocultural case study

Synchronous computer-mediated communication (also known as "chatting") has become an extremely popular Internet application in contemporary society, as a way to communicate electronically with persons from all corners of the globe. While members of academic and business communities are increasingly using synchronous CMC to hold serious discussions, conferences and classes, chat communication is still for the most part recreational in character (Werry, 1996). Only recently have educators come to realize that chatting may provide valuable learning experiences to its participants. The purpose of this study was to investigate interactional and linguistic features of communication among intermediate-level Spanish learners and their teacher in a synchronous CMC context. The study evoked some fundamental constructs of Vygotskian sociocultural theory in order to describe and explain how learners and their teacher collaborated with each other to co-construct meaning in chat rooms. General patterns of learner-learner and learner-teacher interaction were analyzed, as well as learner and teacher perceptions of the use of chat as a language learning tool, and finally, changes in learner output over time. First, it was found that learners appropriated the chat room environment to create their own community of language practice in which they transformed tasks that were assigned to them, went off-task when they wanted to, and had the opportunity to make use of language functions that are not typical of the L2 classroom environment. Second, the learners and the teacher put forth a great deal of perceptions regarding the use of chat rooms in the L2 class, which brought an emic perspective to the study. Third, the Spanish verbal morphology system served as a
springboard for illustration and discussion of changes in learner output over time. Specifically, learners made unique uses of the Spanish verbal morphology system, which the emergent grammar perspective was called upon to explain. Also, learners branched out from overuse of the Spanish present tense, gradually using the other available verb tenses and moods more of the time. The study suggests pedagogical uses for synchronous CMC, as well as future research directions.

6. The relationship of universal grammar to second language acquisition: A meta-analysis

The purpose of this investigation was to synthesize (by means of a meta-analysis) the results of primary research studies, which examined the relationship between Universal Grammar and Second Language Acquisition, in order to discern whether second language learners do have full access to Universal Grammar. In order to proceed with this investigation, primary research studies were retrieved through a multiple channel approach: a combination of manual and computer searches. A set of criteria was established to determine which of the retrieved studies would be included in this meta-analysis. Using these criteria, fifteen primary research studies could be included in this meta-analysis. The unit of analysis for this study is the sample unit of analysis. These fifteen studies yielded 22 independent samples, on which the subsequent analyses were performed. Using effect sizes (Cohen's d-index) as the measure of the outcome of the primary study's sample(s), 70 effect sizes were generated. Each of these effect sizes was weighted and averaged to produce an overall effect size for this meta-analysis. The overall mean effect size produced was 1.25 with a standard deviation 0.68, a very large effect size. In addition, a confidence interval was calculated on this mean effect size. The lower limit was 1.17, and the upper was 1.31. Based on the premise that the mean effect size would approach zero if second language learners do have full access to Universal Grammar, the above results indicate that they do not. Moreover, the confidence interval test does not contain zero, which confirms that second language learners do not have full access to Universal Grammar. Sixteen variables associated with the Publication, Participant and Design characteristics were analyzed to determine if any of these variables had an influence on the effect size generated for each sample. This examination shows that the Target Language being tested does have an influence on the effect size associated with each particular sample. Overall, the results of this investigation contribute to a better understanding of the relationship of Universal Grammar to Second Language Acquisition. Implications for future research are discussed. In addition, implications for teaching of a Second Language are discussed.

From such previous studies, we see clearly the importance of using computer in Education in general and in teaching language in particular; while the teacher of Arabic does not study computer as a syllabus in the programmes of his preparation in the Faculties of Education in Egypt and he does not use it in studying any of the other syllabi till he graduated as a teacher.

It has appeared clearly the impotence of the printed book as a means of presenting the educational matter and also the inefficiency of the other conventional educational aids in face of the inflation of the educational matter and its complexity. All this makes us suggest the computer as a logical substitute to increase the efficiency of education, the productivity of education and facing the deeply rooted problems from which educational system suffer especially those of surficial and demanding nature. Many view the computer as a source of hope to make the inevitable change that has long been waited for in the programmes of preparing the teacher in general and the teacher of Arabic in particular. Our success in this depends, primarily, on how successful we are in preparing flexibly the technical means of the requirements of teaching Arabic language.
Web-Based Knowledge Construction System: REAL (Rich Environment for Active Learning)

Myunghee Kang
Educational Technology Department
Ewha Womans University
Seoul, Korea
mhkang@ewha.ac.kr

Abstract: Two preliminary case studies were conducted to investigate the knowledge construction process of an individual and a team. On the basis of the results, a conceptual model of REAL system has been constructed and the programming for the system has been completed and the beta version is out to be evaluated. Therefore, this paper briefly presents the whole process including the results of two case studies, the conceptual model, and the major functions of REAL system.

Introduction

Ever expanding knowledge-based society puts heavy emphasis on knowledge generation of all members in a society. In order to meet this current need, REAL system was developed to assist members of a society to generate and construct knowledge in their own interested domain as an individual or as a team. Two preliminary case studies were conducted to investigate the knowledge construction process of an individual and a team. On the basis of the results, a conceptual model of REAL system has been constructed and the programming for the system has been completed and the beta version is out to be evaluated. Therefore, this paper briefly presents the whole process including the results of two case studies, the conceptual model, and the major functions of REAL system.

Case studies

First case study on individual knowledge construction identifies four major activities and three influential factors. Information-acquisition (17%), information-transformation (27%), knowledge-construction (42%) and monitoring (14%) are identified as major activities which individuals perform to construct knowledge. Learning strategy (77%), metacognition (18%) and motivation (3%) are identified as influencing factors on knowledge construction.

Second case study on team knowledge construction investigates the knowledge sharing process of members in a small group with a common goal. Twelve weeks of knowledge sharing activities were recorded on videotapes and analyzed using protocol analysis. Interview data of each group member were also analyzed. The study identified the knowledge sharing process as three distinct stages: 'input' stage where the shared goal is identified, 'collaboration' stage where the knowledge is shared, and 'output' stage where the team knowledge is constructed. Major factors that influence knowledge sharing process are summarized into three dimensions: individual, group, and environmental dimensions. Then the sub-categories of each dimension are also identified. Personality, willingness to share knowledge, perception of others in a group, and communication skills are under the individual dimension. Group dynamics, facilitating skills, and incentives are under the group dimension. Information type, time and space factors, and knowledge sharing channels are under the environmental dimension.

Conceptual Model of REAL

A conceptual model for a web-based knowledge construction system, REAL, that may assist an individual as well as a group was constructed by integrating all the activities, dimensions and factors from the previous case studies. Since the knowledge construction process iterates and circulates based on the cognitive and communicative activities as an individual and as a team, the model represents continuous support for an individual as well as a team to construct knowledge. The model also describes the phenomena of internal as well as collaborative knowledge construction. Internal knowledge construction means that Individual learners select their own tasks, acquire and
transform information, and construct new knowledge with incoming information at a given moment. On the other hand, collaborative knowledge construction means that learners collaborate with one another by questioning and/or answering, and exchange ideas for constructing knowledge.

On the basis of the conceptual model, REAL system has been designed and developed to support individual knowledge construction which involves information acquisition, information transformation, knowledge generation/construction, and monitoring. It also embeds functions to check the learning strategies, metacognition, and motivation factors of an individual. For the collaborative team knowledge construction, two types of collaboration – intra group collaboration and intergroup collaboration – are to be supported. Intra group collaboration refers to collaboration among members of the same group. Inter group collaboration refers to collaboration among members in different groups. The system allows intra group facilitator s as leaders of a group to provide important information to others, to manage communications with other groups, and to dismiss the members who do not fit in a group. Also, the facilitator in an inter-group collaboration exists as a guide, stimulates information exchange among groups, and answers questions.

In order to function properly as described in a conceptual model, REAL system includes (1) cognitive tools for an individual knowledge construction, (2) collaboration tools for a collaborative knowledge construction, (3) individual and collaborative knowledge base construction tools for expanding the database by the users, and (4) various agents for assisting participants.

The system also provides concept map generating functions and project schedulers from the cognitive tools, synchronous and asynchronous communications and CSCW(Computer Supported Collaborative Work) functions from the collaboration tools, knowledge base construction functions from the knowledge construction tools and intelligent searching, footprint checking, and other help functions using agents.

Web-Based Collaborative Architectural Design System C@D

Myunghee Kang  
Educational Technology Department  
Ewha Womans University  
Seoul, Korea  
mhkang@ewha.ac.kr

Uk Kim  
Department of Architecture  
Hongik University  
Seoul, Korea  
Ukkim@wow.hongik.ac.kr

Abstract: This paper describes a web-based collaborative architectural design system, C@D which has five features. C@D system provides an integrated collaboration design environment, a set of multimedia databases, visual communication tools, architectural design tools and schedule management tools. Theories and principles of constructivist learning environment design from the field of educational technology have been integrated to develop C@D.

Introduction

Computer applications to architectural design involve a distinctly rich hybrid of geometric, geographic, and annotated information. This condition raises opportunities for collaboration, needs for data integration, and examples of the increasing importance of rich databases as a basis for design work. This paper describes these general issues of collaboration in architectural design integrated into C@D system. Some examples from recent collaborative design studio works, and a specific implementation of software integration where a prototypical data interface and translation tables for multimedia linkage are integrated. And capacity to work together with a web browser will also be presented in the session.

C@D system

People in architectural design work together on shared objects of design, and these objects define the nature of interactions to occur. Thus collaborative design includes more than simple document exchange. It compiles, adds value to, and conducts dialogues over sophisticated artifacts. Increasingly, then, complex data sets may become the focus of research in computer-aided design. Therefore, theories and principals of Educational Technology were applied to design and develop a Web-Based Collaborative Architectural Design System C@D.

Notable features of C@D system

1. C@D system provides an integrated collaboration design environment. Collaboration design environment requires a number of networked computer application softwares which enable multiple users at different locations to share ideas, design information and data both synchronously and asynchronously. C@D system supports this kind of work environment.

2. C@D system has a number of rich multimedia databases. Architectural design information is documented in tow primary formats; text and geometric objects. Project database, case database and scheduling database are constructed with various multimedia formats such as graphics,
images, animated data, video and voice data. In an era of multimedia generation, it would be quite natural to store, search and use multimedia data for design projects.

3. **C@D** has convenient visual communication tools.
   General purpose communication tools such as web mail, text and voice chatting are included in the system. Furthermore, synchronous whiteboard for sharing ideas and data is embedded in the system. Therefore, synchronous / asynchronous and text/multimedia communications are supported in **C@D** system.

4. **C@D** has outstanding web-based architectural design tools.
   In architectural design, visual objects are used for effectiveness and efficiency in communicating with other members who are involved in the same project. At the early stage of design, visual objects are sketched images. As the design proceeds, they become geometric objects that have mathematical properties. To be more precise, physical object specification annotations are added to the objects. For **C@D** system, web-based visual tools for sketching, 2D drawing and 3D modeling are implanted.

5. **C@D** has near-perfect work schedule management tools.
   Design project management involves precise scheduling of design process and workers in various areas such as construction, electrical field, etc. Therefore, **C@D** system provides work calendars for keeping track of work progress. That could be used as checking points.

PICCO - the Pictorial Computer Simulation of a Selected Natural Phenomenon: Description, Demonstration and Research Results

Marjatta Kangassalo, Univ. of Tampere, Finland

The purpose of this presentation is to demonstrate the new version of the PICCO - program, to describe the aim of PICCO as children's spontaneous exploration tool and to introduce research results when using PICCO in day care centres and at school. The chosen natural phenomenon for the pictorial computer simulation, PICCO, was the variations of sunlight and the heat of the sun experienced on the earth related to the positions of the Earth and the Sun in space. It is important to investigate children's science learning and knowledge construction process in new multimedia technology environments, to find the possibilities of new technology for science learning and to reveal those integrated and intertwined cognitive and social processes which are the basis for science learning and thinking by children.
Exploring the use of electronic portfolios in international contexts

Abstract: One of the most exciting developments in the school reform movement is the use of alternative forms of assessment to evaluate student learning and teacher development. Different alternative assessment systems and forms must be judged based on the value of the information they provide for students, teachers, curriculum specialists, principals, parents, and community members. Nowadays, alternative assessment can be supported by technological applications. In this interactive session one alternative assessment form, namely electronic or digital portfolio is discussed as a means of documenting, displaying and sharing student or teacher progress and expertise over long time periods. The interactive session of electronic portfolios is a collaborative effort of researchers and teacher educators from Australia, Finland and United States. The aim of the session is twofold. First, to present the electronic portfolio development process. And second, to explore the experiences on applying electronic portfolios from kindergarten to professional development portfolios. Examples are presented from each of three countries. The presentation is followed with a discussion of similarities and differences in the rationale for the various levels and countries.

One of the most exciting developments in the school reform movement is the use of alternative forms of assessment to evaluate student learning and teacher development. Different alternative assessment systems and forms must be judged based on the value of the information they provide for students, teachers, curriculum specialists, principals, parents, and community members. Nowadays, alternative assessment can be supported by technological applications. In this interactive session one alternative assessment form, namely electronic or digital portfolio is discussed as a means of documenting, displaying and sharing student or teacher progress and expertise over long time periods. The interactive session of electronic portfolios is a collaborative effort of researchers and teacher educators from Australia, Finland and United States. The aim of the session is twofold. First, to present the electronic portfolio development process. And second, to explore the experiences on applying electronic portfolios from kindergarten to professional development portfolios. Examples are presented from each of three countries. The presentation is followed with a discussion of similarities and differences in the rationale for the various levels and countries.

There are many definitions for portfolios, since each definition depends on the purpose of the portfolio and on the perspective of its evaluation. Synthesizing several definitions, a portfolio is a student’s or a professional’s collection of samples of tasks and achievements, compiled by the person him/herself in order to display and review student’ or professional’s knowledge and competencies in relevant and broadly representative manner. Often portfolios also include descriptions about the environment and processes associated with learning and working, as
well as one's own ideas or philosophy on learning, teaching or working in general. (Linnakylä & Kankaanranta 1999.)

For some time now, portfolios have been used by professionals, especially in occupations requiring creativity, originality and independence (e.g. Hartnell-Young & Morriss 1999). In such occupations professional competence is varied and calls for various kinds of knowledge, being typically hard to demonstrate by means of mere education or certificates. The use of portfolios has increased in recent years in the academic world as well.

Purpose is fundamental to portfolio development and portfolios can be prepared for many purposes. The portfolio is always a way of communicating with an intended audience. Previous experiences have attributed electronic portfolio at least with the following advantages:

- minimal storage space
- easy to create back-up files
- portability
- long self life
- learner-centered
- increases technology skills
- through hypertext links it is easier to make argument that certain standards are met
- accessibility (especially web portfolios)

There are specific custom-designed software products for making portfolios, but a portfolio can also be compiled using some general-purpose multimedia software. When planning for drafting an electronic portfolio, one needs to relate his/her user skills and time resources to the features offered by available software applications. The custom-designed portfolio design tools have been made as user-friendly and easy-to-use as possible. Portfolios are often published on discs, CD-ROMs, videotapes, or as paper copies, as well. An increasingly popular option is to publish the digital portfolio on the Internet, as a web portfolio. When creating these web portfolios the tools and programs are typically the same as when making WWW pages. (e.g. Barrett 2000; Linnakylä & Kankaanranta 1999.)

By using technology to store student or teacher portfolios, their work can be made portable, accessible, and more easily and widely distributed. However, the choice of appropriate assessment strategies or programs depends on the assessment context and a variety of other factors, human and technological that exist in a classroom, school or district. Thus, the construction of electronic portfolios should be preceded by a careful examination of diverse strategic questions about the functions and uses of assessment in general and portfolios in particular, but also about the human and technological resources available (Barrett 2000).

Barrett (2000) has derived a framework for electronic portfolio development from two bodies of literature: portfolio development in K-12 education and the multimedia or instructional design process. These complimentary processes are both essential for effective electronic portfolio development. Understanding how these processes fit together and how standards or goals contribute to electronic portfolio development, faculty gains a powerful tool for demonstrating growth over time. From the discussion of both the multimedia development process and the portfolio development process, five stages of electronic portfolio development emerge. These five stages will be discussed in more detail in the presentation with experiences derived from student portfolios.

In schools and universities in Australia, experienced teachers are being encouraged to develop portfolio as part of performance review requirements, or for planning professional development, while beginning teachers are increasingly asked to submit a portfolio to determine suitability for employment (Hartnell-Young & Morriss 1999). Student portfolios are also becoming more frequent. At the same time, Australian educators are being urged to develop skills in the use of information and communication technologies. The Australian example describes the background and content of a project, which is based on creating digital or multimedia portfolios to give purpose for learning technology skills. The project was piloted in 1999 and continues to develop.

The project was devised to link the two trends – ICT and professional portfolios – by assisting teachers to develop multimedia portfolios as a means of learning about technology while reflecting on their philosophy of teaching and their professional achievements. Hartnell-Young and Morriss (1999) suggest that teachers who engage in developing multimedia portfolios will increase skills in technology, enhance self-knowledge, gain in self-esteem and present a forward-thinking image to their employers.

Finnish example presents an action research study, in which digital school portfolios are used interactively as a means for teachers to collaboratively display and assess the pedagogical practices of kindergartens and primary schools. The digital portfolios were published on the web in order to emphasize direct, technology-enriched communication and collaboration among teachers and also to share and discuss the work with a wider audience, e.g. other teachers, teacher students and parents. Participants in the kindergarten and school network were teachers from eight kindergartens, one preschool group situated in a primary school and two primary schools in the region of
Central Finland. Teachers felt encouraged to participation by the need of multilevel collaboration in order to develop qualitative teaching and learning in pre- and primary levels of education.

The project has proceeded through five inter-linked cycles, which will be presented in the session. In the different cycles of the project the processes of portfolio development and becoming computer literate were intertwined. At the same time teachers adopted an interest to utilize ICT in the instruction, as well. Already the first cycles showed that there is an enormous need for the teacher support in computer literacy and in the construction and use of portfolios. This is crucial before teachers can become independent users of information and communication technologies and before they can collaboratively construct expertise in virtual groups.

Facing the Vast Information Network: Finnish Primary School Student Teachers reflect on their Relationship with the Internet

Ilta-Kankaanrinta
University of Helsinki, Department of Teacher Education
P.O. Box 38
FIN - 00014 University of Helsinki, Finland
kankaanr@cc.helsinki.fi

Abstract
Finnish primary school student teachers' (59 individuals) relationship to the Internet was investigated by means of a questionnaire in 2000. The relationship was analysed in three dimensions. The first involved their emotional attitudes: whether they loved or hated it, or if they were worried about being left by the wayside. The worries were examined in detail. Different ones, such as technical, pedagogical and organisational, information-processing and cultural, were analysed from the student teachers' and from their pupils' points of view. Secondly, the student teachers' images of the Internet as an organisation with typical characteristics were analysed. Finally, the proportions of innovation adopter categories in the use of the Internet were summarized. The main results showed that the student teachers worried considerably about their future pupils' relationship with the Internet, especially about information-processing issues. Emotional attitudes were mainly positive and the students usually grew to like the applications once they had tried them. The students described the Internet mostly by using positive attributes regarding its useful contents. It was often seen as a combination of different kinds of people or as an organism. The proportions of respondents in the early innovation adopter categories, such as early adopter and early majority, were larger than might have been assumed according to innovation diffusion theory.

Theoretical Background

In Finland, Tella (1995) created a classification of end users' emotional attitudes towards modern information and communication technologies (MICIT) in general (Tella 1997). His categories include the pioneers; those who love them, or hate the technologies, at first sight; those who are skilful enough to adapt to them: hackers or crackers; those who slowly become fond of new technologies; those who imitate others; those with a superficial attitude; those who are worried about or scared of them; those who dislike even the thought of using information technologies and finally those who are left by the wayside: the dropouts.

The Internet could be compared to other organisations. Morgan (1986) used different metaphors to describe organisations likening them to machines, organisms, brains, the theatre, a political system and a psychical prison. In the context of the Internet, the first three are the most interesting.

The theory of innovation diffusion, developed by Rogers (1983, 1995) consists of several subtheories, one of which concerns adopter categories. According to the theory, these categories are proportionally constant in a population and consist of, in the sequence of adoption, Innovators (3% of population), Early adopters (13%), Early majority (34%), Late majority (34%) and Laggards (16%).

The Empirical Study and Research Problems
Students in Finnish primary school teacher education take a Master of Education degree. The education programme includes a course and lectures in media education, worth two credits. The author of this article distributed a questionnaire to students on the course in media education in 2000. The research problems dealt with the student teachers’ relationship with the Internet:
1. What are the main concerns of student teachers in the use of the Internet?
2. What are their emotional attitudes towards the Internet?
3. What do they see as the main characteristics of the Internet?
4. What kind of organization is the Internet, according to the students?
5. In which adopter category do they classify themselves in their use of the Internet?

The themes of the worries and attitudes were assessed on a six-point scale ranging from “not at all” (1) to “very much” (6). Representations were investigated in open-ended questions. The innovation adopter categories were explained to the students during the course, and they decided into which category they fitted.

The Results and the Discussion

The main results were that the student teachers worried considerably about their future pupils’ relationship with the Internet, especially about information-processing issues and about the danger of learning bad things. Emotional attitudes towards the Internet were mainly positive, and the students usually grew to like the applications after having tried them. The students described the Internet mostly using positive attributes showing appreciation of its useful contents. The Internet was often seen as a combination of different kinds of people, or as an organism. The proportions of people in the early innovation-adopter categories, such as early adopters and early majority, were bigger than might have been be assumed according to the innovation diffusion theory.

The student teachers’ attitudes towards the Internet and how they gradually grew to like it reflected the results obtained from kindergarten student teachers (Kankaanrinta 2000b). Large proportion of early adopter categories was also seen in other student teachers and in-service teachers (Kankaanrinta 2000a).

The student teachers’ relationship with the Internet was revealed to be complex. On the one hand, the students thought that the Internet contained useful and interesting information, but on the other hand they were afraid of the huge amount. This aspect of the Internet is its main characteristic, SWOT: strength, weakness, opportunity and threat to both the pupil and the teacher.

Abstract: We live in a world of complex relationships, united by a myriad of connections, existing in continuous granularities and multiple dimensions. Discovering truths in this complexity requires an ability to decipher causality amidst endless potentially spurious associations. It is our belief that underlying investigative skills are internal representations of external systems. Effective inquiry strategies evolve out of strong internal models of the mechanisms of both the specific and general systems of inquiry. This paper outlines a work-in-progress, involving the creation of technologies which foster the development of more advanced internal mental models of causal systems during inquiry, thus improving reasoning competence.

Introduction

Craik (1943) presents the notion of mental models as internal representations of a system. Black (1992) implies that mental models are the highest form of knowledge representation, an amalgamation of propositions and imagery capable of generating procedures. Schwartz and Black emphasize imagery in mental models, describing them as "depictive simulations" (1996a) representing particular system mechanisms, from which rules are derived (1996b). Kuhn, Keselman, Black, and Kaplan (2000) present the notion of mental models in reasoning as abstract internal representations of causal systems, which underly the use of advanced investigative strategies. The goals of our current project are to extend our existing computer-based study environment, for the purpose of advancing development of reasoning strategies, by building visualization features to induce mental models representing 1) that more than one factor can contribute to one outcome, and 2) of correct system mechanism.

Program Design

Constructivist instructional design frameworks for computer-based study environments emphasize the relevance of self-directed knowledge construction, as opposed to direct instruction of objective knowledge (Wilson, 1996). Research indicates that instruction "situated" or "anchored" in meaningful contexts, with focused pre-set goals, have been effective vehicles for self-discovery learning (Schank, Fano, Bell & Jona, 1993; Black & McClintock, 1996; Brown, Collins & Duguid, 1989; Cognition and Technology Group). Anchored instruction is especially befitting in science education (Goldman, Petrosino, Sherwood, Garrison, Hickey, Bransford & Pellegrino, 1996).

Problem Scenario: Flood Predictor

Flood Predictor, a multimedia research program, created with Macromedia Director, is founded upon anchored, situated and goal-based instructional design principles, supporting the investigation of causal relationships in the domain of elementary hydrology, and induction of evidence-based deductive reasoning strategies, via self-discovery.
Students are situated in the role of a builder working for a construction company, and assigned the job of determining how high to build stilts under houses near a group of lakes. Employees are informed, via text and audio, that, in order to avoid flood damage and to minimize the cost of expenditure on unnecessary materials, they must determine which factors in the region will cause flooding and which will not. To do this, they must call up records of sites by creating unique combinations of features, predict how high flooding will rise, and make conclusions about whether features matters, don’t matter or haven’t found out yet. As well as being asked to make conclusions about whether features matter or don’t matter after each instance of examining records, as a metacognitive que, students are asked to respond to a multiple choice question about how they know that certain features matter or don’t matter in causing flooding.

Five factors are introduced as potentially causal in flooding: Water Pollution (high vs. low), Water Temperature (hot vs. cold), Soil Depth (shallow vs. deep), soil type (clay v. sand), Elevation (high v. low). Three factors (Water Temperature, Soil Depth and Soil Type) are causal within the program scenario. There is one interaction between Soil Depth and Soil Type. The other two factors are not causal within the program scenario.

Reasoning Activity

Within all Flood Predictor versions, participants are guided through investigations modeled upon previous research by Kuhn et al. (1992; 1995). Reasoning activity is operationalized as design of investigation, number of variables held constant & controlled comparisons, outcome predictions, outcome inference and interpretation, and theory change. Metacognitive awareness is activated/reinforced by declarations of inquiry intention, causal prediction, and inference justification. Theory assessment involves participant declaration of initial and final theoretical conclusions about whether factors matter and in which direction, and levels of theory certainty. Inquiry designs are determined by record comparisons made by the participant, who has the opportunity to call up records of any combination of factor values.

A menu set of five menus, one for each factor, permits students to select one of two values for each factor. Records include unique identities of site, the value of each factor in the site, and the true outcome of the unique combination of factor values. For each record selection, before discovering the true outcome, participants make predictions about flood levels, and indicate which variables would be responsible for predicted results/change. Upon receiving true outcomes of a site flood level, participants check whether each factor “matters”, “doesn’t matter” or “haven’t found out”. For each variable participants claim to find out about, they are asked how they know what they know, from:

A notebook is available to store notes at any point during the investigation session by clicking on the “open notebook” button. After each record instance, participants are asked if they would like to type anything in the notebook. Participant activity, including time and ID, is recorded into a text document on the local hard drive of the computer on which the program is installed.

Mental Model Manipulations

Simple Geographic Information Systems (GIS), made up of transparency map layers representing factors and factor values, are introduced as tools for eliciting development of the additive effects mental model. Depiction of environmental system components in space are intended to illustrate that more than one component exists in the same location, leading to easier analyses of combined relational effects. Differently than in previous causal reasoning research, qualitative evidence about each factor is presented, in the form of a "field report," in addition to evidence about covariation evident in record comparisons, with the intention of stimulating a correct internal representation of the particular mechanism of causality. It is expected that experiencing one and/or more of these interventions will lead to more advanced mental models, thus more strategic inquiry strategies. Mental models are assessed using a rubric, partially based upon Jonassen's (1995) suggestions for consideration of coherence, relevance, integration, fidelity of with real world, imagery, complexity, transferability, and inferential ability in assessing mental models, which measures some of these qualities in open-ended responses to how and why flooding occurs.

Results and Future Directions
Studies underway are revealing that GIS are useful educational tools, as well as analytical tools, instigating more advanced additive effect mental models, thus improving reasoning activity, measured as use of controlled comparison inquiries and evidence use, and knowledge acquisition, measured as correct theory changes. Qualitative evidence about factor attributes, leading to more depictive mental models of the particular system, appears to be improving prediction, reducing misprediction, and knowledge acquisition. Results will be reported in a future publication.

Near future goals include incorporating the GIS layers into the computer program, so that students can investigate with the external map layers. Ultimate goals include building a data-based driven web application, capable of distributing and receiving evidence about any system, allowing teachers/students to specify particular content, and displaying system components and relations in diverse depictions and dimensions, as 2-dimensional maps layers, as sets of menus, as particular depictions, as networks, hierarchies, illustrations, etc. The production of such an artifact would allow students to improve reasoning strategies across domains and surface features, and permit researchers to compare cognitive development with various content and knowledge representation.

Emerging Issues in Information Economy & Electronic Commerce: A Strategic Analysis

Nitya L. Karmakar, Ph.D.
School of Management
University of Western Sydney
Australia
E-mail: n.karmakar@uws.edu.au

Abstract: The dramatic growth of electronic commerce (e-commerce) is ushering in a new era of business opportunities we have witnessed in decades. The convergence of information technology, communications and entertainment, reflected in the Internet itself, has the potential to generate significant economic growth. The pace of this growth is reflected by the growth in the information technology sector – the producer of the infrastructure for the information economy. The main interest of this brief report is how this technological revolution will impact upon the global businesses considering its applications, key issues, strategies and challenges in the Internet-driven economy.

Introduction

The information economy & e-commerce are comparatively new phenomena. The heart of the information revolution is that the medium through which people do the important things in life is changing. Now we can communicate and make many everyday transactions electronically. This is the world of e-commerce – where the buyers and sellers conduct their business electronically, by means of online technology. E-commerce increases productivity and can create competitive advantage.

A global overview of e-commerce

E-commerce is growing dramatically and it was approximately US$43 billion in 1998, but it is estimated that online business may sour to US$1.4 trillion by 2003 [Los Angeles Times, 1999]. With the growth in Internet usage, there is a corresponding increase in e-commerce. A recent Angus Reid survey of 28,374 worldwide Internet users, or about 200 Internet users in each of 34 countries gave the following statistics for adults shopping online (Gengler, 2000):

United States: 31%, Sweden: 21% Switzerland: 19%, Canada: 18% Australia: 14%

Japan’s Ministry of International trade and Industry estimates e-commerce could account for business worth 3.16 trillion yen (about US$18 billion) by 2003 (Zielenziger, 2000). The USA is the leader in driving e-commerce due to its dominance on the Internet. Currently over 60% E-Business is taking place in the USA. A report by the US Department of Commerce – The Emerging Digital Economy II says online sales will be about US$300 billion annually by 2005. Internet demographics are changing rapidly. The development is very rapid among many developing countries, for example, China, India, Korea and Malaysia.

Strategic Approach & Benefit
A strategy consists of a fundamental pattern of existing and intended targets, action-guiding principles, the use of resources and interaction between an organisation and market, competitors and other environmental factors. E-commerce should be developed through a strategic framework for running business in cyberspace. The enormous benefits due to the adoption of e-commerce in an organisation and thus contributing further to information economy have been identified many authors (Karmakar, 1999, Karmakar 2000a & 2000b, Karmakar 2001, Tapescott, 1996). To be competitive in the global information economy, and to ensure the participation by all people, national government must remain committed to a world class telecommunications infrastructure that is highly competitive, characterize by high bandwidth at an affordable price, and readily available virtually anywhere in the country. It is essential that the supporting infrastructure be in place for the effective business and community use of online applications and service.

It is widely recognized that a deregulated, competitive telecommunications market is the best way to drive down costs, encourage innovation and increase quality of service. E-commerce allows business to be done more efficiently, as it is driving change many sectors of the economy and producing a more efficient allocation of resources. The main strategy should include global cooperation among companies in this era of rapid technological changes when the reduction in product development cycle is a key competitive requirement.

Getting into electronic business has several advantages (Amor, 2000):

- **Global Accessibility and Sales Reach** – Businesses can expand their customer base, and even expand their product line & equal access to new markets,
- **Closer Relationships** – Business-to-business sellers can grow closer relationships,
- **Free Samples** – Products can be sampled via the Web fast, easily and free of charge,
- **Reduce Costs** – Reduced design and manufacturing cost,
- **Media breaks** – The Internet reduces the number of media breaks that are necessary to transport information and thus reduction of advertising cost,
- **Time to Market** – Shorter time to market and faster response time to changing market demands,
- **Customer Loyalty** – Improved customer loyalty and service through easier access to the latest information and never closing site,
- **Competitive Intelligence** - Improved market intelligence and strategic planning & also customer involvement in product and service innovation.

According to the Organization for Economic Co-operation and Development (OECD), the economic performance of countries like Canada, the USA and the UK now compares favorably with that of former leaders Japan and Germany, and a significant part of this is their aggressive exploitation of Information technology(IT), especially the Internet (Norris & West, 2000).

**Strategic Priorities**

The Internet as an information-sharing tool, and potential as a medium for transactions, create an attractive electronic marketplace (Adam et al., 1999). To gain maximum benefit of e-commerce in the era of information economy we have identified a number of strategic priorities:

- Providing opportunities for all population to benefit from the information economy,
- Delivering the education and skills population need to participate in the information economy,
- Promoting the growth of the world class infrastructure for the information economy,
- Identifying new competitors and market
  - Developing a legal and regulatory framework to facilitate e-shares in the new market in cyberspace,
  - Developing a Web-centric marketing strategy,
  - Influencing the merging industrial rules and conventions for electronic commerce,
  - Implementing a world class model for delivery of all appropriate government services online,
  - Promoting the integrity and growth of content and culture in the information economy,
- Participating the creation and development of virtual marketplaces and intermediaries, now.

E-commerce promises, in some cases, to revolutionize a company's operations. But this revolution requires that the company has the backing, dedication, resources, focus and commitment to move company to e-commerce. It is one of the most significant information innovations that lie at the root of productivity and economic growth. Exploiting Internet's capability allows an organization to create wealth by trading products.
and services with entities it has never met before (Mougayar, 1998). Management of Technology is also very important in this knowledge era to gain competitive advantage.

Conclusions

Electronic commerce requires an evolutionary approach that addresses each piece of the puzzle both separately and as part of an overall strategy. Few organizations are handling the electronic commerce phenomenon as a whole. Rather, they are breaking it into pieces, and implementing different areas separately or in a fragmented manner, mainly because of a lack of understanding of how to manage the complexity of issues and barriers.

Some key criteria for success in e-commerce area: brand-name recognition, low-cost structure, legacy systems integration, leverage of applicable technology, and case of use. Direct communications between suppliers and customers streamlines the supply-chain and delivers new relevant information to manufacturers in real-time (Kalakota, 1997). Finally, it is worth remembering a quote of Bill Gates, Microsoft Co-Founder & Chairman: 'Going digital will put you on the leading edge of a shockwave of change that will shatter the old way of doing business. A digital nervous system will let you do business at the speed of thought, the key to success in the 21st century'.

Interactive History with Learning Affordance for Knowledge Construction in Web-based Learning

Akihiro Kashihara, Masanao Sakamoto, Shinobu Hasegawa, and Jun'ichi Toyoda
The Institute of Scientific and Industrial Research
Osaka University
JAPAN
kashi@ai.sanken.osaka-u.ac.jp

Abstract: The main problem addressed in this paper is how to help learners construct knowledge in exploring existing hypermedia/hypertext based learning resources on the Web. Our approach to this problem is to provide a learning tool, which affords knowledge construction activities involving reflection on the exploration process. In this paper, we describe an interactive history that encourages learners to annotate their exploration history with the reasons why they have explored, which reasons have a great influence on knowledge construction in hyperspace. It also generates a knowledge map from the annotated exploration history, which map spatially represents the semantic relationships among the Web pages explored by the learners. This paper also describes an evaluation with the interactive history system. The results indicate that the system affords rethinking exploration process.

Introduction

An increasing number of hypermedia/hypertext based resources for learning/education has been available on the Web. These web-based learning resources generally provide learners with hyperspace where they can explore the Web pages by following the links among the pages to learn the domain concepts/knowledge in a self-directed way (Nielsen, 1990, Kashihara, Ujii, and Toyoda, 1999). The exploration often involves integrating the contents of some pages that have been explored to construct their knowledge (Thuering, Hannemann, and Haake, 1995). These knowledge construction activities would enhance learning (Jonassen, 1999, Chan et al., 1993). However, learners often fail in knowledge construction since what and why they have explored so far become hazy as the exploration progresses. To what extent the learning has been carried out also becomes unclear (Thuering, Hannemann, and Haake, 1995). Knowledge construction in hyperspace consequently requires reflecting on exploration process that learners have carried out (Kashiha, Ujii, and Toyoda, 1999).

The main issue addressed in this paper is how to support the reflection for knowledge construction in hyperspace. Current work on educational hypermedia/hypertext systems has provided spatial/concept maps as representative reflection aids (Brusilovsky, 1996). The suitability of these aids is founded on semantic relationships among domain concepts/knowledge embedded in the learning resource. However, these can not be always available to existing web-based learning resources since it is hard to identify semantic relationships among the Web pages without analyzing the contents of the learning resources.

Another approach to proper reflection support is to provide a learning tool, which affords reflection activities for knowledge construction (Laurillard et al., 2000). We call such feature of the tool learning affordance. The word affordance is borrowed from the psychology of perception (Gibson, 1979). The concept of learning affordance can be viewed as a basis for evaluating the suitability of learning tools. Web browsers such as Microsoft Internet Explorer and Netscape Navigator, for example, are regarded as web-based learning tool for popular use. Do they have proper learning affordance for knowledge construction in web-based learning? The web browsers provide learners with back buttons and browsing history. Although these facilities afford revisiting the Web pages that have been visited (Tauscher and Greenberg, 1997), they would not always create activities of knowledge construction such as integrating the contents of some pages explored. The browsing history also provides no information of why they have explored, which information plays a crucial role in knowledge construction (Kashiha, Ujii, and Toyoda, 1999), and does not allow them to sufficiently rethink knowledge that they have constructed so far. We can consequently say that the web browsers are not very suitable for knowledge construction in hyperspace.

Designing a more suitable tool needs a careful consideration of exploration process and of what kind of activity should be supported by the tool. Following this idea, we have proposed an interactive history for learning with existing web-based learning resources (Kashihara, Hasegawa, and Toyoda, 2000). In this paper, we describe the interactive history system and its evaluation. The results of the evaluation indicate that the interactive history system affords rethinking exploration process particularly in more complicated hyperspace.

Before demonstrating the interactive history, let us first consider exploration process in hyperspace to discuss what kind of knowledge construction activity should be supported.

Exploration in Web-based Learning Resource

Learners generally start exploring hyperspace with a learning goal. The movement between the various pages is often driven by a local goal called exploration goal to search for the page that fulfills it. Such exploration goal is also regarded as a sub goal of the learning goal. We refer to the process of fulfilling an exploration goal as primary exploration process, which is represented as a link from the starting page where the exploration goal arises to the terminal page where it is fulfilled. The whole exploration process can be modeled as a number of primary exploration processes.

Exploration goal, represented as verb, signifies how to develop or improve the domain concepts and knowledge learned at the starting page. We currently classify exploration goals as shown in Table 1, which are not investigated exhaustively.

An exploration goal arising from visiting a page is not always fulfilled in the immediately following page. In such case, learners need to retain the goal until they find the appropriate terminal page/s. While searching for the fulfillment of the retained goal, it is possible for other exploration goals to arise. The need to retain several exploration goals concurrently makes the knowledge construction more difficult to achieve.

Executing a primary exploration process, learners also make a semantic relationship among the domain concepts and knowledge in the starting and terminal pages (Tauscher and Greenberg, 1997). The semantic relationship is shaped according to the exploration goal. Each exploration goal provides its own way to make relationship between the starting and terminal pages (Kashihara, Hasegawa, and Toyoda, 2000). Integrating several primary exploration processes, learners construct their knowledge structure.

The above consideration of exploration process in hyperspace indicates that it is necessary to rethink primary exploration processes and their integration for succeeding in knowledge construction.

Interactive History

Overview

In order to encourage learners to rethink primary exploration processes that they have executed during exploration, the interactive history provides an exploration history annotated with primary exploration processes. It
also provides a knowledge map, which visually represents relationships among the primary exploration processes, to help the learners to rethink knowledge structure that has been constructed.

The interactive history system first enables learners to annotate an exploration history, which includes Web pages sequenced in order of time they have visited, with primary exploration processes. In order to help learners note down primary exploration processes during exploration, the system provides them with a list of exploration goals, and requires them to select one from the list when an exploration goal arises. The learners are also asked when they find the terminal pages. The interactive history system annotates the exploration history with the information noted down. The annotated exploration history enables the learners to retain their primary exploration processes.

The learners are also enabled to directly manipulate the annotated exploration history to modify/delete the primary exploration processes and to add new primary exploration processes after exploring hyperspace. Such direct manipulation enables them to reorganize their exploration process.

The interactive history system second transforms each primary exploration process, which is extracted from the annotated exploration history, into a visual representation by means of a visualization scheme that describes the correspondence of an exploration goal to a visual representation. It then combines each visual representation to generate a knowledge map. The knowledge map does not obviously represent the contents included in the explored pages, which may be summarized by the page titles. However, this summarized information would be substantially fruitful for learners to reflect on what they have learned.

Annotated Exploration History

In the interactive history system, learners can use a user interface as shown in Figure 1. They can also explore a hyperdocument on a WWW server with one learning goal in the left window. When they want to set up an exploration goal in visiting a page, they are required to mouse-click the corresponding page in the Annotated Exploration History window. The Exploration Goal Input window then appears as shown in Figure 1. The learners can select one corresponding to the goal from the exploration goal list in the window. The page visited currently is also recorded as the starting page of the exploration goal. After inputting the exploration goal, the Exploration Goal Input window disappears.

When the learners find a terminal page of the exploration goal, they are required to mouse-click the exploration goal in the Annotated Exploration History window. The Exploration Goal Input window then appears. They can input the terminal page by dragging the title of the terminal page and pasting into the terminal page section in the Exploration Goal Input window. They can also add the object of the verb describing the exploration goal. It means what to develop/improve in the current page whereas the exploration goal specifies how to develop/improve.

Figure 1 gives an example where a learner explores a hyperdocument on a WWW server with the learning goal of understanding the occurrence of earthquake. The annotated exploration history shows the sequence of the pages visited and primary exploration processes that have arisen. For example, he/she visited the page Animation of the Mechanism in order to rethink the description in the page The Mechanism of Occurrence of Earthquake. He/she then visited the page Seismic Wave since he/she did not know the meaning of the term used in the previous page.

The system also provides another support for helping learners store part of the contents of the page visited currently with Cut&Paste function although they may not always need this support. In hyperdocuments on WWW, in addition, the title tags of the pages do not always represent the contents of the pages. If the learners want to change the page titles, they can input new titles in the Exploration Goal Input window, which new titles should represent the contents the learners explored in the pages. The pasted information and the changed page titles are also used in the annotated exploration history.

Using the information inputted from the learners, the system generates the annotated exploration history as shown in Figure 1 so that the primary exploration processes can be viewed clearly. In the annotated history, each page has the page title. The starting page of each goal is linked with the corresponding terminal page/s. There may be some primary exploration processes without terminal pages since they have not been found yet. The learners can look at the annotated exploration history on their demand during exploration. They can also click the pages in the history to review the content information, which they have inputted with Cut&Paste function.

Directly manipulating the annotated exploration history, learners can reconstruct their exploration process. Each manipulation is done by means of mouse-clicking/dragging parts of the primary exploration processes. There are three basic manipulations: deleting and changing exploration goals/links between starting and terminal pages, and adding new primary exploration process.
Learners are not always required to input the above information whenever they visit pages. Nevertheless, inputting the information during exploration may be troublesome for learners. On the other hand, it enables the learners to make their exploration more constructive. The annotation, in addition, requires a meta-cognitive skill that is indispensable for managing knowledge construction process in existing web-based learning resources. The interactive history system could distract learners, who do not have it, from their learning tasks in hyperspace. We believe, however, it is educationally important to train the learners to improve the meta-cognitive skill so that they can learn in a constructive way. The interactive history can be viewed as a potential tool for this training.

Knowledge Map

In order to make the knowledge map understandable, we have adopted a visualization scheme shown in Table 1. This table shows the correspondence of an exploration goal to a visual representation of the relationship between the starting and terminal pages. For example, an exploration goal to Elaborate is transformed into a set that visualizes the starting page as a total set and the terminal page as the subset. Following such correspondence, the system generates a knowledge map by combining visual representation of each primary exploration process in the annotated exploration history. The knowledge map generation is executed on learners’ demand before/after manipulating the annotated exploration history.
Figure 1 shows an example of the knowledge map that is generated from the annotated exploration history shown in Figure 1. Viewing this map, the learner can reflect on the relationships among the primary exploration processes. For example, he/she can recall that he/she elaborated *The Mechanism of Occurrence of Earthquake* by exploring *Kind of Earth Faults*, and that he/she furthermore elaborated it by comparing *Normal Fault* and *Adverse Fault*.

Before using the interactive history system, in addition, learners need to know how to interpret the visual representation used for the knowledge mapping. In order to explain it, the interactive history system demonstrates few examples of annotated exploration history and knowledge map before starting the actual learning support.

**Preliminary Evaluation**

**Experiment**

In order to evaluate the interactive history system, we have had a preliminary experiment. The main goal of this experiment was to analyze the utility of the system and to ascertain if the interactive history affords rethinking exploration process compared to learning without the system. We also prepared two web-based learning resources as shown in Table 2, which had comparatively simple and complicated hyperspace. Table 2 describes the number of pages, and the number of links per page, which was calculated except for navigation links such as Next, Back, and Top. These can be viewed as the indicators of the complexity of hyperspace each learning resource provides. The learning resource 2 accordingly had a more complicated hyperspace. Subjects were thirteen graduate and undergraduate students in science and technology.

We set four conditions, which were (1) learning in the learning resource 1 with the system (Simple-With), (2) learning in the learning resource 1 without the system (Simple-Without), (3) learning in the learning resource 2 with the system (Complicated-With), and (4) learning in the learning resource 2 without the system (Complicated-Without). Subjects were provided with Internet Explorer as WWW browser under each condition. In this experiment, each subject learned one learning resource with the system, and learned the other without the system. In other words, he/she was assigned two conditions, which were Simple-With and Complicated-Without (or Simple-Without and Complicated-With).

Before learning, subjects were given a learning goal for each learning resource. Under Simple-With or Complicated-With, they were also given the explanation about how to use the interactive history system, and were asked to try it in a sample learning resource whose hyperspace is simple. They were then asked to explore hyperspace with or without the system to accomplish the learning goal. The time of learning in each condition was limited to thirty minutes.

In this experiment, the utility of the system was analyzed with the dispersion of pages visited, the number of revisit per page (Tauscher and Greenberg, 1997), the number of primary exploration processes executed, and the number of revisiting pages that were included in the primary exploration processes. Comparing the averages of them under Simple-With and Simple-Without or under Complicated-With and Complicated-Without, we evaluated the utility of the interactive history system.

**Results and Discussion**

Table 3 summarizes the analysis of the utility. The average number of revisit per page on Complicated-With was larger than that on Complicated-Without although there was a slightly difference between Simple-With and Simple-Without. The average dispersion of pages visited on Complicated-Without was lower that that on Complicated-Without although there was a slightly difference between Simple-With and Simple-Without. These results indicate that the interactive history system makes learners' exploration more intensive in a more complicated hyperspace.

We further analyzed the utility of the interactive history system on Simple-With and Complicated-With. Table 4 shows the average number of primary exploration processes executed, the average number of starting and terminal pages, and the average number of revisiting pages that are included in the primary exploration processes. The average numbers of starting and terminal pages on Simple-With and Complicated-With corresponded to about half of the average numbers of pages visited as shown in Table 3 (54.8% on Simple-With and 51.0% on Complicated-With). In other words, half of the visited pages were related to the primary exploration processes. The average numbers of revisiting the starting and terminal pages on Simple-With and Complicated-With accounted for 74.5 % and 79.9 % of the whole revisits shown in Table 3. These ratios were very high. These results indicate that the interactive history system can afford rethinking each of primary exploration processes and their relationships.

Conclusions

This paper has claimed that knowledge construction in hyperspace requires learners to reflect not only what but also why they have explored, and that learning tool should afford rethinking their exploration process and knowledge structure being constructed by them.

This paper has also demonstrated the interactive history with the learning affordance. The interactive history encourages learners to annotate and reorganize the exploration history to rethink their exploration processes. It also generates a knowledge map from the annotated exploration history, which allows the learners to reflect on what they have constructed during exploration. In addition, this paper has described an evaluation of the interactive history system. Although we need a detailed evaluation with more subjects, the results indicate that the system affords rethinking primary exploration processes particularly in a complicated hyperspace.

In the future, we will have a more detailed evaluation. We would also like to classify exploration goals in detail to represent learners’ exploration process more precisely.

Abstract: Information technology and the Internet are making inroads into almost all areas of our society. The requirements of students and professionals are fast changing, the information society requires lifelong learning in practically all areas, especially those related to information technologies. The educational sector can profit in particular from the benefits IT adds to the ways of learning. The core techniques exists, still the integration into the curricula and the integration of learning environments and traditional knowledge management systems and libraries cannot keep up with the pace of technology development. This article focuses on the use of so called "learning objects" in the field of Operations Research and Management Science (OR/MS). Learning objects refer to pieces of information of different granularity which can be combined, linked and reused. We will demonstrate some of the concepts mentioned above by the LOM editor of the Technical University of Darmstadt and prototype systems developed in the project OR-World of the University of Paderborn and give an outlook on the future development.

Introduction

The idea of learning objects follows a constructivistic view of learning where students actively construct knowledge rather than are being taught by a teacher. Web environments can be considered as an ideal platform for persons holding this frame of mind. Though a traditional web based approach (HTML) is a first step into the right direction, it is not optimal in terms of structure, consistency and manageability. If we consider large scale systems with a very large amount of documents, authors need tools to assist them while creating and maintaining educational material. On the other hand readers often get lost when retrieving documents, the amount of hits often turns out to be irrelevant. The flat description model which HTML offers is not precise enough to allow an efficient search and retrieval process. Due to the lack of support for efficient structuring, retrieval, and linking among very large amounts of documents by standard Web technologies, namely HTML, new technologies which allow a more sophisticated retrieval method, such as a structured Metadata approach, are emerging. In the context of learning objects the Learning Object Metadata standard (LOM) is widely accepted and becomes more and more important (see section 3 for further details, other examples for Metadata classifications are Dublin Core or IMS).

HTML is not consequently separating content, structure and representation of a document. Furthermore HTML is not extensible by additional tags. If we think of learning objects, other tags than <heading> or <bold> for example are desirable. The tagging of learning objects with specialized tags is simply not possible in HTML. Links among documents can only be defined as untyped, unidirectional links. In order to minimize maintenance efforts and costs
it would be desirable to use single source documents (e.g. in the form of XML documents) published on demand in a format of one's choice (e.g. HTML, paper, e-book, WAP, etc.). A dedicated markup language stores structured document information besides the content and enables the rendering of different representations of the source document. This way the maintenance costs for material can be decreased and the material can be made available to different people with adaptive views. Open technologies standards such as XML and dedicated markup languages for documents offer the chance of constructing content which can be (re)used by people independent of their location. The standardization of metadata descriptions has the effect that tools dealing with metadata descriptions become universally applicable. LOM and IMS are excellent examples that a widely used specification which is accepted as a standard can promote immensely to the exchange of data.

2 OR-World

After being developed since about 40 years, contents of OR/MS have reached a high level of maturity. The basic algorithmic and modeling techniques form a stable core of the discipline, whereas implementation issues develop rapidly with new perspectives offered by information technology. This justifies the high amount of developing effort necessary to create such systems. The core contents are well-suited for hypermedia learning because they essentially consist of processes and algorithms, thus implying a dynamic nature. While the dynamics cannot be fully represented in paper-based books, it can very well be illustrated interactively by animations on a computer screen.

The knowledge domain OR/MS is highly interrelated, basic algorithms and methods can be applied to practical problems in varying contexts. Thus, in a graphical representation of the knowledge domain, a graph instead of a strict hierarchy would be drawn. A previous structuring of a content area is helpful for building the links among objects in a hypermedia network. Because OR/MS is already well-structured, it is very suitable for the representation within OR-World.

OR-World is funded within the Fifth Framework Programme of the European Community. The goal of the project is to develop a hypermedia network of learning objects where:

- Each object is well described by a Metadata description.
- Object granularity from media elements to thematic metarstructures can be stored.
- Objects can be reused in the sense of combining objects of lower granularity to objects of higher complexity.
- Dedicated Document Type Definitions for different types of objects are available.
- Renderings in varying target formats can be generated by the system (see [OR-World2000])

LOM is highly accepted and will be used for the Metadata description of our learning objects. In the project. The advantage of a data centered, standardized approach is obvious: An externally developed editor such as the LOM editor of TU Darmstadt can be integrated in OR-World without many hassles. The interfaces to the files/databases where the descriptions are stored may have to be adjusted but the basic data structure is fixed. This way the efforts in software development can be focused on building stable software components which can be reused just like the documents created in the standardized format.

Core technologies such as XML and XSL lay the foundations on which applications can be built. Metadata description is not the only application which can be imagined. One of the main drawbacks of HTML is that one kind of general document template serves to represent the whole variety of imaginable documents from small fragments to articles, books, etc. On a micro level, documents differ significantly in their structure. Within the project dedicated document type definitions for the varying granularities of learning objects will be developed. Currently document type definitions for large documents such as books or technical documentations are available. One example is the docbook DTD which stems from SGML but is also available for XML [Docbook 2000]. Media elements differ significantly in their structure from case studies, tests etc. and for optimal use this has to be reflected in the applied document structure. XML and XSL in this sense are just a means to specify he desired behavior. The structure of documents in the learning context still has to be defined. When a set of document type definitions will be available, the documents built consistently on these definitions can be rendered in different visual representations. Most obvious examples are renderings in the HTML or Acrobat PDF format. We use standard technologies from the XML Apache project [Apache XML 2000], see Figure for a visualization of the process.
Figure 1: Process of generating varying renderings for XML source documents

The output format can also be varied in terms of extent. A case study for example can reveal more and more details or hints of the case. This allows students to approach a case gradually and helps them to solve the case finally.

Besides the rendering an interesting point is that information to be stored in the metadata description according to LOM is already existing in a structured document. E.g. the title or author are often stored in the source document. Since the metadata description is physically another entity mechanism to derive metadata information from the document to be described would be very useful. Most authors in our experience find it annoying to complete the task of setting up the Metadata appropriately. This is correlating to the experiences the TU Darmstadt made and since the appropriateness of the Metadata information determines its value the ease of use is a crucial issue.

3 LOM-Editor

In the following we describe the tool that we use to create the metadata. As the resources are only described it is neither necessary to change the resource nor needs the author of the metadata description physical access to the resource. Therefore it is possible to publish metadata records for various resources, e.g. documents, images, audio clips, videos, animations, virtual reality worlds, or multimedia exercises. A metadata record consists of a set of elements, describing a multimedia resource. Examples of these elements are date of creation or publication, type, author, format, or title of a resource.

To access and discover multimedia information resources in a comfortable way, we developed a user-friendly tool, the LOM editor (Figure 2), based on the IEEE-LOM scheme version 5. IEEE's specification of Learning Object's Metadata (LOM). LOM extends the well known Metadata approach for general documents Dublin Core (DC) with elements to describe additional educational properties of multimedia resources. The elements are grouped in categories which are listed below.:
General: General metadata, such as the title, language, structure, or description of a resource
Life Cycle: Status, version, and role of a learning object
Meta Meta Data: Information about the metadata used to describe the learning object.
Technical: All technical information about a resource, such as the format, the length, browser requirements, which are necessary to use the resource.
Educational: Information about the educational objective of a resource, such as interactivity, difficulty, end-user type, etc
Rights: Commercial use and ownership of a LO
Relation: Links between Learning Objects, to express dependencies, or semantic connections
Annotation: Used to provide additional, eventually more detailed information about a resource
Classification: Elements to classify a resource according to existing classification schemes

Based on the LOM 5.0 draft and a DTD developed by the IMS, we have specified a XML DTD according to the actual LOM scheme. It is therefore possible to save an LOM description as an XML file and also to import existing descriptions. With the use of a free middleware broker implementation called CASTOR [Castor 2000] the Metadata descriptions can also be stored in a relational database like Oracle or IBMs DB2. The editor is implemented in Java, so it can be used on all platforms.
The time effort to describe all properties of a resource is considered as a hindrance to a wide distribution and usage of a metadata scheme. To offer users a faster way to describe the learning resources, the editor is using a template mechanism. If one author is describing similar resources many elements like the name of the author, the target audience or the access right stay the same and don't have to be changed. Using templates with common values, can avoid the necessity to fill a lot of fields again and again.
Another property of the LOM scheme which can be used for building a user friendly editor is the use of the vocabulary elements of a LOM description. For many elements the LOM scheme suggests to use an integer value, which can be mapped to different descriptions in different languages. With the use of Vocabularies it is possible to guarantee a fixed set of values for specific elements to avoid ambiguous descriptions when searching for resources.
Figure 2, shows a screenshot of the current implementation of the editor. One can also see the use of the Vocabulary element for the structure element of the General category. Depending on the selected language to describe a resource, the editor can offer the set of values to the user as a list. It is then easy for the author of the metadata description to select the appropriate value. Changing the language of the user interface, will also change the language of the possible values. As the mapping between the integer value and the language descriptions, is stored in an external text-oriented file. additional language mappings can be added very easy.
Figure 2: Screenshot of LOM-Editor

Conclusion
As more and more descriptions in a standardized form will become available, it will become increasingly attractively for software developers to invest in developing these tools. The critical mass of learning objects has to be reached if they should be successful. Especially in today's information society the ability to find quickly the right information is a crucial factor. The whole bandwidth of educational activities would benefit from one consistent description model and LOM could be the key to transport the structuredness of databases to the World Wide Web, nothing more and nothing less.

Development of a Japanese Reading Support System based on Activating Visual Information

Yukari Kato and Toshio Okamoto
The University of Electro-Communications
Choufugaoka 1-5-1
Choufu, Tokyo 182-8585 Japan
{kathy, okamoto}@ai.is.uec.ac.jp

Abstract: The purpose of this study was two-fold: 1) to investigate the effects of visual information, background knowledge and academic reading experience and 2) to identify the nonnative readers' problems in comprehending Japanese academic texts. Sixty-three foreign students studying at universities and graduate schools in Japan participated in this study. Major findings were as follows: 1) the exhibition of charts and text diagrams did not promote reading comprehension, 2) the students' past experiences of academic text reading influenced the score of the reading comprehension test and strategies of activating visual information, and 3) there was not significant correlation between the amount of background knowledge and the score of reading comprehension tests. Moreover, the cluster-analysis of descriptive data seemed reasonable to support that there would be differences of activating visual information between advanced and novice readers.

1. Introduction

In Japan, there are many foreign students studying at graduate schools of science and technology who have already completed some academic courses or researches in their major fields, but do not have sufficient Japanese language ability for the Japanese academic life. Due to the rapid increase in the number of such foreign students, language institutes and international student centers provide intensive language courses and arrange tutoring programs. Supporting systems like this, however, do not work effectively, due to the fact that students don't have enough time to use such opportunities, as they have to devote most of their time to doing research work in their laboratories.

To solve this kind of problem, some of language learning support systems on the Web have been developed, and proved to be of great help. Indeed, many universities and institutions created such Web-based language learning support systems that are free and open to all users. Unfortunately, almost all systems that have been developed by technological researchers include various complex functions, such as morphological analysis and structure analysis, or use such techniques as natural language processing (Tera et al, 1998; Kitamura et al.1999; Ochi, 1999; Nishina, 2000). Although all of these proprieties are attractive at the first glance, these systems do not have sufficient functions based on real teaching experience and on the insights of language teachers. A possible solution is to base the new language learning systems development on empirical studies of the learners' problems, difficulties and needs.

From the standpoint of a Japanese language teacher, Yamamoto (1995) suggested that intermediate and advanced level learners had some troubles in understanding the parallel structures and long sentences rather than the technical terms (from the results of a Japanese language course for scientists and engineers). She also indicated that the learners needed some help to understand the standard report parts of introduction, conclusion and discussion, which include a complicated structure of sentences and show the relations among many concepts and ideas (Fukako, 1994; Yamamoto, 1995).

On the other hand, it has been proposed in a guidebook of technical writing that readers could grasp the whole structure of a scientific text by using charts and diagrams effectively (Nakajima & Tsukamoto, 1996; Yamazaki et al.1992). It has also been demonstrated in psychological researches that annotated illustrations promoted learners' understanding of scientific explanations (Harp & Mayer, 1997; Mayer et al., 1995; 1996; Shah et al., 1999). Although a large number of researchers have mentioned the effects of visual cues, the question of how to use such information effectively is still open (Shah et al.,1999).

2. Research Goal
Our goal with this research is to investigate whether visual information, learners' background knowledge and academic reading experience influence the reading comprehension of Japanese scientific texts. This study was developed, in part, to provide preliminary data for the development of an effective academic reading support system, which implements instructional devices for nonnative readers.

The following problems were investigated in this study via a questionnaire, designed to analyze the effects of visual cues, learners' background knowledge and experiences on the reading comprehension:

1. How does the presentation of visual cues promote the learners' reading comprehension on scientific texts?
2. How does the readers' experience in academic text reading influence the score of the reading comprehension of scientific texts?
3. What is the relationship between the amount of learners' background knowledge and the scores of the reading comprehension tests?

3. Method

3.1 Subjects

The subjects were 63 foreign students studying at Universities and Graduate Schools in Japan. They were intermediate and advanced learners of Japanese who had received 1-2 years of formal instruction and passed the Japanese proficiency test. There were 42 students majoring in humanities and social sciences, and 21 students majoring in natural sciences and engineering. The percentages of males and females were 63.5% and 36.5% respectively.

3.2 Materials

The testing materials consisted of two parts: (1) a participant questionnaire, (2) a reading passage with some corresponding comprehension tests. The participant questionnaire was designed to investigate the learners' background information and academic experience, such as major, learning experience of Japanese language, existent knowledge on mobile computing, and experience of academic text reading. For the reading passage, we used one chapter from an article that appeared in the Journal of Information Processing, which concerns the application of mobile computing in disaster and emergency situations. The comprehension tests were designed to examine the comprehension achievement corresponding to each of the 3 paragraphs of the reading chapter.

In order to investigate the effects of visual information, we revised the first and third paragraph of the original chapter. First, we divided the students into 2 groups, an experimental group and a control group. The original, unaltered chapter was used for the experiment group, and the revised one, which had less charts and diagrams than the original one, was for used for testing the control group. The second paragraph was used as a pre-test, to examine the hypothesis of similar Japanese language ability between the two groups above. The details are shown in table 1.

</tbody>
</table>

3.3 Procedure

Subjects were tested individually on both parts of the testing material in a single session. In the first part, subjects answered a participant questionnaire aimed at determining the background knowledge and academic experience related to the academic field of the text sample. In the second part, each subject had to fulfill three
different tasks: (a) filling in the blanks of an incomplete text, with the adequate words from the chapter text, (b) describing the main characteristics contained in the charts and diagrams, and finally (c) summarizing the whole reading chapter. Data were collected from students from various universities and graduate schools in Japan by mail. There were 21 subjects in the control group and 42 subjects in the experimental group.

4. Results

We classified the subjects of the experimental group into two sub-groups, based on their reading experience of academic journals:
- experimental group 1: novice reader, and
- experimental group 2: advanced reader.

4.1 Results of the pre-test

To examine the Japanese language proficiency, we first analyzed the scores of pre-test (the second paragraph) that was common to all three groups. There were no significant differences among them, as could be seen in Table 2. The scores were from 0 to 5, with 5 being the best grade and 0 the worst.

4.2 Analysis of Comprehension Tests

We also examined the comprehension tests of the two remaining paragraphs (paragraph 1 and 3) in order to investigate the effects of the presentation of visual information (see Table 3). The presentation of visual cues produced significant differences between the experimental group 1 and the control group (t (41) = -2.77, p<.01). There was not significant difference, however, with respect to the comprehension score of the paragraph 3 and the summary writing capacity between the control group and the two experimental groups. This suggests that the students' previous experience of academic text reading would influence the scores of reading comprehension with the diagram for scientific texts.

The analysis of test data indicated that the subjects, who have already experienced academic journal reading in Japanese language, were able to interpret the main ideas of the chapter correctly. On the contrary, less experienced subjects could not connect the information from visual cues with textual information.

4.3 Analysis of descriptive Data

We collected the descriptive protocols explaining charts (paragraph 3) and diagrams (paragraph 1) in order to investigate effective strategies for activating visual information.

The following procedure employed in this research was as follows. First, the subjects of experimental group were told to describe the characteristics of the diagrams embedded in the paragraph 1. Second, the written protocols were collected from each subject and divided into a word as an idea unit. The number of words summed up 573 units totally. Third, 573 units were classified by their sources and content and placed into 38 categories. Forth, Ward's hierarchical clustering procedure was conducted to compute a distance matrix among
categories (i.e. time information category, disaster information category) As a result of cluster analysis, the dendrogram suggested four distinct categories in Figure 1.

4.3.1 Description of the Four Clusters

As stated above, four clusters were identified form the hierarchical clustering techniques. Cluster1 consisted of seven categories concerning both X-axis and Y-axis of the diagram. In the diagram, X-axis showed the time series and Y-axis indicated the priority of information. Cluster2 included both textual and visual information of the same time series, which summed to nineteen categories. Cluster3 consisted of seven categories concerning the characteristics of individual items in the diagram. Cluster4 consisted of four categories, which demonstrated the items of the diagram. All four clusters should be regarded as the meaningful factors to affect activation of the visual information.
4.3.2 Data Analysis

We collected the descriptive data from subjects of experimental group in order to identify the effective strategies for activating visual information. To investigate strategic differences between the advanced readers and novice readers of experimental group, in regard as the comprehension scores of paragraph 1. We divided both group 1 and group 2 into high-scored readers and low-scored readers. The Table 4 showed that the means and standard deviation associated with this analysis.

We conducted a 2 (level: high-score or low-score) x 4 (strategic clusters: principal vector, paraphrase, characteristics of items, diagram's item) analysis of variance (ANOVA) to examine the relationship between the readers' level and four response categories. The Table 4 showed that the means and standard deviation associated with this analysis. The result of ANOVA were indicated the interaction between level and cluster variables reached significance, $F(3,112) =2.69, p<.05, MSE=5.67$. Compared with the simple effects on two variables, the results were displayed in Table 5. A post hoc test using Fisher's least significant difference (LSD) procedure revealed that high-scored readers used significantly more Cluster2 (paraphrase) than both Cluster1 (principal vector) and Cluster4 (diagram's item). And it was also showed that they used Cluster3 (characteristics of items) significantly more than Cluster1. On the contrary, low-scored readers used significantly more Cluster3 than the remaining three clusters ($MSE =5.67, 5\% level$).

4.4 Correlation Analysis

The correlation matrices reported in Table 6 were computed for both control and experimental groups. Subjects' knowledge correlations were calculated between the amount of background knowledge and the knowledge represented by the scores of the reading and comprehension tests, and the summary evaluation. There was no significant correlation between the amount of background knowledge and the scores for reading and comprehension.

5. Discussion

The present study investigated the effects of textual cues, learners' knowledge and experience and tried to identify the nonnative learners' problems in Japanese academic reading.

Concerning the first research question, our results suggest that the presentation of visual cues does not always promote reading comprehension. In other words, it seems that original charts and diagrams embedded in the text may interrupt the reading comprehension of nonnative readers.

Related to the second question, the analysis of the descriptive data related to the charts and diagrams indicated that the experienced learners could integrate textual and visual information and deduce therefore the main ideas of the chapter. On the contrary, less experienced learners just picked up the raw information from the visual cues and could not comprehend the relation between the various pieces of information. This was due to the fact that less experienced learners had the tendency to choose the words embedded in visual cues as the keywords of the text. In the first text paragraph, however, the diagram showed just examples of the key ideas. As a result, the beginner students were inclined to consider this peripheral information as representing the main concepts.

Related to the third research question, there was no significant correlation between the amount of background knowledge and the scores for reading and comprehension. However, the way to examine the learners' background knowledge could be inadequate, because it just checked whether subjects knew the definition of the technical terms frequently used in the text. Useful knowledge should not be represented only by lists of discrete words and phrases.

In order to develop an effective reading support system, we should closely analyze readers' difficulties in academic texts reading and construct an effective learning/teaching model for nonnative Japanese language learners.

From the viewpoint of reading pedagogy, we have to reconsider how to teach the vocabulary and to show learners how to access visual information. Especially, in order to build up the background knowledge that they need for academic reading, we have to relate the new concepts and knowledge with their existing knowledge. As a future research, we study the design of a method and implementation to relate the new vocabulary with existing knowledge. Moreover, we consider decreasing the difficulty of reading charts and diagrams by showing only a part of the visual information at a time, via simulations and animations.

Abstract: Educators are well aware of teacher support as a form of scaffold that helps learners reach their "zone of proximal development" (Vygotsky, 1978). An online case study conducted over 4 weeks in an elementary school in Malaysia showed that teacher support came in six multiple forms. However, the nature of an online constructivist learning environment presents a difficult task for the lone teacher in supporting all students reach their desired learning level. This paper will discuss the need for intelligent agent technology to support the teacher reach his/her 'zone of proximal support'.

Introduction

Much has been discussed and researched on instructional strategies to support learning in an online environment. Among the reasons for creating an online learning environment are the following: meeting the needs of learners of varying abilities and allowing learners to access materials anytime, anywhere (Mathew and Dohery-Poirer, 2000); accommodating learners of different learning styles (Franklin & Peat, 1998); enhancing communication, information retrieval and sharing (Hackbarth, 1997); providing learners the necessary skills in effective use of technology for the workplace (Freeman & Caper, 1998) and providing for active and integrated learning experiences (Susan, 1997). There is also little doubt with regards the ability of the web to enhance higher-order thinking skills and content acquisition (Vullo, 1993, Follansbee, 1996, Abtar, 2001). Online strategies that have supported such efforts include online discussion, collaboration, retrieval of information, quizzes, assessment, didactic teaching & mentoring (Lyons, Hoffman, Krajik & Soloway, 1997; Pitt & Stuckman, 1997; Hewson & Hughes, 1998; Abtar, Sapiyan and Mansor, 1999). Basically it's all about active learning, a phenomena prophesized by Dewey in 1910 and is possible now with the availability of the interactive and open nature of the web. However, how does the teacher fit into such an environment? With so many reasons to incorporate online strategies for better learning, why is it that these strategies are not easily adopted and practiced? Although there is a plethora of strategies and ideas to enhance thinking and learning, implementing them in the classroom is another matter. The reality of the classroom characterized by a web-based constructivist learning environment (WebClen) presents many challenges with regards the role of teacher. The following sections will briefly present an online scenario and suggestions on how the teacher can be supported to allow for easier and better integration of such strategies.

Teacher Role in an Online Learning Environment

An online template incorporating sound pedagogy (Abtar, 2000) was used to create a web-based constructivist learning environment for Year 4-6 students. Posttest scores showed that there was a significant improvement in student higher-order thinking skills and geoscience content acquisition. In such an environment, the teacher played multiple roles that is: a content expert, a technology specialist, a bilingual expert, a motivator, a cooperative and collaborative learning advocate, and a monitor of student progress. As a content expert, the teacher provided support at three levels. This three tiered approach first involved support at a topical level whereby students
were introduced to the topic with the aid of an advanced organizer. An advanced organizer aids in activating students’ schema when attention is drawn to the preceding and following topics of study. Second, the teacher zoomed into the content for the week and the teacher’s role as an expert involved such skills as probing, clarification, exemplification and use of visual aids. Third, the teacher’s focus shifted to the task at hand, whereby she clarified the task by drawing on local content and by modeling the processes students needed to employ in the understanding of concepts. The teacher provided technology support in three areas, namely hardware applications, general software applications and specific software applications. Hardware support included familiarizing students with computers and managing limited hardware resources. General software applications included helping students understand basic web-based concepts such as ‘http’, ‘URL’, ‘search engine’, ‘refresh’, and managing the MS Windows environment. Specific software applications related to the use of the geoscience web-template included introduction to such terms as ‘username’, ‘password’, ‘next page’, previous page’ and use of specific functions such as ‘save’, ‘edit’, ‘browse’ and ‘send’. As a bilingual expert, the teacher played a major role in helping students translate information from the English language to the native language (Malay language). This involved clarifying meanings of certain words, and translating words from the Malay language to the English language to help learners search the Internet. As an online motivator, the teacher gave feedback to students while evaluating their work online. Offline motivation was given when the teacher approached each group and discussed or commented on their work. Besides this, the teacher in an online environment also played an important role in promoting cooperative learning among learners. The teacher provided support by building group collegiality, by distributing workload, getting the students to handle logistical problems when using the computer and encouraging students to support each other. In monitoring student progress, the teacher gave advice and assessed student work. Advice came in various forms, such as advising students to attempt a particular task on their own before contacting their peers or geo-experts for help; checking student progress with respect to their tasks and giving advice on how to move on; advising students about intellectual property rights especially in a web environment; advising students to read printed notes when the access time on the Internet was slow; and grading student work online.

Engaging Agent Technology

The study found that teacher support was linked to the enhancement of higher-order thinking skills, information seeking and content skills. However, it was found that a constructivist learning environment presents a challenging and demanding work environment for the lone teacher. By virtue of the fact that each learner and each group is given the opportunity to individualize their own learning, the process-based outcomes are never the same at any given moment. As the teacher moved from group to group, so too did her mental, emotional and intellectual disposition. The teacher had to make an immediate and unconscious shift from the needs, responses and task variables of one group to those of another. In other words, a constructivist learning environment demands that the teacher be able to cater to the multiple outcomes during her interactions for a number of different learning contexts. This consistent shifting or changing of attendant gears for the teacher places a heavy emphasis on the human factor in the teaching-learning process. On the one hand, the teacher had to provide for, respond to and help create a positive learning environment in the classroom. On the other hand, there were some tasks that could have been more predictable i.e. tasks which could be performed by the technology itself. Herein enters the role of intelligent agents, which may allow for offloading of some tasks from the teacher herself.

Hawkins (1994) described intelligent agents as independent computer programs that operate within software environments such as operating systems, databases or computer networks (cited in Baylor, 1999). From an educational point, Seiker (1994) sees intelligent agents as computer programs that are capable of simulating humanlike relationships by aiding the user just like another human would do (cited in Baylor, 1999). Aroyo and Kommers (1999) see agent technology as promising in addressing the challenges of learner directed educational environments which have been designed to harness the information and Internet technologies. In this respect, Baylor (1999) prefers to call the intelligent agent a cognitive tool, which is an intellectual computer device that supports learners’ thinking processes. In an educational context, intelligent agents can be created to do the following: a) manage large amounts of information, b) serve as pedagogical experts, and c) create programming environments for the learner (Baylor, 1999). The following section elaborates on two areas of support: managing large amounts of information and providing pedagogical expertise.

Intelligent agent technology has progressed from generic learner support to specific learning support and initiatives taken to create such agents include those by Seiker, (1994), who forwarded COACH, O’Riordan and Griffith, (1999), who created UMAgent and Baylor and Kozbe, (1998), who conceptualized PIM. With such a proliferation of agent technology and the advantages in supporting the teacher, it is timely that such initiatives be
considered for the WebClen. However, for the WebClen, intelligent agents are needed more specifically to help learners to self-assess, get help in translation as well as generate student portfolios, which the teacher can refer to, to keep track of student progress. As an example, the agent can help learners identify errors and suggest alternative strategies in the online activity of gathering information for report writing and writing of critical summaries. Students' answers can be checked against suggested formats, according to each student's ability and progress to the next higher level of learning. Intelligent agent technology can also be incorporated to monitor students working on group projects in an online environment as suggested by Whatley, Stanford, Beer and Scown (1999). The agent can monitor progress made on a collaborative project and suggest ways for improvement as well as how to enhance communication between group members. In the WebClen, two issues that were of concern related to student collaboration with experts were, one, when students copied in verbatim everything that an expert had suggested and, two, when students did not act on suggestions given by the expert. To overcome such weaknesses, agent technology could be created to alert students on the need to paraphrase their answers and probe the learner, alert the expert or supply alternative websites to the learners.

Thus, it can be said that the role of the teacher in a web-based constructivist environment has shifted from that of an information provider to that of a manager of learning. Thus the teacher needs a more efficient support structure to enable the teacher to reach his/her 'zone of proximal support' to manage learners' diverse learning experiences. The power of the computer can be harnessed for this purpose.

Conclusion

This paper has identified the many roles played by the teacher as a manager of learning which inadvertently lead to more demands place on the teacher. The paper also identified how teacher load may be reduced with the incorporation of agent technology. A step forward will be to create these agents and test run them to identify their effectiveness in a web-based constructivist learning environment.

Abstract: A Collaborative Learning Environment (CLE) for second year Physiology students, involving timetabled tutorials, a student-friendly learning space and variety of computer-based and traditional resources, has been previously shown to impact positively on student learning. In these sessions, students used a semester-long group project to explore a topical question in physiology, exercising skills in scientific writing, analytical thinking, communication and collaboration. Limited flexibility of the course management system used in the first iteration of this activity prompted its redevelopment in 2000, this time using a more flexible database system. The redevelopment involved an action research collaboration between faculty teachers and Multimedia Education Unit staff, who put together weekly online activities based on the previous week’s experience. Outcomes of the development included a suite of practical pedagogical structures, increased personal understanding of the operation of computer-facilitated CLEs, and refinements to the database system grounded in the coal face implementation experience.

Background

The development of a model for student-centred learning within a Collaborative Learning Environment (CLE) was a response of the Physiology Department to an increased level of lecture-dominated teaching. The CLE was first set up in 1998 to encourage student interactions between peers and tutors in a friendly study environment in which the tutor acted as a 'facilitutor', to guide and assist. The two-hour time tabled tutorials employed a variety of software and teaching approaches, with the students encouraged to work in groups. Results so far suggest that this general approach has had a significant positive effect on student learning outcomes (Kemm, Kavnoudias et al. 2000 p10).

The philosophy behind the redevelopment of the CLE is in line with calls by Reeves for instructional technology research to be driven by 'use-inspired goals' (Reeves 2000). These goals focus on developing creative approaches to particular learning requirements, while at the same time establishing generalised design models to guide future development practice. In our case, the Multimedia Education Unit (MEU) is interested in generalised online pedagogical architectures for application across the University.
The Physiology Group Project

Part of the weekly Physiology CLE tutorial in Semester 1 1999 was devoted to a semester long project to help students develop higher level scientific communication and writing skills. Each week, student groups were given a task through which they could engage in analytical thinking, reflection and discussion with peers and tutors. The original Group Project utilised the TopClass learning management system which however proved insufficiently flexible for the kind of environment we required. It was necessary to produce detailed instructions on the use of discussion lists, email & course navigation controls, and tutors found it inconvenient to review the discussion process and provide useful feedback to the groups. Students also found the peer review process too complicated and were inclined not to take it seriously. The Physiology team decided to redevelop the Group Project, with the same educational philosophy, but using MEU's OCCA framework which had greater potential to adapt to our intended learning and teaching model, without the limitations of predefined courseware functions.

Online Courseware Component Architecture

The Online Courseware Component Architecture (OCCA) is a low level component framework for implementing pedagogical structures that can support discursive interactions and reflection on learning (Fritze, Welch et al. 2000). It has been developed as an institutional approach for online learning, supported by a central server run by MEU and used in a variety of projects across the faculties. Key features include a generic database for managing learning records and server functions for accessing and embedding these data within Web pages. Using simple HTML pages, departmental staff can create their own learning activities and summaries of student work. Additional Shockwave components or Javascript functions can be used to support more specialised educational functions or discipline interfaces.

Redevelopment of the Group Project as a MEU/Faculty collaboration

The redevelopment of the Group Project provided the opportunity to address three key goals:

- to produce and evaluate the Group Project as a computer-facilitated collaborative learning activity using OCCA,
- to increase our collective understanding of pedagogical and delivery processes associated with CLEs, and
- to further develop OCCA through its application to a real teaching context.

We felt these aims could be best achieved through close collaboration between teaching staff and the MEU framework developer during the implementation. This would enable the developer to acquire a better understanding coalface teaching issues, and insights into how a technical architecture impacts on the real teaching world. The educational aim of the Group Project was for students to develop their understanding of, and ability to discuss, key Physiological concepts. They were to be introduced to the rigorous process of scientific writing and to engage in written debate on the topics. The students were to collaboratively develop a 500-word analysis of a topical physiological question over the semester which would be reviewed by their peers.

Development method

Our approach was to develop the online activities immediately prior to their implementation each week. In this way the content team could refine them in the light student observations, tutor feedback and evaluation questions of the previous week. We considered this a reasonable undertaking, given that there were only two or three tasks each week, the content design was already in place, and we had the safety net of a human tutor during each session. An end-of-semester evaluation and reflection completed the process.

We undertook the development as a form of participatory action research - a self-reflective research enquiry undertaken by us as joint participants in the process (Kemmis and McTaggart 1997 p5). Most of the day to day ‘action’ took place between Kavnoudias and Fritze, who kept reflective journals of the experience. Teaching and
curriculum guidance was provided by Physiology lecturers Kemm and Williams, with other important communications occurring with tutors, students and teaching staff from other faculties using OCCA in different curriculum projects.

Structure of the Group Project

The structure of the project is illustrated on the group's overview Web page (Fig. 1). Each week involved several activities such as building a key concept list, a writing task, reflecting on previous work or reviewing the work of their peer group. The column headings displayed the group's work for one activity. For example, the 'Writing' link summarised the group's writing tasks from brainstorming to the final submission on the one page. The 'Peer interactions' page tabled the draft sent to peers, the peer review and the group's response to that. Each row heading linked to a summary of the group's work for that week.

Outcomes of the developmental research

Evolved pedagogical elements

Particular teaching elements were crafted on top of the OCCA framework, becoming our 'toolkit' of teaching resources. These were structures we found useful for the Physiology CLE, although we believe they would be generally applicable in other areas. Some of these ideas originated from previous projects (Fritze, Johnston et al. 1998; Fritze, Welch et al. 2000), while others emerged within this project.

Other pedagogical elements beyond the scope of this paper include an 'administrator view', 'tutor view', 'rubber stamp', confidence indicators, key word prioritisation task and facilitated group discussions. Various pedagogical features are indicated in the template page that was used by the tutors to review and annotate the work of each group prior to the next class (Fig. 2).

Changes in understanding arising from collaborative re-development

More subjective changes in our understanding are evidenced by reviews of journal entries, post-semester discussions, and reflection on student work. These observations do not form a generalised 'theory' of practice, but are important in developing our own personal conceptual models. We hope that they may also provide useful
insights and promote discussion by others. Some of the emotional aspects and unpredictability of the real work environment are reflected in the observations in Tab. 2.

<table>

Table summarising points made by the Peer Review Group presented side by side with original Group's response. The review was made against 9 criteria points.

Student Peer reviewers award a 'rubber stamp'

The Group thinks review was 'fair' and 'will redraft their essay'

The Editorial Board (ie. tutors) have selected certain preset and entered comments in their assessment of the review.

Preset responses and comments used by the Editorial Board in reference to the rebuttal and submission

The Editorial Board uses this button to save the annotation record that will be viewed by the Group the following week.

Figure 2: Web template used by 'editorial board' to assess the group essay and peer review process.
Thinking about teaching, not tools
In shaping each activity, we found ourselves trying to think in terms of face to face interactions eg. how we might write on pieces of paper and later arrange them on a table.

Serendipity
Delays in programming database reports prompted the development of the administrative page that delighted us with its usefulness. ‘Naïve’ users also sometimes provided ideas. A request to “paste in a picture” into the page made us think. After consideration, it was not included for pedagogical rather than technical reasons.

Value of effective teaching tools
The Physiology staff were excited by the effectiveness of the tutor annotation Web page for reviewing and responding to students.

Portfolios
Even though portfolios had been planned, all of us were delighted at their effectiveness in summarising a group’s work. To the developer, the simple web frame structure meant that the teaching staff could easily extend the summary pages themselves. We realised this could be given to the student at the end of the course as a personal record of their learning.

Changed perspectives via new views
Despite the time spent in the CLE helping students, Physiology staff were interested in how the summary pages of students work increased their understanding.

Value of seeing tools in real use
The framework developer noted the additional insights gained from seeing the software in actual use in the CLE.

Time pressures
Completing the activities each week often placed pressure on us due to illness and other factors. We needed time reflect and were sometimes frustrated when we had no time to implement often quite small changes.

Change of direction
We originally planned to use immediate feedback in some tasks, but decided the reflective self-assessment tasks were of greater use to the student (and far easier to implement).

| Table 2: Some changes in understanding emerging from reflection on the development process. |

Revised functions and extensions of OCCA

The third class of outcome from the regular weekly development cycle involved changes to the OCCA system, necessary to implement emerging requirements of this project. These were either simple page components or more fundamental changes to the framework which are indicated in Tab. 3.

Evaluation of the student experience

At the conclusion of the Group Project run in semester 1 and again in semester 2, we undertook a reflective examination of the whole process, as well as conducting a more traditional evaluation. Briefly, the 44-question questionnaire filled in by the students at the end of semester indicated that:

Seventy-two percent of students found the project enjoyable and eighty percent found that their ability to discuss physiology with others was enhanced. Ninety percent of the students found the program easy to use, instructions were easy to follow, navigation was easy and most importantly, that the instructions, questions and guidance helped to generate discussion amongst the students. The biggest revelation to us, which was not commented on in the
previous implementation (TopClass framework), was that students appreciated the opportunity to hear and read different interpretations of a problem. A comment given referred to 'supporting and extending each others knowledge'. Other frequent positive comments related to the opportunity to peer review, that they enjoyed researching a topic in depth, it was good exam practice, or that they made new friends.

Negative comments concerning the group size led to us reducing this to 3 in Semester 2. Students indicated they needed more help in dealing with conflicting opinions and that not everyone pulled their weight.

Discussion

The re-development of the campus-based Group Project was a genuine collaboration between the Physiology teaching staff and MEU developers of OCCA. In the resulting process of negotiation and exchange of ideas, enhanced versions of the CLE model and generic online architecture emerged. We have shown how a low-level architecture can be used in a participant research study to create a flexible student environment involving open-ended tasks, reflective activities, and feedback between student and teacher.

Thinking about how a student will engage with a given activity should involve more than just consideration of what tool to apply. We found that even the simplest learning activity can be used as the basis of a rich variety of learning situations. For example, submitting a short piece of writing might have value added by associating it with self-assessment activities, feedback comments to tutors, indications of confidence, later reflection on the task, peer or tutor assessment and guiding comments, later re-drafting, incorporation of other existing work and placement within a portfolio of work for the whole subject. Applying these possibilities to a practical learning activity requires careful thought and reflection on the context of use, far more comprehensive than the initial simple task would suggest.

We have reported the outcomes of a development process carried out in a single setting, but more detailed comparisons of online frameworks should be undertaken. These should consider educational principles and the organisational context in a holistic way, rather than focusing on functions and features. We suggest that where learning systems are adopted on an institutional basis, the impact on teaching and learning should be carefully considered and monitored. Collaborative developmental research of the type we have conducted is one important technique that can help inform the implementation or development of such systems.

Abstract: This Paper concerns new access technology in area of new transmission technologies for
providing communicate facilities to the members of value chain – typically individuals and
companies, with distance Education and Training, tourist information, stock trading, banking
services, directory services, exchange rates, flight schedules, and train and bus timetables. Practical
applications include WEB browsers, WAP Gateways and WAP terminals. Wireless Application
Protocol (WAP) provides a universal open standard for pushing Internet and Intranet content and
advanced Value Added Services to mobile phones, PDA’s and other wireless devices. From the
teleoperators and content providers’ point of view, this provides a huge number of new business
opportunities, demanding new skills and new approaches to the business itself. The product is no
longer a communication line but a whole communication solution concept, derived from users
needs and specific applications over the value chain.

The new Value Chain

Background

The present societal movement towards a network society and economy sets difficult renewal goals and puts
developmental pressures on all segments of education and training technology. The development of network
infrastructure and Wireless Application solutions makes it profitable to utilize new kinds of education services and
business solutions, as the access to networking becomes easier. Content industries and telecommunications operators
are intensifying their co-operation. Examples can be found in such areas as electrical publishing, satellite and digital
television, information technology and software. The goal of this activity is to make the distribution of content more
effective. This paper will grapple with problems and facts that appear in the creation of new applications; Education
and content services based on new access technology and partnership network with a case focusing on mobile
Wireless solutions.

Changes in the Educational, Publishing and Training Industry

The lines of demarcation within the area of training industry between service producers are becoming hazier with
the development of digitalization, broadband information technology and internet based solutions. Until now,
telecommunications operators have by in large owned their transfer networks. Today there are an increasing number
of connections and routing services as well information network services providers. Increasing global competition,
digitisation of content, the general use of SGML, XML and HTML formats and the adoption of broadband data
transfer will produce co-operation agreements and strategic alliances among content production,
telecommunications and information technology companies as well as large media concerns formed by mergers and
acquisitions. Therefore is valuable to have different members side by side in value chain The development of a free
market in telecommunications services and broadband cable technology will also effect TV and radio network
operators. Bi-directional cable modem technology offers the possibility of developing faster cable connection that
will facilitate multimedia applications and the broadening of the range of data and video services to several kind of
end users and several organization. In figure 1. is example of value chain that have chance to make the different
collection of active value chain.
The member countries of the EU have encouraged free competition in telecommunications area which it is hoped will develop intensive product and service innovation as well as moderate prices. In some instances, as in Finland, national legislation has slowed development. Under Finnish law, the operator of an existing CATV network must lease bandwidth to the operator of a competing two way information transfer service at the going market rate. Forced leasing has been avoided by the building of the return loop through the telephone system, whereby the CATV network remains a one-way system and does not become part of the telecommunications industry. It is also feasible to produce interactive features so that watcher can use hand held devices and affect to TV program or get more information. These applications can base on HTML or WML languages and have possibility to use VRML. During of autumn 2001 is intention to start digital TV broadcasting operation by Platco Ltd that is a new common company and the members are Finnish digital TV multiplex, YLE, MTV Oy and SanomaWSOY’s Swelcom. Company’s task is to acquire the required licences for the technical solutions of digital-TV, and to is provide current and future multiplex companies with the necessary resources, applications and system. Platco also offers services and licensees to CATV companies. Main purpose is make digital terrestrial television easy to use and offer possibility to use Interactive services. Competition forced the members of value chain centre their working and competence quite narrow area. If value chain operate excellent it degrade operational and production costs.

Conclusions

Increasing global competition, digitisation of content, the general use of HTML and WML formats and the adoption of broadband data transfer will produce co-operation agreements and strategic alliances among content production, telecommunications and information technology companies as well as large media concerns formed by mergers and acquisitions. On the other hand the increased competition and the rapid development of technology will lead to formation of specialized companies in narrow segments of the market. The media and telecommunications giants strongly influence developments, but in order to remain current, utilize the skills of small, innovative companies. The competition among current telephone and internet operators will increase. Both groups are offering mobile services as well as additional services over the existing network. The understanding of telephone operations can be enlarged to touch on Internet operations because POTS services are also delivered via data networks and on the other hand it is possible to get onto the data network via the CATV network. The digitalization of the networks and broadband information transfer will increase the competition among telephone operations as well as with TV and radio broadcasters.

Abstract: We developed a collaborative learning environment (CLE) as a student-centred approach to assist students' understanding of difficult scientific concepts. Computer-facilitated investigative group projects were designed to enhance students' communication and reasoning skills, peer-learning and peer-teaching. Projects were structured around cost-efficient web-delivered tasks, incorporating re-usable interactive web components that store student responses in a server database (OCCA - On-line Courseware Component Architecture). These provide for group discussion, self-assessment and peer review. Student submissions were accumulated in a portfolio to enable them to reflect on their learning. 'Facilitutors' contribute to timely feedback using efficient templates for reviewing and annotating student work. Students work in groups (three per computer) for 4-6 hours on their project within scheduled weekly CLE classes of 40 students with one 'facilitutor' (repeated 8 times). Successful attributes of these tasks are described and evaluated, including strengths of on-campus collaborative learning and appropriate training of 'facilitutors'.

1. Background

The need for intervention in our approaches to teaching

Previous attempts to introduce critical reasoning skills into the curriculum has been attempted at several levels of our teaching program. The need for intervention was shown at many levels:

Graduates: Our research supervisors have reported that our graduate science students are good at reading, understanding and collating information, but are notably weak in identifying, documenting and articulating key issues. Employers told us that our university's graduates need better communications skills (McInnis 2000).

Hons year: Four years ago we introduced a task for which students had to identify information in their literature survey that was seminal, novel, controversial or not confirmed. They needed to be able to justify their selection with a short reasoned and critical synopsis of the material. Students are still unable to complete this task effectively.

3rd year: Two years ago we introduced a paper-based sequence of exercises on original articles with 50 students, in groups of 5. Scheduled collaborative assignments replaced 10 lectures. Student responses were very positive indicating that they thought it effectively improved their reading and writing skills, although they found it challenging. This format was very staff intensive and assessors still found deficiencies in students' ability to identify key concepts and to negotiate within a group.

Information from a 3rd Year Trial for 55 students in 1998:

This study clearly showed a student desire to improve their capabilities to interpret and communicate physiological information and communication skills. Students worked in groups of 5 on a topic covered by three original published manuscripts. They then followed the same schema as in Fig 1 shown below for this project, except that they had considerable staff and postgraduate assistance within the scheduled times and gave an oral presentation on their findings: dealing with key concepts, assumptions and the validity of the conclusions.

Outcomes: Students' indicated that the task introduced was challenging, and that they valued using methods of learning that were unfamiliar to them. The assignments still showed that students had difficulty in identifying key concepts and communicating ideas within their working group— even though they had significant individual and small group assistance.
These basic skills are integral to the successful learning of even our most basic courses and underpin the integration of the material covered in the three separate teaching approaches of our courses: lectures, practical classes and computer-assisted learning sessions.

*The trial demonstrated the need* to develop an additional element for our electronic deliverable teaching strategy to support this initiative. The objective was not introduce it as a separate skill, but to incorporate it as one of our basic approaches to student learning embedding it within overall teaching framework. Such an innovation sat well with the overall course, since electronic and online strategies already underpin all our teaching formats (lectures, practical classes and computer-aided learning).

**Electronic Teaching Approaches in Physiology**
Scheduled computer-aided learning (CAL) sessions were introduced into Introductory Physiology in 1997 as part of an ongoing strategy of decreasing lectures (from 4 to 3 per week) and increasing self paced learning (2 hour CAL sessions were introduced, (Kemm et al, 2000b).

This initiative was directed to help students with their individual self-paced learning, to be more perceptive about their approaches to reading ie. be analytical about what is presented so as to eventually reflect and make judgements about content and conclusions. Small groups were used to expose students to different views and interpretations from which they could resolve their differences and develop a “consensus” point of view. It was simply not feasible to run this innovation as a paper-based study with direct tutor involvement for up to 360 students in Introductory Physiology. - (see below)

2. Aims and Intended Outcomes of the Physiology Small Group Project

The development of a small group project, in which computers are used for presenting the problem, providing interactive feedback and also for peer to peer communication is an important element of our current computer facilitated collaborative learning environment.

**Aims:**

?? To introduce graded weekly tasks into Science Teaching using a Web-based learning structure to further transform our teaching.
?? To assist students to better recognise, understand and communicate key scientific concepts.
?? To extend existing software developed in collaboration with the University Multimedia Education Unit.
?? To build in students a strong skills base, thus preparing students for more difficult tasks in later years.

Our graduates would then have a good appreciation of the professional skills required as graduates (e.g. ability to identify key issues, critical understanding and review of scientific literature, team work, report and grant writing, symposia presentations).

**The planned outcomes and benefits were for students to:**

?? appreciate the words used to describe a scientific phenomenon,
?? appreciate the accuracy of the descriptions
?? identify key concepts underlying the explanations of physiological processes,
?? write with clarity and with the precision required for scientific disciplines,
?? develop the individual and team skills (and confidence) required for analysing scientific information from published sources and from peers,
?? develop a portfolio of their learning activities permitting them to reflect and revise.

**Integration within a course.** This program would take the students through the process of in-depth learning using one of the subject modules in the physiology curriculum for that semester. This skill is essential for developing their ability to critically read and question the Physiology in their final undergraduate and Honours years.

In particular, the project was designed to enhance our final year teaching that involves greater emphasis on group work, assignments and student presentations. Presently students are poorly prepared for these tasks. This electronic resource will be an ongoing development extended to different areas of physiology.
3. Description of the Initiative

Overview of the student activities:
Small groups of students were guided using electronic help through a graded reading task to identify and rank key concepts in a fundamental area of physiology (Hooper 1992). Web-based interactive-help was used to progressively reveal issues for consideration and to assist in the groups' identification and ranking of the key concepts underlying the problem. They were given a collaborative writing task to draft a concise treatment of the problem (500 words max.). Peer review assisted them in generating good writing structures, essential for effective scientific communication. Students undertook a series of tasks over several weeks as shown in the schematic in Figure 1. Although the duration of the project has been shortened in response to student evaluation, the essential features remain as in this first implementation.

![Figure 1](image)

Delivery of the Project:
The first implementation in 1999 used a proprietary learning framework, 'Top Class', to organise the web pages and to provide messaging between student groups and to/from the 'facilitutor'. (The term facilitutor seems appropriate to describe a tutor facilitating the collaboration amongst group members within a large class, assisted by a computer program). However students found the messaging system in 'Top Class' did not suit their purposes in this project and this framework did not allow us to provide the forms of feedback that we considered desirable. In 2000, students undertook Group projects in both Semester 1 and 2. The rest of the report will discuss these implementations which were structured around cost-efficient web-delivered tasks that incorporated re-usable interactive web components which stored student responses in a server database. This is OCCA - On-line Courseware Component Architecture, described earlier (Fritze et al, 2000) and in another report at this conference, (Kavnoudias, Fritze et al, 2001). These components also provided opportunities for group discussion, self-assessment, reflection on learning and peer review. 'Facilitutors' were then able to contribute timely feedback using efficient templates for reviewing and annotating student work.

Students (360) originally worked in groups of 3-6 with a computer in 1999, but now groups of 3 are preferred after student surveys and evaluation of group dynamics showed that large groups had significant problems in sharing workloads. The classes of 40 are repeated several times each week, in a collaborative learning laboratory with 15 computers. Although the project is cross-platform, we chose iMacs because of their reliability and ease of use in delivering computer assisted learning classes.

Students worked on their semester projects in the last 30 minutes of the 2 hours of scheduled weekly collaborative computer assisted learning sessions, described in Kemm et al, 2000a. It was not an optional activity and counted towards student's final assessment in the respective semester long courses. Assessment was based in participation, collaboration and effective use of the processes and less on the quality of the final submission.

Appearance to the students:
Student groups organised their own members and registered themselves on the project Web site. Each week, activities presented on the different Web pages posted corresponding records to the OCCA database for that group. Web pages could contain interactive objects and references to stored records that were dynamically updated on delivery. Each student group was provided with one of four real-world problems to work on. Problems in Semester 1 were introductory, dealing with simple concept analysis. Problems in Semester 2 used the same process on a shorter time scale, but with more complex and topical issues. (e.g. “What are the physiological effects of human growth hormone and why would Olympic organisers consider its administration to be performance enhancing?”)
Students' activities involve preparation of material in their workbook combined with progressively submitting their work on Web pages.

The first week task: was performed individually by students reading around the topic to see what were perceived as the crucial issues. They submitted this by email to their 'facilitutor' and also had it available to share with the other members of the group in the following week.

The second week tasks illustrate activities that students might expect to undertake in the project over several weeks.

?? Brainstorm around the issues and write and submit several sentences that covered what the group thought was important. They could progressively review their work and add sentences, but once submitted they could not be modified.

?? Identify what they thought were the key phrases (or keywords) using their first writings which were made available on a new web page

?? Prioritise these key phrases by dragging them up and down their list.

?? Report on the level of consensus in their group decisions

?? Classify whether each of the listed items was of major or minor importance

?? Indicate how confident they were that their efforts addressed the problem.

The essence of the subsequent weeks' activities was for students to:

?? Learn to appreciate and interpret physiological information and to communicate effectively within a collaborative peer learning environment.

?? Use web-based interactive help that progressively revealed issues for consideration that students could consider in their later drafts.

?? Reflect and review their own work using guidelines provided. This was important to stress the importance of the various processes they undertook if they were to be confident with the quality of their work to submit it for peer review by another group.

?? Review the work of peers using several suggested criteria and justifying each of their ratings.

?? Respond to their peer reviewers' comments, professionally and without emotion, and change their final submission if it was warranted.

The students work was progressively stored in their groups learning portfolio. Additionally, electronic communication was used to exchange information amongst student group members, 'facilitutors' and academics responsible for the project's development.

Appearance to Staff

Various Web page templates were used to give assessors appropriate views that:

?? Summarised each group's activities in a particular week

?? Showed a group's final submissions, the peer review, and their responses to the review

?? Provided views that compared different groups' approaches to specific tasks

'Facilitutors' could use entry boxes on these templates to provide simplified and timely feedback to students on their progression through the problem. Such feedback was saved as records in the database and made visible on appropriate pages accessed by the group. Thus relative assessment of group activities was continual and seamless within the scaffolding, being made easier by being able to scan all class responses for an issue on one template page. The summary templates were also crucial in the final assessment by supervising staff, who were able to bring together the students efforts, together with the 'facilitutors' reports and ranking of each group.

4. Approaches to Evaluation:

General Approach:

A number of evaluation strategies have been used to collect data in 1998, 1999 and 2000. These are part of our overall action research strategy for dealing with global learning outcomes from collaborative computer assisted learning and focussed evaluation of additional standalone learning modules. ‘-

We required human ethics approval for our surveys and logging of student activities in the computer tutorials, since we wanted to be able to correlate individual student’s responses to several questionnaires, their exam results, as well as their ‘facilitutors’ comments and assessments. Such approval required a student’s enrolment number to be replaced by a randomised 'research number', with original records identifying students stored in a secure location and only available under strict guidelines to researchers who were not examiners.
Student Questionnaires

Questionnaires specific to the CLE were used to survey students' attitudes to various aspects of the CAL tutorials and the CLE sessions, in consultation with our educational advisors. These instruments were developed in consultation with our educational advisors.

The student questionnaires had approximately 80 questions designed to reveal students' attitudes and use of the CLE, covering aspects such as their pattern of work with the CLE, development of independent learning skills, relevance of the CLE to their learning compared with lectures, and their attitudes to group work. Approximately half the questions focussed on issues pertinent to the Group Project. Most questions required students to rank their responses on a 5-point scale, supplemented by several open-ended questions. In addition we investigated students' self-assessment of their approaches to learning. We used a modified study process questionnaire to extend the investigation of deep, achieving and surface learning-approaches (Biggs, 1987) so it included additional learner characteristics. Its use is discussed in application to one of standalone interactive tutorials (Kemm et al, 1997) and will be correlated here with other evaluations. We found that students cooperate well with questionnaires and interviews if they are fully informed about their purpose and that the results have been acted upon each year.

'Facilitutors' play a key role in the implementation of the program so their impressions of the course are most relevant to understanding student reactions. They made observations and kept records of students' work and participation in the CLE sessions. Formative evaluation continued throughout with regular formal meetings between the main developer and tutors, as well as many informal interactions amongst the students, tutors and the academic developers whose nearby location enabled and encouraged this latter process. In the recent semester, we provided additional training for tutors to be able to better facilitate group learning processes and make better judgements about students' contributions.

5. Results

The highlights of the questionnaire responses in Semester 2, 2000, with numerical data being on a scale of 5 - with 3 being a neutral response, are as follows: students rated ease of use and feedback on the OCCA-based web pages highly (>3.9). They were neutral/disagreed that the project was a waste of time (2.8). They rated group work as useful, enjoyable and an important part of their development (>3.5). They did not think that the group project increased their knowledge much, but this single exercise was not designed for that purpose. In open-ended questions, most important comments emphasised working with people and discussing problems, researching and clarifying issues. Many students (45%) thought that they should be left alone as they already had the required scientific reading and concise reporting skills, although a formative assessment assignment and exam answers show that they are misled about their own abilities.

As a formative assessment assignment, a written short one hour test for the students was individually given as an open book assignment that required them to transfer these skills to a separate task. It required students to follow exactly the same format as they had undertaken collectively in their group. Only those students who went through the same process they learned in the group project were able to write concise answers. Many students wrote their answers directly and submitted answers that were either too long or made the tight word limit by writing generalities with little scientific content.

As an initial summative evaluation approach, we compared the examination outcomes for second year Science Physiology across 4 semesters. The "Exam result" excludes all collaborative computer aided learning assessments and is proportioned as 60% toward written answers and 40% multiple choice questions (MCQ). The student cohort was divided into high-achieving students (First year Faculty score ≥ 75), low-achieving students (First year Faculty score ≤ 60), and those in between (61-74). Each group was further divided into whether students made an effort or not at their collaborative learning (? 7.0). Analysis of the data showed that collaborative learning assists students achieve significantly higher examination outcomes in the written component, but did not change the MCQ component. These results were markedly higher for all groups but the low achievers (eg 70 vs 63 for high achievers group). However, this improvement cannot be ascribed to any particular attribute of the collaborative learning environment that provides many learning opportunities.

We then analysed student results, investigating if any of our collaborative learning (CL) approaches correlated with the results of students who markedly improved their result over first year. Students were divided into improvers, disappointers and remainder groups. Data showed that improvers obtained a better CL mark. Improvers student cohort primarily improved their scores in questions requiring writing responses. (43 vs 34 for questions requiring written responses for the improvers group compared with the total student cohort).
The improved writing ability of the improvers group correlated only with a high score (>3.5/5) in the group project. Students performing well in the group project also did marginally better in the MCQ component of the assessment. Data indicate that those students who undertook the group project and did well, may obtain improved examination outcomes, especially to written answer questions. A good group project result however did not guarantee an improvement, but certainly the very large majority of the disappointers group did poorly in their written answers and they also performed poorly in the group project.

6. Discussion

The use of a customisable learning environment based on OCCA has given us significant advantages in producing some of our desired learning outcomes compared with our previous efforts to use a high level learning framework that had restricted flexibility. Generating structured collaborative exercises adds value to any high level framework, such as WebCT, while allowing academics to produce effective student-centred learning environments without specialist programmers.

The process of reasoning that has been introduced in this group project work is a first step in developing the training of critical thinking science graduates (with skills in analysis, criticism, aware of different views and with skills to manage those differences – both personally and as a consensus document). There remain some concerns that students have not been able to transfer these skills to other contexts. This issue will be addressed in 2001.

Once our collaborative learning environment is fully implemented, with strengthening of students’ ability to extract and understand physiological concepts by group projects, it is envisaged that more factual material would be taught in a structured student-centred collaborative self-paced learning environment with less emphasis on lecture material.

Abstract: Our previous research provided a theoretical basis for a proposed set of practical design criteria for online assessment tasks. This work has been motivated by our recognition of the importance of not simply transferring face-to-face or distance learning assessment techniques to the online environment. We work largely in a constructivist framework and the key components of our design criteria include using a variety of qualitative and quantitative assessment activities, designing authentic tasks, using collaboration and interaction, providing appropriate feedback mechanisms, utilising online resources, and encouraging student responsibility for and control of the learning process. In this paper two case studies are used to illustrate the application of these criteria, and their effectiveness as online assessment tasks is evaluated. The first case study involves an online portfolio assessment in an Indigenous Australian literature unit, while the second looks at the adaptation of the modified essay question to the online environment in a medical education context. The results of our analysis will inform both the refinement of our design criteria and the development of future assessment tasks.

Introduction

When designing new assessment tasks or evaluating the effectiveness of existing tasks, it is essential that these processes reflect a sound pedagogical base and appropriate instructional design principles. Ten criteria for designing and selecting online assessment tasks was devised as a set of guidelines for appropriate online assessment tasks (Northcote & Kendle, 2000). The criteria are based within a theoretical framework combining the principles of situated learning and constructivism, and were created with the intention of promoting the use of both quantitative and qualitative assessment tasks. Instead of recommending a simple transformation of face-to-face or distance education assessment tasks to the online context, the criteria give practical suggestions of specific characteristics that are suited to online assessment tasks such as the use of online resources.

Major Questions and Motivation

Two major questions are addressed in this paper: firstly, the relevance and composition of the ten online assessment design criteria and, secondly, their applicability to other educational contexts. It is hoped that consideration of such questions will result in answering a more general question: what are appropriate and effective methods of assessment in the online environment?

The motivation for our current work was to evaluate the effectiveness and validity of our previously proposed assessment criteria in two different environments. This micro-application is expected to act as a trial for future macro-application of the criteria. We intentionally applied the assessment criteria in two educational contexts.
that were contrasting in as many ways as possible, enabling us to test their applicability and transferability across a wide range of tasks, students, discipline areas, courses and institutions.

Conceptual Framework for Online Assessment Design Criteria

The theories of constructivism and situated learning form an appropriate basis for designing assessment strategies for online learning environments which go beyond the mere reproduction of knowledge and encourage students to rise to the challenge of deep learning. Constructivism places a focus on the student in the learning process and aims to assist students' progress from their prior level of experience to construction of further knowledge and understanding. Several characteristics of online learning environments allow assessment strategies to pass control to the learner in a constructivist fashion. For example, valuable metacognitive skills are developed as a result of the independent nature of online study, and its flexibility allows students to choose their own style of learning to suit individual goals and abilities. Similarly, convenient online access to a variety of resources encourages learning patterns which more directly reflect the process of knowledge construction than knowledge delivery.

Situated learning builds on aspects of constructivism, and follows the premise that effective learning occurs when content is embedded or situated in life-like, authentic contexts. A replica of the appropriate environment, or a contextual anchor which reflects the conventions of the environment, can constitute a situated learning environment (McLellan, 1994), and should include the following characteristics:

- ensures meaningful, active participation of the student, while acknowledging relevant social and motivational factors
- offers opportunities for collaboration
- allows students to articulate new knowledge and concepts
- promotes student reflection
- offers meaningful learning outcomes with obvious uses in an authentic, real-life context
- offers authentic learning activities, including those which improve the problem solving abilities of students
- provides multiple viewpoints on knowledge and concepts
- allows for coaching and scaffolding where necessary
- offers flexibility of approach for students and teachers
- provides integrated and authentic assessment activities

(Here the citation is not complete. It should be: Herrington & Oliver, 1997 and Wilson, Jonassen & Cole, 1993.)

Assessment tasks for online environments are often able to incorporate many of these characteristics. For example, the nature of online communications encourages collaboration between students, and can allow students to complete authentic collaborative tasks or reflect on their learning and compare it to the experiences of other learners.

This conceptual framework formed the basis for our initial development of design criteria for qualitative assessment tasks (Northcote & Kendle, 2000) and our subsequent criteria for incorporating appropriate qualitative and quantitative online assessment tasks (Kendle & Northcote, 2000). In order to evaluate two online assessment tasks from different contexts, we have combined our work on design criteria to develop the checklist below. Our evaluation asks whether the task:

- necessitates quantitative and qualitative responses?
- has a clear purpose and outcome?
- models an authentic situation?
- emphasises process over product?
- ensures collaborative communication?
- gives students choices?
- links to unit learning outcomes?
- includes feedback mechanisms?
- encourages the appropriate, discriminatory use of online resources?
- enables students to examine and present many viewpoints?

Application of Design Criteria to Two Case Studies
To test our evaluation checklist of design criteria, we chose to apply it to two varied online assessment tasks. The first was a component of a unit delivered wholly online, whereas the second assessed an otherwise face-to-face course. The detailed context of the tasks and the results of the evaluation serve to examine the usefulness of our set of criteria.

Case study 1

In the first case, the online assessment criteria were applied to a unit of study within a pre-tertiary bridging course for Indigenous Australian adult learners. The unit centred around the processes adopted by Aboriginal authors to create works of fiction and showcased 23 Aboriginal authors from across Australia. The assessment component was linked to the three modules of the unit and allowed students to construct their own learning pathway based on their choices of learning activities, thus catering for students' varied learning preferences (Groome, 1995). The main assessment task for the unit is a portfolio comprising three sets of learning activities reflecting the three modules of the unit. The portfolio components were either submitted separately throughout the semester or altogether at the end of the semester. In two of the three modules, the students were presented with a number of activities from which to choose.

<table>
<thead>
<tr>
<th>Evaluation question</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Does the Portfolio ...</td>
<td></td>
</tr>
<tr>
<td>necessitate quantitative and qualitative responses?</td>
<td>Plenty of qualitative responses but few tasks which required quantitative thought.</td>
</tr>
<tr>
<td>have a clear purpose and outcome?</td>
<td>The purpose of each assessment task was usually stated at the outset. Could be worded more specifically in terms of learning outcomes.</td>
</tr>
<tr>
<td>model an authentic situation?</td>
<td>Many of the tasks implied links to authentic situations but few were directly connected to authentic contexts.</td>
</tr>
<tr>
<td>emphasise process over product?</td>
<td>This was a strength of the assessment, especially as it related to the topic of the unit (that is, the writing process).</td>
</tr>
<tr>
<td>ensure collaborative communication?</td>
<td>Some scope for community-student liaison. Required more structured examples of student-student contact.</td>
</tr>
<tr>
<td>give students choices?</td>
<td>Perhaps too many choices were given here: choice of activities, choice of topics within activities, choice of submission formats and timeframes.</td>
</tr>
<tr>
<td>link to unit learning outcomes?</td>
<td>Learning outcomes of unit were frequently referred to in actual explanation of assessment tasks.</td>
</tr>
<tr>
<td>include feedback mechanisms?</td>
<td>Few feedback-to-student mechanisms were provided, perhaps due to the qualitative nature of the tasks. However, feedback could be provided through model responses. Feedback to teaching staff from students was enabled through one of the initial tasks which asked students to comment on their initial impressions of the website.</td>
</tr>
<tr>
<td>encourage the appropriate, discriminatory use of online resources?</td>
<td>A wide variety of online resources were utilised in this assessment task. Assessment task structure could be improved by integrating some exercises which encourage critical evaluation of such resources.</td>
</tr>
<tr>
<td>enable students to examine and present many viewpoints?</td>
<td>Students were encouraged to consider their own views, explore the views of the writers featured in the unit and, on some occasions, were even suggested to investigate the views of their local community.</td>
</tr>
</tbody>
</table>

Table 1: Evaluation of Portfolio Assessment Task

Overall, many of the online assessment criteria were met in this example which was particularly suited to the students for whom it was designed. The online environment wasn't especially well exploited in the design of this...
tasks did not fully expand on the idea of building relationships between ideas, a concept central to Indigenous ways of learning (Hall, 1987).

Case study 2

The second case concerns an online assessment task for fifth year medicine students, who learn through a combination of problem-based learning (PBL) tutorials and clinical experience in hospital wards. A modified essay question (MEQ) format was chosen to assess students' diagnostic reasoning and patient management skills in an authentic way (Feletti & Engel, 1980), mimicking the learning pattern occurring through PBL. An MEQ uses a series of questions based on case information and additional triggers to build a scenario. Commonly, in paper-based MEQ tests, students are not allowed to turn backwards or look ahead in their paper, as subsequent questions may reveal key information for answering earlier questions. The emphasis is on the real-life scenarios which students will encounter, when immediate action is often required. Feedback from implementation of MEQs in paper-based format is that students admit to cheating by turning forwards or backwards.

The online environment was clearly very suitable for this type of test, as it was easy to restrict students from accessing previous or forthcoming parts of the question. Apart from the improved administration of the test, other advantages were perceived, such as the ease of marking typed answers over handwritten, the possibility of initial marking to be automated using keyword searches and highlighting, and the opportunity to provide qualitative feedback to the students in computer-based form immediately after the test had been completed.

<table>
<thead>
<tr>
<th>Evaluation question</th>
<th>Result</th>

<tbody>
<tr>
<td>Does the Online MEQ...</td>
<td></td>
</tr>
<tr>
<td>necessitate quantitative and qualitative responses?</td>
<td>Some questions required objective, quantitative answers while others focused on short answer articulations</td>
</tr>
<tr>
<td>have a clear purpose and outcome?</td>
<td>The task closely modelled the diagnosis and management process students would face as doctors</td>
</tr>
<tr>
<td>model an authentic situation?</td>
<td>Questions were modelled on real-life cases</td>
</tr>
<tr>
<td>emphasise process over product?</td>
<td>The task attempted to focus on the process of diagnosis and management rather than the final result</td>
</tr>
<tr>
<td>ensure collaborative communication?</td>
<td>No scope for collaboration; but future iterations could include peer-assessment and hence allow some collaborative communication</td>
</tr>
<tr>
<td>give students choices?</td>
<td>Students were not given any choices</td>
</tr>
<tr>
<td>link to unit learning outcomes?</td>
<td>Learning outcomes were consistent with the assessment task</td>
</tr>
<tr>
<td>include feedback mechanisms?</td>
<td>Model answers were supplied as feedback to students</td>
</tr>
<tr>
<td>encourage the appropriate, discriminatory use of online resources?</td>
<td>Access to other online resources was not permitted, but future iterations could include access to resources while answering questions, mimicking more closely the real-life situation</td>
</tr>
<tr>
<td>enable students to examine and present many viewpoints?</td>
<td>Students were asked to present varying opinions on diagnosis and management but multiple perspectives (for example, cultural views) were not emphasised, despite being a key component of the curriculum</td>
</tr>
</tbody>
</table>

Table 2: Evaluation of Online Modified Essay Questions (MEQs)

Although this assessment task was primarily trialled online in order to solve the problem of cheating, in the design phase a number of other opportunities were identified and carried out successfully, for example, providing students with feedback in the form of model answers alongside their own answers after the deadline for completing
the test had passed. By its nature, the task was also authentic and clearly relevant. It also allowed for some quantitative responses (e.g., dosages), as well as qualitative paragraphs (e.g., describe what you would talk to this patient about now). The evaluation criteria revealed a number of ways in which the task could be improved, for example, allowing access to other online resources, recognised as a useful adjunct for medical problem-solving tasks (Schuwirth, et al., 1999), and allowing communication and collaboration.

Summary of results and further implications

The results and suggestions for change arising from the evaluation of the two case studies show that the application of the criteria can highlight key issues such as the balance of qualitative and quantitative tasks and the promotion of aspects such as choice and variety. If these criteria were constantly referred to during the design stages, it would appear that a substantially higher quality of assessment task would result.

This application of criteria was also carried out in order to attempt to refine the criteria, and a finding common to both case studies was the concept of feedback being both teacher-to-student and student-to-teacher, although our previous definition of feedback had been intended only in the sense of observations on the performance of students. However, providing students with an opportunity to evaluate the assessment task has proven valuable in our case studies and is more widely recognised as beneficial (Naidu, 1994), and we will pursue this use of feedback through its incorporation into our design criteria.

Overall, the success of applying these criteria in two contrasting settings with very useful results suggests that they may have wider applicability for evaluating the effectiveness of online assessment tasks. In fact, ascertaining the quality of online learning environments in general may be achievable with the use of a similar set of criteria and it is this area of research that we intend to pursue in the near future.

Abstract: With computers, tangible tools are represented by the hardware (e.g., the central processing unit, scanners, and video display unit), while intangible tools are represented by software. There is a special category of computer-based software tools (CBSTs) that have the potential to mediate cognitive processes—computer-based cognitive tools (CBCTs). Only a limited number of CBSTs have been designed specifically for educational purposes. It is the design of the educational environment, specifically the educational intent, that transforms student interactions with a CBST to that of a CBCT. Two examples of CBCTs are described. The Interactive Graphing Tool (IGT) facilitates on-screen sketching of graphs. Students receive qualitative feedback, may revise their articulation of graphical knowledge any number of times, and ultimately, have access to expert answers for comparison and self-evaluation. The Text Analysis Object (TAO) also facilitates an iterative approach to knowledge construction. The TAO allows a student to type extended answers to questions, receive qualitative and limited summative feedback, and access to both expert and ‘good student answers’ for comparison and self-evaluation.

Tools, tangible and intangible

Traditionally, tools have been seen to be manifestations of human technology in the form of some physical object—an inclined plane (screw or wedge), pulleys (cranes), or cogs and gears (gear mechanisms on a bicycle), for example. The purpose of these tools was to enhance human physical power, strength and human capabilities. Examples of physical tools that support learning include the humble pen-and-paper or an abacus. In educational settings we must also consider intangible tools (e.g., language, or mathematical symbols) that support human learning and cognition.

Vygotsky (1978) proposed that learning required two mediational means—tangible tools (technical tools) and intangible tools or signs (semiotic tools). At Vygotsky’s time of writing, technical tools were actual physical entities (as above), whereas semiotic tools were (and still are) the means by which cognitive functions are mediated. Examples include language, numbers, algebraic notation, mnemonic techniques, graphs and diagrams—most of which may be expressed in the form of media elements that are easily stored, retrieved, and manipulated by computers. With the advent of new technologies the definitions of tools and signs in modern times, has blurred—that is, computers have the ability to mediate cognitive processes. (Duffy & Cunningham, 1996, p. 180).

Computer-based software tools (CBSTs)

Computers combine aspects of physical tools (the hardware) and intangible tools (software). Computers are a means of storing, retrieving, displaying, and manipulating signs (e.g., language, graphs, and mathematical notation). In Figure 1 the distinction between tangible and intangible tools is represented, with particular reference to computer-based tools.

Figure 2 illustrates that CBSTs (e.g., word processors, spreadsheets, concept mapping software, authoring software, and computer programming languages) that facilitate interaction between the learner and various media elements (e.g., text, graphs, video, audio) in an appropriate educational context may also be used to support cognition. That is, some of these computer-based software tools may also function as computer-based cognitive tools.
Computer-based cognitive tools

Computer-based cognitive tools (CBCTs)

What is a computer-based cognitive tool? In order to address this seemingly simple question, a number of interrelated issues need to be addressed including the:

- functional aspects of a CBCT;
- development of CBCTs (how do the pedagogical and functional issues influence their construction); and
- utilisation of CBCTs to the best effect.

The functional aspect concerns how students use CBCTs to mediate learning—are there any generalisable criteria (e.g., particular media elements or specific CBSTs)? The developmental perspective examines the software authoring tools used to create CBCTs—are some software authoring tools better for developing CBCTs, and/or integrating into courseware? The effective utilisation of CBCTs involves the concept of ‘educational intention’ or ‘intent’.

A student who uses any cognitive tool effectively must necessarily engage (actively), think (deeply), and articulate their knowledge (Jonassen, 1994). In order to mediate cognition, a computer-based cognitive tool should:

- engage the student actively;
- support a deep approach to learning (thinking and reflection);
- provide support for a student to articulate her or his knowledge; and
- be embedded in an educational environment or context with a particular educational intent.

The key difference between a computer-based software tool and a computer-based cognitive tool is the educational intent or educational context. Thus, CBCTs are learning tools with which students communicate,
articulate their thought processes, solve problems, engage in collaborative processes and think. CBCTs are also charged with instructional intent—the intent of the educational, or courseware designer. The computer is the storage, presentation, manipulation and creation device for various types of media—the technology that facilitates the use and function of a CBCT, and a part of the learning environment. The utilisation of the computer, CBCTs and media elements in order to achieve a particular set of student learning outcomes is influenced by the perspective of teaching and learning held by the educational designer. A CBCT may be thought of as one component in the learning environment that requires computer-based media elements in order to support and enhance student learning.

The student constructs meaning by using the CBSTs in an educational context, by manipulating media elements from a particular content domain. Many CBSTs that by intent and educational context are utilised by a student as CBCTs may be described as generic tools. Examples of CBSTs that have become CBCTs by inclusion in a particular learning environment/context are provided in Table 1.

</tr>
</tbody>
</table>

The focus of this paper is not about the cognitive or metacognitive strategies intrinsic to the learner—but the external tools that extend and enhance their thinking processes. People do not learn from computers any more than they learn from a CBCT. The potential is there for people to learn with a CBCT. An example is a calculator. It is only using the calculator software (a CBST) in an appropriate context, with intent (motivation) that understanding can be arrived at. A student may use a calculator to find the logarithm of a number with little understanding of what a logarithm represents. However, the use of the same CBST in a chemistry class to explore the effects of small changes in the value of pH in a solution (the acidity or concentration of the hydrogen ions in a solution is defined as \(-\log_{10}[H^+]\)) is using the calculator software as a cognitive tool.

Computer-based cognitive tools can facilitate problem-solving by providing tools to access, manipulate and structure data from large, customisable, subject databases (Whithear, Browning, Brightling & McNaught, 1994). Carefully designed CBCTs can scaffold learning by modelling complex environments or expert problem-solving strategies. Computer-based cognitive tools can also provide relevant context-sensitive feedback by requiring a student to externalise (articulate, report, discuss, think-aloud) what are very often, internal processes (Collins, Brown & Newman, 1989).

Many examples of computer-facilitated learning environments have a variety of CBCTs integrated within the software. Exploring the Nardoo (an award-winning CD-Rom) has been developed using a synthesis of the ideas from 'constructivist learning environments, situated learning and problem-based learning in rich information landscapes to form the basis for effective design' (Harper & Hedberg, 1997, p. 14). The Nardoo provides an interface with access to number of very detailed databases of content. The databases contain plant and animal descriptions, pre-determined values of measures of water quality (e.g., nitrogen, oxygen, phosphorous, water turbidity), procedural knowledge, a number of presentation genres for knowledge construction and presentation—accessed by the student using a variety of CBCTs and supported by access to multiple forms of media. There are a number of CBCTs embedded in, and fundamental to, the Nardoo software. They include:

- three student-controlled simulators;
a number of genre writing templates for students to structure their notes and presentations of findings; and

a 'text tablet'.

Principles of successful use of CBCTs

CBCTs must be incorporated into a well-structured CFL environment that does not impose high cognitive demands by virtue of a complex user interface. Students will then be better able to engage in higher order thinking processes involving reflection, synthesis and analysis.

Computer-based cognitive tools are software constructions that:

- are simple for students to use;
- function best in a constructivist learning environment;
- provide the opportunity for students to address meaningful questions in a realistic context and receive appropriate and timely feedback;
- encourage students to 'take on' the ownership of their own learning;
- off-load basic cognitive demands while the learner focuses on higher level processes;
- facilitate the development of deeper and richer knowledge structures;
- facilitate collaborative and negotiative learning experiences that provide opportunities for students to explore, test, and validate their conceptions; and
- are unintelligent tools (unlike those claimed by intelligent tutoring systems) that facilitate a dialogue between teachers and learners and feedback appropriate to the task.

In addition, CBCTs extend some of the characteristics above through their facility to offer intrinsically different representations or views of data and/or phenomena not possible through other means and hence provide new understandings (e.g., powerful user-controlled visual simulations to make abstract concepts more visible).

Computer-based cognitive tools are not intended to make the task easier, or reduce information processing (Jonassen, 1994). In the evaluation of the two CBCTs briefly described here students have (sometimes grudgingly) admitted that a CBCT (e.g., the interactive graphing tool) required them to work harder for the answer. The students also thought this was 'probably better' for them because they couldn't simply click on an answer provided by the lecturer. Using CBCTs requires a student to:

- analyse and compare different representations of content (which may be in different forms of media elements);
- construct, refine and represent mental models; and
- articulate her or his understanding in some meaningful way.

Using CBCTs is not a 'free ride', it is demanding, challenging, and basically hard work. The following two examples briefly illustrate the relationship between media elements, instructional intent, and computer-based cognitive tools. The references provide more complete descriptions.

Cognitive tools in action: Two examples

The Interactive Graphing Tool (IGT) is intended to overcome some of the criticisms of static or animated versions of graphical knowledge. Instead, the IGT requires students to sketch a graph on screen, using the mouse as a drawing tool, and can respond to a wide range of common graph types including logarithmic, exponentials, curves, and straight lines. The IGT facilitates an iterative approach to articulating and understanding graphical representations of knowledge by actively involving students in the construction of these representations, and providing customisable (by the academic) multiple responses for more appropriate feedback (Kennedy & Fritze, 1998). Students receive qualitative feedback, may revise their articulation of graphical knowledge any number of times, and ultimately, have access to expert answers for comparison and self-evaluation. Figure 3 shows both the steps required for teachers to use the IGT, and also how the IGT responds to student input. The IGT has been evaluated in the teaching of kinetics in chemistry.

Another CBCT is the Text Analysis Object (TAO). The TAO facilitates the development of text-based extended question-and-answer problems. The design of the TAO focused upon developing a learning tool that facilitates extended answer/short answer questions. Using the TAO, a student is able to generate a more
meaningful answer by articulating her or his understanding, rather than merely recognising the lecturer's representation of the knowledge, as in multiple-choice questions. The TAO has been designed to support an iterative approach to knowledge construction by requiring a student to type an answer to a question into a text field, submit the answer for checking by a software algorithm, and then receive meaningful feedback. The student then has the opportunity to refine her or his answer a number of times, each time receiving feedback. Feedback provided by

*Figure 3: The functionality of the IGT*

the TAO software engine to the student is determined by using a key word and key phrase search of the text entered by the student. The TAO software engine/ software algorithm has been designed to utilise a two-tiered, hierarchical feedback mechanism—distinguishing between concepts (major ideas or principles) and details (generally factual knowledge) in providing feedback to students (Kennedy, Ip, Adams & Eizenberg, 1999). Academic staff provide the information about concepts and details that the TAO engine uses in providing feedback to students. This is time consuming but valuable if the work is seen as a way of progressively building up effective learning resources. The TAO has been evaluated in the teaching of anatomy to medical students.

Abstract
This paper reports on the design of DNAexplorer, a computer facilitated learning package, which was developed to support the teaching and learning of bioinformatics. The instructional design of the package was broadly based on a model of situated cognition, with particular reference to the nine critical features of situated learning advocated by Herrington and Oliver (1995). The primary features of DNAexplorer's instructional design are described and discussed in relation to Herrington and Oliver’s (1995) critical features.

The Teaching and Learning of Bioinformatics

Bioinformatics is an area of investigation which integrates the disciplines of biology, mathematics and computer science. Related activities include searching for, accessing and analysing biologically relevant information. The ability to access nucleotide and protein sequence databases is essential for scientists wishing to locate genes in genomic sequences, to predict gene function and to determine complex cellular interactions and evolutionary trends.

Teaching bioinformatics presents educators with a number of difficulties. The store of relevant bioinformatics information is increasing at a phenomenal rate which places constant demands on lecturers to provide their students with the most up to date data. In addition to the general increase in information, there has been an increase in the variety of approaches used to analyse nucleotide and protein sequences. An array of web- and PC-based analysis software has recently emerged. Even simple bioinformatics analysis tasks often require the use of many different software packages and databases which need to be applied in a coordinated sequence to ensure a reliable outcome. For example, to investigate the relatedness of microorganisms using nucleotide sequence data requires a number of different desktop applications and several web-based databases. Without intensive instruction or extensive experience, undergraduate biomedical students typically find it difficult to coordinate and integrate the use of these applications.

At the University of Melbourne, traditionally biomedical science students have been introduced to bioinformatics through lectures and practicals. Lectures are used to provide the theoretical background to bioinformatics and practicals are used to help students develop technical competence with sequence analysis databases and software. After delivering the course for a number of years the course coordinators decided that the practical component of the curriculum was problematic. Although practicals were successful in introducing students to the tools available for analysis of genetic data, the lack of a clear pathway between a number applications and web sites meant that the practicals were tutor intensive. Tutors spent much of their time in practicals explaining to students how to navigate between applications and web sites rather than helping students with more conceptual procedures and principles associated with bioinformatics. It became evident that a more effective and efficient method was required to assist students both with their understanding and use of sequence analysis databases and software and the principles and procedures associated with bioinformatics. Computer facilitated learning was an obvious solution to the difficulties...
encountered with the teaching and learning of bioinformatics as the discipline is fundamentally a computer based field of inquiry. Thus, a computer facilitated learning package, DNAexplorer, was developed to allow students to learn about principles and procedures associated with bioinformatics through the integrated use of applications and web sites associated with the discipline.

The Learning Design of DNAexplorer

The learning design of DNAexplorer is broadly based on a model of situated cognition which emphasises the need to place learners in real-life contexts. Brown, Collins and Duguid (1989), who were among the first advocates of situated cognition as a practical learning approach, argue that "useful learning" takes place when students are set authentic tasks or are placed in authentic contexts. They argue that "much school work is inauthentic (sic) and thus not fully productive of useful learning" (p. 34). Based on this and other work in the area of situated cognition, Herrington and Oliver (1995) developed nine critical characteristics of situated learning, comprising three overlapping domains (see Table 1) that, they argued, could be used to guide the instructional design of multimedia learning environments. They subsequently employed this framework to guide the design and development of an educational multimedia program on assessment strategies (Herrington & Oliver, 1997).

Table 1: Herrington and Oliver's (1995) critical characteristics of situated learning.

Our approach, as designers and developers, was to create a multimedia learning environment based broadly on a model of situated cognition paying particular attention to Herrington and Oliver's (1995) framework. Through this approach we hoped to improve students' understanding of bioinformatics principles and procedures and encourage the application of what has been learned. We employed a number of strategies to create an authentic learning environment within DNAexplorer. First, we developed four case-based research scenarios which were based on practicals conducted in the Department of Microbiology and Immunology at the University of Melbourne, over a number of years. The cases present students with realistic microbiological problems—problems they could conceivably encounter as research scientists. For example, in the second of the four cases, students are presented with the task of conducting bioinformatic analysis of *Plasmodium falciparum*, a protozoan parasite that is the most common cause of malaria in humans. When certain mutations occur in this parasite it may become resistant to antimalarial drugs such as sulfadoxine. In the case, the lab that the student is working in has been sent an sample of *Plasmodium falciparum* from an Australian volunteer who was diagnosed with malaria while working in Papua New Guinea. The students' task is to determine whether the sample is sensitive or resistant to sulfadoxine. In order to resolve this problem and complete the case, they are required to perform analyses of nucleotide and protein sequences using a range of bioinformatics applications and databases.

In addition to basing students' learning around real-life cases or scenarios, we employed a number of strategies to create a realistic environment for students. We designed a primary interface that simulates a typical bioinformatics
research environment (i.e. a virtual laboratory and office) which is similar to Herrington and Oliver's (1995) virtual classroom. The laboratory houses equipment that students would encounter if they were working as a research scientist in the area of bioinformatics. Students can rollover these pieces of equipment to see how they work and to access brief explanations of their features. The office environment acts as the home page for the package. Students access the four case-based scenarios from here via the manilla folders on the desk and can preview the content of the cases before opening the folder to begin their investigation. Once students have selected a case, the folder and file metaphor is continued as the interface for each case is set out as a research file (Figure 2). Students progress through the case by turning the file's pages and use a system of "tabs" to between different sections of the file.

![Figure 1: The virtual laboratory and the virtual office](image)

The Navigational Structure of DNAexplorer

The navigational structure of DNAexplorer combines linear and referential organisational structures (Herrington & Oliver, 1997). Each case in DNAexplorer forms the backbone to students' investigation. Students are presented with background material relevant to their investigation and a variety of interactive tasks. Due to the complexity of the content area, students are guided through each case in a fairly linear way, however, they are able to diverge from the primary linear organisational structure by using a system of "tabs" (located throughout their research file) and/or through the use of two support tools: the "NavFinder" and the "InfoFinder".

The Tabs System

Three types of colour coded tabs are employed in DNAexplorer. Red tabs denote learning loops for students. Students enter these sections of the case to access supplementary conceptual information. For example, students may be told about a class of drugs commonly used to treat malaria in the body of the case. To investigate this family of drugs more extensively, students are able to enter a learning loop before returning to the main body of the case. Students can enter and exit these learning loops at any time. Blue tabs allow students to view extended animations of bioinformatics procedures. As mentioned above, bioinformatics procedures often require students to coordinate a number of software applications. Rather than present this information solely in textual form, we thought it beneficial to allow students to view an animation of these, often complex, procedures. Finally, once students have completed a case, grey tabs allow them to access an interactive site map that has jump-off points to major sections of the case, including learning loops and extended animations. This navigational structure gives students the flexibility to move easily between sections of the case to clarify or revise concepts and procedures.
Figure 2: The “research file” interface for cases in DNAexplorer

Figure 3: Interface showing the NavFinder and the InfoFinder as floating windows

NavFinder and InfoFinder

Students have access to two support tools while they navigate their way through cases: the “NavFinder” and the “InfoFinder” (Figure 3). The NavFinder, was developed out of the need to integrate and coordinate applications and web sites associated with bioinformatics. The NavFinder is a separate, draggable, floating window that can be maximised or minimised depending on the students’ needs. The NavFinder fulfills two primary purposes. First, it allows students to navigate easily between the case itself, the office, the lab, web sites and desktop applications. All the applications and web sites students require for their investigation are listed on the NavFinder and are a simple mouse-click away. The NavFinder obviates the need for students to search for applications on the hard disk or search
for bookmarked web sites in their browser, thereby simplifying their navigation between applications and web sites. The second purpose of the NavFinder is to provide students with text based instructions about bioinformatics procedures associated with their case. At critical points in their investigation, students are directed to the NavFinder which contains an additional scrollable window of instructions. It is important to note that the NavFinder provides students with steps associated with performing procedures but neither gives students the “answer” nor highlights the implications of performing such procedures. Students are simply provided with a scaffold associated with complex bioinformatics procedures critical to the investigation of their case.

The InfoFinder is used within cases to present supplementary information and tasks to students and has four roles:
• presenting quiz questions for formative assessment
• displaying short animations of biological principles or concepts
• presenting DNA and protein sequences to be used in subsequent bioinformatics analysis and
• displaying definitions of terms used in the case (glossary).

These four components of DNAexplorer’s navigational system (pages of case content, the tab system, the InfoFinder and the NavFinder) are used together to support students in their investigation of bioinformatics principles and in their application of complex bioinformatics procedures. For example, a typical use of the components of the navigation system may be to:
• enter the virtual office and select a case for investigation
• turn pages in the research file to review the background material of the case
• use a red tab to review supplementary information as required
• use the NavFinder to return to the lab to review the function of a PCR machine
• use the NavFinder to return to the case
• use the InfoFinder to copy a nucleotide sequence
• use a blue tab to review an animation of a complex bioinformatics procedure
• use the NavFinder to launch the DNA Strider (desktop application)
• perform sequence analysis using DNA Strider and using supporting text in the NavFinder
• use the NavFinder to launch the NCBI web site
• compare the outcome of DNA Strider analysis with the NCBI database
• use the NavFinder to return to the case
• use the InfoFinder to answer a formative assessment question on their analysis.

Critical Characteristics of Situated Learning

We believe that DNAexplorer satisfies many of the nine critical characteristics of situated learning proposed by Herrington and Oliver (1995). The design adheres to these characteristics particularly in the “interactive multimedia” domain (Table 1). We have attempted to place learners in an authentic learning context by using a case-based approach and by creating an interface which simulates an actual work environment. We have designed a package that allows students to explore bioinformatics concepts and principles by completing realistic bioinformatics activities and we have used animation to show students how an expert would complete particular bioinformatics procedures. While each case deals with a unique situation requiring students to complete specific bioinformatics procedures, through the provision of four cases (and potentially more) we have provided students with multiple perspectives. Hopefully, students will come to fully understand bioinformatics concepts and principles through their investigation of different problems and scenarios that require similar bioinformatics applications and procedures.

In the domain of “implementation” we also feel that, to a certain extent, we have successfully met the criteria proposed by Herrington and Oliver (1995). We have provided scaffolding and coaching to the learner especially with regards to complex bioinformatics procedures through the use of the NavFinder. However, we are also relying on the context in which DNAexplorer is used to provide further support for students. DNAexplorer is designed to be used in a computer laboratory with the aid of a tutor. Given this learning environment, students should be able to draw on
tutor support when they require it. The second criteria in the “implementation” domain, integrated assessment, has also been incorporated within the learning design of the package. Through the use of the InfoFinder, students are assessed on both products and processes associated with bioinformatics. However, it should be noted that this assessment is only formative in nature and Herrington and Oliver’s (1995) discussion related more to summative assessment. Again, however, we are relying on the greater educational context to meet this criterion. Students will be provided with integrated assessment as part of their study of bioinformatics which, like the formative assessment, should deal with both learning products and processes.

The domain in which we had most difficulty was that of the “learner”. It was difficult to incorporate the elements of collaboration, reflection and articulation in the design of the DNAexplorer. It should be noted that in developing their own educational multimedia program, Herrington and Oliver (1997) admitted similar difficulties, stating that “many aspects of the model could not be incorporated into the software per se” (p. 128). The learning context can again play a role in promoting these aspects of the situated learning environment. Students who have used DNAexplorer to date have been encouraged to use it in pairs, which may promote collaboration and articulation. Through online collaboration this aspect of situated learning could be further promoted via group tasks or problem solving. While review and reflection is encouraged in an implicit way through the provision of an interactive site map and through the use of formative assessment questions, promoting reflection more explicitly is an area where the package could be improved.

Conclusion

It is hoped that the careful attention given to the instructional design of DNAexplorer will be reflected in benefits in terms of students’ understanding of bioinformatics principles and procedures. By taking a situated learning approach, it is also envisaged that students will find it easier to apply their knowledge in real life contexts. The package should enable students to develop the highly demanding skills of gathering, organising and analysing molecular and biological information. Through the use of DNAexplorer students should also show greater confidence in using web- and PC-based resources to analyse molecular and biological information. The package’s case-based structure and navigational support tools give developers the flexibility to accommodate advances in bioinformatics, which is critical in this fast growing area of inquiry, teaching and learning.

Funding for the development of this package was made available through the Teaching and Learning (Multimedia and Educational Technology) Committee at The University of Melbourne.
Supporting Students' Learning with *The Personal Learning Planner*

Gregor Kennedy, Terry Judd, Tom Petrovic and Peter Harris
Faculty of Medicine, Dentistry and Health Sciences
University of Melbourne, Australia

Abstract
This paper describes a computer based, learning support tool called the *Personal Learning Planner* (PLP). The educational context is described and we point to three interrelated demands on students in problem based and self-directed learning contexts. These demands form the basis for the rationale behind the development of the PLP. An overview of the program is provided before an outline of the functionality of each of the developed sections is presented. Future development directions are discussed.

Educational Context and Rationale

In 1999 the School of Medicine at the University of Melbourne introduced a new medical curriculum incorporating problem based-learning (PBL) and self-directed learning (SDL). Space does not allow a full description of the curriculum here (see Kelly, Martin, Larkins & Elliott, 1998; Keppell, Elliott & Harris, 1998) however it centres on a weekly clinical problem or "problem of the week". Each week students are presented with a problem in a small group tutorial. Through group discussion and with the help of a tutor/facilitator, students generate hypotheses about the potential causes of the clinical problem. The group then considers the mechanisms that might underlie these hypotheses. This process allows students to identify aspects of the problem they think require further investigation over the week and these become the students' "learning issues" for the week. Students are then required to undertake SDL where they investigate the problem using the learning issues they have generated. A variety of resources are made available to students to support them in their SDL. Resources include more traditional modes of instruction (such as lectures and practicals) and electronic and paper based resources (including text books, journal articles, web pages and computer facilitated learning modules). Students use these resources to investigate their learning issues over the week, before returning to their second PBL tutorial where, as a group, they identify and discuss the critical mechanisms that underlie the problem. Through discussion and with the guidance of the tutor/facilitator, students work towards a resolution of the problem.

The introduction of the new curriculum represented a fundamental shift in pedagogical focus for the school, reflecting a move from a teacher-centred to a student-centred curriculum. This shift made more salient a number of interrelated demands on students. These demands include a greater emphasis on individual research skills and management of learning and less explicit information for students with regards to what constitutes the core syllabus. Each of these challenges for students is covered in more detail below.

Individual Research Skills

In PBL curricula, typically students are not explicitly directed to course related information or resources. In the context of PBL in medicine, Koshmann, Kelso, Felto Ovich and Barrows (1996) note that students must "identify and utilize resources—person, print and electronic—outside the [tutorial] group that can provide additional knowledge for understanding and managing the patient's problem" (p. 98). The ability to identify and use appropriate resources represents a complex set of research skills. Students must become adept at determining the focus of their inquiry, searching for information, evaluating information returned from their search in light of their goals and ultimately retrieve resources of interest to them (Fink, 1989).
Students must, therefore, develop specific skills related to searching for information. These may include determining appropriate resource catalogues to interrogate (either in the library or online), devising appropriate keywords, applying boolean logic when carrying out an inquiry and modifying their searching techniques when either too much or too little information is returned. Searching for information also requires students to become skilled in gauging the appropriateness and relevance of information given their research goals, often on the basis of limited summary information. Thus, in PBL curricula, the independent research skills of seeking, finding and evaluating information are critical parts of students' learning experiences.

Self-Management of Learning and Planning Behaviour

PBL and SDL, as student-centred approaches to teaching and learning, are typically less directive and constrained and therefore place a greater onus on students to manage their own learning. With SDL particularly, learners must take control of their own learning processes and experiences. Learners "decide how, where and when to learn the content they have identified as important" (Hammond & Collins, 1991; p. 153). Given the freedom associated with student-centred approaches to learning, students may initially feel quite daunted by SDL. As Hammond and Collins (1991) point out, "Learners accustomed to teacher directed learning may have no experience of self-management of learning so it may initially be intimidating." (p.154).

An important component of managing one's own learning is the ability to plan. Lawrence (1991) and Hammond and Collins (1991) suggest that planning is a useful—even necessary—pursuit for students, noting the problems students traditionally have with planning and managing their own learning. Lawrence (1991) argues that, generally, planning is required because some tasks "require attention, effort and organisation, because they are either complex, novel, or both complex and novel..." (p. 85). Students in the new medical curriculum need to perform tasks that are both complex and novel. Tasks are complex because students are presented with ill-defined problems and are provided with an array of resources to investigate them. The content being investigated is, in many instances, also novel for students, while the situation itself is novel with many students being more familiar with teacher-centred learning environments, where the role of planning and management is traditionally fulfilled by teachers and a timetable.

Planning behaviour is often seen as goal dependent and part of either a general or specific problem-solving process (Polya, 1957; Lawson, 1991; Lawrence 1991). A concept of planning behaviour that is contingent on problem solving and goal directed behaviour is consistent with the educational context in the School of Medicine. Students' planning takes place in the context of a "problem of the week" and is seen as part of ing processes. The general goal in this context is to arrive at an adequate resolution of the problem, while specific sub-goals are to investigate learning issues that facilitate this general goal.

According to De Lisi (1987, p.53), the term plan can refer to both "a drawing or diagram such as a map of a town's roads or an architect's blueprint for a building" and "a method of doing something or a procedure, or a detailed program of action". If we apply these definitions to planning behaviour in a SDL context, then we can recognise two distinct activities: "conceptual" planning, where students determine the interrelationships between concepts of interest to them, and "action" planning, where students devise a course of action for their learning.

Information on the core syllabus

Compared to the 'old' curriculum, students in the 'new' curriculum may also find it difficult to determine the degree to which they are covering the syllabus. In the old curriculum students' learning activities were largely constrained by the timetable which prescribed classes and provided little, if any, opportunity for students to consider their own educational goals or to set their own learning priorities. Teachers would often instruct students and tell them what topics they were required to 'learn'. In the new curriculum, timetable guidance is reduced and students are encouraged to construct their own learning pathways by generating their own learning issues. In the problem-based curriculum, determining the required material may also be difficult for students because of the integration of biomedical and clinical disciplines within a problem.

An evaluation after the first year of the new curriculum showed that many students were unsure of the degree to which they were covering the syllabus (Dodds & Sood, 2000). Many students were unsure of the goals in a
number of key areas of study, needed more feedback on their progress and were unsure what constituted essential information. Furthermore, while they were generally very positive about PBL, they often mentioned that they were unsure what was required of them. It seems, therefore, that some mechanism is necessary to provide students with feedback regarding their progression towards the course objectives in this PBL curriculum.

The Personal Learning Planner

The Personal Learning Planner (PLP) was developed to address the three needs outlined above, namely

- to help students develop independent research skills
- to assist students to take greater responsibility for the planning and management of their own learning
- to provide feedback to students on the degree to which they are covering the syllabus.

The PLP is a computer based, learning support tool and has three primary phases (searching, planning and reviewing). The planning phase is divided into two further sections (conceptual planning and action planning). The program interfaces with two databases: a resources' database and a profiles' database. The resources' database consists of a series of descriptions of resources identified by the Faculty as relevant to the medical curriculum and available to students within the University through its various libraries, resource centres, computer laboratories or online. The profiles' database contains individual, historical records of each student's activities within, and use of, the PLP over time.

The PLP will include a short tutorial to introduce students to research skills and the self-management of learning as study skills, however the overarching goal of the project was to produce a program which would achieve its goals by helping students work on their actual course content. That is, rather than instructing students explicitly about "research skills" or "self-management of learning", the PLP was designed to be embedded into curricula thereby implicitly educating students about the value of these skills. A schema of the components of the PLP is presented in Figure 1. While the review phase and the tutorial are still under development the remaining components of the PLP have been developed as a working prototype.

![Figure 1: The structure of the Personal Learning Planner.](image)

The PLP prototype was developed using a Macintosh-based Rapid Application Development (RAD) tool. The decision to use a RAD tool as opposed to a more traditional programming language (e.g. C++, Java) was made to provide maximum flexibility during the development process, enabling us to implement and evaluate alternative functionality of both the planning and searching phases of the PLP within a tight development schedule. Once the PLP's functionality is finalised it is envisaged that a robust, scalable, cross-platform product will be developed. The functionality of the prototype PLP's working components is explained in detail below.
Searching

The searching phase of the PLP allows students to query the resources' database and identify resources with which to investigate the problem of the week. Initially students are asked to enter their learning issues for a particular problem or investigation into the fields provided (see Figure 2). For each learning issue, students then generate keywords with which to interrogate the database of resources. Students can begin investigating the problem by searching for relevant resources using their learning issues and associated keywords. For each search the PLP displays all resources associated with a particular keyword. For each resource, students are able to call up summary information. The summary provides students with the title, author, type of resource (eg. computer facilitated learning modules, textbooks, journal articles and web sites) and an abstract. Students should be able to determine the relevancy of each resource to their own investigation on the basis of this information. Students can select resources that are of interest to them and can view a list of the resources they have selected at any time.

![Figure 2: An example searching screen from the PLP.](image)

Conceptual and Action Planning

The development team decided that both types of planning (conceptual and action) should be manifest in the planning phase of the PLP. That is, students should have the ability to map out the conceptual relationships between their learning issues and resources (conceptual planning) and also be able to organise a specific course of action with regards to the investigation of the problem using these learning issues and resources (action planning). In the conceptual planning section the team attempted to promote students' engagement by asking them to actively construct a concept map. A variety of tools were made available to students so that they could be creative in the construction of their maps and to give them the flexibility to plan in an individual way. Students can create a concept map of the relationships between their learning issues and resources which have been carried over from the searching phase. Students can place “tiles” of their learning issues and resources into an on-screen workspace (see Figure 3). The workspace is dynamic and students can drag tiles to any location and draw links between them. The summary information for each resource is available on a pop-up field so that students can use this information to inform the construction of their concept map. Students are also able to annotate their maps or the links between tiles and may also group sections of the map using different colours and shapes. Different visual backdrops are available to students as another means of prioritising or grouping sections of their concept map.

After completing their conceptual planning, students are able to organise a specific course of action using the action plan. The action planning section of the PLP consists of a dynamic two-way table which has the students' learning issues on one axis and their resources on another (see Figure 4). Each cell of the table represents a potential link between a learning issue and a resource. The links or associations students have made in the previous two sections of the PLP (searching and conceptual planning) are shown as coloured cells for students.
when they enter the action planning section. Different colours are used to represent the different phases and sections of the PLP where students have made associations between learning issues and resources (i.e. searching vs. planning, conceptual planning vs. action planning). Students can create or delete links by clicking on the cells of the table. They are also able to prioritise their learning issues and resources by reordering the rows and columns of the table. To assist with this process, students can review a snapshot of their conceptual plan and the summary information associated with each resource. By completing this process students are able to create a concrete guide for their study activities over the week.

![Figure 3: An example conceptual planning screen from the PLP.](image)

![Figure 4: An example action planning screen from the PLP.](image)

**Resources and Profiles Databases**

The prototype utilises a flat-file resources' database that is accessed locally. Each record in the database comprises (where appropriate) a title, author details, publication details, resource type (e.g. books, computer facilitated learning modules, web site etc.), keywords (for searching the database), and a short abstract. The database is scalable and records can be readily added or removed in response to changes or additions to the curriculum. The profiles' database, which is networked, stores a detailed history of students' searching and planning activities including their learning issues, keywords, selected resources, concept maps and action plans for each problem.
Conclusions and Future Directions

Extensive formative evaluations have been completed on the PLP prototype and these have been used to inform its ongoing development. However, several outstanding issues need to be addressed before the PLP is implemented within the new medical curriculum. The primary development issue at this stage is the functionality of the review phase. Records in the profiles database will form the basis of this phase's functionality and currently it is envisaged that students will be able to review their own learning issues, keywords and selected resources for each week of the curriculum and compare this to Faculty sanctioned learning objectives and resources. This should provide students with an opportunity to evaluate the degree to which they are covering the syllabus. In addition to this information, students will be provided with summary statistics of the learning issues, keywords and resources that their cohort identified to investigate each problem. It is hoped this will encourage students to review, evaluate and reflect on their own planning which is seen as a critical component of planning and problem solving behaviour (Polya, 1957; Lawson, 1991; Lawrence 1991).

It is envisaged that the PLP may also be applied in other curricula which incorporate inquiry based learning (case, problem or project based learning) and SDL. The database of resources would be the only major change in moving from one educational context to another, as resources would clearly need to be curriculum specific. In these educational contexts the PLP would support students in their SDL while allowing them the freedom and flexibility to maintain their learning independence.

Flexible Audit Trailing in Interactive Courseware

Terry Judd and Gregor Kennedy
Biomedical Multimedia Unit
Faculty of Medicine, Dentistry and Health Sciences
University of Melbourne, Australia

Abstract
This paper reports on the development and implementation of a flexible audit trail system comprising a library of auditing functions that can be embedded into interactive courseware and customised to the requirements of researchers and developers. It presents a case study involving the pilot implementation of the system within a piece of medical courseware. The results of this study demonstrate the general utility of evaluation based on audit trails. They also provided the courseware's developers with valuable information on how students used the courseware generally and, more specifically, on how they completed one particular interactive task.

Audit Trails: One Component of Electronic Evaluation

We are currently developing a system of electronic evaluation that addresses three distinct types of evaluation: (i) students' activities and movements within individual pieces of courseware; (ii) students' use of and movements between pieces of courseware, and (iii) students' perceptions of pieces of courseware. The first of these components, based on audit trails, provides developers, evaluators and researchers in the area of educational technology with an invaluable mechanism to record and analyse students' activities within a variety of electronic environments. Misanchuk and Schwier (1992) define and ascribe four primary roles to audit trails:

- Formative evaluation of instructional design; that is, evaluation aimed at optimising the performance of a piece of courseware.
- Basic research in instructional design; for example, investigating how different users interact with a piece of courseware.
- Usage audits for unstructured or public environments; that is, determining which paths or components of a piece of courseware are most visited by users.
- Counselling and advising; that is, supporting the user's decision making within a piece of courseware.

With these four roles in mind we devised a series of essential criteria that we considered critical to the development of a robust, flexible audit trail system. The six criteria we established were:

- Flexibility - the system should be capable of fulfilling all of the roles of audit trails outlined by Misanchuk and Schwier (1992). It should be able to store a range of data types.
- Efficiency - the system should manage data efficiently. It should only record and deliver information specifically requested by the developer/researcher and any information collected should be clearly associated with a specific user action or activity.
- Scalability - the system should be capable of handling an unlimited number of records and of dynamically adding or deleting records.
- Portability - the system should adopt an architecture that can be implemented across a range of authoring environments/software.
- Retrospective compatibility – the system should be easily fitted to existing courseware.
- Ease of use - the system should be easily implemented and require minimal programming effort by developers/researchers.

The first two of these criteria are general and address the various roles of audit trails and the need to provide a robust yet flexible framework and to avoid indiscriminate data collection. The third and fourth criteria are essentially technical requirements that speak to the need to develop a robust yet generic audit trail system. The
The final two criteria are concerned with adoption and implementation; ensuring the system is both useful to and useable by the developer/researcher.

We subsequently designed an audit trail system that sought to address each of the above criteria. As most of the courseware produced within our unit is created using Macromedia Director® we elected to initially develop our system in and for that authoring environment. However, in keeping with our fourth design criteria – portability – we ensured that the system’s architecture was structured in such a way so as to be readily adapted to a range of other scriptable multimedia authoring systems.

The resulting system is built around a library of functions that read and write individual records of user activities to a master record (the audit trail) within the target courseware. These functions interact with the other components of the system, which include client- and server-side administrative applications for transmitting and storing the audit trail data for later analysis. The library consists of a range of functions including timers, counters, item selection and data/text entry from which developers and researchers select according to their needs. Individual functions are attached to or associated with each of the objects to be audited within a piece of courseware and, when activated, these functions report to and dynamically update the audit trail record. The audit trail record can be exported at any time, although this process typically occurs when the user quits the courseware.

As a pilot test of the system, we embedded it into a piece of biomedical courseware called Medical Genetix. The remainder of this paper describes the structure and use of the Medical Genetix courseware, our implementation of the audit trail system within it, and the various findings that emerged from this implementation.

The Structure and Use of Medical Genetix

Medical Genetix is used by medical students at the University of Melbourne to investigate biomedical and clinical aspects of genetic disorders such as cystic fibrosis and thalassaemia. Specifically, it is used as a self-directed learning resource to support students’ investigation of particular medical problems or ‘problems of the week’ (Keppell, Elliott, & Harris, 1998; Keppell, Kennedy & Harris, 2000). Medical Genetix is available for students’ use in the faculty’s main computer labs as well as in tutorial rooms.

Medical Genetix consists of a number of sections and levels that students can easily move between. For example, material on the disorder cystic fibrosis is divided into three primary sections: Clinical Diagnosis, Laboratory Diagnosis and, Counselling and Ethics. The Clinical Diagnosis section is further broken down into Clinical Features, Family Histories and Pedigrees, and Molecular Pathogenesis. Each of these subsections has a series of screens comprising content and interactive tasks that allow students to review material, perform construction tasks, test their knowledge and understanding, or access further information as they require (Metcalfe, Williamson & Bonollo, 1999).

Medical Genetix was made available to second-year medical students to support their investigation of a problem of the week on cystic fibrosis. In the Family Histories and Pedigrees section of the courseware, students can access an interactive task involving the construction of a pedigree on the basis of a supplied family history. The family history details the relationship between family members and their status with regard to the genetic disorder cystic fibrosis (that is, whether family members were carriers, a proband, or had the disorder). The interactive pedigree is completed by dragging “tiles” designating these various states into the correct position in the pedigree on the basis of the supplied family history. Six types of tiles are available for students to use and there are a total of twenty positions to be filled in the pedigree (see Figure 1). If a student places a tile correctly in the pedigree it remains in its position and the name of the individual is displayed whereas incorrectly placed tiles are rejected and returned to their original position.
Figure 1: The interactive pedigree task illustrating the six types of tiles and a partially completed pedigree.

We embedded a selection of audit trail functions into the Family Histories and Pedigrees section of the Medical Genetix courseware, placing particular emphasis on the interactive pedigree task. The audit included which screens within the section were visited and, for the interactive pedigree task, the amount of time students spent on the task, a detailed record of which tiles were dragged, where and in what sequence they were placed, and the number of times students consulted the history and help screens.

Results

A total of 78 students accessed Medical Genetix during the week it was designated as a resource for the medical curriculum. Of these, 49 entered the Family History and Pedigree section; indicating that 29 students bypassed this section altogether. Of those 49 students, 42 arrived at the interactive pedigree. Eight of the 42 students who arrived at the interactive pedigree did not attempt the task. The remaining 34 students, who attempted the task, form the basis of the analyses below.

*two cases of the 34 were not included in this analysis because of incomplete data.
all times are recorded in seconds.
Summary statistics of students' activities while completing the interactive pedigree are presented in Table 1. On average, students spent around four and a half minutes on the task, made a little over fifteen correct tile placements and made around six mistakes while attempting the task. They spent a little over two minutes on the history screen and most accessed it regularly (over 85% of the sample accessed it more than ten times). However, students did not access the help screen regularly or for any great length of time. Eighty-two percent of students did not access the help at all.

We were particularly interested in determining how students were attempting the interactive pedigree task. As a result we focussed our attention on the number of correct and incorrect tile placements (or "drags") that students completed. Table 2 presents frequency counts and percentages of students' correct and incorrect drags. It can be seen from this table that all students completed over half the task (ie. completed over 10 drags correctly) but only one student successfully completed the entire task (ie. completed 20 drags correctly). The average number of tiles correctly placed before students left the task was between 15 and 16 and this seems to be a critical point in the task in terms of students interest or persistence (see Table 1).

Table 2: Number of correct and incorrect tile placements ("drags") made by students

The fact that only one student fully completed the interactive pedigree task raises questions as to why the students were not completing the entire exercise. Was the task too difficult or did the students simply lose interest? We attempted to address this question by considering the proportion of correct tile placements made by students. The number of correct tile placements made by students was divided by the total number of tiles placed by students (ie correct and incorrect drags). The results of this analysis (Table 3) reveal that students had a high degree of success with their tile placements with two thirds of students returning a 70% or better success rate.

Table 3: Proportion of correct tile placements made by students.

In addition to overall success rate, we analysed the final three tiles placed by students in the pedigree (regardless of how many tiles they placed in total). By assessing whether students were leaving the task after correctly or
incorrectly placing tiles we sought an indication of whether students were losing interest in the task or found the task too difficult. An analysis of the last three tile placements is presented in Table 4.

These results indicate the overwhelming majority of students were leaving the task after performing well. Not one student placed all of the last three tiles incorrectly and 26 (76.5%) students placed their last three tiles correctly. Only one student left the task with an incorrect final drag, indicating that 33 (97.1%) students left the task with a correct final drag. This suggests that it was not the difficulty of the task that prevented students from completing it. Rather, given that students were successfully progressing within the task, their failure to complete it suggests that after a certain time they lost interest or had understood the point of the exercise. Further assessment is required to test this hypothesis further.

Discussion and Conclusions

The results of this pilot study demonstrate the utility of audit trails for gathering evaluation data for the purposes of usage audits and formative evaluation of instructional design. Audit trails provided valuable information on the degree to which Medical Genetix was being used by students as a resource to investigate the problem of the week (78 of 184 students (42.4%) used the courseware over one week) as well as detailed information about which sections of the courseware were being used. The audit trail system is clearly able to provide course coordinators with critical and accurate information about the integration of courseware into their curriculum. This is particularly pertinent in student-centred curricula such as the medical degree at the University of Melbourne, which emphasises self-directed learning. Common evaluation techniques, such as self-report questionnaires and observation, struggle to adequately gather information on the resources students use as part of their self-directed learning due to inherent variation in the times and locations that students access resources. Using the audit trail system we developed, data can be gathered easily while maintaining flexibility and freedom of student access.

The audit trail system was used to formatively evaluate a specific interactive task (an interactive pedigree), and provided useful descriptive information. For example, of those students who attempted the task, all relied heavily on the provided history to complete the task but there was substantial variation in both the amount of time individual students spent on the history and the number of times they accessed it. The fact that the majority of students (82.4%) did not access a task specific help screen suggests the task was intuitive and well designed.

Undoubtedly, the most interesting result from this component of the study was that all but one student failed to complete the interactive pedigree task. This, coupled with evidence that students were, in general, successfully progressing within the task indicates the task was not too difficult. There are a number of possible explanations for this finding. Students may have simply found the task too long and lost interest in the exercise. Alternatively, they may have understood the "point" or message of the exercise part way through the task, removing the incentive to complete it. It is also possible that students had completed the pedigree on a previous occasion when using Medical Genetix as a resource in a earlier problem of the week.

The findings with regards to the interactive pedigree have implications for the instructional design of Medical Genetix as well as interactive tasks more generally. They suggest that attention should be given to length of interactive tasks and whether they are able to sustain students’ interest. This is especially relevant if students are directed to different parts of the courseware on the basis of whether they complete a task or not. While decisions about the instructional design of interactive tasks should always be made with the target audience in mind
(students' previous experience and prior knowledge), it is clear that audit trail data can inform the design of these tasks.

The success of this pilot implementation of the audit trail system validates our development of a generic yet flexible method of creating audit trails. By restricting the amount of information gathered using the systems' inbuilt functions (see Judd & Kennedy, 2001) and by focusing on a specific interactive task, we were not overwhelmed by data and were able to gather meaningful and useful information. Care should be taken not to over-interpret the data garnered from audit trails and additional data collection techniques should be used in conjunction with audit data to assist in the analysis and interpretation of results. This notwithstanding, the judicious implementation of the audit trail component of our electronic evaluation system clearly has the capacity to inform and assist both developers and evaluators. The two further roles of audit trails outlined by Misanchuk and Schwier (1992) (research in instructional design and counselling and advising) are also possible with the audit trail system we have developed (Judd & Kennedy, 2001) and will be investigated in subsequent implementations of the system.

Abstract: Good communication in a business context requires a student to select the most appropriate mode of communication (e.g., email, meeting, telephone or fax) and construct an appropriate message. The student has to make decisions regarding content, style of communication, and when to use a particular mode—the student is then faced with the consequences of their actions. This paper presents an innovative approach to addressing these three issues in an interactive CD-Rom environment and preliminary formative evaluation undertaken as part of the development of the software.

Introduction

The Gippsland School of Computing and Information Technology (GSCIT) of Monash University offers a number of undergraduate computing subjects on campus and for distance learning students. One subject, Human Communications, is offered as a distance education subject to students within Australia and overseas. The students in both groups have difficulty learning the nuances of good business communication, particularly those students that do not have English as a first language. This paper discusses the development of an innovative approach to communication problems encountered by a business/computing student—how to decide what mode of communication is the most appropriate to use in a given situation (e.g., email, fax, call a meeting, telephone, memo or letter) and how to construct a message with the appropriate style and content.

The result is the Multimedia Business Game, an interactive CD-Rom that engages students actively in the decision making process. The software is a simulated business environment, where students are required to develop a tender document for a company (Blue Sky). The use of simulated environments is well supported by the literature on constructivist models of teaching and learning (Hedberg & Harper, 1995). The design of the software relies upon the concept of situated learning to support educational design parameters. Games have also been advocated for the creation of more engaging, challenging, enjoyable and meaningful software for learning (Amory, Naicker, Vincent & Adams, 1998). Like most games, the business simulation has rewards and penalties.

Developing a more realistic context for the simulation

Three key issues were addressed by the developers. The first was the requirement for the simulation to behave in a realistic manner once students completed a communication task. For example, in the real world email messages cannot be retrieved, and success or failure to complete the task incurs rewards and penalties, respectively. Unlike many other examples of simulation software (cf., Jonassen, 1998; Phillips, 1997), the business game does not permit students to backtrack and change a message. The student is required to make a definitive decision at a series of decision points (nodes), and having made that decision accept the consequences. The software has only one path, with numerous decision nodes. Figure 1 [Fig. 1] provides a schematic of the design. The arrows represent a one way path for the student. While there are multiple paths, and multiple opportunities for message construction and feedback, once a task has been completed the student is committed to that decision. This is in contrast to many other computer facilitated learning (CFL) materials that facilitate a more flexible approach for students (Harper & Hedberg, 1997; Kennedy & McNaught, 1997; Wilson, 1997). The second requirement was to provide students with some understanding of the effect of message formality on communication outcomes. In the module, the student can construct formal and informal messages, or a mixture of both. Students are required to self-evaluate their perception of the formality of each message prior to sending it. Feedback on discrepancies between message formality and the user's estimation of formality (identified on a sliding bar) is presented immediately to allow the user to adjust their approach in subsequent selections. The
third issue related to potential differences in communication styles between messages that passed internally within the fictitious company, and messages exchanged with external organisations.

Each message has an opening sentence, a middle component, and a conclusion and signoff. Once the message is constructed it is sent, and the student’s choices are analysed in order to provide feedback. The score is then adjusted, either positively or negatively. All scores are cumulative and contribute to a final score for the module. In addition, students also incur time penalties (shown by a simulated calendar on a virtual desktop). For example, if a student decides to call a meeting as a starting point for the task instead of obtaining the tender documents first, two virtual days will be lost (the entire game requires 14 virtual days). At the conclusion of all eight nodes, students are informed of their overall success or failure to complete the task on time and with good communication decisions by a series of outcomes. For example, good decisions result in a company bonus, represented by a congratulatory message and virtual air tickets to a luxury travel destination.

**Formative evaluation**

Formative evaluation has been undertaken using a prototype of the first node as part of the design and development process. Five students with prior experience in the subject were observed using the software, and completed a questionnaire with both open and closed questions. A peer review process was also undertaken. The results indicate that the students find the software more engaging and more interesting than the conventional study materials. The formative evaluation has modified the interface, and refined the feedback mechanism.

**Conclusions**

The programming of the business simulation game is currently in the process of being completed. The formative evaluation has provided information that guided the final form of the software. It is expected that the software will be completed by June 2001.

Coaching Medical Academics in Multimedia and On-line Teaching and Learning Principles

Mike Keppell
Biomedical Multimedia Unit
Faculty of Medicine, Dentistry and Health Sciences
The University of Melbourne
Australia
mkennell@unimelb.edu.au

Abstract: The following paper addresses the implementation of a professional development program in the Faculty of Medicine, Dentistry and Health Sciences at the University of Melbourne. It examines the rationale, approach, evaluation and implications of this training and its effect in transforming traditional academic ideas about teaching and learning. A systems-based approach enhances teaching and learning by utilising the most appropriate and relevant methods as opposed to advocating multimedia and on-line learning as a panacea for higher education.

Medical Course

The medical course at the University of Melbourne incorporates elements of Problem-Based Learning (PBL) and Self-Directed Learning (SDL). The use of Information Technology (IT) is an important feature of the new curriculum. TopClass is utilised to deliver the web-based medical content and multimedia stand-alone modules have been designed and developed to complement clinical cases. This paper will not address the nature of the curricular change and the utilisation of IT for the medical course. This has been examined elsewhere and details are provided in (Keppell, Elliott, & Harris, 1998; Keppell, Kennedy, Harris, 2000). However, with this change there is a need for academics to become familiar with the possibilities of new media for teaching and learning purposes. Medical academics need to see the relevance, viability and usefulness of new media. As part of an initiative to assist in addressing these issues the position of Multimedia Training Coordinator was developed.

Professional Development Approach

The task of addressing multimedia training in the Faculty of Medicine, Dentistry and Health Sciences began by defining "multimedia training" in order to determine "what it means to be trained in multimedia". For the purposes of creating a common definition, multimedia refers to highly interactive CD-ROM or web-based educational modules that utilise varying levels of text, graphics, photographs, video, animations, audio and discussion groups. The purpose of the multimedia module is to complement other forms of teaching and learning strategies. Multimedia should engage the learner and provide interactivity and innovation that generally cannot be created in any other format (eg. lecture, tutorials, print, video, etc). Training refers to both informal and formal instruction. Informal instruction includes coaching of grant writers and grant holders on an "as needed basis" and 'showcases' of projects. Formal instruction includes the Level 1 and 2 Workshops and the TopClass Tutorial.

The aim of the training model is to provide a flexible and responsive approach to academic staff. The approach considers the level of multimedia experience, available time and purpose as different academics require different approaches. For example, an annual symposium provides a forum for sharing ideas within the Faculty. It focuses on discussion about the 'story' behind the design and development of the project so that other staff can learn from these experiences. Informal training occurs through a consultative basis with staff within the Biomedical Multimedia Unit (BMU) http://www.medfac.unimelb.edu.au/bmu/ who provide advice and guidance in curriculum and learning theory, instructional design, graphic design, software and hardware, evaluation and project management. The BMU provide consultative advice at the pre-grant, project and post-project phases. The formal aspects of the multimedia training model centre on three workshops. The main...
theme throughout all the workshops is that academic staff should focus on their strength (content expertise) and complement this strength with designers and developers (instructional designers, graphic designers, multimedia developers, programmers, evaluators, project managers, videographers, photographers).

The aim of the Level 1: 2 hour Familiarisation workshop is to provide an overview of multimedia. The workshop focuses on: What is multimedia? Why use multimedia? When is multimedia useful? How is multimedia produced? As an academic what is my role in multimedia design and development? The target audience for this workshop are academic staff who want to know "about" multimedia rather than the specifics of how to design and develop a multimedia project. The aim of the Level 2: 16 hour workshop is to provide a comprehensive design and development workshop addressing curriculum, instructional design, graphic design, authoring, project management and evaluation. This workshop aims to empower the participant with the ability to create a quality educational multimedia module (of limited size) in conjunction with a design and development team.

Evaluation

Five academics participated in the initial design and development workshop in 1999. They were a blend of academics who had received priming grants which allowed them to undertake a modest project or proof of concept in conjunction with the BMU. The participants were asked to rate each of the topics/sessions on a five point likert scale in terms of 'interest' and 'usefulness'. They were also asked to rate project management, curriculum and learning theory, instructional design, graphic design, software and hardware and evaluation on the same scale. Of top interest was graphic design followed by project management, instructional design, evaluation, software and hardware and then curriculum and learning theory. Of top usefulness was evaluation, followed by project management, instructional design and graphic design, software and hardware and then curriculum and learning theory.

Implications

This paper has discussed a professional development program for multimedia and on-line learning. The approach focuses on blending informal and formal methods which is responsive to the needs of the academics within the Faculty. 2000 has seen further work in assisting some fifteen grant writers; the coaching of thirty academics currently involved in projects and the teaching of the level 2 workshop for 10 academics. The level 1 workshop has been undertaken with approximately 30 academics. A CD-ROM for the level 1 workshop is also being developed. The response to the training approach has been positive with other schools outside the faculty enlisting our services in multimedia training. Further work is continuing to refine the training approach.

Abstract: TeleQACE (Quality Assurance and Continuing Education) is a web-based learning environment that allows medical general practitioners (GPs) to participate in interactive learning at times that suit them. The design addresses the balance between richness of content and bandwidth to reach geographically dispersed regions. The guiding philosophy is shared knowledge and interaction based around actual experience and cases developed by practising academic GPs in consultation with specialists. This paper examines the educational rationale and the design and development of this module.

Educational Rationale

Real-world learning experiences, often called authentic learning experiences, are “those which are problem- or case-based, that immerse the learner in the situation requiring him or her to acquire skills or knowledge in order to solve the problem or manipulate the situation” (Jonassen, Mayes, & McAleese, 1993, p.235). The context of the actual learning situation and the goals of learning can influence the acquisition of conceptual knowledge and the ability of the learner to apply this knowledge. In fact, “the potential usefulness of knowledge is a function of the congruency between the conditions of knowledge acquisition and the conditions of knowledge application” (Koschmann, Kelson, Feltovich & Barrows, 1996, p.92). Authentic learning situations attempt to emphasize this congruency by utilizing real-world problems in their learning context. Situated cognition suggests that learning should be "organized around real world problems in order to induce orientations to learning that are congruent with subsequent knowledge use" (Koschmann, Kelson, Feltovich & Barrows, 1996, p.93; Brown, Collins, & Duguid, 1989). The TeleQACE modules attempt to apply authentic learning principles by examining real-world problems in anaesthetics, gynaecology and snakebite.

Critical reflection is a central approach which is utilised by the GP in their day to day work. Reflection is a metacognitive activity, which refers to a process that involves thinking about thinking. Boud, Keogh & Walker (1985) define reflection as a “generic term for those intellectual and affective activities in which individuals engage to explore their experiences in order to lead to new understandings and applications” (p.19). Schon (1983) suggested that there are two types of reflective practice. He referred to these as reflection IN action and reflection ON action. Reflection in action refers to “thinking on one's feet” or during the event. Expert reflective practitioners generally have the ability to adjust their thinking during the event to solve a professional problem. Reflection on practice involves “turning back thought” on learning or professional practice (Boud, Keogh & Walker, 1985). The TeleQACE modules encourage practitioners to reflect on their own professional practice and share this knowledge in online discussion groups.

Design and Development
The TeleQACE modules http://www.medfac.unimelb.edu.au/teleQACE provide an opportunity for clinicians to share professional information in a secure virtual environment which should assist in reinforcing best practice during episodes of patient care. The aims of the program are to provide an internet site for supporting rural General Practitioners to enhance quality health care. In particular we have developed a learning framework suitable for providing access to health information, continuing educational programs and communication with other health professionals. Rural GPs are provided with practical and relevant information that is useful for the practising GP in rural and remote areas. The primary means of achieving these aims focuses on collaborative discussion groups which allow rural GPs to discuss crisis management and specific events with other geographically dispersed GPs.

As a web-based learning environment TeleQACE allows GPs to participate in interactive learning at times that suit them. A basic case elicits knowledge gaps and suggestions from participants, which are shared through on-line discussion. This discussion guides the construction or development of the 'basic case' into its 'advanced' equivalent. This 'advanced case' is re-presented to the participants, accompanied by relevant reference material, for reflection and interaction. Finally, the outcomes of this process are consolidated, packaged as a 'model case' and archived for ongoing reference by the group. Participation in each module will be an extended and deep learning experience. The initial modules have a rural focus and include snakebite, gynaecology, and anaesthetics. These were selected as a result of the needs expressed by rural clinicians.

The snake bite module allows the participant to reinforce understanding of the signs and symptoms of envenomation and a systematic approach to the initial and ongoing treatment of snakebites. The use of antivenes and monitoring are emphasised in the management. The gynaecology module allows the participant to reinforce understanding of the diagnosis and management of gynaecological (pelvic and abdominal) pain. The base case leads the participant through history, assessment and management of a common, but difficult clinical scenario. The anaesthetics module allows the participant to interact with it to reinforce understanding of monitoring and troubleshooting in general anaesthesia. It presents participants with a non-specific, but potentially serious scenario and leads them through the decision-making processes necessary to manage the problem.

Conclusion

The gynaecology module is currently being trialled with eighty GPs recruited from across Australia. An evaluation is being undertaken on all aspects of the module which will inform the design and development of subsequent modules. Future modules include obstetrics, aged care, prostate problems and complex cardiovascular problems.

References

Abstract: This paper describes a project, which aim is to develop and test different types of mobile (and some wired) learning environment solutions. In this project, the learning environment is seen as a technology based extension of classroom, where technology makes different types of communications possible. Learning itself is done by human to human communication. Some parts of solutions are separately in use, but the whole system would be under testing in spring 2001. First test results would be published during year 2001. This kind of classroom extension may contain some additional value to learning process or motivation.

Introduction

At the Pori School of Technology and Economics (Finland) started a research and development project about wireless communication's capabilities in elementary education. The starting points of the study are the following:

1) Wirelessness. Like WWW, also WAP is studied as one piece of learning environments. However, the WAP -techniques are still quite undeveloped and they cannot yet be fully utilized. Also, the costs of data transfer are still quite high. The disadvantages of wireless PC-techniques include the quite limited operational range and the fairly large size of the mobile computers. However, the costs of data transfer are minor and the performances of the devices can be adjusted to sufficient level for the requirements of a learning environment.

2) Teaching/instruction. As a starting point for instruction is the use of wireless communication in situations where some additional value is to be achieved from it to the teaching. The technology is not used just for itself (technological imperative), but it is tried to be used to support problem-based and/or cooperative learning. (Hakkarainen, Lonka & Lipponen, 1999).

3) Communication. In this study communication is restricted to interpersonal communication. Thus, technology is regarded only as a tool with which a mobile learning environment applying to and effectively maintaining social knowledge construction is made possible. (Bereiter & Scardamalia, 1993; Bereiter, 1999).

The purpose of the learning environment of this study is to emphasize Vygotsky's idea about children learning from each others. A portable mobile learning environment makes possible many different forms of communication with which the children can discuss learning problems or tasks even without seeing each others.
The communication may be delivered for instance as traditional phone calls, image calls, literal text messages, online chat boards or off-line message boards. All these forms can be carried out between two or more partners. It is also possible to arrange for each learner a personal working area where the others can send messages and the learner can respond to them in a way he/she prefers. The traditional teacher-centered instruction is also possible in the mobile learning environment of this study, but it is assumed that the learning will be self-directed to social inter-studential knowledge construction.

**Technical background**

The xClass server software is now in develop process. Some parts of it are separately in use and the whole system would be ready in spring 2001. is scaleable so, that different types of terminals (work stations) can have access to information delivered by server. Possible types of terminals are LAN –workstations, wireless LAN –workstations (laptops), WAP –phones, PDA –terminals and mobilephone integrated WWW-terminals. The server software finds out, which type of terminal are in use, and communicates with terminal by required language. All data, stored in server is meta-data labelled, and so there is only one type of stored documents which is translated into requested form.

In spring 2001 the main research field is in GPRS –network usage because its accessibility, though WLAN –networks in school use would be more cost effective. WLAN –network is also under research, but because the limited range of WLAN it is not examined as an all around solution in wireless learning systems.

**Visions**

The xClass should give added value for example problem-based learning exercises. Often, when complex exercises are done outside the classroom, teachers work becomes quite hard: the teacher must instruct and control every pupil, but when pupils are around the schoolyard, it comes almost impossible. Also, when doing outclass exercises, the need of instructions arises heavily. Often for having advises children have to run after the teacher or the teacher have to run after children to control them. It is also common, that completed exercises don’t reach the aims of the planned exercise because of the lack of the instruction.

With such technological environment, teacher need no more use time to find pupils. Teacher can just connect pupils with their environment tool - a PC, mobile or PDA - and give instructions by text, speech or video interface. Pupils can also contact other pupils, which are doing the same exercise, and get advises from them. In such case the environment supports Vygotsky’s social learning theories. There are also a group management point of view: If there is a connection between the server and the workstation, the teacher knows, that pupil (or at least the machine) is in the schoolyard. In the future the location services can be added to xClass. Before that, the line between guidance and control must be well discussed.

Interaction and learning: Learning results in multimedia geometry -game

Harri Ketamo
Pori school of technology and economics
Pohjoisranta 11
PL300, 28101, Pori, Finland
Harri.ketamo@pori.tut.fi

Abstract: The aim of this study was to develop learning materials with computer supported user observation. The results of this study showed a clear connection between the usage of the learning material and the learning results. Those most explanative variables were 1) time between two user events, named as interaction. 2) Relative error, which was calculated by dividing the number of incorrect answers by the total number of events. According to these results, fast interaction with few mistakes achieves no learning effect, because of too easy learning material. On the other hand, when interaction is very slow and there are lots of mistakes, the learning material seems to be too difficult. In generally the learning material should be difficult enough to effect thinking. Thinking could be achieved either as a inner process, when interaction between material was slow, or with fast interaction, when amount of mistakes increases.

Introduction

According to constructivism, people construct their own knowledge. This means that construction process is active in the nature and students' understanding is tied up with his or her previous experience. Thus, learning is a constructive process, where students actively construct their knowledge through interaction with the environment and through reorganization of their mental structures (Chi & Bassok, 1989). The learners are builders of knowledge structures rather than the recorders of information (Mayer, 1992). The high level of student's activity in comparison with traditional learning situation is the main argument for the using information technology in education. Multimedia, which is based on learning theory (Moreno & Mayer, 1999), computer quid building environments like LEGO/Logo (Resnick, 1996) and intra- or internet based social knowledge building computer tools like CSILE (Bereiter & Scardamalia, 1993), are all examples of good attempts to increase the quality of students learning. From the constructive point of view, the interaction between computer and user is the most important issue in computer supported learning materials.

Www gives also promises to be very rich environment for educational research, many powerful data collection algorithms can easily be added to www -based learning materials. In this study, the data about interaction and mistakes was collected with such data collecting algorithm (Ketamo & Suomala, 2000)

Research questions and method

Research contains three groups of six years old children: experiment group 1 (n=21), experiment group 2 (n=20) and control group (n=30). All groups were pre- and post tested considering their geometric skills. Measures of the study are done during April 2000.

Two different www -based learning materials about geometry, polygons exactly, were written for this study. These learning materials contain sections with active input and also sections with passive input. Experiment group 1 got learning effect with learning material that requires active input. Experiment group 2 got learning effect with learning material that requires both, active and passive input. The control group did not get any educational effect.

The research questions of the study can be summarized as follows: 1) What kind of general learning results has been achieved? 2) What kind of differences, in use of different learning materials, between children with good geometric skills, average geometric skills and poor geometric skills can be found? 3) Can learning results be explained by use of the learning material?

Results

When considering the learning effect of testing within the control group through different skill groups, we can find an interesting difference. The average skilled pupils in geometry have learned most from the test (improvement ~10%). Low skilled pupils have learned a little less from the testing than average skilled (improvement ~7,5%). High skilled pupils has learned from the testing only about a half that the other groups (improvement ~4,5%).

Because the strong learning effect of testing, it is more interesting to focus on the real learning effects of the learning materials. Real learning effect can be estimated by subtracting the learning effect of the test from the improvement percents, differently in each skill group.

Only low skilled pupils have had real learning results from the learning materials (table 1). When considering experiment group 1 we ca find a statistically significant difference in real learning results between low skilled pupils and high skilled pupils (t=2,215 p=0,044). Because results in both experiment groups are quite like the same, we consider added experiment groups in different skill groups. With this combination we can see, that there are
statistically significant differences between low skilled and average skilled groups ($t = 2.090, p = 0.042$) and between low skilled and high skilled groups ($t = 3.028, p = 0.005$). According to this result, we can say, that low skilled pupils have had significantly more benefit from these learning materials than other groups.

<table>
<thead>
<tr>
<th>Test group</th>
<th>Skill group</th>
<th>real learning effect %</th>
</tr>
</thead>
<tbody>
<tr>
<td>experiment group 1</td>
<td>low / average / high skilled pupils</td>
<td>11.4 / 2.1 / -1.3</td>
</tr>
<tr>
<td>experiment group 2</td>
<td>low / average / high skilled pupils</td>
<td>11.5 / 0.3 / -3.9</td>
</tr>
<tr>
<td>exp 1 + exp 2 (added)</td>
<td>low / average / high skilled pupils</td>
<td>11.4 / 1.2 / -2.4</td>
</tr>
</tbody>
</table>

Table 1. Improvement percents and real learning effect in experiment groups.

Interaction in different skill groups within use of different learning materials differs significantly (table 2/top). In experiment group 1. The interaction in low skilled group was significantly slower than in average skilled ($p = 0.030$) or high skilled group ($p = 0.048$). In experiment group 2 the situation is opposite. The low skilled group uses little faster interaction in learning material use than the other groups, but there are no statistical significant differences between groups.

<table>
<thead>
<tr>
<th>Skill group</th>
<th>interaction (s/event) in exp. 1</th>
<th>interaction (s/event) in exp. 2</th>
</tr>
</thead>
<tbody>
<tr>
<td>low / average / high skilled pupils</td>
<td>14.1 / 9.7 / 9.3</td>
<td>5.9 / 9.4 / 7.8</td>
</tr>
<tr>
<td>low / average / high skilled pupils</td>
<td>mistake % in exp. 1</td>
<td>mistake % in exp. 2</td>
</tr>
<tr>
<td></td>
<td>8.7 / 8.9 / 7.6</td>
<td>18.1 / 8.4 / 7.7</td>
</tr>
</tbody>
</table>

Table 2. Mistake percents in different skill groups.

In the bottom of table 2 the mistake percents are considered in different skill groups. In experiment group 1 all skill groups have done approximately as much mistakes. In experiment group 2 the low skilled pupils have done much more mistakes than other groups. Although there seems to be quite a difference, the variance in single cases was so big that no statistical significant difference can be found.

**Conclusions**

Combination of these result seems to be interesting: Only the low skilled group have had real leaning effect from the learning materials, which alone is not a surprise according to former studies. The surprise is in use of the learning materials. When low skilled pupils in experiment group 1 have had a longer interactions, but as much mistakes than others in experiment group 1, the low skilled in experiment group 2 used faster interaction and make much more mistakes than others in experiment group 2. After all, average skill and high skill pupils did not get real learning effect from the learning material, but they used material approximately like same, not depending on learning material in any way.

Those average and high skilled group in both experiment groups gives us a good viewpoint to learning effect: In experiment group 1, where the learning material was requiring active input, the learners was forced to think if they did not want to make mistakes. It seems that they were thinking more than others, because interaction was slower, but there were no more mistakes than others. In experiment group 2 learners was first used just clicking the elements and that style continues through whole game. This naturally affects more rethinking of the incorrect answers. In generally, it seems that for learning it is not important how the thinking effect is achieved, most important is that material is so difficult that it requires thinking. For the average and high skilled pupils of this study, the learning material does not offer challenges, so it does not work.

NESTOR-Integrated Tools for Active Navigation and Constructive Learning

Izida Khamidoullina, Université de Liège, Belgium; Thérèse Reggers, Université de Liège, Belgium; Romain Zeiliger, Université Lumière Lyon 2, France

In order to involve learners in the meaningful cognitive processing of the delivered information, we need cognitive tools such as knowledge-based navigational aids. We present NESTOR Navigator, a graphical web browser, which allows constructive navigation with the help of a visual map and supports collaborative learning. NESTOR’s approach is to provide an interactive environment where users construct themselves their knowledge. One of the main objectives of NESTOR, beyond engaging learners in constructive browsing, is to support the asynchronous and synchronous exchange of browsing experience among a group of learners.

Abstract: A vision for learning...

A DAY IN THE LIFE OF A 16-YEAR OLD
Woke up this morning at about 1 lam. After a quick wash, I logged onto to my personal webportal. A pop-up box reminded me that I’ve completed downloading my fav MP3 clips... and a few video clips which I need for a project presentation for Mr Wong’s class. My online calendar reminded me of the appointment with Peter and the guys at 12pm at Starbucks. We need to discuss our group’s project assignment. Mrs Chew needs us to hand in a proposal by tomorrow. Did a quick check to see if I had any emails. A few. Not too important ones. Except for one from Dr Pawas asking me to send him the link of a new really cool e-comm website which I discovered yesterday. Did a quick reply to the email. OK, done. Now I’m ready to meet the guys... no need for any notes or books... just need my notebook. And mobile... hmm... take my advice... don’t leave home without them...

A DAY IN THE LIFE OF A 40-SOMETHING-YEAR OLD
Sent the kids off to school and I’m back home. It’s 8am. A cup of hot coffee in one hand, the other on my trusty notebook. Lets check the news... hmm...this looks interesting. Let me send the link to Wong... it should be useful for what he’s teaching. OK, let’s check online calendar and email. Right. 10am meeting with Jerry’s group at Coffee Club to discuss some problems they’re having... 2pm meeting faculty visitors from Indonesia in campus... 4pm meeting with faculty staff to discuss new open book exam regulations... that reminds me, it’ll probably be helpful to check what others have done on this issue... OK... search ERIC... open book exams... Right, let’s save these articles and get them printed out later. Hmm... there’s some time left before the 10am meeting. Let’s check the discussion forum on the course which I’m facilitating... well... looks like the kids are really getting into the debate. OK, but let’s try and get them to focus on the real issue... let me post this message on the forum. OK, that’s done. Now let’s check on the web development course I’ve enrolled in...

These scenarios are not quite science fiction. They are becoming a reality for more and more people. Formal education is happening outside the confines of the physical classroom. Computers and in particular, the Internet have created new learning scenarios for both the student as well as the teacher. Portable computers and mobile devices that are connected to each other through network and telecommunication technologies have created yet another set of scenarios. These blur the lines between home, classroom/campus and external community. They also blur the line between work/study and play. The availability of information at the fingertips and on demand as well as communication channels which are open 24 hours a day is making lifelong learning less a rhetoric and more a reality.

One of the paradigm shifts from old to new economy is from perfecting the known to imperfectly seizing the unknown (Productivity Digest, 2000). It was with this in mind that NgeeAnn Polytechnic embarked on an initiative to equip all students with notebook computers operating in a network-enabled campus environment. This is termed the Mobile Computing (MC) Initiative. This paper will present three key arguments based on the Access-Cost-Quality model to support this initiative.

Background
NgeeAnn Polytechnic first introduced the use of notebook computers in early 1997. A pilot group was formed to test out this initiative. The survey results indicated that students favoured the use of this approach despite the initial technical problems which they had to contend with. Students' responses strongly indicated that the use of notebook computers encouraged independent learning and facilitated communication.

On the external front, the pressure for schools to adopt the use of technology was evident. Computer literacy was seen as a critical skill set to prepare students for the new digital economy. The government had prepared an IT masterplan which served as a blueprint for the implementation of IT infrastructure and initiatives to "create new national competitive advantages and enhance the quality of life in Singapore". Education was key to ensure the realisation of this goal to develop the nation state into an intelligent island (IT2000 Report, 1992). Subsequently, the government formulated the IT2000 and Infocomm 21 Masterplan.

In 1999, NgeeAnn announced that it would equip all its first year students with notebook computers by 2005. There would be a phased implementation of this initiative starting with the first batch of 450 first year students from the Accountancy Department. At the same time, the institution had begun installing network points in classrooms and canteens. In July 1999, wireless access points were installed at the Library and other public access areas in campus. Thus, mobility afforded through wireless technology became a key element of the MC Initiative.

Why Mobile Computing?

Sir John Daniel, Vice Chancellor of the UK Open University, in his keynote address at the TechEd99 convention referred to the "eternal triangle" of forces and tensions affecting educational institutions (Refer Figure 1. Daniel, 2000). Cost, access and quality are forces which appear to pull institutions in different ways. The introduction of technology has amplified this tension. Cost is a major consideration for any institution wanting to implement its technology plans. Not only do institutions need to plan for an initial up-front capital cost investment, it needs to also consider the recurrent cost components as well. Technology appears to provide greater access to learning opportunities for the masses. Seen from the perspective of the digital divide, the gap between the haves and have-nots, however, it appears to limit real access to those who are in control of the technology. Quality, as seen from the perspective of technology enhancing learning effectiveness, has always been a topic of debate amongst educators — does technology improve students' learning?

![Figure 1: Cost-Access-Quality Triangle](image)

There are three arguments to consider when planning for a mobile computing initiative. These relate to the three factors of cost, access and quality. The assumption is that the adoption of technology in education is a given. The question is what form should the technology take? Do we have a case for notebook computing?

1. **The Cost Argument**

    Consider the conventional model used by most educational institutions where computers are purchased and set up in laboratories for student usage. Cost is borne entirely by the institution. This
includes purchase of software, network cabling and equipment, and furnishing. Rooms need to be
dedicated as computer laboratories. Technicians need to be hired to maintain the systems.
Administrators need to be employed to manage the booking procedures. After the normal school hours,
the computer systems are left unused. If required to work after the laboratories are closed, some
students would have their own computers to work from home.

Now consider the model where students own their portable computers. They can use them at
home and they can bring them to school when required. They purchase their own software which they
maintain themselves. They are taught to take care of their own computer systems. The cost to the
institution is thus limited to the provision of network infrastructure in campus and if need be, to
provide for dial-in utilities and services from outside of campus for students to access the campus
network facilities.

In this regard there are substantial savings for the institution. One may argue however, that this
cost has merely been passed on to the student. The issue becomes one of perceived value to the student
(and to his/her parents who sponsors the investment) as well as one of affordability for those who
genuinely cannot afford the associated costs. The issue of perceived value is related to the next two
arguments on access and quality. The issue of affordability can be addressed through financial
assistance schemes.

2. The Access Argument

In the conventional model, there is always limited access for student usage unless there is a one
to one ratio of computer to student, as in the case of the MC model. Personal ownership and mobility of
the computer equipment makes learning anytime, anywhere (using the computer) possible. In a
computer laboratory, rules and regulations exist to control what the student can do and what he/she can
access. This is not the case when the student owns his/her own notebook computer. Every classroom
can become an instant computer laboratory when students with notebooks gather together. Public
spaces in the campus become spaces for students to use their computers to work or to play. One may
argue that students could be spending more time playing than doing serious work with their computers.
But does it matter? From the point of view of measurement of utility of any hardware as an investment
indicator, then one argues that it is better that the equipment is being used than not at all. A more
important outcome of students using the computer more frequently is that they become increasingly
computer literate—the very skill set which we want our students to have in order to compete in the
digital economy.

Personal ownership is a very powerful learning motivator. Consider the growth of the internet
when internet became accessible to the masses and browsers became something which users own and
can customise. Consider the growth in the popularity of software language when the coding was made
freely accessible for programmers to use. Consider the increase in use of mobile phones (or
handphones) when the device became a personal asset item. The value of a student owning his/her own
computer allows the change in lifestyle which now assimilates the use of the technology and making it
increasingly ubiquitous in nature.

3. The Quality Argument

Does technology improve students’ learning? Many educators have debated this. Arguments and
counter-arguments abound between staff from the pro-technology camp and the “traditionalists” who
quote the many research papers which point to a “no significant difference” phenomenon in comparing
the use of technology against conventional classroom teaching approaches (Russell, 1999). The
argument perhaps is less about the adoption of technology per se but how the technology is being used
to advance students’ learning. The constructivist approach to learning has gained significant acceptance
amongst educators who favour this approach to teaching over traditional instructivist approaches.
Reeves in describing the role of technology as a continuum between “surrogate instructor” at one end
and “cognitive tool” at the other, advocated the use of technology as a cognitive tool when used in a
constructivist manner (Reeves, 1999). Biggs contrasted between two teaching strategies, one, on what
the student does and the other, on what the teacher does and proposed that the former is more effective
for learning than the latter (Biggs, 1999). He quoted from Shuell:

It is helpful to remember that what the student does is actually more important
in determining what is learned than what the teacher does.

It is argued therefore that because students own their computers, there are greater opportunities
and reasons for teachers to design learning activities that require their students to use the computers to
construct their learning. And because students have access to their own computers and have personal
ownership over them, there are greater opportunities for them to create their own learning outside of teacher-driven activities.

Conclusion

Since the MC Initiative was launched, many concerns were voiced by faculty particularly in areas related to teaching and learning. Changes had to be made not only to classroom management and practice but also curriculum design. These concerns provided opportunities for management staff and faculty to rationalise the benefits of the initiative. Healthy skepticism serves to moderate unreasonable assumptions associated with use of technology. Technology is afterall merely a tool. It is what we make of it that will determine its value for our stakeholders. Through the MC Initiative, our students have become an active investment partner in the use of technology to advance learning. So, what do you think? Do we have a case for notebook computing?

Abstract: A virtual reality physics simulation (VRPS) is an educational system using virtual reality interface, which brings together a 3D model of some real apparatus and a virtual visualization of some physical situations with an interactive manner. VRPS enhances students' understanding by providing a degree of reality unattainable in traditional two-dimensional interface, and supports the creation of sensory-rich interactive learning environments. In this paper, we will present the recent development of a computer-based virtual reality simulation, which will permit students to learn physics concepts such as wave propagation, ray optics, relative velocity, electric machines, etc. in the level of high school physics or college.

Introduction

Virtual reality (VR) technology may offer strong benefits in science education not only by facilitating constructivist learning activities but also by the potential to provide alternative forms of learning that can support different types of learners such as visually oriented learners. VR, a new communication medium, is usually identified by a collection of technological hardware including computers, head-mounted display (HMD), eye phones, and motion-sensing data gloves. Virtual reality is defined as a highly interactive, computer-based, multimedia environment in which the user becomes the participant with computer-generated virtual world. A key feature of VR is real-time interactivity in that the computer is able to detect user inputs and instantaneously feed back to modify the virtual world. VR world can also be used to circumvent the physical, safety, and cost constraints that limit schools in the environments of learning-by-doing they cannot provide. For example, it would be impractical to allow students studying nuclear physics to go into the nuclear reactor unless VR program provides the 3D reactor with HMD and data gloves. This type of activity can be performed in a virtual world.

Distance learning is now popularized in recent years because of fast development of computer systems and spreading Internet connectivity. One of the major restrictions in the science and engineering education for distance learners is difficulty of laboratory activities. An alternative way to overcome such difficulty is using the simulation programs running on Web browsers instead of hands-on experiments. But, most of such programs are displayed in 2D which is a lack of reality.

The virtual reality simulation program is one of the solutions for hand-on experimentation with full of reality. Furthermore, physical phenomena, which are neither easy to perceive nor to be measured in usual experiments, can be scientifically visualized in a virtual world and can be viewed in many different ways traveling over VR laboratory. In addition, the dangerous experiments, high cost experiments, and complicated experiments can be realized in VR system for distance learners.

In this paper, we will present the recent development of a computer-based virtual reality simulation, which will permit students to learn physics concepts such as wave propagation, ray optics, relative velocity, and electric machines, etc. in the level of high school physics or college. Development of the simulation programs involves the following steps: instructional design, 3D modeling, experimental setup constructed by 3D objects, keys to control, and 3D animation control program for visualization of the 3D model.

VR simulation programs in physics education

We have used the 3D Webmaster software for authoring VRPS programs. 3D Webmaster is one of powerful windows application for creating interactive 3D Web Page. 3D Webmaster is the browser platform that lets you display, move around, and interact with worlds that you are creating virtual world. It lets you adjust viewpoints, display options, and device configurations, to add the final touches to your world. The worlds you create can be displayed
on the fully interactive environments in 2D HTML pages. You can add URLs to objects so that you can link directly from your virtual world to any other 2D or 3D page on the WWW, or interaction between the world and your HTML. In order to create realistic worlds you can use script language (Supercape Control Language, SCL) to control behaviors to objects in the world, perform complex actions, and modify your worlds based on user’s actions in your HTML documents.

The VRPS sample programs developed in this study are described below.

![Figure 1. AC generator (left) and Water wave (right)](image1)

![Figure 2. Specific heat (left) and Action and reaction (right)](image2)

Figure 1 shows the principle of AC generator where student navigates and controls the generator by dragging and clicking the mouse, and the propagation of water wave. Figure 2 shows the experiment of specific heat where student learns by doing step by step, and experience of action and reaction where student walks virtually on a thick board located in frictionless floor. We have developed many other VRPS program such as wave propagation, ray optics, relative velocity, electric machines, etc. in the level of high school physics or college.

**Conclusions**

There is a need to develop new VRPS programs for distance education as well as regular class room. The VRPS program is useful for teaching materials as a hand-on experimentation with full of reality, visualization of invisible physical quantities, replacement of dangerous, high cost, and complicated experiments.

OMETZ: Virtual Learning Civil Community

Booki Kimchi, Center for Educational Technology (CET), Israel; Irit Lifshitz, Center for Educational Technology (CET), Israel

The OMETZ program came about as a result of cooperation between the Movement for the Quality of Government in Israel and The Center for Educational Technology (CET). OMETZ: Hebrew acronym for Citizenship and Social Involvement; The word meaning in Hebrew is: courage.

OMETZ is a unique civic education program that integrates active study of democracy and social involvement with a specially designed virtual learning environment on the Internet- OMETZ Website. The program promotes democratic values; enables youth to be involved; to practice basic democratic rights and obligations; and encourage social awareness and involvement among school-age children. OMETZ program bring together secular and religious Jewish children and Israeli Arabs children, ages 13-17, that learning in separate systems schools, into a virtual, dynamic learning civil community, that allow them, to study together, to talk, to share ideas, dreams, problems, conflicts, information and knowledge. OMETZ Website, designed especially as a civic education center. We develop special training courses for teachers, for political science students, for mentors and moderators. All of them become also active members of the learning community. One of the general issues we focus on is: how can we wisely use, Web-based educational programs, such as OMETZ, for confrontations with the reality we are facing in Israel and in other conflict aria in the world?
A Framework based Approach for Intelligent Multimedia in Education

Kinshuk, Hong Hong, Ashok Patel* and Chris Jesshope
Massey University, Palmerston North, New Zealand
kinshuk@massey.ac.nz

*De Montfort University, Leicester, United Kingdom

Abstract: This paper describes an approach for multimedia representation within the intelligent educational systems to facilitate better domain competence acquisition by the learners. The implementation of the approach is dependent on the educational framework, which is adopted in the educational system. In this presentation, it is discussed for the systems providing domain competence using Exploration Space Control framework to support learning-by-exploration. The presentation will demonstrate the application of the approach in the design of TILE environment, which is a multimedia based educational delivery system with intelligent student support.

Introduction

This presentation demonstrates the application of a Multiple Representation (MR) approach to multimedia technology. The MR approach makes use of the underlying educational framework within intelligent educational systems. The approach attempts to arrange the individual multimedia objects (such as audio, pictures, animations) into a multimedia interface world where the relationships of the objects to the world are governed by the educational framework. Learners are provided with various forms of interactivity to suit the pedagogical goals of the intelligent educational systems. For this purpose, various multimedia objects are identified with respect to various tasks required for domain competence. This approach ensures the suitable presentation of domain content to the learner by guiding the selection of multimedia objects, navigational objects selection, and integration of multimedia objects to suit different learner competence levels. The approach does not try to replace the well-established interface design guidelines. The attempt here is to assist the educational system's designer from learner's point of view. A vast literature is available covering the subject of use of multimedia in education, but one cannot find any guidelines within this flooding amount of information that show how to proceed from original idea to the definitive multimedia based systems (Lara & Perez-Luque, 1996).

The implementation of MR approach is dependent on the educational framework adopted in the intelligent educational systems. In this presentation, it is discussed for the systems providing domain competence by using Exploration Space Control framework (Kashihara et al., 2000) to support learning-by-exploration. The MR approach is being applied in the TILE environment, which aims to provide integrated system for the management, authoring, delivery and monitoring of distance education.

Motivation and Context

The success of the learning process in an intelligent educational system depends on how the system presents the domain knowledge to the learner and changes its presentation in terms of complexity and granularity according to learner’s progress. Tutoring strategies are the major source of taking decisions regarding domain knowledge presentation. Adequate educational framework gives a way to create effective and efficient tutoring strategies for a given domain. Many researchers have emphasised the need of suitable educational framework in the use of multimedia technology in educational systems, with some researchers particularly considering intelligent educational systems.

Pham (1997) pointed out that many multimedia based educational systems in current existence have placed too much emphasis on the affective and psychomotor aspects and lured the learner by using spectacular effects provided by images, animations, video and sound. In such systems, the emphasis has shifted from adequate learning outcomes and cognitive development, and the goal of knowledge acquisition seems to have diluted.
(1991) warned that it should not be assumed simply because a visual component is present, that the instructions will be coded into long term memory.

Rogers et al. (1995) suggested that the solid foundation of intelligent tutoring systems should be utilised as a platform for a more sophisticated control of multimedia objects in a learning environment. Nicol (1990) argued that the interfaces for learning should be designed considering the same principles that good teachers use. Pham (1997) concerned that little considerations have been given to the cognitive, pedagogical and psychological aspects of learning while designing multimedia based educational systems. He emphasised that a good educational multimedia system must not forget educational objectives while taking advantages of advance technology.

Multimedia technology can contribute to the success of learning only if it can adequately represent the tasks and concepts of domain. Rheingold (1990) recommended that the multimedia presentation should also be capable of supporting the goals of the system. The Multiple Representation (MR) approach is predominantly dependent on the educational framework in which it is being applied. This research work is focused on learning-by-exploration. Exploration Space Control is a framework to support such learning process. The application of MR approach in TILE environment within Exploration Space Control framework will be demonstrated in this presentation.

Discussion

There has not been much consideration of use of multimedia technology in the educational systems with the view of educational theories. This paper suggested one such consideration in the form of Multiple Representation approach for domain competence acquisition. An implementation of the approach using Exploration Space Control framework was also discussed with the description of a system built using the approach.

There are many areas in which the research demands further consideration. Currently the Multiple Representation approach is applied to the disciplines with focus on exploratory learning. The requirements of other learning processes also need to be considered. Research is also required to extend the approach on student's learning styles or some other established user classification.

Authoring Techniques for Educational Video Data

Arno Klein
Department of Computer Science
Artificial Intelligence
University of Erlangen-Nuremberg
Germany
aoklein@immd8.informatik.uni-erlangen.de

Abstract: Due to the requirement for new forms of multimedia enriched lecture in various online and virtual education services, a growing demand for recording and authoring of different educational or informational events, e.g., lectures, seminars or conference talks, has to be considered. Such recordings can only be authored efficiently, if content-based accelerators for accessing recorded video streams are established. This article introduces techniques for the (semi-)automatic production of comprehensive and intuitive visual summaries for video sequences that can be used for efficient, content-based authoring of video recordings in many areas of multimedia enriched education.

1. Introduction

Efficient authoring of video recordings from discussions, lectures, seminars or conference talks often fails because of the lack of compact and intuitive visual summaries. Therefore the video author has to view video sequentially without semantic navigation support, thus wasting a lot of time. Current research prototypes (e.g., CueVideo from IBM[1], Srinivasan et al., 1999) implement some extended video navigation support features (e.g., increasing playback rate), nevertheless this decreases video viewing time only by a small percentage (see Gupta et al., 2000). In order to achieve better performance through richer semantic navigation possibilities, we have to think about new and better ways for (semi-)automatic creation of visual summaries for video recordings.

Such new visualizations depend mainly upon content of the recorded video sequences. Following this article presents a technique for creating semantically rich visual representations through preparation, online support during recording and interactive refinement of recorded sessions.

2. Techniques for the creation of visual summaries

Fully automatic techniques for creating visual summaries for video sequences are already known but mostly they deploy heuristic algorithms (see mBase and VideoManga, Uchihashi et al., 1999) depending on calculation of importance descriptors from neighbouring images in video sequences: great changes between neighbouring images indicate important positions, no or small changes indicate sequences of less importance (see Maybury, 1997). Sections of great importance according to this algorithm are summarized by calculation of clusters and selection of one “representative” keyframe for each cluster. In Fig. 1 keyframes are indicated by a small blue triangle beneath the timeline.

Figure 1: mBase visualization technique from Parc Xerox

One big advantage of this technique for generation of visual summaries is the fact that different and robust algorithms for keyframe extraction are available and the process is fully automatic. This qualifies this technique for processing big video archives and a great range of different video material. On the other hand generated video summaries may consist of arbitrary and strongly varying quality because no knowledge at all about video

content has been applied in the process of keyframe generation and the assumption that strongly differing frames indicate sections of great importance will barely be proofable.

Other techniques try to summarize video content through application of formal icon languages (see Davis, 1993, 1995). Icons for different abstract spatial and temporal relations and objects are designed and attached to sections of the video sequence (e.g. arrows for description of moving directions or icons for different abstract geometric shapes). Multiple icons in different semantic hierarchies can be attached to the same section or to overlapping sections which can interactively be switched in between by the user. One major drawback of this approach is the fact that such systems have to rely on a comprehensive set of icons universally enough for different appliances. New icons can only be produced by graphically skilled persons, therefore extension of expressing capabilities is expensive and complicated. Furthermore quality of visual summaries depends strongly on intuitive design and correct assignment in different abstract description hierarchies of icons.

Different approaches also exist for representation of more technically motivated descriptions of video sequences. These techniques often determine different automatically calculated information, e.g. brightness, colour histogram, camera movement, and produce visual, timeline-based representations of video sections for supplementary presentation together with the described video sequence (see Tonomura et al., 1993, Ueda et al., 1993). Such representations do not include semantic information and can therefore be neglected for the following considerations.

3. A structured approach to video modeling

Systems may generate substantially better summaries, if they can rely on manually or (semi-)automatically provided structuring information. This information can be used for comparison with important events in the video stream thus inducing a structure on the video sequences. Such a process is naturally strongly dependant upon the type of the recorded video streams but nevertheless it is a feasible way for recordings of lectures or discussions which are of primary interest for the scope of this article. Here such important events may consist in recording the timestamps of slide changes or of sections with different speakers during a discussion.

For the structuring information needed a priori one can think about e.g. taking the prepared outline of the lecturer or agenda of the discussion leader. With this structuring information one can identify different, coarse grained semantic blocks by the end of the recording.

This section wants to give guidelines and algorithms for generating visually rich and intuitive summaries of video sequences which can be refined interactively by the multimedia author and improved by linking additional material to the visual representation.

a. Automatic vs. pragmatic approach

Ideally we would like to have comprehensive and robust algorithms for scene and video object detection in order to construct semantically correct summaries. For example if the lecturer shows a physical object we would like to have algorithms which detect this event and - even better - which also categorizes the shown object based on an existing domain ontology. Furthermore reliable speech recognition and speaker detection would help a lot in automatic construction of video summaries. Unfortunately systems partly implementing such features solely exist as research prototypes. Nevertheless some automatic detection and recognition techniques are now robust enough for utilization in automatic video summarization applications (e.g. algorithms for keyword spotting in recorded sequences, see Srinivasan et al., 1999).

b. Visualization of structured video data

An often used metaphor for visualization of video sequences is the “film strip”, a concatenation of small images captured at different positions from the corresponding video stream (see Fig. 2). For longer sequences there are normally fewer images captured per time unit or there are means for interactively choosing the presented resolution and time interval (e.g. by scrolling the film strip along time axis). This visualization method has the disadvantage that video sequences can not be presented as detailed as necessary when we need to have a global view onto the visualization at the same time. Indeed video strips can be cut and hierarchically arranged in different temporal resolutions but this approach makes it difficult to intuitively understand global relations between video sections. Furthermore this visualization will definitely be difficult to overlook if additional materials with relations to other sections of the video have to be visualized.
i. **3D visualizations for video sequences**

In the following section this article wants to introduce techniques for intuitive visualizations of video sequences in 3D virtual environments. One advantage of this kind of visualization can clearly be found in the greater information area compared to conventional 2D approaches. Thus more accompanying additional information can be made available and temporal and causal relations can be understood more easily. But navigation in such 3D virtual environments can be quite complicated with normal input devices (e.g. mouse, keyboard), so great importance has to be given to the support of extended navigation mechanisms.

ii. **Navigation and information support**

Supporting interaction and information mechanisms may consist in intelligent navigation support based on the knowledge of what is presented in the video stream. Therefore we can develop methods which support

1. navigation in virtual space through absolute, relative and content-based time specifications (e.g. "go to the first discussion");
2. navigation through interaction with presented video strips and automatic "moving" of the viewing platform to well-suited places.

Therefore navigation support methods have to determine the right positions in virtual space for arbitrary time specifications and additionally have to compute well-suited, context dependant viewing directions and angles into the 3D scene.

iii. **Visualization metaphors**

Visualizations of complex structures are heavily dependant upon intuitive visualization metaphors. Consequently they contribute a big part to usability of the selected visualization, together with the definition of the meaning of available dimensions in the virtual environment.

1. **Dimensions and arrangement in 3D video spaces**

For representation of video sequences in 3D virtual spaces this article suggests the following arrangement of semantic objects: Video strips of sequences in different temporal resolutions are computed (this can be done during recording time or interactively on demand) and scaled to fit the selected temporal resolution of time. These video strips can then be arranged in virtual space according to the following criteria:

- The X axis of the visualization is interpreted as time dimension.
- The Y axis is used for video strips in different temporal resolutions which are arranged in hierarchical ordering. In order to maintain temporal continuity, video strips are turned by an individual factor (depending upon their length) into Z axis direction. Therefore temporal refined video strips of specific sections are not aligned in parallel to the main video strip.
- The Z axis is dedicated to visualizations of additional material (e.g. slides) or semantic relations which are pointing out of the context of the currently authored video sequence.

In order to keep this arrangement easy to survey the recorded sequence is split into several sections which are visualized side-by-side as semantic spheres. Relations and interdependencies between those spheres are shown as labled, directed arcs which are connecting corresponding semantic spheres.

This approach can be an exceptional advantage if sequences with strong interdependencies are visualized. By choosing from different metrics for positioning of video sequences in virtual space, dependencies between visualized segments and importance of those segments may be emphasized as needed (see Frécon & Smith, 1998).

2. **Variation of presented level of detail**

Selection of different temporal resolutions for video strips allows a context dependant variation of presented...
detail information. Assumptions about importance of sequences based on the presented level of detail may be stated: the more detailed a sequence is presented, the more important it is for the visualized video stream. Furthermore the extent of presented information may be adapted by variation of the viewing angle onto the virtual scene.

More detailed visualizations of certain segments may be calculated on demand if the author wants to zoom further into the scene. This concept is normally referred to as a semantic magnifying lens (see Gupta et al., 2000) which allows to present arbitrary levels of detail depending upon user interaction.

3. Principle of locality

The position of the virtual viewing platform in the 3D universe can be changed context dependantly in order to present relevant information in the foreground or in short distance of it. Selection of a temporal or semantically defined position in the presented visualization implicitly determines position of the viewing platform as well as viewing direction into the scene.

4. Cyclic refinement of semantic information

Up to now no statements about the problem how different video sequences may be identified for visualization have been made. Following we suggest a model of cyclic refinement of structure information based on a suitable domain ontology. We assume that an intuitive visualization easily allows to detect deficits in attribution and categorization of presented video sequences. Such sequences can then be attributed in more detail by interaction with the video author. Necessary information about meta data is acquired through usage of a shared and cooperatively extendable domain ontology for teaching and presentation resources.

a. General process model

The proposed model may be seen as a continuous balancing of structured attribution of a recorded event represented by a directed graph with its corresponding 3D visualization. Temporal sections in the video stream are compared to semantically defined segments induced from the directed graph representation, based on timestamps of easily identifiable events acquired during recording. This brings together two different modeling techniques:

1. Semantic modeling of content based on directed graphs.
2. Modeling of temporal sequences based on timestamps of easily identifiable events.

Combination of these modeling approaches gives us a visualization of temporal media that may be refined interactively. The general process model reflects ideas from the waterfall model of software development (see Fig. 3).

b. Preparation of recording

Process model presumes that the recording is planned and subdivided into - at least - a coarse grained structure. For recordings of lectures and seminars this can be done e. g. by specifying chapters and relating slides which are to be presented. For discussions normally an agenda will be prepared and made available with additional material for each participant.

Once the structure is conceptionally planned it must be designed by using a description language capable of expressing hierarchical decomposition and attribution and which can enforce structural and perhaps semantical integrity. Well suited for this purpose are models based on notations from the Resource Description Framework (RDF) specification and the RDF Schema (RDFS) recommendation of the W3 consortium. The XML-based notation specifies notions of objects, concepts and relations for semantic description of documents. Furthermore construction of different concept hierarchies is supported by subclassing of objects and relations. By specifying a semantical validating RDF schema for the structure description, syntax as well as semantics of the designed...
description can be checked.
The result of the initial structure specification consists of a RDF description of the recording. Temporal relations (see Allen, 1983) between identified sections and concepts are implicitly specified due to the hierarchical decomposition.

Figure 3: Waterfall model of semantic attribution

c.Realization of recording

Basic information for the dynamic model is acquired during realization of the recording. This may partly be done automatically (e.g. recording of timestamps for slide changes of computer-based presentations), but manual approaches are reasonable as well if suitable support systems for the manual recording of timestamps for interesting events are available. Such support systems must be capable of establishing relations based on coarse grained structuring information from the preparation stage, between events and content. Systems also must be able to record efficiently and flexibly additional unplanned activities and events.

The more detailed the recording of the dynamic model is done “online”, the more precise and intuitive visualizations can be calculated. This means better performance for technical implementations, because visualizations of sections which semantically belong together may be already calculated during recording.

d.Authoring

After the end of the recording enough information has been collected for a first structured visualization of the video stream (for instructions how to do this cf. section Visualization of structured video data). Essentially three different tasks based on this visualization have to be performed:

  5. Interactive refinement of attribution.
  6. Definition of temporal and semantical relations.
  7. Attribution of unplanned sections.

In order to support the author in accomplishing these tasks, the system should create and manage a bi-directional linking between video player and visualization: changes of the time position of the video player are reflected by transformations of position and viewing direction in the visualization. Navigation in the 3D environment modifies time position of the video player respectively. Navigation support methods for identifying video sequences by absolute and relative time specifications must be provided in order to assist users in working with the 3D visualization.

For the process of refinement of attribution temporal and spatial areas have to be specified in the video player as well as in the visualization. In the visual summary this can be achieved by marking a specific region of 3D environment which corresponds to a sequence of interest in the video stream. This capability is also needed for creation and management of temporal and semantical relations which can be divided into relations between different sections of the same video summary and relations to/from other video summaries. Furthermore references to additional multimedia materials are also linked to temporal and/or spatial sections of video sequences.

8.Realization of a prototype

In order to proof the proposed ideas a prototype for the 3D visualization is currently implemented in Java, using optional APIs like Java Media Framework (JMF<sup>5</sup>) for support of playback and recording of video streams, and Java 3D<sup>6</sup> for realization of the 3D virtual environment for video strips. The prototype includes views for visualization of the hierarchical structure of XML files, a 3D virtual video world for visualization of video sequences as video strips and a row for multiple video players (for each visualized recording there exists one separate video player). Calculation of the visualization of video strips is done according to specifications found

in the input XML files. Interaction with the video strip can be done by selecting a video strip in the 3D visualization: the corresponding video player then jumps to the specified position in the video sequence and plays it.

Prototypes of support systems for preparation and structuring of the recording have also been implemented. Work is going on for an import of structure and data of a Microsoft PowerPoint presentation (e.g. slides as images, slide topics). Recording of slide change events and camera movements is done by embedding PowerPoint as a COM server into an event recording application.

With improved implementations of those prototypes we are planning to start recording of a computer science lecture in mid 2001 for a period of two semesters. Results of the processing will be presented to attending students of the lecture who are supposed to use the visualizations for preparation of examinations or as an additional source for information.

9. Summary

This article has introduced an approach for a structured, semantic visualization of recordings of lectures, conference talks or discussions and similar kinds of video recordings. It suggests to integrate preparation phase tightly with the final visualization by defining a semantic structure and match it with timestamps from the dynamic model of the recording. The computed visualization is interactively refined in order to match the imagination of the video author.

For visualization of video sequences a 3D virtual video world is suggested. Video sequences are represented as video strips which are arranged appropriately according to a presented algorithm. This approach leads to a comprehensive and intuitive visualization of video sequences.

Abstract: We propose an architecture of a multimedia repository for online educational content, that helps to manage the continuously growing amount of electronic learning material. The multimedia repository can be embedded in educational learning environments or in Content Management Systems. It is designed to manage a large amount of interactive multimedia and hypermedia learning material, provides a centralized access to all stored content, preserves the physical quality of the learning material and offers functions for content based searching, browsing and retrieval in different qualities, depending on the users environment and location.

Introduction

As more and more educational content becomes digital and will be delivered and presented electronically some questions arise such as how to administer the continuously growing amount of electronic content or how to manage the large variety of electronic presentation techniques and storage formats. Each author and provider of electronic learning content will be forced to build up a smaller or larger archive, in which the whole electronic learning content will be stored. The main purpose for this need is the wish to preserve the technical quality of the content, to keep an overview of all content available and of course to reuse already created content in new productions. But how can such a content management be done? In order to find an answer, we divide the problem how the management of electronic content can be realized into a few smaller problems such as:

- How to document content it in the right form, so that something can be searched for by using this documentation
- How to store content in the right way, so that it can be found again
- How to store content in the right format, so that some parts of it or the whole content can be retrieved and reused
- Where to store content, so it can be accessed instantaneously for retrieval or reuse

To solve this storage management problem, a general management of content storage has to be introduced. One proposed solution can be realized as a part of a Content Management System (cf. Kleinberger, Müller 2000.1 and Kleinberger, Müller 2000.2), which is responsible for the management of digital assets, the storage of digital media, the access to stored media and the support of retrieval, reuse and production processes.

How does the content now look in modern education? New learning material will be built up more and more of multimedia and hypermedia content-(cf. Steinmetz 2000 and Holzinger 2000). We deal with texts, pictures and graphics, with hypertexts, multimedia and hypermedia but also with active objects like applets, servlets and scripts because learning is still mostly an interactive process. All these objects, media types and their combination can be summarized in the term “essence”, while all descriptive and administrative data about essence accordingly are the “metadata” (see definition of content, essence and metadata in Kleinberger, Müller 2000.2). content is according to this definition the sum of essence and metadata.
Typically the metadata is carried together with the essence to provide easier searching and access to the essence. Especially in the case of multimedia or hypermedia objects, these objects are coded in a way which is difficult to be indexed or to be searched for. Often there are logical relationships between the essence and the metadata such as timecode references. For example, an abstract may relate to a particular time span in a video material, and a usage restriction will usually also apply to a particular time span in a video material. As a result the content now not only consists of only one object, but is built up from a variety of essence and metadata objects.

In consequence a Content Management System has to provide a storage management as a core component which stores all the objects the content in eLearning is built up from: Essence (multimedia and hypermedia) and metadata (structure and presentation information). There have to be different storage areas according to different requirements for the objects stored in these areas. Metadata and essence objects have different characteristics such as access method, object size, access time etc. and therefore need different treatment.

We can summarize the requirements for a storage management for hypermedia and multimedia eLearning content in the following terms:

- Storage of multimedia eLearning content
  - Store content, consisting of different essence and metadata objects
  - Store multimedia documents consisting of multiple formats and multiple physical objects
  - Provide different storage areas with different access methods for different kinds of essence and metadata
  - Examples of content: audio, video, animations, text, pictures, hypertext, hypermedia
- Flexible access to the stored documents for retrieval and reuse
  - Allow proper documentation of essences in a generalized manner
  - Provide indexing mechanisms to extract metadata and semantic information automatically
  - Provide advanced search capabilities for essences using extracted metadata information
  - Offer filtering and scaling methods for retrieval according to available bandwidth or location
- Integration in teaching and learning environments
  - Decentralized implementation with transfer and replication mechanisms
  - Remote access facilities with broker mechanisms
  - Integration of rights management

In the following section, we describe one possible solution of a multimedia storage management for the application domain eLearning, which bases on a multimedia repository architecture.

**Application domain eLearning: The L3 project**

The L3 project (L3 stands for Life Long Learning (cf. L3)) is a project founded by the German government with the goal to create a technical and organizational infrastructure for a lifelong further education. The solution approach emphasizes two different points: On the one hand the creation of an educational infrastructure which uses new media efficiently and can be used by all interested people, independently of their education or social position. On the other hand the development of organizational structured and economic business models with which the developed infrastructure can be operated at a medium term.

The central component of the educational infrastructure is a multimedia repository which manages online educational content, especially multimedia content like audio and video. The educational multimedia content consists of learning objects which can be structured hierarchically in courses and lessons. The actual relationships between the learning objects are defined in a course structure definition which is represented in XML. Metadata for the learning objects is represented in an XML notation of the IMS metadata specification version 1.0 (cf. IMS) which is based on the IEEE LOM definition 3.5 (cf. LTSC) with some changes and extensions. We have extended the LOM definition ourselves with the structures necessary to store all metadata information not already included in LOM, i.e. the course structures. Media objects are references out of the metadata objects to physical media objects stored in the multimedia repository.
Repository Architecture

The proposed multimedia repository architecture in L3 takes care of all requirements for a multimedia storage management given above. It provides different interfaces to both end user applications and additionally to components of a Content Management System which is embedded in the learning environment. The basic features of the multimedia repository provided by its internal functions and interfaces are:

- The management of a large amount of interactive multimedia and hypermedia learning material
- The provision of a centralized access to all stored content
- The preservation of physical quality of the learning content
- The provision of functions for content based searching, content browsing, retrieval and reuse

To fulfill all requirements for a multimedia storage management, the internal structure of the multimedia repository has been separated into dedicated components, each of them realizing certain functions and providing special interfaces. A general classification into two component groups can be made due to the different load profiles the multimedia repository is faced with for metadata and essence.

On the one hand the multimedia repository has to do the work of a classical database system. It has to handle a great amount of user load and to answer a lot of user inquiries with adequate computing power. This can be compared with a typical database load profile. On the other hand a very performant storage system is required, providing capability of handling large multimedia objects, managing a large storage area (typically in a file system) and providing high data throughput over network and audio/video interfaces. This can be compared with a typical file server profile, here with auxiliary interfaces such as streaming servers and audio/video encoders and decoders.

In classical information technology both load profiles, database and file servers, are handled by different system configurations and software solutions. For example database servers are typically well equipped with a huge main memory and computing power (e.g. multiprocessor) whereas file servers are well equipped with a performant hard disk system (e.g. Hardware-RAID-Controllers, FC-interfaces, HSM-Systems, Caches) and fast networking interfaces.

To realize a repository for multimedia objects, both load profiles have to be addressed. Hence the multimedia repository is internally organized into at least two different components according to the classification: a repository addressing the database load profiles and a media server addressing the file server load profiles. Figure 1 summarizes the basic features of the two components:

<table>
<thead>
<tr>
<th>Load Profile</th>
<th>Software</th>
<th>Requirements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repository</td>
<td>Many accesses, Computing Intensive</td>
<td>Computing Power,</td>
</tr>
<tr>
<td></td>
<td>Database, Fulltext Search Engine, Web Server</td>
<td>Memory</td>
</tr>
<tr>
<td>Media Server</td>
<td>Less accesses, High I/O Throughput</td>
<td>Performant Storage, High I/O Throughput</td>
</tr>
</tbody>
</table>

Figure 2 shows the general separation of the two components repository and media server.

The multimedia repository stores all the metadata information about the educational multimedia content. This is the descriptive metadata for the educational content like author, theme and any other metadata information like special attributes for certain domains. Because an educational content object is mostly embedded in an environment, compound documents consisting of content objects can be structured into a course. The course structuring information is stored in the multimedia repository a metadata information, too. All metadata information can be queries by XQL or searched for with a fulltext search engine. The multimedia repository provides adequate services and interfaces for these functions.
On the media servers side an essence manager is responsible for the management of the media objects the learning object refers to. The essence manager includes a metadata management which stores the technical metadata about the physical media objects. Since a media object can also consist of more than one physical media object (e.g. files), the essence manager furthermore manages containers, which aggregate physical media objects into material lists which are then referenced by media objects. Physical media object can be stored in different formats and different bandwidths, e.g. RealVideo, MPEG-1 or MPEG-2. Formats are distinguished in stream lists which point to the location of the physical media objects as files in a file system. Retrieval access to a physical media object can now be gained through a corresponding stream server. Figure 3 shows a more detailed view on the repository and media server, in which the media servers components stream server and essence manager are detailed.
There are different stores for the learning objects, the media stores and the metadata for essences. Objects are stored in a database management system, file system, HSM-System or in a storage management system. Various services like import/export services (for importing and exporting complete packed learning objects (courses) including metadata and essences into and out of the multimedia repository), a web retrieval service (for retrieving media objects) and a Linda interface (cf. Schoenfeldinger 1998) (for accessing all administrative and metadata related functions) are provided to support authoring and course packaging tools, mediators (which support course navigation) and eLearning client applications.

In a typical installation both components, repository and media server are installed on separate computers, each built up of the appropriate hardware components in computing power, main memory, hard disk storage and network interfaces depending on the load profile.

 Logical structure of eLearning content in L3

In L3 the learning objects are structured hierarchically with a top course element. A course consists of several lessons. To each lesson a content and a test is assigned. Content and tests refer to media objects. The actual relationship between these objects is defined in a course structure, which is used by a mediator application to navigate in between the course.

Media objects can either be references to local physical media objects, which are stored in the media server storage, or external media objects. For local media objects the media server provides the suitable interfaces for accessing and retrieving. External media objects reside outside the multimedia repository. They are referenced by an URL. It is the responsibility of the mediator application to interpret this references correctly and to access the external objects via HTTP on an external web server or file system. The media objects point to one or more physical media objects, depending on the physical representation of the learning content. This can be any kind of object type including audio, video in different formats and qualities, keyframes, texts, web pages, etc. Figure 4 explains an exemplary structure of a L3 learning object and the allowed references to physical media objects:

![Course Structuring in L3](image)

Figure 4: Course Structuring in L3

In the L3 object model all elements belonging to one course form one learning object. Every part of a learning object is assigned the corresponding metadata. All metadata information is represented in an XML mapping with appropriate Document Type Definitions and validating parsers, that check valid structures. Metadata objects are
tagged with GUIDs (Global Unique Identifiers), which identify each object uniquely. Physical media objects are distinguished in type via mime-types and also identified via GUIDs.

Conclusion

The multimedia repository can either be embedded in educational learning environments or in Content Management Systems. The general software design is developed in layered building blocks, in which each layer consists of a set of services offering CORBA-Interfaces to other services, system components or client applications (see Thomas 1999). This allows for a decentralized implementation, which is very important in learning environment where the users (learners) typically do not stay in the same place as the learning content is developed or stored. If there is to be a division in learning centers and service centers analogous to the L3-project (cf. L3) there have to be:

- Transfer and replication mechanisms for moving content between centers
- Remote access facilities with broker mechanisms for transparent access wherever the content lies
- Filtering and scaling methods for retrieval according to the available bandwidth between leaning centers and service centers
- Rights management for regulating access for learners but also for providers of content

Answering Authentic Needs by Using the Internet: From an Instructional Setting to the Real World

Esther Klein-Wohl
English Unit, The Open University of Israel
esterkl@oumail.openu.ac.il

Abstract: Internet based learning offers unique opportunities to expose teachers and pupils to authentic learning experiences at different levels of interactivity, and facilitates enquiry while emphasizing the practical implications for production. It also promotes the need for contact with the outside world and culture, and recognises the relevance of knowing how to operate new technologies. The act of using the Internet in teacher training and in school instruction assumes a model of education which is conducive to the construction of knowledge and which has relevance to what can be useful and productive in dealing with authentic needs. This presentation describes a model of an Open University in-service methodology course for teachers of English as a foreign language which teaches a content area and represents a model of instruction. While focusing on the content of the course, the participants are exposed to a delivery system which includes features they can easily adapt to their own teaching environment. The rationale is based on the construction of teachers' knowledge, an awareness of the importance of a teaching paradigm that models teaching and learning, and the development of the capacity to face the real world both within and outside the instructional setting.

We are in a period when strong efforts are being made to develop a new kind of professional community in education - one whose ethos is built around the continuous study and improvement of teaching and learning, and the direct application of knowledge to real life situations. Educators are attempting to design environments conducive to the construction of knowledge which have relevance to learners' authentic needs.

In such a constructivist view of education, we aim at developing a learning environment which facilitates the enquiry of learners but also emphasizes the practical implications for production, both in the immediate setting and in the long term. Within the general framework of constructivism, knowledge is emerging rather than static, learning means seeking meaning within one's expanding frame of reference, building knowledge and checking it against the concepts of others, and connecting what is being learned in the instructional setting with real life demands (Richardson, 1997).

The theoretical underpinnings for such a view are that new concepts can have multidimensional effects: They can change ways of organizing knowledge and can provide new material for associations and problem-solving (Ellis, 1993). Meaningful learning is also likely to go beyond the classroom and provide skills and strategies that will impact future actions. A further underlying assumption is that the design of a useful instructional model must incorporate a computer environment of some kind, since we strongly believe in the increasing importance of computer literacy for functioning in the real world. Indeed, one of the ways of bridging the gap between the instructional environment and life outside the classroom is knowing how to function with the technology.

Rationale: The rationale behind the design of this Open University in-service methodology course for teachers of English as a foreign language is based on the construction of teachers' knowledge, an awareness of the importance of a teaching paradigm that models teaching and learning, and the development of the capacity to face the real world both within and outside of the instructional setting. We
have created a course based on a task-based syllabus (Long & Crookes, 1992), which is teacher-directed in its conception but highly learned-centered in its actualization (White & Weight, 2000).

A salient feature of teaching is that it requires continuous adaptation and demands new learning in order to solve the problems of each moment and situation. Therefore the process of knowing how to transfer pedagogical skills and strategies from one context to another is essential to help teachers solve problems and reach their students more effectively. Horizontal transfer refers to the conditions in which a skill can be shifted directly from the training situation. When the work and training settings are very similar, a skill can usually be transferred "as is" with little additional alteration and learning. On the other hand, if the two contexts are very different, vertical transfer is needed. Vertical transfer refers to conditions in which the new skill cannot be used unless it is adapted to fit the new conditions wherein an extension of learning is required before the skill can be applied. Such transfer is more likely when there is a greater gap between the context of training and the conditions of the new situation: the newly learned skill being different and thus not easily fitting into the new situation. The distinction between horizontal and vertical transfer refers to the amount of adaptation and reinterpretation that is necessary if the skill is to be effective in the new situation. Familiarity is the key. The greater the degree to which a new skill fits into already familiar patterns, the less adjustment will be needed.

Because English is the subject that our experienced teacher trainees teach, we have been able to take advantage of the globalization of English and the fact that it has become the main medium for international communication and technology (Kern, 2001). English provides us with a window to the real world as well as with additional opportunities for accessing information. As a result, we have created a framework which links pedagogical perspectives on teaching and learning to elements of Internet input in order to achieve our particular desired educational outcomes.

Design of the Course: The 15-week course is transmitted via the Internet. It consists of weekly readings from selected professional journals provided to the teachers in a printed anthology, and of questions related to these readings delivered through the Internet. Some of the questions focus on the theoretical principles discussed in the articles while others are application tasks which the trainees are required to think about, plan and implement in their own teaching context. The trainees' reflections and reports about the practical tasks, the presentation of individual and of collaborative projects among participants, the discussions, as well as all other interactions are asynchronous and occur on-line. Depending on the nature and the purpose of the communications, some involve the trainees only while others include the trainees and the instructor.

The participants are responsible for finding and sharing Internet sites and articles which are topically related to the subject matter at hand and which they feel will enhance their knowledge and increase their teaching repertoire. In addition, three areas which may be problematic for teachers are selected on the basis of negotiation with the trainees. Each chosen area serves as a topic for on-line discussions for a period of four weeks, with the specific aim of finding appropriate solutions that will emerge from sharing ideas and drawing applicable conclusions. At the end of the course, trainees submit an individual portfolio which includes some of the above and a journal in which they are asked to reflect on their experience of the course and its practical relevance to their teaching context.

The design of the course is based on a Presentation, Practice and Production (PPP) model (Willis, 1996). Planning the presentation of the content, getting the participants to practice and execute the required tasks, and eventually take what has been learned beyond the framework of the immediate environment into a wider world seems to reflect a sensible definition of an educational mission. In other words, we take the view that one of the secrets of successful learning lies in the process of transfer -- the effect of learning one topic or skill on another situation.

In this context, the teacher trainer presents the course content, encourages the teacher trainees to practice what is being learned within the framework of the course, and hopes that eventually some of the elements of the course, including the strategies and skills presented, will be utilized (in horizontal transfer) adapted and perhaps even reproduced (in vertical transfer) by the trainee in his/her professional world (as a teacher) and personal world (as an Internet user).

Similarly, the teacher prepares and presents materials in class, encourages the pupils to practice what is being learned in the school, and hopes that in the future some features of what has been taught and learned will be useful in the pupils' lives outside the classroom. The presentation and practice stages...
feature mostly in the school setting while the production stage is expected to first occur in the instructional environment, and eventually filter through beyond that environment into the pupil's big wide-world. In other words, pupils will operate first on the basis of horizontal transfer and then proceed to a vertical transfer of the skills and knowledge they have acquired.

How is this model of teacher training for a Methodology course for teachers different from others? The method of delivery via Internet not only teaches a content area - Methodology for teaching English as a foreign language - but it also represents a model of instruction for their own use in their classrooms. While focusing on the content of the course, the participants are exposed to a delivery system which consists of features they can easily adapt to their own teaching environment; at the same time they are expanding their personal horizons regarding the use and potential of the technology.

Flexible Course Configuration based on a Modular Course Model
and a New Reference Mechanism

Anette Knierriem-Jasnoch
IKTT
Marktplatz 9, D-64711 Erbach
Germany
Anette.Knierriem@zgdv.de

Abstract: This paper presents a new course model for IT-based flexible teaching and learning. In particular, the re-use of learning material and the configuration of goal-oriented and learner-adapted courses are addressed. IT-based courses should be no longer monolithic but a flexible traversal of course modules. The emphasis is on the introduction of learning modules dedicated to the characteristics of a learning process, and a new method to configure flexible courses on the basis of these learning objects. In order to fully support the re-use of learning material, meta data are added to the learning objects. Therefore, standardization activities like the Instructional Management System project, the European ARIADNE project and the IEEE Learning Objects Metadata are considered.

Keywords: IT-Based Learning, Learning Modules, Course Configuration, Meta Data

Introduction

High-quality electronic learning material has to be multimedia, based interactive, individual, and adaptable to the learner’s knowledge, learning goals and learning progress. These demands cause high development costs and hinder a widespread usage of electronic learning environments. The production costs can be reduced by sharing them among a large user group. To fulfil the high quality on one side and the requirements of widespread use and re-use on the other side, electronic learning material has to be modular and courses have to be a flexible traversal of course modules. In the following, an object-oriented course model with a new highly flexible reference mechanism is introduced. At first, the basic concepts and the different kinds of learning modules are described. Then, a new method of referencing these learning modules by immediate, conditioned and indirect references is introduced. At least, a meta data model illustrates how meta data may support the re-use and in particular the dynamic use of learning modules.

The Basic Concepts of the Course Model

The basic structure of the course model is shown in Fig. 1. Structure objects, in a micro view, define a single course segment which is a well-defined composition of content, presentation and interaction. In a macro view they define the course structure and the combination of several course segments to larger course units. A structure object may point to any number of further structure objects. The method nextSegment() denotes the next course segment. Furthermore, structure objects may reference elementary learning objects, interactive learning objects, interaction objects, and presentation objects.

The class elementary learning objects describes the monomedial learning content: a concrete content is combined with a specific object. Elementary learning objects send messages to presentation objects to display the contents. The method selectContent() extracts the content that corresponds to the actual course configuration. The presentation objects typically display the content of elementary learning content in the learning-frontend. Therefore, the method present() is used. The interaction objects handle the interactions with the content and are used to control the course. Interaction objects may send messages to all other objects. These messages may have different
intention, e.g., for an elementary learning object it may be a content selection and for an interactive learning object it may be its activation. Each message is also sent to the corresponding structure object in order to track the actual state of the course segment.

The interactive learning objects are an integrated combination of elementary learning contents, presentation and interaction objects. In particular, they are used with highly interactive learning content; the interactions with the learning contents have to be explicitly programmed. By building an adequate class hierarchy for the single course model elements, the specifics of the classes (text or graphic, button or slider) are first realized within the class itself. Thus, a functionally methodical interface can be created which hides from the implementation and platform details and from the properties of a special medium. Therefore, the interface is extensible, reduces the amount of interfaces and supports the author by his original task: producing content and configuring courses.

The Learning Modules

Elementary Learning Objects

The elementary learning objects contain the basic knowledge of the learning units. They are atomic, monomediai modules, e.g. text, graphics, audio or video modules, typically developed with standard editors (MS Word, Adobe Photoshop, etc.) and stored in standard or quasi-standard formats. In (Tritsch 1996), a reference model for tele media is suggested which may serve as a basis for describing and structuring the elementary learning contents; it is extended within this course model.

The new course model suggests a clustering of elementary learning objects and provides a so-called container object, that may contain several elementary learning objects for a well-defined topic, only differing concerning the target groups and the learning levels. A schematic realization of this mechanism is shown in Fig. 2. Within a textual content, different paragraphs can be extracted (1); for graphics, different pictures will be stored (2); and a video can serve all user groups (3). The container object provides for the content, whether it consists of a complete file (3), is extracted from a file (1), or is chosen from several files (2). The content selection is hidden...
Interactive Learning Objects

In contrast to the elementary learning objects, interactive learning objects do not need external presentation objects and allow a direct manipulative interaction on the presentation area assigned to the learning content. Thus, these objects are especially appropriate to gain knowledge by explorations. The medium computer is much more used by these contents, while the combination of elementary learning content and presentation objects corresponds more to the traditional way of conveying learning content. Combining these two facilities in one common course model supports both: the classical way of conveying knowledge and the new possibilities supported by the medium computer.

Interactive learning objects offer the methods of the elementary learning objects, the presentation and the interaction objects, and are an aggregation of these three object types. Because of the inherent interactivity of the learning content, the content and the specific behavior of these objects have to be programmed by the learning material author. One possibility is the realization of these objects as Java applets; they can be used in several environments and are, in principal, platform independent.

Interaction Objects

Interaction objects are all the classical interaction elements as they are known from the user interfaces (buttons as the superimposed concept for push or toggle buttons, sliders, etc.). Typically they are hardware-oriented and thus platform dependent. Solving the platform dependency is done by the learning-frontend which means that the concrete instance of an interaction element is realized when it is displayed. Interaction objects within the course model only represent the functionality and do not directly correspond to the interaction elements at runtime. They can be seen as virtual input devices.

Presentation Objects

The presentation objects provide the functionalities to present the elementary learning content. This can be realized in different ways, from plug-ins up to integrated and almost monolithic solutions whereby the presentation unit is part of the system. Therefore, a message channel is established between the elementary learning objects and the corresponding presentation object, and a method within the presentation object is addressed. The course model itself hides these realization aspects. Thus, the courses are portable to several IT-based learning environments and may follow different implementation paradigms. The presentation objects can be seen as virtual output devices.

Structure Objects

Structure objects are used to determine the course structure and the course control, i.e. the sequence of the learning content. Therefore, they contain three elements:
- references to the used objects (in particular elementary and interactive learning content),
- information concerning the layout and
- a state machine for the control.
A detailed discussion of the references follows below. The layout information for the visual positioning of
each object is also contained in the structure object. The positions are transferred during the activation of the referenced object. A state machine is also part of the structure object. Within this state machine, the sequence of the course segment is anchored and it serves for the control and the monitoring of the learnflow.

The Reference Mechanism

So far, the basic concepts of the course model and five types of learning modules have been described. Within this chapter, a new mechanism to combine these learning modules in a flexible manner is introduced. Referencing learning modules in an object-oriented context means the establishment of relations between objects. If these objects are persistent, i.e., they are stored in a data base, the referencing can be done by referring to unique identifiers (Object Identifier - OID). The main problems of this "classical" kind of referencing are:

- Unidirectional relations
  - Mostly, the references are unidirectional, which means that they point from the referencing object to the referenced objects. The objects do not know who references them (comparable to the hyperlinked documents in the WWW). If objects are deleted, it is hard to find and delete all links that point to them.
- Location dependent referencing
  - Because the referencing object wants to reference a dedicated object, the object's location has to be known and may not change. Thus, a migration from one data base to another is not allowed.

These problems can be solved by so-called "indirect references". This means that objects are referenced by a description of the desired object based on unique qualifiers, e.g., the topic of the course, the context and the target group. The realization of indirect references is supported by meta data. Meta data know their objects (instances) and are able to resolve the requests without "visiting" the specific object. Thus, meta data have to be independent objects with an anchored semantic.

These independent meta data objects may be used in search requests to treat a specific learning content. For a structure object it should be hidden whether the referencing is performed directly or indirectly. Thus, a direct integration of the query into a structure object is not desired. Therefore, and also to handle direct references bidirectional, the references are modeled by an independent class, which is used by a structure object to build course structures. The advantage of this kind of referencing is the "best-in-class" approach, which means, that the best fitting object is found when the references are resolved. Thus, the possibly best knowledge conveyance is guaranteed. This approach may cause problems because reference resolving may start when a course segment is activated and thus runtime problems may occur. The effects can be decreased by suitable implementation methods and tools. Referencing an object within a structure object is done by the abstract super class Reference. For elementary and interactive learning objects as well as for structure objects this reference is resolved by an object of the classes directReference or indirectReference, and for presentation and interaction objects always by an instance of the class directReference. As shown in Fig. 3, the class directReference is further divided into the classes immediateReference and conditionedReference. While an immediate reference directly establishes the relation to the target object, a conditioned reference points to several alternative target objects. Theses are identified by a first order predicate logic and imitate the case construct. Thus, direct references may point to several target objects depending on conditions.

If the course author exactly knows which learning object he wants to integrate into the course, he typically uses an immediate reference and directly names the learning object. If he wants the learning objects to be dynamically chosen, e.g., in dependence on the test result, in dependence on the learner's preferences or in dependence on the learning environment's equipment, he uses conditioned references. Since the conditioned references are a sub class of the direct reference, the author has to specify the conditions and to name the learning objects.

The Meta Data Model

To support the re-use of electronic learning material, a modular learning material structure as developed before is not sufficient. Furthermore, a mechanism is needed that maximizes the goal-oriented usage of the available modules. Meta data are such a mechanism. Meta data are used within the introduced course model to describe the structural and content-specific properties and the behavior of an amount of objects satisfying a com-

Figure 3: Class Hierarchy for the Reference Concept

A single object receives its specific properties while values are given to its attributes. The meta data attributes, their categories and their value domain uses the standards draft proposed by the IEEE working group LOM (LOM 2000), the ARIADNE project (ARIADNE 2000) and the Instructional Management System (IMS) project (IMS 2000).

Meta data are also used for a content-related retrieval of learning objects and are given to each module class described above. Meta data are realized as independent objects and each meta data object points to all related learning objects derived from it. These relations between meta data objects and the related learning objects are illustrated in Fig. 4. The object’s specifics, like its data base or its location are hidden, and in consequence, the data base requests can be formulated independent of the location. In addition to the structure descriptions, the meta data also contain control aspects concerning the learning material presentation. The presentation of learning material requires knowledge of the medium (e.g. the MIME-types within the WWW context) to identify the dedicated program that may display the file. To support context-specific restrictions of the learning modules and its suitability for different knowledge levels, more content information has to be provided. For example, video sequences could be limited to those sequences which are necessary to reach a certain learning goal. These additional properties differ from medium to medium and thus, a medium-adapted support is necessary.

Conclusions

A new reference mechanism to support a flexible and dynamic course configuration was introduced. The usage of immediate references enables course authors to directly address the learning modules they want to integrate into a course. Conditioned direct references also allow for direct addressing but additionally they allow for the dynamic selection of learning modules in dependence on several decisions possibly made during the course traversal, e.g. test results or to learner interactions. Indirect references contain most flexibility concerning the learning modules’ selection but may terminate in uncertainty. To fully use the facilities such a highly flexible reference mechanism offers, it was shown, that courses have to be modular and that meta data may support the flex-
Figure 4: Relations between Meta Data and Objects

Flexible course configuration is a key issue to re-use learning content in different courses and to serve learners with different knowledge and learning goals. The introduced course model may be the basis for the implementation of several IT-based learning systems. It has been partially realized within the DEDICATED Modular Training System (DEDICATED 1995) and the project IDEALS (Lindner 1997). Learning material designed according to the proposed concepts follows the intention of international activities: harmonization and standardization of learning content, learning services and learning technologies (LTSA 2000, PROMETEUS 2000).

Abstract: This is to introduce an on-line drill/quiz making system that can be operated on a Web page. This system can easily and instantly create drill and quiz pages with scoring and log functions to be published on the Internet even by a novice. Drill pages made by the system have been used in our language classes to help the students improve their listening skills. The goal of our research is to make customized on-line exercise pages with an automatic grading function for classroom use, in any subject. Both multiple-choice and fill-in-the-blanks questions, either in English or Japanese, or in any other languages as long as necessary fonts are installed in the machine, can be created by the system. Both the two types of questions can be put together on the same page. The number of questions is limited within ten on one page, but the number of such pages can be limitlessly created, and then several of them can be selectively bound together, also automatically, into one compound drill, which makes it possible to give on-line examinations.

Introduction
We have been engaged in developing systems by which we can make and conduct Web-based on-line examinations and drills. So far we have developed four systems, such as Saiten (meaning grading or scoring in Japanese), Nyushi (meaning entrance examination), Shiken (meaning examination) and New Shiken:
(2) The Nyushi System in 1999 (http://koby.rikkyo.ac.jp/final99)

The drills and examinations created on each of these systems have been actually used mainly in our English classes at Rikkyo University and Mie University. The new shiken system, the last one on the list above is being experimentally used in Kobayashi's English listening classes, to make supplementary review exercises to be given to the students each week, and to be modified into a stable and better system. Some examples can be tried at the following page: (http://toby.rikkyo.ac.jp/english/shiken/shiken.html)

Purpose of our project and research
The purpose of our project is three-fold.
(1) To make an archive of on-line drills and tests to be used on a Web browser.
(2) To make an archive of audio/video materials which can be shared and used on these drills and tests.
(3) To present an on-line drill/quiz creator for free use for anybody, particularly for teachers to easily make on-line drills and exams: We are trying to develop an ideal system by which on-line drills can be made with ease, hoping that teachers in any subject all over the world can make their own on-line drills so that they can share such Web pages of drills on the Internet.

1040
The New Shiken System

1. Functions

Our newest system can be operated by going to a Web page on the Internet. It has functions as follow: (See the Web design below.)

1. The list of all on-line drill/quiz pages
2. The script (source code) of each page
3. The answers to the questions of each page
4. The creator's page to create a single page of drills/quizzes
5. The creator's page to create a compound page of drills/quizzes
6. The log page

Creator's page

Creator's name (4 letters): [entry]
Password: [entry]

Functions
- List of all the pages
- Script of the page (Fill in the the box at the bottom, too with the name of the page)
- Answers to the questions (Fill in the the box at the bottom, too with the name of the page)
- To Create a Single Page Drill (Fill in the the box at the bottom, too with the name of the page)
- To Create a Compound Page Drill (Fill in the the box at the bottom, too with the name of the page)
- Log Page

The name of the page (4 letters or numbers): [entry]

[Next] Confirm the information above and click this button.
Ignore a warning window or message and go on to the next page.

The best function of this system is the fourth one by which more than one single page can be integrated into one compound drill page with the total score suited to it automatically incorporated to the newly made page. On this system, the learners can do the exercises on the pages created by the teacher and they immediately receive their results. The teacher can look at his/her students' results or scores on the log page. Even a novice can use the program by simply going to a Web page where he/she can create pages and they can be automatically uploaded, by clicking the button at the bottom of the creator's page. The drills can be done on any machine with an Internet browser connected to the Internet.

2. Procedure of creating an on-line drill/quiz page by the New Shiken System.

1. The user (teacher) goes to the creator's page.
2. The user copies the example HTML, pastes the HTML in the text box on the page, changes the example questions to his/her own, then the user puts the answers to the questions in each of the answer boxes also on the same page.
3. The user sends the questions and answers in the boxes to the program by clicking the button on the same page.
4. The drill page will be automatically made by the program in our server.
5. The returned message will tell the address of the newly created drill page.
6. The user has a dry run of the page and improves it, if anything is wrong, by repeating the above procedure. The user can refer to the source code and answers of each page preserved in the program when he/she improves it.
7. The user makes as many pages as he/she wants to.
8. The user goes to the page to make a compound drill/quiz page. He/She selects several pages which have been already created, and then clicks the button at the bottom to see the combined drill/exam page.
A Collaborative Learning Support Based on Inference Mechanism of Group Actions and Reactions: Framework and Evaluation

Abstract: For the collaborative learning, it is necessary that computer-support systems should grasp the learning process for deriving answer among participants and coordinate smartly so as to make all participants well-understood. Therefore, our objective is to construct the collaborative learning support system which supports the learning by generating appropriate advices for the learning group according to the situation. In order to enforce the students' abilities to cope with various exercises, to discuss various viewpoints as well as to derive the answer are necessary. So, the extent of discussion as well as the progress of deriving answer are also focused as a learning situation. To handle such learning situations respectively, the resolution derivation scenario and the divergent tree are introduced. In this paper, we describe the mechanism of grasping the learning situation and evaluate our experimental results. The result indicates the effectiveness and gives the perspective for improving our system's functionality.

1 Introduction

Nowadays, Internet and Intranet are very popular and provide a powerful interaction environment without depending on the physical distances among participants. However, there are many problems when such an environment is applied to the collaborative learning as an infrastructure for educational fields. In order to cope with the problems, various approaches/methods have been investigated. For example, as for the construction of cooperative groups, the mechanisms to find the appropriate co-learners according to the students' learning situations or understanding levels were proposed (e.g. Ikeda, et al.[1]). Also, as for the promotion of smooth discussions, several interaction models were proposed for the purpose of detecting conflicted situations or grasping the students' contributions for discussion (e.g. Tedesco, et al.[2]), and so on. These researches provide effective learning environment for deriving answer from viewpoint of promoting interaction.

On the other hand, it is also important to focus on problem solving process in addition to such coordination facilities for interaction. In case that participants tackle exercises attended respectively with right answers, it is necessary that the computer-support systems should grasp the learning process for deriving answer among participants and coordinate smartly to make all participants well-understood. For example, Constantino-Conzalez, et al.[3] introduced a private coach for each student to the learning environment where students discuss solutions to construct appropriate ER diagram. The private coach monitors the participation of corresponding student and also compares his/her ER diagram, which was prepared beforehand, with that of group, in order to encourage them to share and discuss the solutions which have the conflict with group's. Nakamura, et al.[4] provided a pseudo student who corresponds to each learning student, grasps the learning situation of corresponding student, and participates into the discussion in order to activate the discussion.
In the collaborative learning, students do not study individually, but behave as members of a group. Moreover, well-collaborated group has more knowledge than individuals. Therefore, it is effective to manage the learning situation from a viewpoint of the group activity, but not of individual students. Our objective is to ensure the effectiveness of collaborative learning by generating appropriate advices for the learning group according to the situation. Currently, the target learning situation is limited in order to manage the learning group easily: the final answering path of the learning group is always unique. Under this consideration, the learning group is able to be regarded as one supporting object.

In this paper, we describe the mechanism of grasping the learning situation of our collaborative learning support system for mathematical exercise and evaluate our experimental results. In Section 2, we address the system configuration and the mechanism of grasping learning situation. In order to enforce the students' abilities to cope with various exercises, to discuss various viewpoints as well as to derive the answer are necessary. So, the extent of discussion as well as the progress of deriving answer are also focused as a learning situation. To handle such learning situations respectively, the resolution derivation scenario and the divergent tree are introduced. Then, in Section 3, the system evaluation based on our experiment is shown. The result indicates the effectiveness and gives the perspective for improving our system's ability. Finally, we conclude our paper in Section 4.

2 System Configuration

2.1 Interaction tool

![Diagram of Interaction Tool]

Figure 1: User-interface in collaborative learning support system
Figure 1 shows the user-interface in our collaborative learning support system. When a student participates into the learning group, his/her name appears on information space to make his/her existence explicit for others. Collaboration activities for attaining the goal take place on the answerboard screen and interaction space in the public space. Interaction space is prepared for free conversations and functions as a chat system. On the other hand, answerboard screen is regarded as a blackboard in our real world in which learning group's answer is organized. In this screen, only one student, who acquires the input right, is able to fill in. Currently, the exercise applied in this system is mathematic and, as for the correctness of the system's behavior, there are some limitations for the representation of equations. Therefore, the support tool for inputting equations in our public space, which is called “calculator”, is provided. The system grasps the learning situation only from inputs written on this public space, such as answerboard screen and interaction space. On the contrary to the public space, our private space is a plain text window in which each student is able to use freely. The description written on that space is not shared by other students.

2.2 Mechanism for Grasping Learning Situation

During the learning, students are able to resolve some learning situations that are not so seriously ineffective through the discussion: so, our system does not watch up detailed learning situations. However, our system is required only to catch the learning situations that seem difficult for students to cope with by themselves. Two following viewpoints are focused as the learning situations: progress of deriving answer, and extent of discussion. Figure 2 shows the conceptual diagram for these viewpoints. When the answering steps in all answering paths are arranged as Figure 2, the learning situation is transformed by projecting to X-axis, which indicates the progress of deriving ratio, and Y-axis, which represents the extent of discussion in the system.

![Figure 2: Learning situation](image)

In order to grasp the progress of deriving ratio, the resolution derivation scenario is introduced. The resolution derivation scenario represents the answering progress according to the time sequence, and consists of ordered states which correspond to individual answering scenes. Each state contains statewords which are the identifiers of the state itself. When the stateword is input during the discussion, the system specifies the current answering state by keywords matching and then marks the state by means of a pointer called "current". Each state also has its own derived ratio in whole answering process. Therefore, the change of the derived ratio for state, pointed by "current", shows the progress of learning. In addition to "current", the system also contains pointers called "upper" and "lower", by which understanding range of learning group is represented. Based on these pointers, impasse situation such as no-progress of deriving answer is detected. Furthermore, students who cannot understand the current answering step are grasped by the distance between the derived ratios for the states pointed by "current" and "lower". More details about this mechanism can be seen at Kojiri, et al.[5].

On the other hand, the extent of discussion is able to be regarded as different answering viewpoints expanded during the discussion. The difference among answering paths is defined by the ratio of uncommon answering steps in whole answering process. Each answering step depends on the preceding answering...
steps: once different answering viewpoints are adopted, the following answering steps are based on different viewpoints even if their specifications are the same. Thus, the difference among answering paths is defined as a derived ratio for divergent points. For the purpose of grasping the different degrees, the divergent tree is introduced, which arranges whole answering process into a tree structure according to the divergent points among individual answering paths. In the divergent tree, each path corresponds to the answering path and the node with child nodes is the divergent point. A node contains nodewords which discriminate both each node and the derived ratio of the corresponding divergent point in whole answering process. The system calculates the range of the difference among answering paths, derived during the learning, and assists the students to notice other answering paths of different viewpoints. More details are able to refer to Kojiri, et al.[6].

Based on this mechanism, current version of our system detects ineffective learning situations: no progress has been made in a specific time; understanding levels in learning group are too different; no well-discussed answering viewpoints exist; and so on.

3 Experiment and Consideration

3.1 Experiment

For the experiment, the learning group was organized by four university-students; two freshmen, one bachelor, and one master students. The experiment took place in a computer room, but they were seated separately enough not to talk in face to face. All students were familiar with communication through computers to some extent.

The exercise which we prepared is shown bellow. 4 different answering paths are prepared based on the answers collected beforehand from 10 graduate students of our laboratory members. In the mathematical exercises, the answering paths are able to be divided into several stages according to the answering methods to be applied. Therefore, statewords and nodewords are defined as the equations which are derived in those stages, respectively.

**EXERCISE:** When \(x > 0\) and \(y > 0\), give the smallest value of \((x + 1/y)(y + 1/x)\)

3.2 Results and Consideration

Figure 3 is the result of the learning according to the resolution derivation scenario and the divergent tree. In this figure, the changes of learning situations, which are called “scenes”, are shown with their triggered inputs. As individual scenes, the true understanding levels of students, which we asked afterward in detail, and the learning situation of what the system grasped are represented. The true understanding levels of students are indicated by the circled alphabets such as A, B, C, and D, which correspond with four students respectively. In this experiment, the student A knew which answering method takes a correct answer when the exercise was proposed. Other students understood the exercise gradually through discussion.

As for the learning progress along the resolution derivation scenario(Figure 3(a)), since students input their opinions after they became sure of them, the learning situation grasped by the system was somewhat behind in comparison with that in our real world. In addition, the system cannot understand the real situation if students do not input their opinions to the public interface: for instance, the student A's understanding level was not grasped because he did not insist. However, these mis-understandings are no problem as long as the learning proceeds smoothly.

During the experiment, two kinds of situations were detected as ineffective situations: one was impasse situation that there was no progress of deriving the answer for a certain period, and another was that some students who could not understand current answering step and did not insist their opinions may exist. For the former situation, COMMENT's 1, 2, and 4 were generated as advices. These advices functioned effectively to the learning situation. That is, after COMMENT's 1 and 2 were derived, the student A proposed hints for deriving answer so that the understanding levels of individual students became higher. As for COMMENT 4, the student B wrote an answer to the answerboard screen. On the other hand, comments corresponded to the latter situation can be seen as COMMENT's 3 and 5.
Although these comments seemed unnecessary for this learning group, they are still appropriate for the collaborative learning in the web world which our system focuses on, because members in the group may be uncertain in such environment so that it is necessary to ask for other students' understanding levels occasionally. In this case, the student B confirmed other students about the current answering step after the COMMENT 5 was generated.

As for the derived answering paths detected by the divergent tree(Figure 3(b)), the answering paths which students considered were marked by circled alphabets. When the learning started, only a student A knew the answering path correctly and the system grasped that no one understood the answering path. During the discussion, paths 1 and 2 were derived, but because of the flexibility of the keyword matching, the system also detected the path 5. Finally, the path 2 was successfully detected as the group's final answering path. So, after the answer has been derived at scene 10, the system generated COMMENT 5, in order to make the learning group consider underived answering paths, such as paths 3 and 4.

As a result, the system was not always sufficiently able to grasp the learning situation correctly, especially when there were students who did not insist their opinions explicitly. However, the advices that the system generated when it detected ineffective learning situations affected to the learning group effectively to promote the discussion activity.

4 Conclusion

In this paper, we addressed our system that supports the collaborative learning from a viewpoint of promoting collaboration. Also, we introduced the mechanism of grasping the situation of learning group. Then, we evaluated our system based on the experiment results. The results show that our grasping mechanism could detect the learning situation sufficiently which had occurred during the discussion.

Finally, for our further research, we have the following topics:

- to generate the timely effective advices according to the grasped learning situation,
- to cope with more flexible learning situations: that is, to free from limitation described in Section1,
- to generate teaching/studying materials, and so on.

Acknowledgments

The authors are very grateful to Prof.T.Fukumura of Chukyo University, and Prof.Y.Inagaki and Prof.J.Toriwaki of Nagoya University for their perspective remarks, and also wish to thank our research members for their many discussions and cooperations.

l.hodgson@unsw.edu.au

Abstract: Version 2 of the Universitas 21 (U21) Learning Resource Catalogue (LRC) has been completed. The catalogue is a repository of IMS metadata (records) of learning objects. The prototype of the catalogue had hundreds of records of vastly different type and size (granularity). This great range of objects came about because learning objects have been defined in very simple terms yet they can vary greatly in size and complexity. The learning objects were described in IMS terms, and characterised by metadata that can be lengthy and complex. It was recognised that a classification of learning objects at a high level (prior to assigning metadata) can convey much information to a user and simplify the process of determining the type and characteristics of a learning object. This classification system of learning objects is presented and demonstrated here. Examples of two of the five classes are: basic objects that have no inherent educational context; and objects that have a technological pedagogical model with embedded content. The classes enable a high-level search and identification of object descriptions (records) stored in the catalogue. The structure, function and utilisation of the online catalogue using learning object classes and metadata will be demonstrated.

Introduction

In a previous paper, Koppi et al. (2000) described the value of a Learning Resource Catalogue (LRC) to a teaching and learning institution and illustrated how an online catalogue of learning object metadata (IMS: http://www.imsproject.org/) had been prepared and utilised by a consortium of universities (Universitas 21). This paper is concerned with the catalogue system relevant to this group of universities. There are other examples of database systems using the concept of learning objects such as ARIADNE (2000) and MERLOT (2000).

Upon examination of the collection of learning object metadata from several universities in the Universitas 21 LRC database (Version 1) it became clear that the concept of a ‘learning object’ was very wide indeed. One of the variables of the objects was the size (granularity) which had a wide range. Wiley et al. (1999) were also concerned with the difficult problem posed by the large range in size of learning objects and that large learning objects had limited reusability. In fact, an entire curriculum could be seen as a learning object. For U21 purposes, it was concluded that prior to the creation of metadata for cataloguing purposes, it would be useful to have a sorting mechanism for the learning objects.

Learning objects, have been defined simply by the IEEE’s Learning and Technology Standards Committee as: “any entity, digital or non digital, which can be used, reused or referenced during technology supported learning” (http://ltsc.ieee.org). This simple definition means that there is a very wide range of learning objects that have been created by many different people.

In keeping with the definition, a learning object entity may be simple, such as an image, or much more complex, such as a learning program containing images, text and activities. This latter entity may be considered to be a single entity or to be an agglomeration of several entities, i.e., objects embedded within objects. A fundamental part of the
definition is that the entity can be reused. The more complex the entity (containing multiple objects) the less reusable it actually is. Reusability is a matter of degree – an entity may still be a learning object even if the reusability is limited.

One of the reasons for the diversity of learning object types is that the creators of learning objects may be very different people with different skills, such as subject matter experts e.g., academic staff who provide specific information, educational designers who provide a pedagogical model, or a programmer who builds a technical framework. A learning object may be created independently by any one of those classes of people. It is also possible that one person creates an object that contains information in an educationally structured way and that same person also creates the technical implementation. A learning object classification system has facilitated the identification of learning objects and their utilization.

Classification of Learning Objects

One of the authors (Lisa Hodgson) was responsible for designing and refining the classification scheme utilised by the U21 LRC. Five classes have been used. These are listed here and then each class is described with examples.

1. Raw asset
2. Learning asset
3. Task or exercise
4. Pedagogically derived technological application containing content
5. Pedagogically derived technological application devoid of content

Class 1: Raw asset

This can be defined as an object with potential for use in an educational setting although it contains no inherent educational context. Raw assets are learning objects that have massive potential in reuse in a virtually unlimited capacity. Examples of raw assets include:

- A picture of a master painting
- A topographical map
- A video of an apple falling from a tree
- An audio clip of a famous concerto
- A poem

These raw assets have the widest reusability potential as they can be customised and adapted to suit a wide range of contexts, disciplines, learner levels, and pedagogy. To have meaning in an educational setting, either the course creator or the student must put them into a context.

Class 2: Learning asset

While similar to a raw asset, a learning asset has been placed into an educational context by the addition of certain information. Examples of learning assets include:

- A picture of a master painting with facts, such as the artist who painted it, the period it was painted and the techniques used
- A topographical map with an explanation on the procedure for reading the map or the purpose and uses of such a map
- A video of an apple falling from a tree accompanied by an explanation of the theory of gravity
- An audio clip of a famous concerto with information about the structure of a concerto, or definition of minor and major keys using the music to illustrate the theory
- A poem with information on the use of metaphor in poetry
• A paper or article explaining a concept or theory

Both raw assets and learning assets are dominantly passive objects in that they do not explicitly require the user to interact with the knowledge i.e., no task is given.

A learning asset is loosely equivalent to a resource that a lecturer may source to accompany a lecture. A learning asset can therefore be associated with a didactic lecture. The learning asset is a resource that is put inside a context or used to explain a concept.

Raw and learning assets are classes of learning objects that have very little or no learning theory or pedagogical framework. The potential for reuse of both is high, however a learning asset is slightly less reusable, depending on the complexity of the educational information given with the learning asset – the more complex, the less reusable.

Class 3: Task or exercise

A task or exercise can be a learning object. The activity is usually within a context or discipline and can (but may not) include raw and learning assets to aid in the task execution by the student. This class differs from the raw asset primarily because it is always contextual; a student must carry out an activity and attain a particular level of performance in a particular context. While raw assets may have an implied learning objective (e.g., after viewing the video of a falling apple, students may relate it to the theory of gravity), they do not include a means of the learner exploring that implication. Examples of task or exercise learning objects include:

• A picture of a master painting with a task asking the student to write an essay on the use of colour to convey mood, or explain the dominant techniques employed by this artist as illustrated in this typical work
• A topographical map with an explanation of how such a map is created and a task asking the student to create their own topographical map of their environment
• A series of multiple choice questions that explore the understanding of gravity
• An audio clip of a famous concerto with an exercise that asks the student to map the compositional structure of the piece of music
• A selection of themes and a request that the students write a poem based on one of the themes using metaphors as a primary structuring tool
• A group of papers or articles introducing a theory and a structured-writing task that asks students to summarise the various viewpoints expressed

Class 4: Pedagogically derived technological application containing content

This class of learning objects, while similar to the previous class, is different in that the learning objects have embedded content. It may include a whole course or curriculum and has the disadvantage of having the lowest reusability. To be useful it must fit all the teacher's parameters, such as, pedagogical framework, user level, context, and technological delivery mechanism. It also has the lowest re-development needs being already complete and ready for implementation. However, if modifications need to be made they may be costly. Because these objects are complex, it may be difficult to link with other similar objects to make a coherent learning experience for students. Examples of this type of learning object include:

• A web role play with a united nations scenario and defined roles for student participation
• A multiple choice assessment module that test students on their understanding of organic chemistry
• A module that allows students to annotate a set of x-rays to highlight abnormalities
• Problem based mode of enquiry module that uses small groups to investigate the viability of alternative methods of fuel besides petroleum-based products

Class 5: Pedagogically derived technological application devoid of content
This class of learning object is a technological application of a pedagogical model. It may be thought of as a shell or template (e.g., WebCT), and is a technological framework without content or context designed according to a pedagogical rationale. This type of learning object has a high degree of reusability because it has a structure, but the content is added by the course designer. Lecturers or course creators would utilise such an object (provided that it was governed by an appropriate pedagogical model that would permit relevant learning experiences) by adding specific content and context to customise the object to their course.

The disadvantage of this learning object, in terms of reusability, is that it requires compatibility of technologies between the object, the delivery system and other objects or components such as recording of grades and student tracking. Careful consideration into the standards and tagging of such objects will be required. Examples of this type of learning object include:

- A role play simulation generator which allows a lecturer to set up a scenario that allows students to participate in a role play
- A multiple choice self-assessment module that allows lecturers to create a bank of questions and generate quizzes for student self-assessment
- A chat room that enables two way communication between teacher and student
- A module that allows students to annotate images and write comments which can be saved together
- A problem-based enquiry module that allows lectures to add problems and resources and organises students into teams to undertake the problem solving activities.

**Utilisation**

Version 2 of the Universitas 21 Learning Resource Catalogue has many refinements in the tools for creating catalogue records that utilise IMS metadata to describe learning objects. In addition, a classification of learning objects has been employed. The classification occurs at a high level prior to the creation of IMS-based metadata. The catalogue can be searched on the class of learning object as well as on other criteria. The structure, function and utilisation of the online catalogue will be demonstrated.

SITUATED AND SOCIALLY SHARED COGNITION IN PRACTICE:
Designing a Collaborative Network Learning Experience for Adult Learners

Vesa Korhonen
Senior Researcher
Department of Education
University of Tampere, Finland
Email: kaveko@uta.fi

Abstract. The main purpose of this presentation is to draw attention to assumptions that guide the instructional design process when implementing and organizing network-based learning environments in practice. In this case, the situated and socially shared cognition model and participation metaphor create the guiding paradigm for collaborative learning action, which stress the socially shared knowledge construction and collaborative context of learning environment. The case design reviewed here is the Nursing Science module in Open University, which is carried out through a WebCT-based network learning environment. As a conclusion, a collaborative learning model and instructional design paradigm integrating the dimensions of intentionality, content, context, community, participation, facilitation and self-assessment, are discussed.

Key words. Situated cognition, socially shared cognition, collaborative learning, network learning environment for adult learners

1. From individual to socially shared cognition: searching for a collaborative instructional paradigm

There is a growing tendency to strive for integration of individual and social dimensions in new learning environments. Situated cognition, or a situated learning approach, has made a significant impact on educational thinking since it was first analyzed and introduced by Brown, Collins and Duguid (1989). This instructional paradigm has been further developed by Jean Lave and Etienne Wenger (Lave 1988, Lave & Wenger 1991; Lave 1997; Wenger 2000), whose work has been instrumental in providing the research base and practical implications for the theory. A community of practice is seen as an environment where knowledge construction occurs and where culturally derived norms are formed and learned (Billet 1998). On the other hand, the sociocognitive view stresses the development of socially shared cognitions in groups. Social interaction is seen to be a paramount site for the development and practice of cognition. One might expect groups to perform better than individuals on various tasks, including learning, concept attainment, creativity, and problem solving. (Levine et.al. 1993; Scardamalia & Bereiter 1994). Both these views are heavily based on the work of well-known educational thinkers like Vygotsky and Dewey. The use of these kind of collaborative learning ideas as an approach to the design of learning environments has significant implications for the instructional design of web-based learning environments. As an instructional strategy, these situated or socially shared cognition
models have been seen as a means of relating subject matter to the needs and concerns of learners (Shor 1987) and coordinating cognitive interaction with others (Levine et al. 1993). These social ideas of learning understand it as a sociocultural and collaborative phenomenon rather than the action of an individual acquiring general information from a decontextualized body of knowledge (see Kirshner and Whitson 1997). The core idea in design is that knowledge and skills are learned in the collaborative contexts that reflect how knowledge is obtained and applied in real-life situations. In general, knowledge is understood as a result of social construction and production of meaning. Learning is understood as an interactive discourse with shared knowledge and enculturation process to the culture and institution behind the shared knowledge.

Learning becomes a social process dependent upon transactions with others placed within a context that resembles as closely as possible the practice environment. Anna Sfard (1998) discriminates between two differing metaphors for instructional design: the acquisition metaphor and the participation metaphor. The acquisition metaphor refers to human learning as acquisition of something. Learning is understood as knowledge acquisition and concept development in mind. This gives a one-sided idea of what learning and knowledge are. One can characterize the assumption of knowledge as dualistic. Knowledge is seen as a permanent and immutable truth that the learner is trying to absorb. Generally, learning is seen as an individual mental and inner state and reception of knowledge. Instead of that, the participation metaphor sees learning as participation in a certain community's meaningful action. Learning is understood as a socialisation and growth process into that community, where the culture, shared knowledge and values are absorbed. What is central is the dialogue where knowledge is shared and constructed and where the meaningful experiences are coming about. When organising learning, this directs attention to the development of communities and environments of practice, not individual learners only. The situated and socially shared cognition views and participation metaphor create a guiding paradigm where learners' social and communicative skills are supported, guidance for collaboration given and the whole learning environment can function as a knowledge-building community.

2. The Case Design Reviewed

The case design reviewed here is the Nursing Science module in Open University, which is carried through a WebCT-based network learning environment. These program platforms developed for web-based instruction, like WebCT, Lotus Learning Space, Future Learning Environment (FLE) and many others, contain discussion groups, group work areas and other communication channels, which support learning as dialogue, knowledge sharing and knowledge construction with other learners. Information networks provide possibilities for this kind of communicative learning without the limits of time and study place commitments. The development of collaborative learning practices is seen as important, which is something more than just combining and directing individual learning processes together. In this case the Nursing Science module was divided into three courses, which all share the same organised structure (see Fig.1).

When outlining the collaborative basis and participation metaphor in practice it is important to pay attention to the organisation of communication and learning processes in the learning environment. In this case learning is not only virtual; it also involves contact teaching as orientation and small group work under a mentor’s supervision. The task of the small group is to continually assess the intellectual growth of the individual and the community of learners. In an
adult learning group, the mentor fosters the notion of cognitive apprenticeships (see Brown, Collins, and Duguid 1989). When virtually participating in a network discussion group, individual learners witness how colleagues solve problems and have developed their own solution paths. In an ideal situation, these tools and methods of cognitive apprenticeship include discussion, reflection, evaluation, and validation of the community’s perspective. Instructors (teacher and mentors) must provide a scaffold for new learners, that is, know the type and intensity of guidance necessary to help learners master the situations they face in the new learning settings. As learners acquire additional skills, less support will be needed. Instructors recast their roles from content transmitters to facilitators of learning by tracking progress, assessing products produced by learners, building collaborative learning environments, encouraging reflection, and helping learners become more aware of contextual cues to aid understanding and transference (Ottoison 1997).

The educational basis of participants was a specialist vocational degree in the field of nursing or a first year university examination in Nursing Science in Open University. Most of the participants are females. The target group is interesting because it is not considered a typical network learner group. The central requirements in these network courses are to participate in network discussion and to construct a learning portfolio. The learning portfolio consists of several assignments: learning diary, analysis of network discussion themes and written home assignment. Students are encouraged to do the home assignment and analysis assignment together with a fellow student (or students).

The main research question in this case was to try to find through these collaborative learning experiences some evidence and conceptions of creating a general design paradigm for collaborative network learning settings. The main research data collection and analysis method was qualitative content analysis of the authentic learning diaries from the first two network study modules. Descriptive statistical data supported the analysis. The content analysis process was carried out resting on the situational and sociocognitive learning theory. The learners’ concrete experiences were
constantly compared with these theoretical assumptions. The whole qualitative analysis is thus a result of a discourse involving theoretical and practical conceptions, not the learners’ experiences alone.

3. Experiences of Collaborative Learning in Network Context

The community of students attending these network-based courses consisted of two larger groups: altogether 39 students in the Tampere area and 13 students in Lohja. Both locations have their own mentors supervising one or several smaller study groups. An average nursing science student in network studies in this case is a 37-year old female with family who is active in working life (age range from 23 to 54 years). It is notable that 61.5% of them had previous experience of adult education in Open University. Some of them had attained a remarkable amount of university level courses. Almost everyone had also work experience from the field of nursing (average 11 years).

Content analysis of learning diaries showed that the learners’ study attitudes, goals and approaches for learning in this case were quite disparate. The learning environment experienced and constructed by learners was different from that organised by instructors. From the perspective of the learner's personal goals it is a matter of exchange and practical value of the education and personal meaning of studies as well. The approach to learning and personal meaning of studies can tell us more of an individual learner’s goal structure, underlying motives for participation and strategic choices during the studies. In this case, the vocational approach to and goal for learning was predominant. Almost half of the participants (48.1%) could be classified into this category during their studies. Vocational, practical goals for learning refer to acquiring qualifications for work and applying the knowledge to practice. The aim is to promote professional expertise and growth. The essential interest focuses on how studies can be connected integrated into practice and how knowledge can be utilized. Personal growth and theoretical fascination are of secondary importance. This places demands on situational and collaborative learning: how to formulate meaningful and authentic assignments and themes, which serve the vocationally oriented learner's needs? The learning diaries also contained references to flexibility of network studies. These kind of learning possibilities were better accommodated to work requirements and life situation (i.e. shift work) than regular extension studies. Network studies enable learning for adults without the limits of time and study place commitments. Many adult learners were also able to learn better and with greater depth through these network studies. However, online courses require self-motivation on the part of the learner: the learning process is best characterized by internal motivation. Learners must be also able to manage their own time and set deadlines for themselves. Failed time management was often cited as reason for difficulties in online learning.

Participants created their own knowledge out of the raw materials of experience, i.e., the relationships with other participants, the activities, the environmental cues, and the social organization that the whole learning environment developed and maintained. As Young (1993) suggests, learners should be offered situations that will engage them in complex, realistic, problem-centered activities that will support the desired knowledge to be acquired. For network learners the studies in this case involved working with theoretical and practical problems and the development of their own qualifications. Situated cognition reminds us that adult learners are a rich and diverse source of stories; data that can transform the study group from a source of transferring knowledge from instructor to learners to a resource for interpreting, challenging, and creating new knowledge. Interactions among the learners and environment holds the promise of having learners directly intervene in and change the processes that surround their lives at home, in the
community, and at the workplace. Learners in a situated environment must be encouraged to identify their own questions, goals, and issues that arise through emerging theme discussions in the network or as self-evaluation through learning diaries. In general, we reached the conclusion that the social and cultural environment where the learning occurs essentially influences the knowledge creation in the learning process. In this case, we learned that adult learners need opportunities in the learning environment to participate actively by formulating and evaluating problems, questions, conclusions, arguments, and examples. Face-to-face group meetings with mentor as well as network discussion groups worked fine for this. In an adult group of this kind, collaborative learning refers to creating the conditions in which participants will experience the complexity and ambiguity of learning in the real world (i.e. working life). Different kinds of group arrangements (face-to-face and/or virtual) proved to be successful instructional tools in this.

4. Conclusions

Collaboration and shared cognition in learning places the learner and the community of learners in the center of the instructional design. In our network study groups learners were called to learn by analyzing their goals, asking questions and formulating problems, to obtain information relevant to these questions and to interpret this information and share their experience with others. Collaborative learning was based upon consensus building through cooperation by group members (see Sharan & Sharan 1992). In the case design reviewed here, our collaborative learning model integrated content, context, community, participation and facilitation (see Anderson, Reder & Simon 1996; Choi & Hannafin 1995; Brown, Collins, and Duguid 1989, Lave 1988) with intentionality and continuous self-assessment. Thus, the network learning environment design in this case could be structured according to the following principles:

- **Intentionality** - support for personal goal analysis and placement
- **Content** - support for autonomous acquisition of information and shared knowledge construction;
- **Context** - the situations, problems, themes, values, beliefs, and learning environmental cues by which the learner gains and masters content;
- **Community and collaboration** - the organization of groups for knowledge-building with which the learner will create and negotiate meaning of the knowledge and situation (small group with one or two colleagues - mentor group - network discussion group - entire group);
- **Participation** - the social organization of process, rules and roles by which learners working together and with experts solve problems related to study themes and everyday life circumstances;
- **Facilitation** - facilitation according to cognitive apprenticeship model; and
- **Self-assessment** - continuous authentic assessment in the form of learning diary and learning portfolio.

When organizing learning, these assumptions direct attention to developing learning communities and environments of knowledge-building, not individual learners only. The construction of knowledge is viewed as the product of interaction between individuals’ prior knowledge and socially constructed knowledge. This kind of collaborative learning is a negotiated and transformational process, in which individuals test and contest their knowledge with others. What is also important is the self-assessment of learners, which is well suited to process oriented learning. What we realized was that this kind of instructional paradigm works particularly well for adult learners of theoretical science study modules.
References

Abstract: This brief paper reports the design, progress, and preliminary results of a study conducted to determine the nature of online dialogue among pre-/in-service teachers after training in the use of a student/teacher hypermedia software tool. Teachers were trained to use behavior support software for students with emotional behavior disorders. An online discussion following the training was designed to allow participants to discuss the program. Data were collected via an electronic archive of all participant responses. Analysis includes the coding of types of responses as well as qualitative determination of emerging themes. Questions about level of understanding, support offered, evaluative comments, and critical thinking were analyzed. Study design, data collection tools, and preliminary results will be shared with the audience.

Software to Support Students with Emotional Behavioral Disorders

Integration of students with emotional behavior disorders (EBD) into the public schools is problematic (Simpson, 1999). By successfully changing problematic behaviors and developing skills for success, children with EBD are likely to improve their learning and social experiences at school. Little focus has been placed on assisting this population through specialized software to date. One new program, a multimedia tool to help children develop self-management skills, is now available. KidTools (Fitzgerald & Semrau, 2000) is a software program designed to provide students tools to manage their own behavior, and to provide teachers with information about the strategies. Through the use of these tools, children are likely to benefit from the positive supports to maintain more control over their behaviors. However, students must be taught and then guided to use this software system effectively. Likewise, teachers must understand the background and implementation of the software tools. However, according to Woodward, Gallagher, and Reith (2001) a dilemma exists in that the developer’s intent and the teacher’s use often do not coincide.

Design of the Online Discussion for Implementation of KidTools

In this study, the interactions of teachers learning to use the KidTools (Fitzgerald & Semrau, 2000) behavior support software program were archived in the forum discussion section of a web-based teaching software program. Often during online discussions, participants are reluctant to begin the discussion. Therefore, it was necessary to encourage discussion through provocative open-ended questions as well as in-process prompts for more meaningful and in-depth dialogue (Bonk, et al., 1998). In order to prompt participant involvement, forum topics and open-ended questions were posted before the discussion began and discussion leaders from the research team sustained participant involvement with prompts. Research questions in this study are:

1. Did social discourse during the on-line discussion demonstrate a higher level of understanding or innovative use of the KidTools software?
2. Did social discourse during the on-line discussion provide evaluative feedback about the software?
3. Did emergent themes suggest that the intent of the software developers was intact?
4. Did teachers provide scaffolds for their colleagues?
Methodology

The conference was held as an open-ended discussion for pre-service and in-service teachers with three experts online for ten days, followed by continuing, non-facilitated discussion for five days. The topic of the conference was self-management strategies for children. All participants received a CD with the children's program KidTools to review prior to the online discussion.

Participating volunteers were asked/prompted to discuss implementation issues during the online conference. After the conference, data analyses for frequency and types of contributions were performed. A qualitative analysis determined emerging themes associated with the instruction, implementation and use of the KidTools behavior support software. A coding system was adapted for this study from one created by Oliver, Omari, & Herrington (1988).

Preliminary Data

There were 97 participants in the conference (33 active participants), three national experts, and two software developers involved in the conference, with 131 messages posted. The average postings during the facilitated portion of the conference were 15/day with an average of 24 themes per day, in contrast to an average of 2 postings per day with 2 themes per day during the non-facilitated portion of the conference. Demographic data were collected to discern participation patterns from user differences based on training setting, reason for participation in the conference, access to Internet, prior teaching experience, and previous experience in electronic conferences.

Importance of the Work

Coding of archived responses during asynchronous on-line electronic discussion helps us understand the type of responses and accumulation of learning that occurs (Henri, 1992). The coding system was used to analyze statements and social interaction among teachers who participated in workshops to learn the behavior support software. When providing in-service training, trainers assume immediate implementation of what was learned. The post training discussion format helped sustain the dialogue about the use of these behavioral supports and assisted in implementation. Information was gained to improve future online discussions as supplements to in-service training. The online discussion also aided developers in evaluating whether the software was used as intended, and if not, what features or changes are desired.

olzang@macam.ac.il

Abstract: The Virtual Friends project consisted of electronic mail exchange between pre-service student teachers and high-school pupils with learning disabilities over a period of four months (one semester). The purposes of this project were to enhance the professional growth of the pre-service teachers and to concomitantly advance emotional, social and academic goals for the participating adolescents. Each of ten student teachers mentored one pupil with severe learning disabilities via e-mail. The student-teachers also engaged in an electronic discussion forum with their student-teacher peers, their field supervisor and their college-professor. This paper focuses on the contribution of electronic communication to the training of pre-service teachers in four areas: (1) elevating their self-efficacy beliefs, (2) deepening their understanding of adolescents with learning disabilities, (3) practicing collaboration among pre-service student teachers and (4) enhancement of their skills with electronic communication tools.

Introduction

The use of electronic communication, such as e-mail and discussion group, becomes common in academic settings, more so in university courses than in teacher education environments (McComb 1994; Topp 1966). The use of electronic communication offers many advantages, such as the lack of time and space limitations, fast communication with relatively low cost (Harasim 1996), and potential learning of contents and skills, including reading and writing (Reil 1991-2). Further benefits of such communication includes the removal of psychological boundaries which exist in face-to-face communication, giving enough time for reflection and the planning of reaction (Hedrick, McGee & Mittag 2000), and increasing students responsibility to take an active role in their learning (McComb 1994). The use of electronic communication can support also meta-cognitive activities, needed to acquire pedagogical skills. The electronic discourse can become a platform for reflective thinking of the becoming teacher about knowledge of content, strategies and teaching experiences and also about him/herself as a person and as a professional teacher (Carter 1990). The research demonstrates that reflective experiences in the teacher preparation stage can enhance pedagogical experiences in the field (Gipe & Richards 1992). Student teachers, even those that do not tend to actively participate in face-to-face discussions in the classroom, may become active in electronic discussions (Harasim 1993).

The term student teacher reflects the internal tension in the status of the to-be teacher. S/he needs to take double role: as a student and as a future teacher, and has to shift culturally, from the role of a student in the course of his/her job preparation to that of a teacher upon completing his/her studies. Hamilton and Pinnegar (2000) claim that if we expect student teachers to develop from students into teachers they should be given the responsibility to care for others and not just to be taken care of. To widen their interactions, pre service teachers should communicate with their teachers as well as their peers, field mentors and pupils. Unfortunately, the electronically-based interaction research in teacher education refers mainly to the interactions between the...
college professor and a group of pre-service student teachers. To enhance the knowledge construction of the student teachers, Hedrick, McGee & Mittag (2000) suggest to include in these interactions also pupils from elementary/high school and field supervisors. The Virtual Friends activity described hereby gave the student-teacher an opportunity to mentor a pupil with special needs, to become an attentive friend who listens to his/her concerns, to show empathy and to deliver caring feelings.

The Virtual Friends project

This project consisted of electronic mail exchange between pre-service student teachers and high-school pupils with learning disabilities over a period of four months (one semester). Its purposes were to enhance the professional growth of the pre-service teachers and concomitantly to advance emotional, social and academic goals for the participating adolescents. Ten student teachers mentored each a pupil with severe learning disabilities via e-mail. Via the electronic discourse the pupils expressed their fears and dreams. They told their virtual friends about daily events, disagreements with parents and friends, social isolation and disappointment for not meeting parents and teachers expectations. They described their school failure experiences and asked for advice regarding drugs and violence. The student teachers read attentively the e-mails, carefully avoiding any judgmental statements. In return they told the pupils about their daily hereabouts and future plans.

The student teachers were also engaged in an electronic discussion forum with their student peers, their professor in a course on learning disabilities, which they all attended concomitantly and their field supervisor.

The contribution of the activity

To study the contribution of the electronic communication to the training of the pre-service teachers we examined the students dialogues in the electronic discussion forum. 204 letters were written to the forum, of which 122 by the student teachers, 50 by the college professor, and 32 by the field supervisor. 70% of the discourse in the forum included discussions (initiated mostly by the students (33.3%) and the professor (31.4%), and few by the supervisor (5.4%). Other parts of the discourse consisted of information about computer usage and requests/suggestions for technical assistance (3%), announcements (10%), and social discourse and caring talk (17%).

The electronic-based discourse evolved throughout the project. At first the student teachers expressed their concerns regarding their competency to be mentors to these students with special needs and their ability to use the electronic media. Four months later and upon completion of the project they described the contribution of this activity to their education in the following four areas:

(1) Elevating self-efficacy beliefs: The student teachers stated that following their participation in the project they felt more confident in their ability to listen attentively to pupils personal needs and to guide them. They also felt more skilled with the computer and its use for inter-personal communication. My success in these relations via the e-mail fills me with confidence to do similar activities also with my future pupils, and I learned how to use e-mail, and it can serve me to establish professional communications as a teacher.

(2) Deepening their acquaintance with the population of adolescents with learning disabilities: During their pre service training the student teachers did not meet adolescents with learning disabilities. The e-mail communication enabled them to become closely acquainted with these pupils, and to learn about their special educational and social needs. This demonstrated learning through doing and it was supported by the discourse in the electronic discussion group as I would like in the future to teach this age group (adolescents), the electronic communication enhanced my sensitivity to their difficulties, their priorities in life, and their perceptions about the world. Now I know more about their linguistic-communicative problems and how their reading and writing deficiencies block their ability to express themselves. At the same time, the student teachers emphasized that they look now at the pupils as active, social, and emotional needs, and not focusing on the difficulties only.

(3) Practicing collaboration among pre-service student teachers: As described earlier, the student teachers had a computer-mediated discussion group (electronic forum) at their disposal in which they could reflect on their on-line dialogue with the high-school pupils both among themselves and in cooperation with the college staff and in-service teachers. In this electronic discussion forum, the
student teachers could express doubts, ask questions, and offer mutual support concerning their virtual friendship with the pupils with special needs. This collaborative framework created a sense of a learning community, with members and rules of its own. The students highly appreciated the electronic discussion group as a means to professional collaboration and mutual support. I felt that it was a place where we could think together and that we could get professional advice from peers.

(4) Enhancing skills with electronic communication tools: Although the pre-service training curriculum includes various courses in computer skills, the student teachers emphasized that this activity was an example for authentic learning about computerized usages in education. I can now actually realize how I can use electronic communication to achieve educational and social goals.

Conclusions

The Virtual Friends project linked theory and practice (Korthagen & Kessels 1999) and accompanied the students' professional development with an on-going reflective learning via the electronic discussion forum (Korthagen & Wubbel 1996). The dialogue in the electronic forum contributed to the development of the corpus of knowledge pertaining to learning in general and the learning of pupils with disabilities in particular. Through this activity, the student teachers learned content knowledge (standpoints and needs of adolescents with special needs and how these are reflected in their relationships with other people), about the influence of non-academic factors on learning (change in social status in the family and among the peer group, and its influence on learning), about the field of didactics (how to use language that is not complex, but is still challenging, in the dialogue with the pupil), and about themselves as people and as professionals. They learned to know the pupil as a whole person with cognitive, social, and emotional needs, without a specific focus on the difficulty only. In parallel, the high-school pupils with learning difficulties also benefited from the virtual environment. They could share their learning and social doubts with an older friend, improve their learning skills of reading and expressing themselves in writing, and practice their interpersonal communicative skills. The computer turned into a friendly instrument for them, and they used it as a word processor and as a means to communicate.

The student teachers recognized the high potential of electronically mediated learning experience. All of them declared that they would willingly initiate such an activity in their own classes.

Exemplary-based learning: a new way of Web-based training

Andriani Kraan & Henk Sligte
SCO-Kohnstamm Instituut, Universiteit van Amsterdam

kraan@educ.uva.nl, henks@educ.uva.nl

Abstract: In April 2000 the European project Collaborative language independent development environment for exemplary based re-usable learning objects in IP learning platforms (CODEX-IP) started to create: an innovative learning model - exemplary-based learning (EBL); a new development process for the collaborative development of re-usable learning objects between training centres in different language areas; a new integrated development environment based on EBL and the development methodology. In this paper the EBL model is explained shortly.

First EBL-guidelines

After a literature study the first guidelines for EBL instructional design were formulated:

- Examples function as learning objectives (as they show in a visual way what will be learned)
- The end-user is responsible for choosing one’s own learning path based on the available examples (which is related to learning on demand, learner centric learning, personalised learning)
- Content parts are as independent as possible (as learners can learn in a non-linear way)
- Examples are taken from a realistic context for the end-user (to make the content as relevant as possible for the learner).

An example of a result functions as a:

- Learning objective, it shows the learner what can be learnt via the instruction;
- Demonstration of a result, it shows what the learner can do or make;
- Anchor, to help the learner connect new information to his cognitive structure;
- Navigation element, it helps the learner to go to the topic he wants.

An example of a result includes a title, a visual presentation of a typical result with all the important attributes and a sentence for clarification. At the same time a demonstration of a process can function as an example as well, which is related to the master-apprenticeship idea.

Pilot studies

A pilot study was carried out to gather information and suggestions about the first EBL guidelines for instructional design. In total 24 people tried out a web-based Word 2000 training on "Paragraph formatting", 10 persons from the Netherlands, and 14 persons from Spain. They had a different background and a diverse level of Word knowledge and skills. The persons worked for 60-90 minutes with the learning environment, did a small test, filled out a questionnaire and were interviewed about this questionnaire afterwards. Although the trial groups were small, it seems that the persons with a high level of Word knowledge and skills preferred short instructions (procedures) for carrying out a task. Users with a low level of Word knowledge tend to prefer step-by-step exercises in which they are more guided by carrying out a task. Due to their prior knowledge they have more difficulties with understanding the steps in the procedures. They had a need for step-by-step exercises but also for the more 'do-it-on-my-own' exercises in which the learner can test whether or not he/she understands a procedure. The trial group found it helpful to have first an example of the result of a task as they could see what they could learn in a section.

Working with the learning environment

Figure 1 shows the process of working with the learning environment in an on-the-job situation. It starts with a problem at the workplace (e.g. the learner doesn't know how to make a footnote). The learner can choose to read the
(short) procedures to carry out a task, to read more about these procedures (read explanation), to practice and/or to contact others to help by a problem at the workplace.

Figure 1. Process of working in EBL-environment

Elements for an EBL-learning environment

Elements for training based on EBL can be: overview of the content of the course (both graphical and textual), examples of results of processes, description of procedures, demonstration of procedures, prior, extra and related information, guided exercises, exercises which can function as self-tests. Because the different parts of a programme should be worked through in the order the end-user prefers, the content should be as independent as possible.

EBL-Parameters

To characterize EBL 19 parameters were formulated in a total of four categories: organisational aspects, process of learning and teaching/training, content, and technological aspects. An example of two of them:

<table>
<thead>
<tr>
<th>EDUC 5</th>
<th>Modelling</th>
<th>Discovery-experimentation</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

This dimension focuses on how tasks and skills are learnt. Both use the strategy 'learning by doing' but with a different accent. In EBL the focus is on modelling. After the learner finds the example, which represents the problem, it is shown how to solve it. Exact steps are given by providing the procedures. Step-by-step exercises help the learner to carry out the task without problems.

<table>
<thead>
<tr>
<th>EDUC 6</th>
<th>Reproduction</th>
<th>Performance</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Reproduction and performance are results of learning and closely related to declarative and procedural knowledge. Is the training focussed on knowing the meaning of the icons of Word toolbars (reproduction) or on making a bulleted list (performance)? The objective of an EBL-environment is that learners can carry out specific tasks.

In this first year the development and learning environment with the integrated building blocks is developed. In the second year EBL and the environments are tested in companies in Belgium and Spain.

Abstract: The paper focuses on the cognitive contribution of the aesthetic experiences to learning in a higher education setting. Specifically, it examines whether the use of students' imagination and their visual expression contributes to the genesis of the students' epistemological beliefs. The paper reports on a qualitative case study in an educational psychology course within a pre-service teacher education program. Using the analysis of student-created mixed-media projects, it offers a discussion of the role of the students' imagination in construction of meanings associated with beliefs about learning. Part of the analysis explores specifically whether specific kinds of the aesthetic experiences help foster students' creativity and imagination, and whether those experiences influence the students' beliefs about learning.

Statement of Problem

This study is motivated by the disconnection between the quality of learning experiences in the contexts of higher education settings and the nature of creating one's own system of beliefs and understandings. While the dominant approaches to post-secondary teaching treat the student learning experiences as mediated largely through cognitive rational processes, a large body of literature suggests that the individual's beliefs are shaped by imaginative, non-rational processes, which involve intuition, improvisation, and the act of creating a new form of some sort (Arnheim, Dewey, Eisner, Greene). This study focuses particularly on the processes of creation embedded in the aesthetic experiences and artistic forms of expression, examining the ways in which these experiences influence learners' epistemological beliefs—beliefs about learning. If one is to agree that epistemological beliefs define the way and the form in which knowledge schemata will develop for an individual (Spiro et al., 1996), then one would agree on the need for providing a certain quality of learning experiences within an academic program. This quality should meet the demands of complexity faced by the graduates in organizational and social structures upon graduation, among other skills, an ability to see multiple solutions to a problem (multiplistic thinking) and to act flexibly in novel situations are often required. Such skills can be fostered when the belief about learning is formed tolerant of the notions of ambiguity, situation-adaptive assembly of knowledge, and self-reliance. In other words, the skills required of the graduates can be enhanced when their belief systems are characterized by the features more conducive to the processing of complexity—a process "in which aesthetic satisfactions are pervasive" (Eisner, 1985).

There are post-secondary educators who do not consider the aesthetic experiences as essential instruments in the development of epistemological beliefs. In consequence, their teaching approaches fail to attend to the ways in which imagination and creativity influence learner’s thinking. The critique of the current instructional practices in higher education illuminates on the reasons that limit the development of epistemological beliefs of prospective professionals. Specifically, it calls attention to the fact that over-reliance on rational ways of learning and the dominance of verbal expression cause two serious problems: (1) Oversimplification in students' thinking, which reveals itself in their adherence to the "either/or" paradigm (Brunner, 1998). This paradigm manifests itself: in linear thinking; looking for one correct answer to a problem; intolerance to the ambiguity of the demanding situations at work or the divergent nature of human relationships. (2) Detachment of post-secondary learning experiences from the students' life and work contexts and perceptions of self-worth (Dirxk, 1998). Within the classroom discourse, which often focuses on “talking about practice”, the students run the risk of becoming detached from their future communities of professional practice, i.e. of being insufficiently prepared to a discourse of practice—"talking within practice" (Martin et. al., 2000). Therefore, while in the degree program, the prospective professionals often
remain alienated, in a sociological sense, from the performative world of their future work. The understandings gained in the college classroom are, therefore, hard to use in the contexts of real life.

The answer to this problem might be in integrating certain types of learning experiences into college-level education, specifically those that involve student imagination and creativity through exposure to aesthetic experiences. Such experiences have a potential to support multiple pedagogical objectives, expose the students to transdisciplinarity of related issues within the course content, and engage them in a complex communicative exchange, allowing for acquisition of the language of “multiplicitness”.

A number of studies report on the importance of imaginative ways of knowing in the contexts of adult, career, and vocational education (Marsick & Volpe, 1999; Marsick & Watkins, 1997; Saavedra, 1996; Taylor, 1998). In higher education literature there is little that deals with notions of reflective learning as an imaginative process, mediated through images, feelings, and emotion (Keifer-Boyd, 1997; Wagner, 1999; Warren, 1995). Referred to as a mytho-poetic view (Dirkx, 1998), this perspective on learning puts learners’ experiences at its core and suggests that making meaning of one’s experience is apprehended through symbols and images. In other words, the shaping of one’s epistemological belief involves the aesthetic modes of thought.

This study focuses on a particular form of the aesthetic experience—visual expression, examining its contribution to the genesis of the students’ epistemological beliefs. Visual experiences—the creating and observing a piece of art, for example—can help deal with the indicated problems through the potential of the visual images to serve as modeling devises for a learning activity, contributing to discoveries of systemic relations between the discrete pieces of knowledge. Combined with the consolidating capacity of verbal expression, visual images help generate new understandings of what was gained in the earlier learning experiences. The analysis of data implied such focus by examining examples of students’ visual expressions of their thinking about learning—the student-created multi-media documents, such as self-portraits, conceptual maps, individual web sites, photo imagery and digital video—works of art created by students individually and collectively.

**Conceptual Framework**

Using the analysis of student-created mixed-media projects, the study explores the role of symbols and images in the construction of students’ understanding of the processes of learning. This analysis is situated within perspectives on activity theory, which stems from the cultural-historical school of Russian psychology (Vygotsky, 1978, 1971; Leontiev, 1978; Luria, 1976). The advancements in these perspectives invite the study of cultural artifacts as integral and inseparable components of human activity that mediate the sense making of this activity (Judin, 1978; Norman, 1988; Wartofsky, 1979). Within a productive process of such sense making, a metaphoric thinking and, particularly, the visual images, become icons that play a decisive part. They allow for the limits of certain experiences to be altered by discovering new systemic relations. They offer opportunities for what Eisner calls “imaginative sees to generate theoretical interpretations that give the particular situation a fresh significance” (Eisner, 1998).

The second point of departure is grounded in the views of Arnheim, Tuft, and Funch on the role of nonlinguistic symbol systems. These are particularly instrumental in “reading” the students’ “visual explanations” the visual representation of thoughts and understandings. According to Tuft (1996), the act of visual design becomes an act of insight, creating the basis for change in one’s perspective on learning. Images and symbols, especially those evoked by the artistic forms of self-expression, serve as “arresting metaphors” (Stein, 1998). They heighten the ability to make sense of one’s learning experience through selective perception. A series of meanings one makes over time in a variety of learning experiences contributes to construction of one’s epistemological beliefs. By watching for the repetitive refrains and ‘arresting metaphors’ in an understanding about the kinds of interpretations students make about certain concepts introduced. These interpretations, in turn, inform about the students’ current epistemic positions.

This study elaborates on the propositions above by describing how the students’ visual representations can contribute to change in their epistemological beliefs.

**Context of the Study**
The study examined representations of beliefs about learning by entry-level prospective teachers at a large Mid-Western University. Specifically, it examined a series of visual explanations constructed by the students as part of their reflection on the experiences of the course—exploring, seeing, getting to know, and representing their thinking about learning—within the social and discursive structures of the course on educational psychology.

The course included a series of interactive classroom events where students were engaged in continual acts of emotional and intelligent deliberation, often in artistic forms. Such events included a variety of projects planned, conducted, and reflected upon by the students, individually and collectively. Among the projects were "teaching sessions" in which groups of students presented their topic of investigation, related to educational psychology, to the rest of the class. Such "teaching" might have included a "session-on-line", that is a group of teaching students should have created a session to be taught and assessed online. Another type of the project was an Electronic Newsletter that reflected on a series of essays written by the class on a particular topic. The newsletter provided an opportunity for a group of students to read, think about, reflect on, and represent their interpretations of their peers' thinking about the same topic. A student-recorded and edited digital video became yet another form of student visual expression of thinking about learning. By capturing peers, presenting their visual explanations of learning and talking about those, the video would have revealed the specific selections of the interpretive themes which a group of students would have come up while constructing the video.

While having the students represent visually their thinking about learning, the teacher explored the opportunities of multimedia instructional systems. The technology component of the instructional environment—web sites, computer-based presentations, digital video—specifically designed by the teacher to support certain kinds of cognitive tasks, aimed to reflect on the interplay of the conceptual and situational aspects of the course, along with multiple representations and knowledge interconnectedness inherent in hypermedia. Such environment was designed to help create multi-dimensional instructional cases that would enhance crafting each student's art of a reflective teacher. Such an environment was designed to help create multi-dimensional instructional cases that would enhance students' imagination and creativity and also tap into their conceptions of what it means to learn.

**Data Source**

Research data included mixed-media documents created by the entry-level pre-service teacher students over the summer semester 2000: conceptual maps, photographs, individual and collective web sites, presentational files, and video-records of the classroom events. The group included 20 undergraduate students, predominantly white, about half males and half females. Most of them had middle-class high school background. Approximately half of the students were in their late 20s and early 30s (some enrolled in a post-baccalaureate program), while half were in their early 20s. Few students had their own families and children. The majority of the students were exposed to web design and the use of technology in the classroom for the first time.

The study specifically examined the features that the students' artful projects possess, in other words, features that display certain kind of students' thinking. The students' written work (autobiographical accounts of their past learning experiences; comments on the class events and peers' projects; reflections on the readings and video materials) was used in support of their visual explanations. Data also included video- and audio files, documenting students' talk about their classroom experiences as well as questionnaires and surveys completed by the students at the beginning and the end of the semester. Open-ended, 1-hour interviews were conducted with the students during the following academic year. Data further included curriculum materials and multi-media documents developed by the teacher and characterizing instructional cases, within which the students' experiences were embedded.

**Methodology**

The study examined the student-created visual explanations from three major perspectives: (1) What kinds of visual explanations were created by the students in mixed-media formats? (2) Whether (and, if so, how) the visual explanations influenced the students' understanding about learning? 3) Whether any inferences can be made regarding the students' epistemological beliefs? Visual explanations were described through vocabularies used by the students in writing as well as artistic representations other than writing—such as portraits, design patterns embedded in the web pages and Power Point presentations as well as conceptual maps.
A qualitative, interpretive approach is employed to examine the ways in which students' visual representations of thinking might contribute to change in their epistemological beliefs. The analysis of students' beliefs about learning is done in an assumption that different epistemological beliefs manifest themselves through different visual images of knowledge and learning. The rhetorical structures inherent to visual representations can inform us about the ways and the form in which knowledge schemata is shaped for an individual learner. To categorize the rhetorical structures in students' visual representations, we employed propositions of the grounded theory (Glaser & Strauss, 1967) and pursued a constant comparison analysis of the emergent themes, as they interplay while the analysis unfolds. This process included systematic coding procedures and conceptual integration.

The students' visual explanations of their individual 'theories' of learning were juxtaposed to their verbal articulations: the essays that the students wrote in reflection to the various classroom events and the video watched in class; their autobiographical accounts of learning experiences, as well as the transcripts capturing the students' talk about their understanding of learning (during the class meetings and the interviews). To categorize the rhetorical structures in students' visual and verbal representations, we employed two groups of contrasting criteria that are associated with the features of two kinds of epistemological positions (criteria adapted from Spiro et. al.1988):

1. One is associated with oversimplification of complexity known to be related to:
   - Single representations; analytic compartmentalization; orderliness; intolerance of ambiguity; rigid prescriptions from memory; concepts detached from life experiences; passive perception.
2. The other is characterized with opposing features—more conducive to the processing of complexity: Multiple representations (the use of multiple explanatory frameworks, assembling partial representations to form complete accounts); synthetic integration and interconnectedness among the parts; disorderliness and heterogeneity (expects deviation from routine); tolerance of ambiguity; use of pre-existing knowledge in a combinatorial manner; experiential tone of concepts.

These criteria were used to describe the nature of the visual and verbal explanations of the students' thinking about learning. The juxtaposition of the students' visual and verbal explanations was mapped onto the timeline, in which the time units were comprised of the critical course events—events conceived as aesthetic experiences, the design of which sought to provoke certain kind of students' responses providing for partnership between the students' intellect and intuition. An example of such an aesthetic experience might be a response to a loosely structured task, opened to students' choice of conceptual themes (i.e., open to their own purpose for reasoning) and representational genres (i.e., open to their creativity). For instance, it can be a response to the task of expressing visually one's understanding of connections among learning experiences one might have had in the past, so that to illustrate one's own current theory of learning. A mid-term exam became such task, while combining three forms of the students' expression—written, oral, and visual mind-mapping. A collective share time where the students revealed their perceptions of the preferred expressive means ('My second Language' session) and the exposure to a movie, chosen specifically to elicit the students' current understanding of learning through a rich and provocative texture of the video material, represent two other examples of the 'critical' course events.

The openness to the students' own choice of the frame(s) of reference, the form (i.e., a history; a family of visual "novels"; a functional block-chart, etc.), their own vocabularies, as well as their own expressive means makes a student's reflective action an aesthetic experience, with its internally coherent purpose and a space for intuitive discoveries. The outcome is a fiction. One can fantasize about it, pretend about it. As a fantasy, it stirs one's feelings about self and the worth of life. Some researchers tend to think this has to do rather with character than the intellect. Such outcome, however, implies utility of a special order: seeing one's self anew, which is to Arneheim - to begin thinking anew. When it comes to reflecting on one's own experience, then it is likely that seeing anew and thinking anew would trigger the re-considering of the questions like: Who am I? What do I believe? How did I come to know it? The indications of students' attendance to the questions like these — the vocabularies used in written assignments and the connection of the concept to the aesthetic properties in their visual, imagery explanations—were further analyzed as to whether any plausible inferences could be made regarding the students' epistemological positions. While the author did not anticipate finding a one-on-one correspondence between affect that might emerge within an aesthetic experience and the students' epistemological development, some proof of a significant relationship between the two was found. This allows to suggest the intuitive antecedents of epistemological beliefs.

Findings
conveyed verbally and visually and mediated by technology—shape an emergent content of the course with its emerging language, which, in turn, provides the basis for processing feelings and emotions. We also argue that the processing of feelings triggers the students’ imagination and the act of creating visual forms that display certain kinds of thinking. Such acts of creation generate a more discriminating perspective and manifest a mode of educational inquiry ‘beyond the confines of rational discourse’ (Taylor, 1998). Finally, we contend that the use of visual expression becomes a mediating tool shaping the predisposition for change in one’s perspective on learning and teaching. Students construct reflective multi-media documents through free design, collaborative interpretation, and creativity. The act of creating these documents results from individual and collective improvisation. Provoked by the lived experiences of the students’ creative acts, the “inner work” (Palmer, 1998) generates, in turn, new symbols, associated with greater self-awareness of one’s own perspective and new understandings, both at individual and collective levels.

Implications for Higher Education Teaching

Based on these findings, the ideas below outline useful implications for pedagogy. These ideas seem to be of particular relevance for teacher preparation programs: (1) the students’ visual expression fosters critical reflection, creating a kind of “awakeness” (Greene, 1978) and representing the process and the means for explorations of self in relation to the epistemology of learning; (2) images and symbols, evoked by visual expression—those resulting, for example, from the interpretive "reading" of a peer’s drawing or creating a reflective video-clip—bridge the school (content), the home, and the self, freeing the students’ creativity; (3) these images and symbols heighten the ability to make sense through selective perception, contributing to the construction of beliefs about learning; (5) multi-media instructional systems, which involve the students’ explanation of their thinking through artistic media (other than writing), shape public space for personal reflection and enhance the emerging language of “multiplicitness”, the ability to use multiple frames of reference an alternative to the dominating “either/or” paradigm (Brunner, 1994; Spiro et al., 1992, 1988).

Conclusion

The paper joins an on-going debate on various ways of knowing, The analysis of the student created mixed-media projects focuses on the cognitive contribution of visual expression and the role of imagination in learning within a higher education setting. The paper addresses specific aspects of the instructional approach, which employ aesthetic modes of thought and use the student visual explanations in an effort to foster multiplistic thinking of pre-service teachers.

Parallel to analyzing the role of visual explanations in influencing the students’ epistemological beliefs, the paper presentation also seeks to illustrate the process used by the teacher (who is also the author of the paper) to interpret her students’ visual explanations. In addition to a traditional text of the paper, a “product” of the study will be presented, which uses the multi-media presentational formats to illustrate the emergent research themes (for instance, an interactive web site with digital movies and photo imagery provided with annotations). One such theme is the relationship between the researcher’s “logic of discovery” and the “logic of demonstration” (Nisbet, 1976). The investigation into this theme helps shed light on the ways in which the aesthetic modes of thought might be helpful for the researcher’s understanding of qualities of learning and teaching that otherwise might be unseen.

Visual Thinking in Service to Crafting a Teacher

Olga Kritskaya, Michigan State Univ., USA

The poster-demonstration will introduce a qualitative case study in an educational psychology course within a pre-service teacher education program. The study focuses on the cognitive contribution of visual expression and the role of imagination to learning in a higher education setting. The poster has two purposes: (1) Using examples of the student-created multi-media projects, to offer a display revealing the contribution of students’ visual representations to their thinking about learning. (2) Using examples of the instructional multi-media cases, to share the lessons learned from an instructional approach, which employs aesthetic modes of thought in an effort to foster multiplistic thinking of pre-service teachers. Analysis explores specifically whether the use of specific kinds of the aesthetic experiences helps foster students’ imagination and whether those change the students’ beliefs about learning. By integrating photo-collages, portraits, conceptual maps, and digital video, the display attempts to make the research themes more visible.
Scenario-based Design of Flexible Hypermedia Learning Environments

Huberta Kritzenberger, Ronald Hartwig, Michael Herczeg

Institute for Multimedia and Interactive Systems
University of Luebeck
Seelandstrasse 1a
D-23569 Luebeck
{kritzenberger, hartwig, herczeg}@imis.mu-luebeck.de

Abstract. Software development processes need to cover usability relevant information. Although several methods have been proposed how to collect usability relevant data, there is a lack of suggestions on how to deal with this information and how to ensure that it is available in a proper way at the relevant stages of the software development process. This paper proposes a framework to store and retrieve usability relevant data using object-oriented OOA and OOD methods together with scenario-based analysis. As this framework combines advantages of all these methods, uses a XML-based, relational database with server pages and networking, it is an ideal repository for distributed design teams.

1 Introduction

The focus of this paper is on usability engineering in the development process of adaptable web-based course material. Such applications are under development at our institute for the domains of e-business and web-based education training material for virtual universities (cf. Hartwig/Kritzenberger/Herczeg 2000).

As hypermedia are used by users with many different goals and levels of knowledge (cf. Kritzenberger/Herczeg 2000), there is a need for systems that allow to modify and adapt parameters accordingly. Although adaptability has been a long time the primary domain of artificial intelligence research (cf. Brusilowsky 1998) there is a growing interest of usability engineers (De la Teja/Longrè/Paquette 2000). They see part of the success of developing software adaptable to the indiv needs and preferences depending more on managing the development process and integrating the assessment data produced at each stage of this process than on increases of information technologies.

Therefore, much attention has been paid to the software development process with several attempts to improve it and to integrate usability information into it, e.g. ISO 13407. Ideally, the usability engineering (UE) starts with the definition of the potential users and an analysis of their work situation in order to specify design requirements. The analysis phase focuses on understanding users and processes needed for their work and the result of the analysis should be documented by means of user-centered work-modeling techniques. Several techniques are available to do that, like survey technique similar to market research, contextual research (cf. Holtzblatt/Beyer 1993) or participatory design. Regardless which technique is actually used for analysis, normally a lot of data are produced, as demonstrated for example for contextual research. The data produced in one phase can hardly be recorded in appropriate ways and integrated or reused in other software development phases. Therefore, it does not make a great difference for the practice of software development processes, if these data are gathered or not. Data have to be usable by different members of a design team at a different stage and with different backgrounds. Furthermore, the members who are active at different stages of the development process will raise new data, which add to the conceptual design model and should therefore be available, too.

2 Knowledge Management for Usability Engineering

Usability engineering (UE) is an iterative process of development, which consists of six stages: analysis, requirements specification, design, implementation, evaluation and maintenance. In all these stages data are produced which are also needed in the following stages by different members of the software development team. In our approach all members of the design team, which in the development process of learning environments consist of content author, designer, producer and quality manager, use a relational database with a web front-end. This database should include all the context information as
well as the content of the teaching units. In a first step this information is only presented to the involved persons but no contents are automatically generated.

For database organization object oriented techniques are used (cf. Hartwig/Kritzenberger/Herczeg 2000). Classes of information like “user attributes”, “organizational requirements”, “content”, etc. are identified and then may be freely combined into "views". These views are role dependent, for example the content author may concentrate on the analysis data and the contents. Whereas the producer, who has to implement the learning unit, may need additional design rationales added by the designer. A quality manager can base his evaluation of the system on the requirements identified and documented during the analysis phase. As the size and the number of the learning units is difficult to handle, techniques of the OOA are used, e.g. abstraction, inheritance and generalization. If for instance many different user groups are to be considered, they may be ordered hierarchically: “All users”, “users of the teaching unit”, “A special group within these user group”. Attributes of the most general object (“All users”) are inherited by all following objects and then, e.g. the designer’s view includes all attributes, from the general to the specific ones. OOA techniques, like underspecification and refinement make the handling of large object sets easier and allow all participants to start with rather raw data and to refine them during the iterative process. Using OOA techniques based on a database has several advantages. The database supports the complete lifecycle of the course unit and makes all information and design rationales available again for maintaining or updating the course. As the contents of the database are XML(XHTML)-based they can be included into the courses with less manual effort. Furthermore, the connection of each unit to the position and role in the database is kept. Additionally for each production phase there is appropriate additional information available, like design rationales and the related context information. Updating a content in the database automatically updates the course and avoids inconsistencies.

3 A Task Analysis and Design Framework

The following framework layer represents a generic model (cf. Herczeg 1999, Herczeg 2001), which covers the specific characteristics of the user population as well as the situational factors and the process of using the software, e.g. a hypermedia learning environment. It is based on the concept of object-oriented system design. It was developed in the context of interactive applications (cf. Herczeg 1999) and proves more and more to be a generic platform for analysis and design of software systems.

The following figure shows the task analysis framework, which is a set of object classes from which a model of the system can be built. It enables building a functional as well as a contextual model. It uses the basic ideas of object-oriented analysis and design (OOA, OOD), but enlarges the object classes with extra attributes covering context of use information, e.g. describing the conditions of use, the environment, goals etc.

![Figure 1: Task analysis framework (from Herczeg: 1999:26)](https://example.com/figure1.png)

The framework consists of the following entities:
Managed Objects: defines the resources managed by the system, e.g. for the domain of educational material these are the modules of the application and information space.

Tasks: have to be performed by those agents, who use the system according to their role. For the domain of the learning environment tasks are typically performed by learners as learning tasks, e.g. doing exercises, trying out, memorizing something, constructing and so on). Tasks define tools, which help or enable executing the task. In educational material (like web-based training systems) the task can also be systematically specified by a learning theory.

In our example of educational material this means that the task can be described as “learning” at the highest level of abstraction. In the sense of a refinement hierarchy, at a more detailed level, subtasks may be described as “basic orientation”, “acquire knowledge”, “apply knowledge”, “transfer knowledge”, and so on. At the most detailed level the model may describe atomic tasks. This leads to the idea of a refinement hierarchy of the task in which the behavior of the system is described at increasing levels of detail. The lowest level of detail is that of atomic pieces of behavior. In the direction of the aggregation hierarchy the system has subsystems at the next level of aggregation, which are themselves part of a compound system at the next higher aggregation level.

Roles: are represented by agents. In the case of educational systems this means that the role is represented by agents, who are the learners.

Agents: describes users and their profiles, which may be active in one or more roles. Learners may be diverse, but learners may also have several characteristics in common and can therefore be divided into several user groups. In this case role would be identical with defined user group. In this case the role represents also to some extent the context of learning, which is widely defined by characteristics of the learner and the profile associated with this specific learner group (cf. Kritzenberger/Herczeg 2000).
**Tools:** support for the execution of tasks. In the example of educational systems this can be represented by a teaching or pedagogic model. (The leading question: Which method fits best for reaching specific teaching goals?)

The framework described above is realized in a prototype (cf. Figure 3).

![Prototype screenshot](image)

Figure 3: Screenshot of prototype modelling a course unit on medical terminology

Figure 3 shows a screenshot of the prototype modelling a part of the course on medical terminology (subject: adjectives) as part of a course of studies in medical computer science. In the left frame there are the elements from the framework with task, tool, managed learning object and user group. In the right frame there is a view on the managed learning object “Adjectives”. The screenshot shows an under the heading “Verweise von anderen Objekten” how the content authors had considered an ordering and logical sequencing of the content. Furthermore there is general didactic knowledge on how to structure courses, which should also be considered when the course unit is constructed. This information needs to be stated explicitly, if it should be present in all stages of development and forms a kind of meta information if the learning objects should be re-used with different views on the material, e.g. for building a course for another user group.

### 4 Enhancing of OOA with Scenarios

As discussed in the previous section, data are collected, specified and stored according to the described framework. As the framework allows for further attributes describing parameters of the context of use or user characteristics, it is possible to add information, which is essential for the usability of the system. Usability relevant information is for example characteristics and needs of special learner groups. These data provide specific information, which can be gathered by data collection in organizations by asking questions like who are potential users, or by analysis of imagined scenarios (cf. Carroll 1995).

Let's make an example from the domain of educational material to get things more clear. For the use of educational material it is normally important to be aware of the previous knowledge of the users, as the learning material has to be adapted accordingly. Although this seems to be a very clear parameter for system variation, these data are less precise than they seem to be. For example, it is not clear right from the beginning, in what way the educational modules have to be altered,
because usability information like previous knowledge is not sufficiently defined. Nevertheless, it is important to assess these data and possibly refine this information in the course of the development process unless it is precise enough to make relevant design decisions. If it is integrated into the object-oriented framework, it can be handled with object-oriented methods, as demonstrated with the following example.

An example scenario: Learner groups in a virtual university

The educational material offered in a virtual university will not only be used by traditional students of universities but by a variety of different users. Therefore, one can distinguish different user groups, which can be further distinguished by their basic needs according to the available educational material. For example, learner group 1 wants to do basic studies in the domain in order to pass exams and earn diploma. The learners want to study all modules relevant to the curriculum, need guided tours to differ relevant from irrelevant knowledge with respect to passing exams. Learner group 2 wants to do postgraduate studies. They have already passed an exam and have learnt how to learn. Learner group 3 does not want to go through all the knowledge modules offered in the database, but wants to study only some modules for task-oriented knowledge acquisition. Often a current problem or a knowledge gap is the starting point for learning. Learner group 4 is characterized by exploring the knowledge domain according to personal interests. The behavior of learners in this group is comparable to browsing libraries, reading books and magazines.

Figure 4: Hierarchy of learner groups demonstrating attribute inheritance for usability information

The data are stored as XML data records in a relational database (cf. Kutsche 2000). An important advantage of this method is that classes of information are introduced. Such classes are for example, “user attributes”, “content” and so on. These classes can be freely combined into views on the database, like the example of a role dependent view in figure 5 illustrates. In general, modeling and storing of classes with varying attributes allow flexibility in storing and selection of data. To take again the example of the learning environment, this data organization allows to cover attributes, which are valid for the whole context, and attributes, which are valid only for certain parts of the context. Moreover, another advantage is object-orientation, which allows generalization or abstraction with different detailing of information at different abstraction levels. So, developers don’t have to deal with too many irrelevant data and information. Even numerous and complex attributes stay manageable, because specific attributes are only valid for certain user groups.
Another helpful quality of XML-based relational databases for the development process is, that it can be easily translated into other SGML-type languages like XHTML or LaTeX in order to visualize and document the contents. As the framework is web-based with server pages and the database is capable of serving a network, it is available for each of the members of the design team to insert data directly and can be used even for distributed teams.

5 Conclusions

The object-oriented framework described above allows flexible management of usability data during the whole development process. Even complex and informal data, e.g. from scenario descriptions, can be included and selected according to situational and role specific needs of users. As far as our experience with the application of hypermedia learning environments is concerned, the framework offers the possibility to include learning modules and connect usability information on different levels of abstraction. For the our application of a learning environment this will also be a basis for adaptation criteria.

For the future work, the framework for modeling learning environments will be further detailed. As software engineering is an iterative process that requires constant updating, the usefulness of our framework will be further proved by practice.

Abstract

This paper discusses how the author developed a Multimedia Program Measurement Instrument in consonance with proven design principles from the behavioral and cognitive sciences for instructional design and using several software tools. This is a program developed for her dissertation research, which was used for the initial pilot and field testing in the Spring and Summer 2000 semesters followed by a second pilot and field testing and Final Experimentation in the Fall 2000 semester at the University of Central Florida, C&I Instructional Systems. Her study is concluding in the Spring 2001 semester. The research study addresses the effect of three types of icon symbol formats viz., abstract, drawing-pictorial, and photographic-pictorial on a user’s learning and performance. The measurement instrument consists of a lesson followed by a quiz on the “Advanced Features of a Digital Video Camcorder”. Divided into three parts, the first part discusses the design of the interface and how principles of design was applied for ease of use. The second part of the paper discusses the tools for creating the multimedia program and to capture user’s action and scores on the test. The paper is concluded in the third part by drawing up suggestions for applying similar approach to a variety of uses, whether standalone CD-based or web-based.

The Design of the Interface

Factors that were given primary consideration in designing the multimedia (Fleming and Levie (Eds) 1993) measuring instrument interface for ease of use, mental effort (Winn 1993), attention (Aspillaga 1996) and clarity of presentation were: consistency, predictability, simplicity (Haag and Snetsinger 1993) and information density (Mandel 1997 and Tullis 1997). The program interface starts with a ‘welcome login’ window where the user enters personal information. The whole experiment is concisely, briefly and clearly explained using a minimum of text and presented via pop up boxes while the user mouses over the conceptual words. This is done to keep mental effort of a user to a mimimum. The user is then familiarized with the lesson interface explaining what to anticipate, what a user is allowed and not allowed to do during the experiment. During the lesson (trials and sections) the user is guided by pop-up text prompts telling the user to go to next lesson, trial or when done with the last trial section to proceed to Quiz.

Using a real-world (Mandel 1997) digital camcorder metaphor, the screen has a jpeg DVCAM photo (Fig 1) which serves three purposes viz. as a background for the content area (DVCAM); as a context that acquaints the users on the location of the parts and control dials and, as a bounding box that holds all icon, text and movie information. This background appears throughout the Lesson only. For text, the location, size, color and type of font (Ross 1988) stays the same for the different types of information. For example, the font type (AGaramond), color and size and location for the ‘Step Number’ button stays the same throughout the lesson. The same rule applies to the heading and prompts. The importance of the text information determined the size of font, i.e. words such as ‘Lesson, Camera, Program, VCR and Quiz’ needed to be emphasized and had to use (font size 14) than the heading text (font size 12). The icon images were of the same size and location with a buttonized, raised 3-D look. Predictability was solved by using a consistent design of having the icon in the upper left corner, step number on top of the icon, text meaning below the icon and process meaning in motion video on the right of the icon. This arrangement made it easy to locate information minimizing confusion and getting lost on the interface. Textual prompts appeared whenever a section, trial or lesson was concluded, guiding the users on the next thing to do so they avoid feeling uncertain on what to do and where to click next. The objects on the interface such as the icon, the text explanation and the movie file which appeared after the icon is invoked are grouped in close proximity within a 3.5” radius. I maintained the same radius for presenting the single-answer multiple choice question. I used a bigger 4.5” radius for the several answer multiple-choice questions. This avoids the information seeking behavior of the eyes to move around the interface when trying...
to locate information (Tullis 1997). This kind of perceptual grouping also allows for making meaningful associations among the information being presented (Winn 1993). Overall, the interface has a simple, uncluttered look.

Location of information stays consistent in every window

800 X 600 Window Size

The DVCAM image serves as a contextual background throughout the lesson. Screen color used was black which contrasts and makes the icons stand out.

Buttons and active links appear only when they are needed and prompts appear only at appropriate times

Fig. 2 Screen Capture of the Lesson Interface (not to scale)          Fig. 1 Buttonized Images

The Tools

The Lesson is divided into three sections. One section is devoted to presenting the sequential steps to set the Canon ZR digital video DV camcorder DVCAM to CAMERA mode. Once in that mode, the DVCAM can be set up in various ways which will have an effect on the recorded output. For illustrative purposes and to show the basic difference between digital video recording in contrast to standard analog video recording, the option of setting the DVCAM to DIGITAL EFFECTS for the Camera Menu was chosen. The steps lead to the last part of finally setting the DVCAM to Digital Effects and then shows the different types of effect one can use for a project. Of the seven built-in digital effects, only 4 viz. Fade-Trigger, Art, Sepia and Strobe were used. Another section is devoted to presenting the sequence of steps to set the DVCAM to PROGRAM Mode. In this mode, six options are available to suit the recording environment. For illustrative purposes the LOW LIGHT option was selected. When set to Low light, the DVCAM is able to record in dimly-lit places. The other section is devoted to presenting the sequence of steps for setting the DVCAM to VCR mode. When in the VCR mode, a user can view the recorded product.

The DVCAM image serves as a contextual background throughout the lesson. Screen color used was black which contrasts and makes the icons stand out.

Buttons and active links appear only when they are needed and prompts appear only at appropriate times

Perceptual Grouping – Buttons, objects such as a group of menu buttons, in this case, group of information that relates to the icon being grouped together are meaningfully associated with one another.

Fade-Trigger: At Start, the scene gradually fades in from a black screen. When stopped, it gradually fades out. Wipe: At Start, the picture begins as a thin vertical line in the center of the screen gradually expanding sideways to fill up the whole screen. At Stop, the image is wiped from both sides of the screen. Scroll: At Start the picture appears from the right hand side of screen expanding sideways to fill up the whole screen. At Stop, the image is wiped off. Art: Adds a point-like solarization effect to the image. Black and White: Records the image in black and White. Sepia: records a monochrome image with a sepia tint. Strobe: On-screen actions become a series of still images i.e. slow motion effect.

Auto
Each step is represented in three different icon design. For that reason, MS Image Composer and JASC PaintshopPro were used. Image Composer was useful for minimum photographic image enhancements such as cropping, erasing, sharpening, blurring and texturizing. PaintshopPro, another image editing software's, Drawing Tool, not only allowed me to draw freehand shapes, geometric shapes, vector arrows etc. but was also handy in enhancing graphic objects. Through its Image and Effects Menu, I was able to fill shapes e.g. arrows with colors, rotate the direction of vectors and enhance their brightness and illumination. The last feature was particularly useful in enhancing the photographic-pictorial symbols resulting in a sharper, clearer image. When all the graphical digital assets were completed, each one was given a uniform dimension and applied a Buttonize effect to give it a raised clickable 3-D look (Fig 2). Video files were created by first recording the different steps in analog format. Using a software converter called DAZZLE, these analog files were converted into MPEG files. Once captured and saved onto the PC's hard drive, these MPEG files were enhanced, edited and cut. When set in Snap Capture and View mode, these same MPEG files could be used to extract JPEG images as well. To create the whole multimedia program, Macromedia Authorware Attain 5 was used. Authorware is an object-oriented, multi-platform authoring tool which recognizes various file formats for animation, audio, video, text and graphics. Its Knowledge Objects Application shell was useful in developing the LOGIN portion which is where the user inputs personal information such as name (first, last and middle) and subject number. Knowledge Objects are mini programs that a developer can add to the main authorware application. There is a Quiz Knowledge Object, an Application Knowledge Object, a Movie Controller Knowledge Object etc. The rest of the multimedia measuring instrument program was completed using the flowchart, icon-based authoring approach.

To track the user's actions, a screen recording software called Camtasia was used. Time and scores on the quiz are captured on the hard drive. These MPEG files dynamically records all of the user actions in real-time and can be replayed later for review. User's behavior on the program reflected by the movement of the cursor appearing as an arrow or a hand can then be observed during replay.

Conclusion

The behavioral and cognitive design principles guiding the creation of the multimedia measuring instrument can be used for similar learning, performance and evaluation exercise for different content areas in interactive simulations, CD or web-based training and other technology-related training. The tools I used for creating the instrument are but a few of the many applications available. It is now common practice to download trial versions of even the fanciest software for 30-45 functional days. After the elapsed period, these downloaded applications will stop working and will prompt the evaluators to purchase the product. Much of my instructional technology application try outs are done this way.

Do new media need new didactic methods?

Patrick Kunz  
Centre for Teaching and Learning  
Swiss Federal Institute of Technology (ETH)  
Zurich, Switzerland  
kunz@diz.ethz.ch

Abstract: The need of new didactics is an often heard claim in the context of the integration of new information and communication technologies (ICT) in education. This paper pursued this question and found, that most of the effective applications of ICT in educational settings are not based on a completely new didactic approach. However, the call for new didactics seems to be grounded more on a lack of knowledge about existing didactic possibilities than on a real requirement.

The confusion of media technology and pedagogy

ICT have made incredible advances over the last few decades. From room-filling machines, computers have continually downsized to desktop and even portable models. The latest generation of computers actually deserves the label “multimedia”. Parallel to these innovations, the internet has become a service that is now also available to the average individual. But the real power of multimedia and internet is to be found in the concept of “hypertext” and its extension “hypermedia. These innovations are interesting not only from the technological and economical viewpoint, they also offer new possibilities in education. However, do these new ICT require “new didactics” as claimed?

The short answer to this central question is “No, new didactic methods are not stringent prerequisites for an effective integration of new ICT into educational settings” (Kerres, 1998, p.30). Many effective examples of ICT applications in education are based on known didactic concepts and methods. For example, computer-mediated communication often reverts to the seminar model of classroom teaching. Or CD-ROMs: They are often used in a not very innovative way simply as replica of books enriched with animations, video and sound. But on the other hand, very sophisticated CD-ROM based multimedia productions also exist in which the principles of “discovery learning” are applied in a very effective way. Furthermore, the same didactic methods that make the best out of traditional classroom lecturing, will also contribute to the success of tele-teaching by television or videoconferencing.

The call for new didactics seems to be founded in a fundamental confusion between media technology and pedagogy. Although the insights of Clark are now 15-20 years old, they have not lost their timeliness: media are simply vehicles to deliver instruction (Clark, 1983, p.445). ICT have no impact on underlying theories of learning, although they play an important role in designing instruction and delivering content and information. Furthermore, it is not only the technologies that have changed over the last decades. Psychological theories of learning have also changed significantly - evolving from previous cognitive theories, constructivist theories have recently come more and more into vogue. Parallel to this evolution of theories of learning, a wide range of new didactic methods have been developed: discovery learning, problem-based learning, anchored instruction, cognitive apprenticeship etc.

Integration of ICT: Pedagogy driven instead of technology driven.

The challenge today is how to transfer this know-how to the new ICT (Kerres, 1998, p.30), rather than the often heard question “How must instruction be adapted to new ICT?”. An urgent issue for research in didactics is how to integrate the new media into existing didactic concepts in order to foster the most efficient and productive

The collective term information and communication technologies (in the following abbreviated as ICT) will be used in this paper to denote all systems and applications based on computer and telecommunication technologies, for example, internet, CD-ROM, multimedia applications, tele- and videoconferencing systems.
learning possible (Eberle & Abplanalp, 1999). A central aspect consists in the question of which media or combination of media do best fit which educational purpose. However, up to now empirical research did not succeed in proving the superiority of a specific medium in a defined learning environment (Kerres, 1998, p.28; Russell, 2001). In most cases where the use of computers was found to be advantageous "...it was not the medium [itself] that caused the changes but rather a curriculum reform that accompanied the change." (Clark, 1983, p.445). Empirical research on media in education is hampered by the superimposition of instructional method and media. Consequently it can be deduced that media themselves have little influence on the achievement of learning goals. Thus, looking for the one best medium is little reasonable and even irrelevant. Instead it is the choice of suitable instructional approach that must take precedence over the decision for or against a certain medium. First the educational needs, second the suitable didactic approach and only third the selection of an appropriate medium (see figure 1, left side).

![Figure 1: The decision-making pyramid in the choice of an appropriate medium for an educational setting](image)

Unfortunately, in most of the cases the implementation of ICT is technology driven. Too often the wish or availability of new technologies dictates the agenda (Kerres, 1998, p.28). In these cases, technology is either used to only enrich teaching environments as peripheral or optional offer, or - at the other extreme - institutions try to substitute teachers with new media by imitating traditional face-to-face instruction. Neither of these approaches genuinely improves learning. In such technology driven scenarios, the instructors change their curriculum and adjust their didactic approach to fit the demands of the technology (see figure A1, right side). If the curriculum has to be changed, it must be because there is a better method that can only be brought about with new media, and not vice versa. In order to effectively exploit the potential of new ICT, educators themselves must meet two additional criteria: Firstly, a solid knowledge on the part of the lecturers of at least the basics of didactics is imperative. Secondly, it requires a certain amount of imagination and creativity to successfully combine this didactic know-how with the possibilities offered by ICT. With sufficient creativity, it is feasible to produce not only efficient ICT-learning environments but even to create entirely new didactic methods. It is challenging and interesting to follow the different ways that are tried out with new media. But even if new methods evolve, ICT do not need a new theory of learning. Hence, the claim for new didactics is based on a lack of knowledge about existing possibilities didactics offer already today than on a real requirement.

Summary

- New ICT do not need new didactics.
- It is not the medium but the didactic approach that is responsible for the changes in learning efficiency.
- The educational objectives determine the choice of the didactic approach. The didactic approach again together with the circumstances of the whole learning environment determine the choice of the media.
- The possibilities of new ICT can only be fully exploited if the involved instructors dispose of the relevant didactic foundations.

Abstract: We developed three types of communication board systems to promote class-to-class collaboration for environmental learning. Each board has advantages and disadvantages. We can summarize these between learning context and idea-comment relationship. On a communication board system, we can see links between a comment and its target idea on the web page. On the other system, they can read comment chains about some topics easily and even be able to discuss something on the communication board, but comments are apt to have weak relation to the original web page, which represents a learning activity by a classroom. It is better to combine some other media with the communication board in order to have a successful and balanced collaboration.

Background

One of the most important purposes of the Internet use in elementary schools is to promote collaboration among children in distant classes. Communication through the Internet among classes should be activated to attain the purpose. It is very rare for Japanese children to communicate independently with friends in distant schools during class work. Most teachers tend to lead children’s learning contexts and put the students together into a series of similar learning activities. This seems to conflict with individual or group use of the Internet for learning. In reality, each teacher usually creates a lesson plan, and children use the Internet in accordance with the plan.

This leads to a situation that is not suitable for Japanese elementary children to communicate with a general electric bulletin board system, because it requires personal communication. We need a special BBS system to promote both class-to-class and personal electric communication. We started developing a kind of communication board system to meet these needs in 1996 (Dept. of School Programs of NHK, 1998).

The first system was named DBC-Web. After that we developed other types of communication board systems. The later systems are developed based on some requests from users of the former systems. The improvement of the system was mainly focused on styles of children’s communication. We tried to promote more frequent and interactive argument on the systems. For future development, it is essential to recognize the advantages and disadvantages of each system.

Outline of each Communication Board System
This system is based on a card database system named D.B.C. (Database for Children), which was developed with SuperCard in 1993 for environmental learning at Fukumuro elementary school. Each card of the original D.B.C. has a "picture field" for a photograph or a picture by the learners, a "data field" for location, temperature, climate, and other data, and an "opinion field" for learners' opinion related to the information in the other fields.

The DBC-Web enabled learners to publish the data on the D.B.C. to a web site. Children go on field research trips and make a brief investigation about their surroundings. They input outcomes from the activities to the D.B.C. Finally they display the data on a classroom web site (Fig. 1).

The gray outlined frame is for data on the D.B.C. and the page has three other frames: card changer, comment browser and comment field. The left frame is to select the data card to view (card changer field). Children are able to get comments from other elementary students by way of the bottom frame (comment field) and read them in the middle frame (comment browser). Each data card has a different comment log. Children can exchange opinions about each card.

-Health of the Earth (1st model)

The second communication board system works together with a TV program series titled "The Only One Earth" (Kurokami et al. 1999, Dept. of School Program of NHK, 1999). This series is made to facilitate environmental education at 5th and 6th grade of elementary school and includes 20 different shows. Each shows are 15 minutes long and produced to be used in usual lessons of integrated curriculum. We are supposing that every class using the system is watching most of the series.

A series of TV program has a long story to show audiences about various environmental issues. At the initial period some concrete issues like air pollution, water pollution, and garbage disposal. Gradually these issues are integrated into more abstract theme like ecology system.
A teacher conducted in-depth learning about environmental issues after watching the TV program. Pupils made web pages in groups or in a class about their activities and the results of their learning. These web pages were put on our communication board system server. The communication boards were connected with each web page (Fig. 2) published by classes that participated in our project.

We transplanted rice seedlings from two places, one from our place and the other from Ishikawa Prefecture (Home land of Tokuda elementary school), on June third.

Hello, friends in Karo Elementary School. I had a nice time at the last video conference. I was surprised at and envious of your large rice fields and a number of lives. As you told me, I spread chemical fertilizer immediately. I was frightened by the frog without legs. Could you please send the frog for us to investigate?

**Fig. 2: Health of the Earth (1st model)**

Communication on the board is based on the context of activities done in each classroom. Distant learners are able to produce comments to every other class. For example in Fig. 2, the web message in the left frame is about a rice planting activity. Beneath the message and photograph, there is a message informing others that they found a frog without legs in their rice field. On the right side, we can see comments from another school, which says the pupil was frightened to see the legless frog. This interaction can be a bud of more fruitful communication between their classes.

**-Health of the Earth (2nd model)**

This is the revised version of the 1st model. With this system, there is no need for learners to send HTML documents to our Internet server. Users register their own web page (URL) to the communication board system. They usually make their own web pages about various classroom affairs. If they want to get comments from, they just send the URL of the page to our comment board system.

When learners access a registered web page from our communication board system, two windows appear on the desktop. One is the page accessed and the other is a communication board. A school or a class has just one communication board on this model. Therefore whole comments will relate to the story of learning activities published on the class web page.
Advantages and Disadvantages of Each System

We can learn a lot from these three types of communication board systems.

As the DBC-Web is a kind of database system, every finding by children on field trips can be saved on the system. Each record has a connection to children's investigation so it contains very concrete findings without interpretation or explanation. On the other hand, information on the DBC-Web is broke up into pieces and the number of records is too big to be read by project friends. At the same time, the relationship among records can't be represented in any way. It is very difficult to get any idea about the story of classroom activities from the information.

Health of the Earth (1st model) consists of web pages sent by project classrooms and communication boards for each web page. Children in a classroom have to organize their ideas with findings on fieldwork and make one or more web pages, while an electric bulletin board is generated for each page. They can get the same number of bulletin boards as web pages. As web pages and bulletin boards have a one-to-one correspondence, it is very easy to find the target idea of comments from distant learners. On the other hand, distant learners intending to produce comment to the whole message of the site faced some confusion. There is no way to do that and every comment is forced to be written on the same communication board. This makes discussion on the board difficult.

On Health of the Earth (2nd model), we lose the connection between communication board and target idea. We get context of comments at the price. Comment chain is continued to enable users to discuss something on the board. From a learning management view, children need not make special web pages to send to our Internet server for the project. This saves time so that children can spend more time doing fieldwork or other research.

Possibility of Communication Board in Educational Use

Collaborative learning on the Internet has many advantages and disadvantages. For instance, advantages include exchanging vivid local information, making it easy to think globally, and promoting learning motivation.

We can list risks of faulty information from distant learners, relying too much on others to get information, and being time consuming as a few disadvantages. Educators have to find a balance between the good and bad points.
**DBC-Web**

- Every finding by children can be saved on the database.
- Every data has a photograph on the data sheet and the image of the information is easy to grasp.
- Each data is related directly to findings of the investigation.
- Too many cards are produced to be read and understood by co-learners.
- Relationship among records can't be represented.
- Whole activities of a class are difficult to understand.

**Health of the Earth (1st model)**

- Findings of the fieldwork is made up into web pages and this can be a good chance to re-understand of their work.
- Every web page reflects a context of learning.
- Target page of comment is clear.
- Comments are scattered on each communication board.
- It is almost impossible to trace comments in time flow.
- Discussion on the communication board is difficult.

**Health of the Earth (2nd model)**

- Findings of the fieldworks is made up into web pages and this can be a good chance to re-understand of their work.
- Context of communication can be saved.
- Discussion on the communication board is easy.
- Participants need not make special web pages for the project.
- Target page of comment is not clear.
- Communication on the board is not always related to the web pages.

<table>
<thead>
<tr>
<th>Table: Features of Each Communication Board</th>
</tr>
</thead>
<tbody>
<tr>
<td>From this small history of our communication board systems, we may add a new viewpoint to a list of weights: learning context or relationship between target idea and comment. On one system we can see the relationship clearly at the sacrifice of losing context of comments, and on the other system we can get context instead of the relationship.</td>
</tr>
<tr>
<td>Communication boards can promote collaboration among some distant classrooms in a sense, but we always take notice to compensate for the lost weight with other media like video letters, and videoconference. Communication boards become more useful in combination with other educational media.</td>
</tr>
<tr>
<td>Actually, 13 classrooms participating in our project this year are using video conferencing frequently. Communication between/among classrooms is direct and synchronous, but the chance of the conference is limited. Because of difficulty of coordinating schedule and connection fee, possible period of the conference is about an hour a time. Sometimes, hot arguments about a complicated theme occur on the limited condition. Usually, however, it is difficult for children to reach any conclusion in a conference.</td>
</tr>
<tr>
<td>Meanwhile, discussion on the BBS was asynchronous and gave children a longer time to think about the theme. Messages could be sent individually at any time. The opinions of each child could be expressed on the board.</td>
</tr>
<tr>
<td>Teachers always read their messages and follow the stream of the discussion and determine when to have videoconferences. The focus of the videoconference is also lightly controlled by teachers. They use videoconferences and BBS according their purpose.</td>
</tr>
<tr>
<td>We have to suppose that communication between/among classrooms is supported not only by our communication board systems but also by the other media and even by teachers and children.</td>
</tr>

Dept. of School Programs of NHK (1999). *10 Schools Network Project Report*
Doing research on web-based learning

Leena Kuure, Univ. of Oulu, Finland; Saarenkunnas Maarit, Univ. of Oulu, Finland; Taalas Peppi, Univ. of Jyväskylä, Finland;

Interaction in technology-supported collaborative learning environments can be beneficial for learning in many ways (e.g. Lehtinen 1997, Järvelä & Häkkinen 2000). At their best, they may help their users to transform the practices of learning and instruction. As for the research perspective into web-based learning, many aspects of the working process can be captured through the electronic data, automatically stored throughout the study project. However, we should carefully consider to what extent it is possible to make generalizations concerning the effects of technology on learning outcomes with the aid of a single source of data. A central concern related to the research of technologically mediated communication and learning is the choice of an appropriate research approach to capture the complexity of the phenomena under investigation. This poster discusses a discourse approach to the study of web-based learning.
Developing SLA in New Language Learning Environments

Anna Kyppö
University Language Centre
University of Jyväskylä
Finland
akyppo@cc.jyu.fi

Abstract

The paper reports on the findings of a study conducted on the basic courses of Slovak. The purpose was to examine the development of Slovak language acquisition in the new learning environments (self-access centre). Communicative competence was explored from the perspectives of language production and language process, and it was assessed by means of language level tests and self-assessment questionnaires. Both intro- and retrospective methods (questionnaires, analyses of learner diaries) were used to reveal the learners' attitudes towards the employment of new language learning environments and towards learning Slovak in general. The study showed that some students were reluctant to use the self-access centre utilities for their self-study due to their beliefs in traditional learning methods and lack of computer literacy. However, those students who were able to utilize the new learning environments achieved better results than those who were not able to utilize them. The study is an example of the acquisition of a less frequently taught language in new learning environments and a case of overcoming prejudices. As such, it contributes to the development of pedagogy of less frequently taught languages.

Introduction

It is a well-known fact that SLA (Second Language Acquisition) requires a lot of time and effort, and that teaching alone can seldom produce fluency needed in authentic language use. In addition to teaching, the learner must also develop skills for continuous learning and self-assessment (Rasanen & Randell, 1999; Karlsson et al., 1997). Furthermore, the use of the Internet, as one of the primary media of literacy and communication, requires the development of information literacy which involves the ability to find, organize and make use of information (Warschauer & Kern, 2000).

The growing requirements for efficient learning and teaching, institutional saving policies and the need for learning something new were the main factors for creating a supplementary self-study program of Slovak for Finnish students. The main focus was on the development of SLA (Second Language Acquisition, Slovak Language Acquisition) skills and competencies and promoting self-directiveness in language learning. Multimedia applications (text, sound and video) were applied in the first stage of the program (language, culture, literature studies) and network applications (information search, use of electronic communication tools, discussions and simulations) in the second stage of the program.

The Study

In the first stage of the program, the communicative competence of the learners was explored from the perspective of language production. All students from the basic up to the advanced level were tested at the beginning and at the end of the term. Language level tests were complemented by questionnaires which aimed at revealing students' attitudes towards learning Slovak (use of learning strategies, motivation) as well as their attitudes towards the use of new learning environments.

In the second stage, the communicative competence of the learners was explored from the perspective of the learning process. Five students were observed from the basic up to the advanced level. The observation began in 1999 and is still going on. Their learning process has been observed in the classroom, by means of questionnaires, personal discussions and learning diaries. Language proficiency development has been assessed by language level tests (at the beginning and at the end of the term). Their experiences of using new learning environments have been discussed during feedback sessions.

A separate group was composed of distance students and some advanced level students who were unable to participate in the contact classes (5-7). Teacher-learner communication was provided via electronic communication tools only (online communication, e-mail). This group participated in the contact feedback sessions only once, otherwise the feedback was given in the electronic way.

Findings

Some examples of the SLA skills and competencies practiced in the self-access centre were as follows:
Listening skills: audio/video tasks; communication based on speaking and listening; peer working

Speaking skills: audio tasks; guided conversation and pronunciation practice, role plays, simulations; peer working

Reading skills: reading www-texts; library search skills; Web-sites; combination of texts and other media; vocabulary building

Writing skills: process writing (essays, letters); e-mail; combination of texts and other media; peer reviewing

Communication skills: intercultural skills practice; e-mail discussion groups, news groups, www-chat

The purpose of practicing the SLA skills and competencies in the new learning environment was to enhance different skills of listening, speaking, reading and writing, to investigate and process authentic linguistic and cultural information, to enhance autonomous (self-directed) learning, to build learning skills and participate in some collaborative projects (research communicative networks). The last but not the least significant purpose was to build electronic literacy - ability to write and read in the new media (Warschauer & Kern, 2000). As Lemke points out in Warschauer & Kern (Warschauer & Kern, 2000), in a learner-centered curricular learning paradigm someone else decides what the students need to know, and usually it is the teacher, but in interactive learning paradigm learners determine their own learning goals and interests. Autonomous (self-directed) learners are able to take charge of their own learning and use the communication opportunities on the Internet (p. 176). This was obvious also among the groups studied here.

The most eager Internet users were also the most autonomous learners, able to employ all the possibilities of acquiring authentic knowledge about the language, history and culture. They enjoyed the flexibility and freedom of choice offered by the Web - the possibility to use the teaching materials at home, to communicate with the teacher and other students at any time they wished (teacher’s response via e-mail), etc.

Some students found the use of self-access facilities difficult due to lack of experience and technical support. Multimedia applications were welcomed but the use of computers was avoided at the beginning. Lack of good electronic materials in Slovak is also one reason why printed texts were preferred. Some students preferred a more ‘traditional’ way of learning Slovak probably because www-materials in the Slavonic languages are scarce in general. On the other hand, they also seemed to believe that learning Slavonic languages in an unconventional way is not even possible.

For some learners the new learning environments provided new exciting learning experiences (interactive tasks and facilities that allowed for direct communication with the teacher). They helped to increase their motivation, self-confidence and progress, as well as enhanced their capacity of self-directiveness (information search, discussion and chat-groups, etc.).

Conclusions

The use of new environments for learning less frequently taught languages requires much more training in information technology and especially in the pedagogy of network-based instruction. In principle, there is a great appeal and challenge in the prospect of using the www and self-access instead of the classroom - the richness of the authentic world providing opportunities for interactive learning. However, the key question is not only how to use information technology for language learning and teaching but also, how to teach the language in such a way that the students would become enabled to utilize the technology available and to overcome any student- or teacher-stereotypical concepts of language learning and teaching in general. And that is an issue which concerns all languages - whether widely or less frequently taught and used.

The Third Generation of Computerized Counseling

Jari Laarni
Center for Knowledge and Innovation Research
Helsinki School of Economics and Business Administration
Finland
laarni@hkkk.fi

Abstract: How we cope with social situations can be thought as a form of expertise that can be learned. Computerized counseling is an interesting new alternative for learning social skills. A more far-reaching application is automated counseling which is based on a host computer and a pocket computer or a wearable computer. This kind of system has the advantage for making it possible to help people in real-life situations. In this paper I outline the basic structure of computerized mobile counseling.

Introduction

Pocket computers are becoming very popular. These computers have, at least, three important properties: mobility, sharability and context sensitivity (e.g., Inkpen 1998). Mobility means that they, for example, provide access to Internet resources, even when they are carried out by users during day-to-day activities. Sharability, in turn, makes it possible to share information using computer technology, and context sensitivity provides sensitive to the location in which pocket computers are used. These properties make pocket computers particularly suitable for specific purposes. Here I will present ideas how to use pocket computers that are connected to a main computer to assist people who are seeking psychological help.

In recent years it has been developed computerized forms of psychoeducational counseling (for a review, see, e.g., Wagman 1988). At present the most far-reaching application is automated psychotherapy or counseling which is based on a host computer and a handheld or wearable digital assistant. My aim is to develop foundations for this kind of application. The principal purpose is to develop a fully automated counseling that can, for example, help clients in different contexts. Here I provide an initial exploration of this issue.

Theoretical Background

The work is based on the theory of person schemas (e.g., Horowitz 1998). Person schemas include, e.g., self schemas, schemas of another person and role relationship models. The repertoire of schemas determines by which way interpersonal relations are structured. I use abstraction hierarchies to present social transactions. Abstraction hierarchies are hierarchical descriptions of the goal-relevant restrictions for a specific problem area (Vicente & Rasmussen 1990). Abstraction hierarchies are, for example, used in cognitive psychology to describe goal-oriented performance in different domains. The main levels of these descriptions, from the lowest to the highest, arc function, tactics, strategies and purpose. The idea here is that we all are experts in producing complex behavioral patterns in social transactions, and different people use different strategies and tactics in social situations.

What is common to conflict situations is the fact that negative emotional states emerge and people use different kinds of behavior patterns to handle conflicts. If the aim is to get rid of negative emotions and defensive behavior patterns, the first task is to become aware of these patterns and get some insight into their causes. Next, we have to make new plans, learn new practices and decide to use them. According to Horowitz (1998), behavioral change is based on three important stages: awareness, insight and decision. These changes, in turn, occur at three major levels: states of mind, altering defensive controls of ideas and emotions and person schemas.

Computerized Counselor at Your Service
A computer-based counselor may help the client at all these stages and levels. In order to do that it is necessary that the host computer has specific information resources. Firstly, the computerized counseling system has to possess knowledge about its own behavior and that of the client (Wagman 1988). The computer should have a database of the self schemas, state of minds and defensive mechanisms that are typically used to reduce emotional arousal. The system must also have a database concerning possible social situations and possible strategies and tactics to handle these situations. Secondly, at the diagnostic phase, the computer must become acquainted with the user. The client uses text or speech to describe how he/she operates in different kinds of stressful life events: what the client thinks, how he/she behaves and which kind of emotional states the stressful events evoke. During these interviews the computer gathers knowledge of the client's schematic structures related to self and others and his/her defenses and emotional states in social situations. Experiences in development of computerized psychiatric diagnostic interviews (e.g., PsychDiagnoser) can be utilized in developing the diagnostic system (Zetin & Glenn 1998).

The personal digital consultant may help the client in several different ways. Firstly, based on interviews it may present personality profiles and make suggestions how to handle particular conflict situations. At this stage, the aim is to promote recognition and understanding of maladaptive states of mind and behavioral patterns. For example, using computers, it is possible to practice new skills in simulated transactions. At the next stage, the client uses a handheld counselor in real-life situations. For example, when the client is approaching a stressful life event, the animated consultant may suggest how to cope with it. In addition, text, music and videos can be used to promote more adaptive states of mind. At the evaluation phase, the client gives feedback to the system, and the system, in turn, evaluates the client's behavior.

**Future of Computerized Counseling**

Advances in computing technology make it possible to develop context-sensitive consultants. In addition to the location within which the system is used, it could, for example, be sensitive to the people with whom the client is interacting. In the not too far distant future, the computer may also recognize changes in autonomous responses and alert the client if his/her emotional state is changing. All the knowledge concerning the client can be analyzed and stored. This database can function like some kind of external autobiographical memory register. The computer may later use the database to present to the client optimal solutions to emotional problems.

**Evaluation**

Will computerized counseling ever succeed? It can be argued that face-to-face therapeutic contact is essential to the successful treatment process. One possibility is that, even though automated counseling is primarily aimed at being used without face-to-face therapeutic intervention, it is also possible to include it in a part of a traditional therapeutic process.

A computerized counseling system necessarily remains quite rigid, if a fixed set of schemas, states of mind, behavior patterns and emotions are programmed. That is, there will never be a complete match between the client's personality and the suggested personality profile, and thus, the solutions the computer offers will never be ideal.

Multisensory Virtual Environment for Supporting Blind Persons' Acquisition of Spatial Cognitive Mapping – a Case Study

Orly Lahav & David Mioduser
Tel Aviv University, School of Education
Ramat-Aviv, Tel-Aviv, 69978, Israel
lahavo@post.tau.ac.il

Abstract: Mental mapping of spaces, and of the possible paths for navigating these spaces, is essential for the development of efficient orientation and mobility skills. Most of the information required for this mental mapping is visual information (Lynch, 1960). Blind people lack this crucial information, thus facing great difficulties (a) in generating efficient mental maps of spaces, and therefore (b) in navigating efficiently within these spaces. The work reported here is based on the assumption that the supply of appropriate spatial information through compensatory channels (conceptual and perceptual), may contribute to blind people's spatial performance. A multisensory (haptic, auditory) virtual environment simulating real-life spaces has been developed and tested. A description of the learning environment and results from a pilot study are presented.

Rationale

The ability to navigate space independently, safely and efficiently is a combined product of motor, sensory and cognitive skills. This ability has direct influence in the individuals' quality of life. Mental mapping of spaces, and of the possible paths for navigating through these spaces, is essential for the development of efficient orientation and mobility skills. Most of the information required for this mental mapping is visual information (Lynch, 1960). Blind people lack this crucial information, thus facing great difficulties (a) in generating efficient mental maps of spaces, and therefore (b) in navigating efficiently within these spaces. A result of this deficit in navigational capability is that many blind people become passive persons, depending on others for continuous aid (Foulke, 1971). More than 30% of the blind do not mobilize independently outdoors (Clark-Carter, Heyes & Howarth, 1986).

The work reported here is based on the assumption that the supply of appropriate spatial information through compensatory sensorial channels, as an alternative to the (impaired) visual channel, may contribute to blind people's spatial performance. Research on blind people's mobility in known and unknown spaces (Golledge, Klatzky & Loomis, 1996; Ungar, Blades & Spencer, 1996), indicates that support for the acquisition of spatial mapping and orientation skills should be supplied at two main levels: perceptual and conceptual levels.

At the perceptual level, the deficiency in the visual channel should be compensated with information perceived via other senses, e.g., touch and hearing. Haptic information appears to be essential for appropriate spatial performance. Haptics is defined in the Merriam-Webster dictionary as "of, or relating to the sense of touch". Fritz, Way & Barner (1996) define haptics as "tactile refers to the sense of touch, while the broader haptics encompasses touch as well as kinesthletic information, or a sense of position, motion and force." Haptic information is commonly supplied by the cane for low-resolution scanning of the immediate surroundings, by palms and fingers for fine recognition of objects' form, textures, and location, and by the legs regarding surface information. The auditory channel supplies complementary information about events, the presence of other people (or machines or animals) in the environment, materials which objects are made of, or estimates of distances within a space (Hill et al., 1993).

At the conceptual level, the focus is on appropriate strategies for an efficient mapping of the space and the generation of navigation paths. Research indicates two main scanning strategies used by people: route and map strategies. Route strategies are based in linear (therefore sequential) recognition of spatial features. Map strategies, considered to be more efficient than the former, are holistic in nature, comprising multiple perspectives of the target space (Fletcher, 1980; Kitchin & Jacobson, 1997). Research shows that blind people use mainly route strategies while recognizing and navigating new spaces (Fletcher, 1980).
The Proposed Study

Advanced computer technology offers new possibilities for supporting blind people's acquisition of orientation and mobility skills, by compensating the deficiencies of the impaired channel. Research on the implementation of haptic technologies within virtual navigation environments reports on its potential for initial training as well as for support and rehabilitation training with sighted people (Giess, Evers & Meinzer, 1998; Gorman, Lieser, Murray, Haluck & Krummel, 1998), as well as with blind people (Jansson, Fanger, Konig & Billberger, 1998; Colwell, Petrie & Kornbrot, 1998).

In light of these promising results, the main goals of this study are:

- The development of a multisensory virtual environment enabling blind people to learn about different (real life) spaces that they are required to navigate (e.g., school, work place, public buildings).
- A systematic study of blind people’s construction of cognitive maps of real spaces by means of the virtual environment.
- A systematic study of the contribution of this mapping to blind people’s spatial skills and performance in real environment.

The Virtual Environment

Developer/Teacher mode

The multisensory virtual environment simulating real-life spaces comprises two modes of operation: Developer/Teacher mode, and Learning mode.

The core component of the developer mode is the virtual environment editor. This module includes three tools: (a) 3D environment builder, (b) Force feedback output editor, (c) Audio feedback editor.

By the 3D-environment editor, the developer can define the environment characteristics: size and form of the room, and objects (e.g., doors, windows, walls, rectangle, cylinder). The Force-feedback output editor allows attaching Force-Feedback effects (FFE) to all objects in the environment. Examples of FFE are vibrations produced by ground textures (e.g., stones, parquet, grass etc), force fields surrounding objects, friction sensation. The audio feedback editor allows the attachment of appropriate audio units to the objects, e.g., “first window”, “turn right”.

Figure 1 shows the environment-building editor screen, by which the researcher/teacher can build new navigation environments, according to the users’ needs in progressive levels of complexity.

![Figure 1: 3D environment builder](image)

Learning mode

The learning mode includes two interfaces: User interface and Teacher interface.
The user interface consists of a virtual environment that simulates real rooms and objects. The subject navigates this environment using the Microsoft Force Feedback Joystick (FFJ). The feedback received while navigating the room includes sensations such as friction, objects' force fields and vibrations. By using the FFJ the subject can get foot-level information, equivalent to that she/he gets by his feet as he walks in the real space. In addition auditory information is generated by a "guiding computer agent", aiming to provide appropriate references whenever the subject gets lost in the virtual space. Figure 2 shows the user-interface screen.

The teacher interface integrates series of features serving teachers during and after the learning session. Several monitors on the screen present updated information on the subject's navigation, e.g., position, objects reached. An additional function allows the teacher to record the subject's navigation path, and replay it to analyze and evaluate her/his performance (Figure 3).

![Figure 2: The user interface](image)

![Figure 3: The teacher interface](image)

The Case Study: A blind subject's performance within the Force Feedback Virtual Environment and in the real environment

The pilot case study aimed to analyze a subject's performance regarding five main aspects:
(a) Technical issues in using the virtual environment (e.g., use of FFJ, response to FFE).
(b) Ability to identify the virtual environment's components (e.g., identification of objects, recognition of spatial features).
(c) Navigation and mobility within the virtual environment.
(d) Construction of a cognitive map of the simulated room.
(e) Performance in the real environment.

Method

Subject

G., is a twenty-five years old, a late blind (G. became blind at the age of twenty). He is a computer user for more than three years, using voice output.

Procedure

The study consisted of three stages: familiarization with the virtual environment, navigation in the virtual environment, and navigation in the real environment.

At the beginning of the familiarization with the virtual environment stage the subject received a short explanation about its features and how to operate the FFJ. A series of tasks were included regarding: (a) FFE and audio feedback; (b) mobility within the virtual environment (at varied levels of complexity). Data on the
subject's performance was collected by direct observation, and by video recording. This first stage lasted about three hours.

The navigation in the virtual environment stage included three tasks: (a) exploration and recognition of the virtual environment; (b) a target-object task (e.g., walk from the starting point to the blackboard in the room); (c) a perspective-taking task (e.g., walk from the cube - in a room's corner - to the rightmost door - the usual starting point). Following the exploration task the subject was asked to give a verbal description of the environment, and to construct a scale model of it (selecting appropriate components from a large set of alternative objects and models of rooms).

Several data-collection instruments served this stage: a computer log recording mechanism, which stored the subject's movements within the environment; video recording; recording of the subject's verbal descriptions; the physical model built by the subject. The second stage lasted about three hours.

The navigation in the real environment stage included again two tasks: (a) a target-object task (e.g., reach and identify an object on the rectangular box); (b) a perspective-taking task (e.g., walk from the rightmost door to the cylinder). Data on the subject's performance was collected by video recording and direct observation. The third stage lasted about half an hour.

Results

Familiarization with the virtual environment components

G. Learned to work freely with the force feedback joystick within a short period of time, walking directly and decisively towards the objects. Regarding mobility, G. could identify when he bumped into an object, or arrived to one of the room's corners. From the first tasks G. could walk around the object's corner and to walk a long the walls, that by using the FFE and the audio feedback.

Navigation within the virtual room

Exploration task

G. navigated the environment in rapid and secure movement (Figure 4). He first explored the room's perimeter, walking along the walls. After two circuits he returned to the starting point, and begun to explore the objects located in the room. Figure 4 shows the intricate walk paths in the exploration task. The exploration session lasted about 43 minutes.

Figure 4: Subject's navigation in the virtual environment

Target-object task

To get to the required object G. navigated the environment applying the object-to-object strategy. From the door (the starting point) G. walked to the cube and from the cube to the target - the blackboard (Figure 5). G.
reached rapidly the target—in 20 seconds—by choosing a direct way.

**Perspective-taking task**

Here once again G. applied the object to object strategy (Figure 6): he went from the cube (the starting point in this task) to the box, and then to the target, the door (which was the starting point in the previous tasks). G. chose a direct way, and completed the target in 52 seconds.

---

**Cognitive map construction**

After completing the virtual environment exploration task G. was asked to construct a model of the environment. As shown in the picture of the model composed by G. (Figure 7), the subject acquired a highly accurate map of the simulated environment. All salient features of the room are correct (form, number of doors, windows and columns), as well as the relative form and size of the objects and their location in the room.

---

**Navigation in the real environment**

The subject walked through the real environment from his very first time in it in a secure and decisive behavior. At the first task (reaching a target object: the leftmost box), G. used the entrance door as initial reference, and walked along the walls in direct way to the box. He complete the task in 32 seconds. At the second’s task (perspective-taking), G. applied the object to object strategy, and completed successfully the task in 49 seconds.
Discussion

The case study reported in this paper is part of a research effort aimed to unveil if and how the work with an haptic virtual environment supports blind people's construction of spatial cognitive maps and their navigation in real environments.

The case study results are encouraging. The subject, G., mastered in a short time the ability to navigate the virtual environment. He developed a fairly precise map of the simulated environment, and the completeness and spatial accuracy of this map became evident in two revealing situations. The first was the physical model built by G. after navigating the virtual room - the simulation of a space he did not know. The second was his impressive performance in the real environment. He entered the real room which he had not known until then, and which he was not given the opportunity to explore, and completed efficiently and in a very short time the different navigation tasks.

Based on these and other preliminary results, a systematic empirical study (involving 30 subjects) of the effects of the haptic environment on blind people's navigation abilities is currently being conducted. The results have potential implications at varied levels, for supporting: blind people's acquaintance with new environments; their acquisition process of spatial knowledge and skills; their learning of concepts and subjects for which spatial information is crucial.

Intelligent Agents for Support of Distance Learning Environments

Thresa Lang
Veridian
10455 White Granite Dr. Ste. 400
Oakton VA U.S.A.
Thresa.Lang@veridian.com

Abstract: In this paper the author explores the use of Intelligent Agents to support the design and functioning of distance learning environments. Intelligent agents in this paper refer to software agents with an artificial neural network (ANN) component. The use of this technology will help educational institutions provide quality instruction to an increasing number of students without an equivalent expenditure of resources. The technology facilitates the creation of authentic simulations and allows the instructor to provide individualized instruction to students using the most effective approaches for each learning style.

Introduction
The classroom instructional paradigm forces the teacher into the center of a web of classroom activities, where individual strands representing learning objectives, evaluations, and even class discussions come together to be manipulated, directed and monitored. In this situation, the overworked teacher is frequently left with little choice but to adopt the traditional lecture format, where the emphasis rests on product delivery instead of student learning (Wilson, 1995). It is only to be expected that as student enrollment increases the amount of individual tutoring and feedback given to the student by the instructor decreases.

In an attempt to address the issue, many institutions invest in technology and offer distance education courses as a supplement to the traditional programs, without changing either the course content or presentation paradigm. However, traditional teaching approaches are incompatible with the effective use of technology in addressing both learning approaches and individual learning styles (Evuleocha, 1997).

A well-constructed environment for distance learning will present the course content in a multimedia format, ensuring that a variety of learning styles are accommodated. Ideally, the environment will be constructed so that it also automates performance tracking and assessment. When this administrative burden is removed from the instructor, there will be more time to work with the students and address learning issues. In an environment that includes intelligent agent technology, each student can receive tutoring, feedback and interaction on an individual level.

How the Agents Function
The neural network component of the agents supports the recognition of a broad range of input signals. A multimodal system is ideal for on-line learning environments because of the integration of speech, gestures, text, voice, images, real-time video and traditional pointing and selection tools (Pavlovic, Rajeev, & Huang, 1997). It is obvious that such systems need the fault tolerance of neural network technology in order to differentiate between valid information and noise. This type of system is ideal for the development of web-based learning simulations.

The pattern recognition abilities of neural networks are vital to tracking student progress in a learning situation where the instructor is not constantly present. The network enables the agent to track patterns in student responses. The pattern shows which areas are misunderstood or poorly understood, so that tutoring can lead the student to mastery before the weakness affects the learning of other related concepts as well. The agent has access to the expected response from a database of knowledge from human experts. The agent compares the expected response with the actual response to determine whether it is sufficient. When there can be improvement in the response, the agent selects the most appropriate tutorial material and presents it to the student. Once the agent has identified the individuals' learning pattern, it can predict student responses and prepare personalized corrective strategies and materials regardless of the number of students being taught. The agent can independently choose to apply these strategies before the student
realizes that there is a knowledge deficit in a given area. This pattern recognition capability is so precise that even application of the early versions of this technology was able to identify patterns in student learning that were so subtle that a human would miss them, and could differentiate between actual learning problems and errors made through carelessness or fatigue (Lively, 1992).

**Agents in Simulations**

Simulations are very useful in situations where the student needs to perfect skills prior to actually using them in real-life situations. For example, in chemistry, they have been in use for some time for identifying chemical components in mixtures, and optimizing formulations. Another application has been in the training of meteorologists and others in the atmospheric sciences, which use simulations to track and predict the outcome of atmospheric events. The use of simulations for training even stretches into the field of pharmacology, where neural networks create simulations that can accurately predict the medicinal properties and effects of drugs (Widrow, Rumelhart, & Lehr, 1994).

The medical field is now using similar programs for artery tracking to help diagnose coronary artery disease (Hanna & Campbell, 1995), simulated neurosurgery, and new surgical procedures. The new simulation training in some cases incorporates even the sense of touch. Medical students practice “threading flexible endoscopes down a virtual patient’s throat or manipulating the long surgical instrument used in laparoscopy…suturing tissue and inserting a catheter into a vein using laparoscopic tools.” (Sorid & Moore, 2000, pg. 26). These simulations provide a complete learning environment and are adjustable to the individual student. They pinpoint areas of weakness and prepare the students psychologically for dealing with any complications that may arise during actual surgery. The natural language processing capability present in many of the simulations understands and processes natural language so that students can verbally present questions to the agent and receive appropriate responses (Billinghurst & Savage, 1996).

Tow recent examples are Adele and Ali, both from the University of Southern California Information Sciences Institute’s Center for Advanced Research in Technology for Education. Ali, or Automated Laboratory Instructor, is an agent that facilitates undergraduate chemistry courses through the use of web-based virtual laboratories. The environment includes a set of web-based simulations controlled by the student. The student is provided with visualizations of the experiment being simulated as well as receiving a realistic and complete set of data for analysis. The simulation includes a tool set allowing the students to use, collect, analyze and manipulate the data as well as the Laboratory Instructor. The instructor guides the students through the material, monitors their progress, provides feedback and tutors individual students by recommending relevant materials to help them address their specific learning difficulties. (Johnson & al, 1999).

Adele is an agent is used for training in family medicine and geriatric dentistry. It was designed to run on conventional desktop workstations with conventional interfaces. In order to expand the agent’s effectiveness, it runs in a student’s Web browser so that Internet resources can be used during the lesson. Designers solved the problem of network latency by placing the agent’s reactive behavior on the student machine.

The agent persona is generated using a behavior state approach consisting of a library of searchable behavior fragments. These include visual segments showing the repertoire of movements, audio clips accompanied by a commercial speech synthesizer to serve as utterances, and occasionally segments of other background sounds, such as music. A behavior-sequencing engine dynamically joins selected fragments at run time. The result is that Adele displays seamless behavior and appearance to the student.

**Conclusions**

Intelligent agent based simulations are an excellent option for institutions that are attempting to expand their offerings while providing efficient husbandry of institutional resources. The capabilities of the technology allow instructors to address a range of learning styles as well as provide individual instruction for each student.

The Invisible Student:
Total Technology Control of Course Delivery and Management

Richard Dwight Laws
Independent Study
Brigham Young University
United States
dwight_laws@byu.edu

Abstract: The architecture of the Brigham Young University delivery system for some independent study students is unique. Students may complete the following steps on the Internet: (1.) browse for a course, (2.) explore a particular course, (3.) register for the course, (4.) submit lessons, 5. receive faculty feedback (from a large database), (6.) take tests, and (7.) receive grade/transcript. These are all accomplished using technology. There will be no human intervention, thus the notion of an “invisible student.” However, evaluations show high performance and high satisfaction among students. The major benefit to the delivering institution is unlimited enrollment capability. Some classes have thousands of enrollments and the system is not overloaded. Students appreciate the immediacy of everything, and particularly the answers to all missed questions (something they rather experience in the classroom).

Introduction

Brigham Young University (BYU) currently has 206 courses on the Internet, 115 of which are college courses, 59 are high school courses, and 32 are personal enrichment courses (noncredit). Evaluations were collected from over 10,000 students who used the Internet for these courses in the year 2000. Responses showed high satisfaction on the part of the student in three areas. First was the instantaneous feedback to all missed questions (more feedback than most students were used to receiving). Second was the personable response of the faculty. No attempt had been made to fool the students, but the evaluation showed that most students thought the feedback was synchronous. It was asynchronous. From the beginning, the system design consisted of a large databank of feedback statements, designed and written by the faculty, which were then sent to the student, based on the answers that they supplied. The third high satisfaction response was the opportunity the students had to check their progress on the Internet at any time.

A major benefit that occurred among students using these courses was the increased completion rate. Traditionally, the completion rate for most independent-study programs in the U.S. has been around 60 percent. Students enrolled in the BYU Internet courses have a 70 percent completion rate. No research has been completed to explain this increase, but students seem to keep a better momentum because of the immediacy and scholarship of the responses they receive to their work.

The Model

When the Brigham Young University independent-study system was designed, the notion of ample feedback to every missed question was the foundation for the system (not just correct-incorrect). Existing distance education models that used faculty synchronously had limits to enrollment and speed of feedback. Therefore, the BYU model was designed to house large numbers of feedback statements for the students. Faculty were paid to write well designed asynchronous feedback for the database. The system could then handle many students without overburdening the faculty. The system could then be completely managed by the computer.

To support the feedback concept, other technologies were designed to make the systems completely independent of time, space, place, pace, or faculty. The following components were designed for the system: 
- a web course catalog • automatic registration and credit card clearance • internet delivery of course instruction • internet lessons submission • computer grading of all submissions, including tests and final course grade •
computer feedback for all missed questions (as designed by faculty) • testing • grade posting • personalized Web report card accessibility for all students • and transcript distribution.

With the system in place it became possible for a student to shop around in the catalog, select the course of choice, examine the course content, register (credit card), receive a password to allow access to the course, submit lessons, submit tests, receive grading on all submissions, receive a final score, and finally receive a computer generated transcript in the mail—all without human interaction. Although excellent student services are available for all students, it is theoretically possible for a student to come and take a course from independent study and receive credit/transcripts without anyone knowing he or she was there. The invisible student.

Strengths/weaknesses

The attitude of some faculty is that asynchronous learning is a weakness. However, face-to-face instruction, however strong it may be, is not necessarily a reality even in the classroom. Consider large classes where individuals never have access to the teacher. Also consider shy or less aggressive students who seldom get interaction even in small classes. While lack of synchronous interaction may be perceived as a weakness, research has for years shown that distance education is not significantly less effective than on-campus classroom education. Thomas L. Russell (http://teleeducation.nb.ca/nosignificantdifference/) compiled 248 research reports, summaries, and papers dating from 1928 to 1996 into a meta-analysis which he called “No Significant Difference” Phenomenon. Michael P. Lambert, executive director of Distance Education and Training Council, in Washington, D.C. (1999) said, “It is clear that distance education is here to stay….Within the next three years, I predict that 3 out of 4 institutions of any significant size will be offering distance education courses.” However, Lambert is well aware that “the faculty is the single biggest asset of any university and is at the same time the single biggest stumbling block to the rapid adoption of distance learning techniques on a massive scale.” Lambert says that, “some faculties fear distance learning, seeing it as a threat to their jobs, to academic freedom and to sound learning.” But Lambert predicts that “over time, most faculty will learn to love distance learning and come to see it as a personally liberating and empowering force, where they will become tutors and facilitators.”

Management

While the invisible student is only invisible if he or she chooses to be, the system is benefiting him or her in many ways. In the BYU system the internet courses are easy to update and keep current (unlike printed inventory that must be used before reprinting). They are easily formatted and changed to be attractive and conveniently navigated. The cost of courses have remained a reasonable price per credit hour.

Benefits also accrue to BYU Independent Study. The system has reduced mail handling by 400,000 pieces per year even as enrollment has increased.

Conclusions

The current BYU independent study-system has shown that Internet courses result in a quality learning experience for the invisible student, one that they report to be highly satisfying. Students are particularly laudatory of the feedback component. At the same time, BYU Independent Study has been able to handle unlimited enrollments and still have a commendable degree of student services. The system has also proven to be profitable.

Development and Evaluation of a Web-Based Learning Program for Pharmaceutical Management Professionals in Thailand

Layton MR, Chadbunchachai S, Sakolchai S
Faculty of Pharmaceutical Sciences
Khon Kaen University
Khon Kaen 40002, Thailand
lmanee@kku.ac.th

Abstract: The usefulness of the Internet technology especially the World Wide Web (WWW) is incredibly enormous. Since the decreasing cost and rapid growth of technological advances have created a promising dimension in the teaching-learning interface, it is vital to exploit such innovation to improve the educational value of technology in pharmacy education. The purpose of this project is two-fold: firstly, to assess the needs on knowledge and skills that are considered essential among pharmaceutical management professionals as well as the use of the WWW by those individuals in both private and government sectors. Secondly, to evaluate the effectiveness of a newly developed web-based educational program by comparing the course participants' satisfaction, pre-test/post-test score as well as their perception on time and cost savings versus a traditional learning program. The research findings from this pioneer study can be a valuable resource for modifying courses to enhance pharmacy continuing education in Thailand.

Background Information/Statement of Problem

The use of the Internet, especially the World Wide Web (WWW), is dramatically increasing. There are tremendous advantages in using web-based computer-aided instruction in education (MacKenzie & Greenes 1997). For the effectiveness of such educational media compared with a traditional learning method in health sciences, though few studies exist, evidence indicates that a web-based program is more likely to be better or on par with traditional programs in terms of course management (Poling 1994); enhancing problem solving skills (Chishlom et al 1996); employing teaching-learning practice (Hedaya et al 1999); course interaction and satisfaction (Engle & Parent-Stevens 1999). On line discussion capabilities allow student-student and student-instructor/guest speaker to interact and network with one another more practically. Thus, advanced educational technologies are encouraging the development of distance learning on the “anywhere, anytime” premise (Grillo et al 2000). Numerous programs offering higher education degrees as well as certificate and other non-credit courses have been initiated, relatively few, however, in the healthcare discipline (DiPiro 1999). Further training and development of technology in pharmacy education is necessary and will continue to be explored (Zarotsky & Jaresko 2000).

Regarding technology development in Thailand, the awareness is evidently reflected by government support in terms of infrastructure as well as human resources investment during the past decades (Palasri et al 1999). Due to the high impact of the Internet on Thailand’s development, it is extremely crucial that both government and private entities work together toward the long-term benefits of the country. Furthermore, the Pharmacy Council of Thailand recently enacted the new regulation on pharmacy licensing which requires the pharmacists to have continuing education credits for the periodic license renewal. This policy will have an impact on those professionals working in either the private or government sectors. Consequently, as Khon Kaen University is regarded as the hub of education in the Indochina region, it is vital to redefine our educational standards and capabilities in order to sustain in the higher level of competitiveness during this digital globalization era. Ultimately, by exploiting the educational technology to enhance pharmacy education, we can not only support the National Education Policy on expanding opportunities for higher education, but we can also contribute toward helping the Thai society improve its continuing educational system by creating knowledgeable and updated professionals.
Project Details
Goals and Objectives
The overall goal of this project is to explore the potential of using web-based educational technology in continuing pharmacy education in Thailand. Our study population will include the pharmaceutical management professionals who graduated BS in Pharmaceutical Science from 1980 onwards and are currently practicing or working in the pharmaceutical-related field. There are five specific objectives in this project, which includes:
- To assess the needs on knowledge and skills considered essential in their related job responsibilities.
- To assess the knowledge, skills, access to, and use of the WWW.
- To assess the key components that learners perceive to be important to their learning in continuing pharmacy education.
- To develop a web-based learning course according to their needs.
- To evaluate the overall satisfaction and effectiveness of the developed web-based learning course in comparison with the traditional program.

Methods
This study comprises four phases for a period of two years beginning in March 2001.

Phase I: Survey of educational needs and technological accessibility
Validated questionnaires survey will be mailed to the member list of the Pharmacy Council of Thailand for needs assessment on knowledge, skills and continuing pharmacy education that are considered essential among professionals. The feasibility of educational multimedia use among those individuals will also be explored in terms of skills in computer/WWW application as well as their access and use.

Phase II: Developing educational multimedia program
A topic of workshop course will be selected from Phase I Survey based on practicality. Educational multimedia such as computer-generated slides and presentations, course information and other plethora of useful links on the WWW including web board and exclusive listserv for course participants will be developed.

Phase III: Implementing the educational multimedia program
The workshop course will be introduced for the period of six months starting in October 2001. Participants will be randomly assigned to attend either the web-based or the traditional workshop course. The instructors for each course remain the same in both groups. Feedback on course information, educational materials and media for each workshop module will be closely monitored throughout the program.

Phase IV: Evaluating the effectiveness of educational media
The effectiveness of the newly developed web-based learning program will be assessed in terms of participant’s satisfaction; analysis of the networking activities; improvement of pre-test and post-test knowledge scores of each workshop participant; as well as their perception on time and cost savings versus the traditional program.

Collaborative Learning: A Web-based Case Study

Quynh Le, Univ. of Tasmania, Department of Rural Health, Australia; Thao Le, Univ. of Tasmania, Faculty of Education, Australia

Collaborative learning is not confined to classroom-based learning. It can be incorporated into Web-based education. In collaborative learning, students work together as members of a learning community such as working on a problem-solving task by questioning each other, and discussing and sharing information. Some of the best features of Web-based education are flexibility, independent learning, interactive communication and collaborative learning. Quite contrary to the misconception that the Web reinforces learners' isolation, this paper supports the view that the Web can be used constructively to create a collaborative learning discourse. A case study was conducted to examine how the use of the Web could enable students and teachers to work collaboratively in a university context.
The Web in the Eyes of the Learners

Quynh Lê
University of Tasmania
Australia
Quynh.Le@utas.edu.au

Thao Lê
University of Tasmania
Australia
T.Le@utas.edu.au

Introduction

Web-based learning experiences have been introduced to students. Thus, it should accommodate the views of the learner about the web and its role in education. In pursuit of this idea, a qualitative study was conducted to examine university students' attitudes towards the Web. Students were invited to participate in Web-based discussion as part of their learning experiences. The collected data were examined and discussed. Apart from positive and negative attitudes toward the Web, students' views were presented from a social critical perspective.

Learners' perception

Laurillard (1993, p.14) suggested that there is little research generally on student learning at the university level and that university course outlines invariably focus on content, rather than on why or how students will learn. In her view, teachers should mediate learning in the sense that they should understand something fundamental about how students learn and make learning possible for them. Internet-based courseware has been introduced to on-campus and off-campus teaching. The concept 'virtual class' is no longer something to imagine but has started to receive increased attention from educational researchers in interactive multimedia. Research on Web-based education tends to focus on two major aspects: the technicality of courseware construction and its educational rationale.

A qualitative study was conducted to examine university students' attitudes towards the Web. The use of a discussion board in this study was to identify the meanings and concepts underlying learners' attitudes. Both undergraduate and postgraduate students were targeted. There were approximately 200 students each year. They were required to participate in Web-based discussion as part of their learning experiences.

Over 400 messages were collected over a three-year period. Most of them were approximately 100 words in length. Their responses covered positive and negative aspects of the Web and its role in education. Most responses (74%) pointed out both aspects. The rest tended either to praise the Web (17%) or condemn the Web (9%). Education students were particularly targeted as they were familiar with Web-based teaching and they were introduced to a courseware on communication as a component of their course. There were three discussion topics covering four different aspects relating to the theme 'the Web and its role in education'. Each topic started with a discussion statement, which aimed at stimulating responses from learners. The three discussion statements were on the role of the Web in education, critical educational Web, and learners in courseware development.

Here is a summary of the results.

• Learners viewed the Web as a powerful resource, an inspiring teacher and an innovative device, which gives learners motivation, responsibility and independence in learning. The Web provides a dynamic discourse, which could not be replaced by the traditional face-to-face teaching. Learners can travel virtually in a world of knowledge and interaction. Below is a sample of learners' responses about the positive aspect of the Web.
"I had no idea what the Web is about. When I started to use it for my assignment which required us to search for Web-based journals, a new window opened for me. After a period of confusion and uncertainty, I could not get away from the Web. It is so useful to me not only academically but also for many things such as how to search for things on the Web. It is amazing! How could I study without it!!! Impossible!"

- Computers have permeated society to the extent that one starts to examine the negative effects computers can create to society in addition to the benefits they have brought so far to business, education, industry, and daily life. Though there was overwhelming praise for the contribution of computers to education revealed in the qualitative data described above, students also seriously questioned the negative aspects of computers in education in general and of the Web in education in particular. The negative effects range from mild points such as superficial, impersonal to serious condemnation such as imperialistic, politically disempowering, socially destructive, commercially driven. Here are two samples of negative responses from learners.

The first sample touches on the use and abuse of the Web.

"I was completely turned off when I attempted to search for some cultural information on the Web. Most of the time I was bombarded with obscene sites dealing with sex, business exploitation, political propaganda and so much rubbish on the Web. Some were very explicit and others were disguised. Of course, you can say: we have the choice: to read and not to read them. This is not the point. The crucial point is that Web-users are exploited in the name of freedom and flexible learning."

The second sample reveals a different kind of imposition.

"We are asked to avoid discriminatory language in academic writing. That is fair for those who were brought up and now living in that cultural context. I come from a different cultural background which has different values and behaviour regarding religion, gender, political ideas. Do I need to ignore them and conform to the new ideology because of my choice to study at this institution? We need to be aware of the sensitivity of those issues if we want to use the Internet for a wider range of learners."

- Apart from many responses, which reflect some concern as well as admiration for the Web and its role in education, learners also offered some ideas which should be taken into consideration by Web instructional designers and teachers. Issues raised in their responses include the importance of partnership in Web-based courseware development, learner-centred approach of Web-based teaching, and learners as critical partners.

"We are asked to avoid discriminatory language in academic writing. That is fair for those who were brought up and now living in that cultural context. I come from a different cultural background which has different values and behaviour regarding religion, gender, political ideas. Do I need to ignore them and conform to the new ideology because of my choice to study at this institution? We need to be aware of the sensitivity of those issues if we want to use the Internet for a wider range of learners."

Conclusion

The Web has recently brought innovative ideas to teaching, learning, and research. In Web-based education, courseware developers need to take into account the notion ‘learner-friendly’ in constructing Web-based software for on-campus as well as off-campus teaching. For any educational software to be learner-friendly it must start with the learners. This study has shown what learners expect of us. Now, it is our challenge to take their views constructively and creatively.

Interactive Video Distance Education Classroom Design For Effective Instruction and Learning

Chien-Chih (James) Lee, Mississippi State Univ., USA

Classroom design is crucial for effective instruction and learning. Two major problems exist for instructors and students in interactive video distance education design: (a) the constraints of instruction and learning caused by the interactive video distance classroom equipment arrangement and (b) the dissatisfaction of instructors and students with the physical features. Given the expense of interactive video distance education classrooms, institutions need to understand the perceptions of those using such classrooms in order to improve existing and future classroom design.
The Application of Self-Organised Learning for Educators and Students in a Knowledge-Based Economy: A Reflective Experience

Vivien Lee Looi Chng
Temasek Business School
Temasek Polytechnic
Singapore
looichng@tp.edu.sg

Steven John Coombs
School of Education
Sonoma State University
California, USA
steven.coombs@sonoma.edu

Abstract: A technology-led knowledge-based economy will require workers to be equipped with new economy skills and dispositions for creating significant and relevant meaning out of the large chunks of transmitted data. In the spirit of building learning organizations, this paper proposes a two-pronged strategy of promoting self-organised learning (S-o-L), originally developed by Harri-Augstein and Thomas, amongst educators and students. As an enabling framework based on social constructivism, it offers educators engaged in action research an approach for managing and reflecting upon change through the use of thinking tools such as the Personal Learning Contract. For students who are expected to learn independently in situations requiring problem-solving skills, much akin to real life contexts, this paper also considers the application of Learning Plans as a tool for personal project management. We conclude that S-o-L promotes skillful critical thinking through a systems thinking process of continuous reflective learning.

1 Introduction

The wave of telecommunications advancement flooding the world with a massive overload of information has resulted in a new surge in educational reform. With the pressing demands of policy makers in directing system-wide institutional changes involving a continuous state of personal change-management re-organisation, educators are expected to improve teaching practices in the light of newly developed educational theory. Likewise, students face increasing pressures to be prepared as knowledge workers for the so-called new economy through developing new skills for critical and creative thinking as a means for problem solving using reflective technologies (Coombs, 2000). The key to coping in such an ever-changing environment is to encourage learners to be constantly learning and re-learning as Thomas and Harri-Augstein (1985) describe:

the exponential rate of change in today’s world is making ever-increasing demands of on human learning and today’s thoughts will become the chains of tomorrow’s mind unless we face the problems of re-learning and continuing to learn throughout our lives. Freedom to construct our personal destinies by creatively adapting to change requires an ever-increasing capacity for learning. To achieve this, learning has become a consciously growing process rather than a ubiquitous part of life (p. xxiii).

This paper reviews the principles of self-organised learning (S-o-L) developed by Harri-Augstein and Thomas and considers its value as an enabling framework for change-management and information management in a learning organization. Using case study samples based on an action research study that investigated the frustrations faced by school children in a local Singapore primary school using the World Wide Web as an information source, it also specifically considers the pedagogical value of conversational thinking tools in guiding the reflective process and how the technology can be used as an assistant to this kind of systems thinking.
2 Self-Organised Learning Builds Learning Organizations

Senge (1990) describes a learning organization as one "where people can continually expand their capacity to create the results they truly desire, where new and expansive patterns of thinking are nurtured, where collective aspiration is set free, and where people are continually learning how to learn together". The five disciplines crucial in building a learning organization are personal mastery, mental models, shared vision, team learning and systems thinking (p.1). These five disciplines are also subsumed in the definition of S-o-L.

S-o-L is based on the group learning theory of social constructivism as well as instructional design axioms that provide a practical set of thinking tools that enable systematic reflection on one’s experience to construe personal learning. According to Harri-Augstein and Thomas (1991), all human learning within the S-o-L conversational paradigm is defined as the “conversational construction, reconstruction and exchange of personally significant, relevant and viable meanings with awareness and controlled purposiveness” (p.23).

Deriving S-o-L’s “structures of meaning” is based upon George Kelly’s (1955) Personal Construct Theory (PCT). From a psychological perspective of systems-based thinking, it states that individuals self-manage their inner reflective process, constructing knowledge and modelling concepts of the world experienced through a complex process of personal “hypothesis testing” between past and present experiences. In constructing personal constructs, the “personal scientist” adopts a holistic world-view, linking one’s personal experience with societal influences and behaviours (Coombs and Smith, 1998). This attitude towards systems thinking is described by Senge et al (2000) as “a different way of looking at problems and goals not as isolated events but as components of large structures” (p.78). In order to achieve this ideal, Senge also describes mental models where assumptions and mindsets are suspended "so people can explore and talk about the differences and misunderstandings with minimal defensiveness", providing opportunities for creative paradigm shifts (p.67).

In S-o-L, a Learning Conversation of a dual nature is carried out by the “conversational individual”. Two conversations exist; one from within our self, to our self, and another externally, with others (Thomas and Harri-Augstein, 1985). Coombs (1995) differentiates these two types of reflective learning psychological experiences as “inferential” and “referential” Learning Conversations. Thomas’ and Harri-Augstein’s notion of the conversational individual assumes “human beings as meaning, construing, negotiating and attributing personal learning as a form of conversational knowledge construction (p.20). To Senge et al. (2000), the essence of such social constructivism is much akin to team learning: “discipline of practices designed, over time, to get the people of a team thinking and acting together” (p.73). This results in the matching of one’s individual perspectives with a common shared vision. He suggests that the most effective practice for team learning is that of the conversational dialogue, “a sustained collective inqui experience in the immediate context, resulting in a “collective sensibility, in which the thoughts, emotions, and resulting actions belong not to one individual, but to all of them together” (p.75). Such an ideal is achieved if there exists a degree of personal mastery in acquiring a dual awareness of vision and reality and the thinking skills to mediate the differences. The role of schools and teachers in S-o-L environments is to create the social context where students have time to reflect and to be proficient and skilled in making the choices that will help one arrive at personal mastery in reconciling and coping with the differences experienced. Such self-mastery is at the heart of managing personal change.

S-o-L pedagogy is therefore a student-centred learning approach where one is responsible for one’s own behaviour while managing one’s own actions and directions through critical reflection (Coombs & Wong, 2000). This is achieved in both an individual and social group learning context. This conversational psychology provides both a pedagogical and systems thinking approach that fits into a social constructivist model of learning and explains knowledge construction through reflective elicitation and self-organisation of one’s thinking experiences (Coombs & Smith, 1998 & 1999).

2.1 Self-Organised Learning as a Model of Action Research for Educators

An agenda of developing learning organizations justifies the case for the introduction of action research (AR) into schools. While researchers have often been regarded as impractical ‘know-alls’ of theory, who impose their opinions on practitioners without an appreciation of the real social context, there is a need for a change in this mindset. By recognizing the researcher as a mutual stakeholder and a genuine partner of the change-management process, resources can be shared and problems resolved more efficiently and effectively. This policy of the action researcher operating with equanimity within the workplace and identifying ‘research
questions' based upon mutually identified needs drawn from problems to be resolved within the social situation, was identified by Coombs (1995) as an AR process of ensuring "social parity". He recommended that all participatory AR studies within learning organizations implement this practice as both an ethical social policy and research methodology.

According to Elliot (1991), AR is "reflective practice which aims to improve the realization of process values" (p.51). AR gives systematic attention and validation to the importance of empirical data gathered from personal experience as a basis for reflecting upon how classroom practices can be improved. As such, the onus is on the practitioner to acknowledge the need for improvement and hence to research on changes implemented and experienced. By taking control of the research agenda, the teacher-as-action-researcher becomes responsible for both defining and implementing the acceptable quality of outcomes, i.e. stakeholding through task-management. Given how intense the pace of change is, and how our teachers rarely ever have the time to evaluate their own teaching, AR as reflective practice is a practical approach for the management of change and new information. Dewey (1933) describes the reflective teacher as "active, persistent, and careful consideration of any belief or supposed form of knowledge in the light of the grounds that support it and the further conclusion to which it tends" (p.6). Schon (1983) similarly describes the participatory action researcher as one who is engaged in reflection-on-action, such that teachers' who have recently just left the classroom are immediately reconstructing and reconstruing events and actions as a professional act. Underlying these definitions of reflection is the notion of "conversational constructivism", where reflection on personal experience becomes a learning opportunity (Coombs & Smith, 1998).

More than just self-centred internal reflection, social constructivism also plays a role in S-o-L for AR. Through collaboration with the other stakeholders in the school environment, shared meaning is achieved and the ideas generated are more relevant to the social context at large. This sharing leads to increased creativity in the solutions designed, accompanied by increased ownership, and acceptance of outcomes. Professional partnerships like this ought to be promoted as essential forms of organizational social interaction and survival for coping with the ever-increasing number of change-management events resulting from the effects of globalisation upon societies around the world. Schools are not insulated from this globalisation process, as governments quickly respond to international league tables of educational results and instruct their education ministries to come-up with quick reform packages and implementation cycles. A good example is the recent Third International Maths and Science Study that placed the US unfavourably in the international league. This, amongst other reforms, has resulted in the Californian Department of Education rapidly bringing in new forms of testing in schools in a bid to improve results-based “standards”, placing extra burdens on teachers and administrators.

The S-o-L individual organises one's reflections through "conversational tools" such as the Personal Learning Contract (PLC) and Purpose-Strategy-Outcome-Review (P-S-O-R) templates. These tools are an effective means for making sense of disparate pieces of data, as they offer an avenue to scaffold learning in a systematic reflective manner. With information organised, meaningful making takes place as links are made and relationships formed between discrete ideas. From a critical evaluation of situations, the action researcher is more discerning when making decisions. Coombs (1995) describes such forms of knowledge creation, using S-o-L content-free technology to manage information, as Knowledge Elicitation Systems (KES).

2.2 Self-Organised Learning for the Student

S-o-L pedagogical resources offer conversational tools for the students' in the form of Learning Plans (LP). Coombs (2001 in press) describes a LP as a conversational tool that allows for the skills of critical thinking to be modelled through practical tasks simulating the real world. LPs offer a flexible, content-free technology allowing students to both scaffold and manage their own learning. This is possible as the LP design breaks learning events into small tasks and activities with opportunities for students to apply their understanding at regular reflective milestones. Student-centred scaffolding is workable as the LP defines discrete learning pathways that gain access to what Coombs defines as the principal resource "Learning Nodes". Teachers operating as Learning Coaches can negotiate LPs with students to arrive at customised solutions with the scope for self-directed learning (Coombs & Smith, 1998). LPs are thus a flexible project management critical thinking tool with built-in curriculum and assessment goals.

More than just chance-based discovery learning, there is systematic reflective problem solving occurring in a well-focused activities-based learning environment. The learning tasks making up the LP are designed as real-world simulations that play an important social function of helping the learner to personally identify with
3 Action Research through Self-Organised Learning

The key learning problem identified for this AR project at a local primary school was that the students had no idea of how to manage the large chunks of information resulting from their research using the World Wide Web. As such, they simply adopted a "cut and paste" mentality by copying chunks of information into their written reports. It was decided within the social context of the AR team that the key educational problem facing teachers was the students' lack of critical thinking ability to manage data. The school was interested in evaluating the learning expectations and increasing transfer between in-school and out-of-school experiences.

From an information processing perspective, such a reflective learning approach has its basis in constructivism. There are many meanings and personal perspectives from which to experientially structure and frame the world and there is no single or correct meaning that learners should accept, no ultimate shared reality (Duffy and Jonassen, 1992). Situating cognitive experiences in socially authentic tasks and increasing transfer awareness of their problem solving skills necessary for independent learning and inculcate a positive attitude towards critical thinking through empowering student control of the curriculum tasks to be achieved.

Figure 1: Personal Learning Contract

Learning Objectives
1. List examples of evaporation.
2. Infer that when water evaporates, it enters the air as water vapour.
3. Explain how wind affects the rate of evaporation.

TASK 1: REVIEW OF CONCEPT
Collect the necessary materials from the teacher's desk and take 20 minutes to complete Task 1.

1. Study the photographs:
   a. Sample A: Drying of puddles of water
   b. Sample B: Drying of clothes
   c. Sample C: Drying of vegetables, fruit
   d. Sample D: Drying of our lives after birth and periposition
2. Record your answers in the worksheet attached.
3. Identify what's common amongst the photographs.
4. What process has taken place?
5. Next, put a drop of rubbing alcohol on your finger.
6. What has taken place?
7. Write your conclusion in the space provided.

TASK 2: FACTORS AFFECTING THE RATE OF EVAPORATION
Task 2 is an activity in which you will determine how wind will affect the rate of evaporation. You have 35 minutes to complete Task 2.

1. In the basin, you will find two handkerchiefs. How are they alike?
2. Wet the two handkerchiefs completely.
3. Hang the two handkerchiefs in the classroom on the line provided by your teacher.
4. Note the time on the clock and record the time in the worksheet.
5. Use a fan to blow on one of the handkerchiefs for 10 minutes.
6. At the end of 10 minutes, stop the fan. Record the time in your worksheet.
7. Fold the handkerchiefs and record your observations about the wetness of the two handkerchiefs.
8. Record the time.
9. Continue blowing at the same handkerchief for another 5 minutes.
10. Fold the handkerchiefs after 5 minutes. Record your observations.
   a. What do you think has happened?
   b. Where has the water gone?
   c. Why have the handkerchiefs felt different?
   d. What conclusions can you make?

TASK 3: BONUS ACTIVITY: USE OF CD-ROM
1. Complete the quiz in unit 3 of the CD-ROM.
2. Record the time you took to complete the quiz and your score in the worksheet.

The abstract concept and model personal knowledge from the experiential event. Such a controlled reflective process gives voice to prior knowledge, designing experiential linkages between past and present learning, thus increasing meaning making to a greater depth of personal relevance. To support such student-centred learning, the "Learning Coach" guides and supports the learning process (Coombs, 1995). They help students come to an awareness of their problem solving skills necessary for independent learning and inculcate a positive attitude towards critical thinking through empowering student control of the curriculum tasks to be achieved.

Figure 2: Learning Plan
The final cycle of reflection resulted in the identification of LPs (see Figure 2) as a potential tool to meet the AR goals. When the refined solution was presented to the school's Principal, it was accepted with much enthusiasm. The team felt that a general approach of teaching using real-life examples would be more effective in teaching information management. It was also felt that more than just critical thinking skills, it was attitudes towards critical thinking that should be imparted to students. Halpern (1997) describes these critical thinking attitudes as the willingness to plan, exhibiting flexibility, persistence, willingness to self-correct, mindfulness and seeking consensus. The acquisition of these attitudes should result in greater transfer of critical thinking across subject disciplines. It was also decided that the teachers themselves should be engaged in using this new technology and hence a workshop was organised for the Primary 5 teachers in March 2000 to introduce the pedagogical and practical aspects of designing and authoring their own LPs. The LPs designed by the teachers in accordance to their own classroom needs were implemented over a two-week time frame.

Evaluating and designing pedagogical tools and procedures for evidence through improved thinking dispositions is described by Halpern (1997) and can be based on the general structures of meaning heuristic offered by Harri-Augstein and Thomas (1991). The three-step critical thinking criteria suggested is (i) elicitation of items of meaning, (ii) the sorting of relationships and (iii) the display of final patterns (p.271). Following the analysis of the questionnaires completed by the students who had been introduced to LPs, it was found that the critical thinking dispositions of the students' had been enhanced. For example, a student with the willingness to plan said, “I like lessons using learning plans because I can do what I plan”, whilst flexibility is suggested by the remark, “No need to listen to teacher and have freedom to think and do what we are thinking”. A willingness to self-correct was fed back by: “You can refer to the learning plan if you still don't understand” and consensus-seeking illuminated as: “We work in pairs so if we don't understand, we can help each other.”

4 Implications for Education

S-o-L clearly offers a comprehensive pedagogical framework for educators and policy makers who are considering school reform programs involving critical thinking scaffolds. As an approach to problem solving and learning, it new levels of professionalism can be reached. As Thomas and Harri-Augstein (1985) expound, the principles underlying S-o-L rely on the educator to be self-motivated, reflective, critical, flexible, creative and disciplined in the spirit of effecting positive educational change. Well-integrated AR can become a natural extension of the professional duties of an educator, a change which the Ministry of Education in Singapore has begun advancing. This is a change, which other education systems could also be looking into.

Being a content-free technology, where the methods are independent of the topic learnt, knowledge elicitation systems are intended for a wide educational audience. With its basis of drawing upon the specific content of each user’s reflective experience as their own unique and necessary resources for personal growth and development, S-o-L should have wide appeal to all educators and instructional designers. As a systematic procedure for constructively recruiting resources into learning, S-o-L provides validity and reliability via the reduction of “personal prejudices, biasness, disruptive feelings and wilful -o-L technology offers systematic thinking procedures “in which the personal meaning of the client can be collected, unadulterated by any need to simplify or translate it into a common or standardised language” (Thomas & Harri-Augstein, 1985, p.18). Such a thinking technology support for learners' is also espoused by Jonassen (1996), who describes pedagogical procedures for using computers in education as critical thinking “Mindtools”. The use of the S-o-L derived PLC, P-S-O-R and LP can easily be integrated into administrative and curricular educational systems across all levels and cultures. They work best when presented in the form of computerised templates which are easily adaptable to the specific needs of each user’s set of learning tasks (Coombs & Smith, 1999).

5 Conclusion

From the teachers' perspective, this AR project will contribute towards professional development in Singapore, for while AR is not a new field of educational research, it is an area that generally has not been widely implemented in Singapore's schools. It is timely that Singapore's Ministry of Education is now considering ways of actively promoting AR as an attempt to change the professional profile of the teacher. The classroom teacher is envisaged as a teaching professional engaged in active reflection, problem solving, and, more importantly, taking control of decision-making and risk-taking. Such a change in the professional
development mindset is required if schools aspire to be learning organizations capable of embracing institutional change-management in an innovative manner (Senge, P. et al. 2000).

As a learning tool for students, LPs can be an aid to guide the student's research process. The introduction of LPs is a start towards imparting to students the essential life skills of information management through new pedagogical strategies to deliver critical and creative thinking. This will be especially suited for younger students who are overwhelmed by the open nature of starting research from scratch. The LP can, for example, complement the use of an encyclopedia by providing guiding and critically reflective questions with focused instructions towards self-managing relevant aspects of the content. This is important as it eases students into the use of "reflective technology" through a user-friendly "critical thinking scaffold" (Coombs, 2000) and thereby avoids engendering attitudes of discontentment, or fear, when dealing with massive amounts of what appears to many as distracting and unrelated, disparate pieces of data.

Starting with a scenario of the educational challenges in the 21st century, this paper has attempted to craft a response to these new economy demands by highlighting the relevance of S-o-L for educators and students. S-o-L has the potential to empower learners and learning through building upon their confidence to take control of their own learning situations. In a borderless world, there exist many possibilities for information exchange and intellectual globalisation, and, as such, the pedagogical principle of social constructivism will remain of great value in any model of instructional design. Our schools and teachers must be prepared for this quest of implementing S-o-L pedagogy into the curriculum through team-based action research professional development.

The Design and Implementation of a Web-Based Distance Learning System: Problems and Issues

Miwha Lee
Pusan National University of Education
Pusan, Korea
mlee@pusan-e.ac.kr

Abstract: The purpose of this study was to design and implement a Web-based distance learning system for foreign language instruction. Until recently, few Web-based instructional systems have been developed for secondary foreign language learning in Korea, mainly due to technical problems on Korean Windows and Web environments. These problems come from the lack of appropriate input and output solutions to the special characters with diacritics of European languages. This study addresses the problems that arise in the design and implementation of a Web-based distance learning system for foreign language education, suggests solutions to the problems, and discusses the issues related to the implementation of the system.

Introduction

As our society has been characterized by a shift towards the Age of Information, the computer and network technology has come to be widely available at every level of society. It has become the dominant technology of our age and has revolutionized our society. As evident in other social institutions, there has been a need of a new paradigm in educational and training contexts. The emerging paradigm, a “learning-focused paradigm,” entails the characteristics that distinguish industrial-age and information-age educational systems (Kang & Kim, 1999; Lee et al., 1999; Reigeluth, 1999). The educational system based on a new paradigm supports learner-centered instructional contexts and fosters place-time-independent distance learning in a globally accessible, open system with diverse, multiple perspectives.

The goals of foreign language education include communicating with other people in a newly learned language and developing a better understanding of other cultures. It is an essential factor for foreign language instruction to present linguistic information of both verbal and non-verbal elements in rich contexts with hyperlinked multimedia so that various types of decoding and encoding processes of language learning can be made possible (e.g., Borras & Lafayette, 1994; Curtain, 1991; Oprandy, 1994; Oxford & Scarcella, 1994; Schitai, 1989). In recent years, the Internet has been increasingly utilized as an effective instructional tool for distance learning in foreign language education, since the Web can become a multimedia-based content provider and delivery medium for both verbal and non-verbal elements of communication with versatility and interconnectedness. In the Web-based distance learning process, a hypermedia-based instructional system with the attributes and resources of the World Wide Web is used to provide meaningful learning environments for the needs of individual learners ( Clinch, 1999; Harasim et al., 1996; Hiltz, 1994; Khan, 1997; Kearsley, 1996; Lee et al., 1999; McManus, 1995; Owston, 1997; Ritchie & Hoffman, 1996). To this end, the present study attempted to design and implement a Web-based distance learning system for foreign language education.

The purpose of this study was to design and implement a Web-based distance learning system for foreign language instruction. Until recently, few Web-based instructional systems have been developed for secondary foreign language learning in Korea, mainly due to technical problems on Korean Windows and Web environments. These problems come from the lack of appropriate input and output solutions to the special characters with diacritics of European languages. This study addresses the problems that arise in the design and implementation of a Web-based distance learning system for foreign language education, suggests solutions to the problems, and discusses the issues related to the implementation of the system.
Input of Special Characters and Diacritics

Most European Languages contain diacritics or special characters such as é, à, ñ, ß and ð, in addition to using the Roman alphabet. Since the local code pages of those European characters are used to define Korean characters, the Korean versions of the operating systems can support neither their IME (Input Method Editor) nor APIs (Application Programming Interfaces), including displayed outputs and fonts. Moreover, each country tends to use its own keyboard on which the characters are displayed differently. To solve these problems, hence, the instructional system implemented in this study has redefined the code pages of European and Korean languages in the UTF-8 (Universal character set Transformation Format), and has recomposed twelve sub-sets of TrueType fonts. Input methods have also been developed to solve these problems so that special characters or diacritics can be easily entered with Korean/English 101 keyboards that are most widely used in Korea. A particular input editor using Active-X control has been developed to support European characters with diacritics as well as Korean characters for use in the instructional system.

The instructional system developed in this study makes it possible to type in special characters of sixteen European languages including Danish, Dutch, Finnish, French, German, Hungarian, Icelandic, Italian, Norwegian, Polish, Portuguese, Romanian, Slovenian, Spanish, Swedish, and Turkish. It can also support the Russian and Greek characters and the International Phonetic Alphabet by completely redefining the keyboard array. As shown in Table 1, only two or three keys are used to feed one character with diacritics. The symbols for the diacritics were cautiously chosen so that they were not already in use for existing meta-languages such as tags (<, >) or parentheses ((,), [], {}, ). The input system takes into account the order of 'alphabet + diacritics' as in handwriting, which is appropriate for human cognitive structure.

Learning Modules

For the purpose of this study, a Web-based distance learning system was designed and implemented for French language instruction. This instructional system appears to be one of the first Web-based distance learning systems for French language education in Korea. The instructional system consists of the learning modules and computer-mediated communication (CMC), as shown in Figure 1. The learning modules were designed to adapt to
the learning needs of individual students. Students can explore and navigate the hypertext-based learning materials, designing their own instruction. Teachers and tutors can become facilitators in the learning process. The learning materials provide multimedia-based, situation-specific information to improve four main language skills (listening, speaking, reading, and writing) in foreign language instruction (Frommer, 1989). The learning materials can help enhance students' extra-linguistic as well as linguistic competence. The learning materials are composed of four modules: (1) listening ('Ecoutez-moi'), (2) speaking ('Je parle français'), (3) reading ('Lisons'), and (4) writing ('Je sais écrire').

Figure 1. Overview of the Web-Based Instructional System

The listening module presents expressions in context with immediate text feedback to improve students' listening comprehension, as shown in Figure 2. Studies have indicated that listening skills in language learning and communication is important, especially at the early stages of foreign language instruction (Jakobsdottir & Hooper, 1995; Rubin, 1994). The speaking module, designed with an emphasis on conversational practice, asks questions based on given situations presented as a picture. It includes the pronunciation section in the beginning level, which presents French phonetic and phonological rules in relation to orthographic rules with text and sound examples and compares them with those of Korean language.

Figure 2. Example of the listening module

The reading module shows paragraphs in a variety of styles and includes interpretations and in-depth explanations regarding morphological, lexical, syntactical and semantic-pragmatic rules and expressions used in each sentence, as presented in Figures 3. The writing module enables students to gain pragmatic competence in their writing skills and provides questions related to context-based composition. Concerning the grammatical rules of the previously presented sentences, the learning modules provide charts, pictures, and examples as well as explanations about those points. Each module also provides question-and-answer sections in the forms of multiple-choice, fill-in-the-blank, or essay test. Students can answer the questions using the input editor mentioned above and then immediately receive feedback through the database structure. In addition, the learning modules provide an online bilingual dictionary developed for use in the learning process.
Computer-Mediated Communication

Research has shown that computer-mediated communication (CMC) has been recently used extensively in distance education to support electronic communications in various modes of interaction (e.g., Berge & Collins, 1995; Fetterman, 1996; Paulsen, 1995; Todd, 1996). Computer-mediated communication enables both synchronous (real-time) and asynchronous (non real-time) communication and supports interactions of one-alone, one-to-one, one-to-many, and many-to-many (Paulsen, 1995).

Since the instructional system of this study has been developed for distance learning, how to support more individualized learning process has become increasingly important. Throughout the development process of the instructional system, a great emphasis was put on computer-mediated communication. The instructional system implemented in this study, hence, provides Internet-based computer-mediated communication, as a useful tool for various modes of interactions among teachers, tutors, and students. Computer-mediated communication of the instructional system is composed of announcements, bulletin boards, and e-mails, as presented in Figure 4. The announcements include general instructions regarding navigation of the instructional system and show FAQ’s (Frequently Asked Questions) on the learning materials or technical problems. The bulletin board deals with management-related interactions such as a school calendar and logistics. The e-mail allows for individual communications.

User Interface

In designing and developing the user interface of the instructional system, an emphasis was placed on user-friendliness and efficiency. Since the majority of distance learners are reported as novices in computer use (Han & Lee, 2000), a simple, intuitive design with a text-based menu, rather than a complicated design, was preferred. In addition, the instructional system utilizes well-designed TrueType fonts, which support Unicode’s such as ‘Lucida Sans Unicode,’ ‘Berdana,’ and ‘Times New Roman.’ Although RGB color values technically allow for a variety of
color, many computers in use at schools can still display only 16 colors due to the type of video display adapter they use. The basic color of the instructional system was carefully selected based on color-effectiveness studies (e.g., Moore, 1996; Pett & Wilson, 1996; Weinman & Heavin, 1996). Given current access speed to the Internet via modems or LANs (Local Area Networks) in schools, a minimum level of animation was used in order not to disorient students in the learning process (Jeong & Yoon, 1998).

The user interface was designed to differentially provide to each of the user groups, depending on the authorization status, since the user groups need different modes of interaction within and among the groups. For consistent and systematic delivery of information, any subsequent hyperlinked information is displayed on the same page. To this end, the interface was implemented using Active Server Page (Hillier & Mezick, 1998) and Dynamic-HTML (HyperText Markup Language) (Homer, 1997), which enables to present different types of multimedia learning materials on the same page. Figure 5 shows an example screen of the user interface of the instructional system.

Figure 5. Example of the user interface

Conclusion

Until recently, few Web-based distance learning systems have been developed for secondary foreign language education in Korea, mainly due to technical problems on Korean Windows and Web environments. For the purpose of this study, a Web-based distance learning system was designed and developed for French language instruction. It appears to be one of the first Web-based instructional systems to provide solutions to the input and output problems that arise in the implementation of most European languages as well as French on Korean Windows and Web environments. The instructional system of this study was designed to provide a flexible, individualized, interactive, and efficient learning environment where students can actively participate in the learning process to improve their language skills through navigating the hyperlinked multimedia learning materials with interactions of computer-mediated communication among teachers, tutors, and students. The instructional system has been integrated into the curriculum of distance education and has been currently used in the foreign language courses.

Gender and Learning Strategies within Cyberspace

In-Sook Lee
Sejong University
98 Gunja-dong, Gwangjin-du
Seoul, Korea
Inlee@sejong.ac.kr

Abstract: It is a very recent phenomenon for gender differences to receive attention in the cyber-learning environment, even though research on Computer Mediated Communication (CMC) goes back to the 1970s, to an earlier stage in computer technology. The current study identified gender differences in learning strategies and in the relationships among those learning strategies, including interactions, information processing, textual encoding and decoding, sincerity, and persistence. The results provide valid evidence for the importance of considering gender differences in motivational and behavioral learning strategy components in the cyber-learning context.

Introduction

Distance education is moving into a new generation: Internet-based cyber education. Today, functions and advantages of the Internet will be further utilized for education, especially learner-centered education. Learner issues and, especially, learning strategies are significant factors for success in cyber education (Bonk & Dennen, 1999; Bopry, 1999; Willis, 1994; Smaldino, 1999; Simonson, 1999; Dille & Mezack, 1991; Lee, 2000; Lyman, 1998; Thomas & Bitter 1998). The importance of self-regulated learning strategies in academic performance and achievement has been well established in the traditional face-to-face environment (Dansereau, 1978; Weinstein, 1978; Gagné, 1985; Zimmerman & Martinez-Pons, 1986; Zimmerman & Martinez-Pons, 1988). But, few have been done in the multimedia context and even fewer in the cyber context.

The literature in distance education supports the idea that learner issues are critical factors for achievement and satisfaction levels in distance education (Bonk & Dennen, 1999; Bopry, 1999; Willis, 1994; Smaldino, 1999; Simonson, 1999; Dille & Mezack, 1991; Lee, 2000; Lyman, 1998; Thomas & Bitter 1998). Given the work and thoughts evident in this area, it is essential to put learners’ characteristics at the forefront of the planning and implementation of cyber education. The goal of planning cyber education programs is to provide learning experiences and environments based on each learner’s needs so as to ‘makes the sum of each learner equivalent’ (Simonson, 1999).

The most commonly discussed characteristics in the related studies include learners’ experiences, learning styles and strategies, cultures and communities, social context, and affective and motivational domains in cyberspace. Burge (1993) found that learning strategies were important to choice-making, expression, group interaction, and the organization of information. Eastmond (1993) showed that learners in computer-conferencing-based courses employed strategies for dealing with multiple discussions, information overload, asynchronicity, textual ambiguity, processing of online information, and deciding what contributions to make. Lyman (1998) suggests that cyber learners need to develop six learning strategies called ‘information literacy’ in order to best benefit from the Internet, especially in a resource-based learning environment. Lyman identifies five such learning strategies: knowing when there is a need for information, identifying the information needed, locating the needed information, evaluating the information, organizing the information, and using the information effectively. Willis (1994) suggests that for adult learners to succeed in distance education they need tolerance for ambiguity, autonomy, and flexibility; and factors indicating failure include preference for a great deal of structure, face-to-face lectures, and the opportunity to interact with instructors.

In summary, cyberspace is heavily expected to be tremendously learner-centered. Learner-centered environments require learners to make decisions by themselves throughout the learning process and to have a
high level of self-regulated learning abilities. For these reasons, it is critical for learners, in particular for novices, in a cyber-hypertext environment to acquire appropriate learning strategies. For learners who cannot manage effectively the complexity of the cyber communication environment, there may be a need for explicit modeling or scaffolding support. Nonetheless, relatively little attention to cyber learning strategies is found in the current literature.

It is a recent phenomenon for gender differences in cyberspace to receive any attention. Probably due to the short history of cyberspace within educational sectors, still little attention has been paid to gender differences in general and even less to gender differences in self-regulated learning strategies. Lack of learning strategies might be one of the main reasons why learners are hindered in their pursuits (Balajthy, 1990; Steinberg, 1989). If learners effectively control and regulate their own learning processes, the flexibility, openness, and wide array of choices of the cyber learning environment may serve them the best.

Therefore, this study sought to identify gender differences in motivational and behavioral learning strategies, seemingly the most widely demanded in the cyber learning environment. Those learning strategies include interaction, textual information encoding, textual information decoding, sincerity, and persistence. A second purpose of the current study is to examine and clarify gender differences in the relations among the five learning strategies.

Methods

The participants were 156 undergraduate students, 35 males and 121 females from a medium-sized university in Seoul, Korea. The participants were varied in terms of their academic backgrounds and years in their programs. All of the courses were integrated with a web-based instruction tool, UniverCampus. Cyber learning and instruction in this research was characterized by basically asynchronous, text-based, open, and learning-task-oriented space, and was combined with face-to-face classes. Throughout the semester, the participants were encouraged to contact assistants and the professor as they needed. At the beginning of the semester, a one-hour long orientation covering how to use the online tool was offered. A 16-item survey was administered during the final week of the semester. The questionnaire was organized based on a factor analysis into five categories of interaction, textual information encoding, textual information decoding, sincerity, and persistence. Each item was designed with 7-point Likert scales, using values of 1 for “strongly agree” and 7 for “strongly disagree”. Post-hoc, internal consistency reliabilities of the categories were measured with the following Cronbach’s alphas: Interaction (.84), Textual information encoding (.83), Textual information decoding (.72), Sincerity (.81), and Persistence (.81). A t-test was computed for the questionnaires and 7-point Likert items with negative descriptions were reversed for convenient interpretation.

Results and Discussion

Interaction

Two questions were asked with respect to behavioral strategies for actively initiating issues and providing feedback to others in the cyber learning space. Regardless of gender, learners slightly skewed negatively in the interaction ratings. Meanwhile, significant differences were found between genders with regard to active feedback strategy (t = -2.433, p < 0.05) but not with regard to initiating discussions.

Males perceived themselves as more actively presenting feedback to others. This finding can be discussed in terms of the main features of the current research context, which are text-based, open, formal, and task-oriented. In this context, learners are expected to conduct open discussions on specific issues, rather than personal, individual, and social dialogues.

Earlier findings indicate that this environment is dominantly favorable to males (Refer to Kramarae & Taylor, 1991; Herring, 1994; Spender, 1995; Fishman, 1997; McDowell & Schuelke, 1998). In this context, female students would have relatively higher apprehension to communication (especially through textual encoding) than
males. On the whole, female students were motivationally or behaviorally discouraged against posting opinions and providing feedback. Apprehension and discouragement would have seemingly negative effects on full or appropriate use of learning strategies required for success in the cyber communication system.

**Textual Information Encoding**

Two questionnaires were asked with respect to textual information encoding as one of information processing strategies. The results are presented in Table 2. Although both genders responded positive, there were highly significant gender differences in perceived difficulty ratings for presenting written ideas and opinions in cyberspace. Females experienced significantly more difficulties in online-written expression than males ($t = -2.457, p < 0.05$). There was the same pattern in the analysis of real life writing difficulty ratings ($t = -2.348, p < 0.05$).

Apprehension differences in textual encoding are consistent with the prior research (McDowell & Schuelke 1998; Fishman, 1997; Schellhas & Brenstein 1998). The current research revealed that apprehension of textual encoding in daily life was strongly related with apprehension of textual encoding in cyberspace ($\gamma = .70, p < .000$). The earlier and the current findings indicate that learner characteristics in real space are highly transferred into cyberspace or multimedia environment.

**Textual Information Decoding**

Five questionnaires were used to determine gender differences in textual information decoding. In general, males perceived themselves to have more behavioral strategies in overloaded textual information decoding than females. The results are presented in Table 3. When information was overloaded, females skipped significantly more participants' postings than males ($t = -2.457, p < 0.05$). Without considering overload, in contrast, there were no significant gender differences in the degree of reading ratings ($t < 1$). Yet, both genders skewed slightly negatively in the ratings. In addition, when textual messages were overloaded, females (mean score=4.33) tended to have more difficulties in selecting and appreciating them than males (mean score=3.8), albeit not at the 0.5 significant level ($t = -1.917, p = .057$).

The cyber-learning environment promotes many-to-many and multiple discussion, in which information is quickly piled up. Decoding (reading) texts is 'time consuming due to its textual ambiguity' (Mason, 1994), and overloaded textual information would put more psychological stress on females than on males. The results suggest that females would have less learning strategies for managing overloaded online information, and the heavily text-based learning environments like this may lead females to lower academic achievement.

**Self-regulation: Sincerity**

This study used five questions about sincere effort ratings including the items of which are presented in Table 4. The results indicated significant differences between genders in the degree of submission ratings consistent with instructions ($t = 2.598, p < 0.01$) and in the degree of submission ratings after a due date ($t = 2.00, p < 0.05$). Females submitted significantly more assignments consistent with instructors' directions than males. Meanwhile, males had more tendency to submit assignments after a due date than female students did. These two ratings were the only ones in which females out-performed males at or over the 0.5 significant level, among the learning strategies items discussed in the current study.

In general conditions, ignoring the factors of time management or consistency with instructions, however, the differences in sincerity ratings of the two genders did not reach an acceptable significance level (all $ps > .35$). For both genders, sincere efforts to participate in a required activity were very positively skewed.

The cyber-learning environment demands high learners' self-regulation (Keegan, 1990; Mason, 1994; Bonk & Dennen, 1999; Lee, 1999a; Lee, 1999b; Lee, 2000). Thus, self-regulated strategies such as sincere effort, diligence, and persistence are very important for learners to facilitate their learning process. The current study reveals that instructional intervention through required assignments or learning activities can function as affirmative facilitators of sincere self-requisition for both genders. Yet, females outperformed males in sincerity ratings in accuracy and punctuality.
Self-regulation: Persistence

Two items were employed to determine whether any differences existed between genders with respect to persistent behaviors to solve any instructional or logistical problems during the cyber learning process. The results are presented in Table 5. There were no significant differences between genders; both genders tended to be slightly persistent in learning under technical problems.

The Relations of Five Learning strategies

What are the relations among the five learning strategies with gender differences? For both genders, higher levels of textual decoding ($\gamma = .35; \gamma = .43$) and sincerity ($\gamma = .60; \gamma = .34$) were correlated with higher levels of interaction. In addition, for both genders, higher levels of textual encoding ($\gamma = .45; \gamma = .33$) were correlated with higher levels of textual decoding. Interestingly, however, persistence for both genders was not associated with any of the other learning strategies at the satisfying significance level. Textual decoding was not associated with sincerity.

The results indicated gender differences in the relations between interaction and textual encoding and between sincerity and textual encoding. For males, textual encoding was highly correlated with interaction ($\gamma = .50$) but not for females ($\gamma = .14$). For females, textual encoding was highly correlated with sincerity ($\gamma = .27$) but not for males ($\gamma = .20$).

Although correlation data cannot address causality, it appears that the learners who are better in textual information decoding are those who are actively engaged in and can present ideas in cyber discussion. Accordingly, learners' skills in textual decoding are an important component to be considered for both females and males. In a similar fashion, these learners were more likely to outperform in textual presentation; yet, the correlation was stronger for females. In addition, both genders that were sincere in learning participation were more interactive in the cyber discussion.

Results of the current study provide some instructional implications. Improving females' textual information encoding strategies may lead to more use of sincere efforts in learning; improving males' ones may lead to the use of interaction strategies.

Implications for instructional design and research

The goal of this study was two fold. First, this study investigated gender differences in motivational and behavioral learning strategies in the Internet-based cyber-learning environment. Second, this study examined gender differences in the relations among learning strategies, including interaction, information processing—textual encoding and decoding, sincerity, and persistence. The results provide valid empirical evidence for the importance of considering gender differences in motivational and behavioral learning strategy components in the cyber-learning context. There are highly significant gender differences in the category of textual encoding strategies, in which males showed stronger behavioral and motivational learning strategies ($t = -1.810, p = .01$). And there are, to some extent, gender differences in the category of interaction ($t = -1.810, p = .07$) but not at the .05 significance level. The findings are not entirely surprising, since they replicate many of the existing findings from the areas of communication, linguistics and sociology, and so on.
Currently dominant modes of cyber courses demonstrate structures and functions in favor of males. Of greatest potential leading to gender inequality and favor of males in a cyber-learning environment are its text-based, public, and information overload natures. However, it should not be taken for granted; we have to move toward a gender-equal cyber-learning environment.

The results of the current study have implications for instructional design and research which might respond to learning strategies in favor of both genders. The following instructional interventions should be considered to overcome potentially negative impacts of those natures on specific genders.

Considering that females experienced more difficulties in thinking and expressing in a written form, an effective instructional strategy is to offer alternative interaction modes. Dialogue-like interaction such as real time chatting, audio learning resources, and verbal interactions should be used more substantially. Females' difficulties in public postings and interactions also should be considered in the design of learning activities. It is apparent that informal, social, or individualized learning and interaction opportunities may improve certain gender-oriented online learning environments. Instructional interventions for small group discussion and individualized learning materials should be embedded in cyber learning.

Moreover, because that females tend to experience difficulties in reading others' messages when especially overloaded, there is a need for the interface design which might help individual learners to search, organize, and present information in their own convenient way. Similarly, it is equally useful for mediators to regularly provide summary notes of shared information and ideas among learners. Besides all of the previous instructional interventions, one can teach explicit learning strategies to certain individuals and genders that, to some degree, lack study skills or embed them within a cyber program.

Some potential limitations of this study should be noted. The study population consisted of undergraduate students majoring in Education and minoring in Teacher certificate programs, which limits the generalizability of the results. Extending the population to various majors and colleges could produce different results. In addition, because the research context was very limited, it was not possible to investigate a wider array of online learning strategies. Finally, all the motivational and behavioral learning strategy variables were measured with self-report instrument; this study did not include qualitative data to confirm the ratings of interaction, information processing—textual encoding, information processing—textual decoding, sincerity and persistence. Extending the study to qualitative data could further support the results of the current research and have more in-depth implications.

Cooperative Filtering System using Intelligent Agent
: A Case of Educational Portal Site

Abstract: This paper is a study on the design and implementation of the cooperative filtering system using an intelligent agent for the educational portal systems. Generally educational portal sites have many addresses of homepage related education and e-learning system. Therefore, the portal site has a very difficult task with maintaining a consistent of linked site. In addition it is impossible that administrator personally examines all dead sites in searched education site and the index DB. Most portal site used intelligent agent for automated filtering. But filtering by agent brings overload on network and system. To solve this problem, we designed and implemented a mutual cooperative filtering system to filter off dead site using a mobile agent. This filtering system was applied to the educational portal system for elementary student and teacher. For viewing efficiency of this system, we made an experiment that compared a cooperative filtering agent system with a stationary filtering agent system.

Introduction

Web-based instructional homepages are used in many computer assistance medias and also the numbers of education sites are on the increase extremely. An extremely increase in number of homepage raises a question whether a student can search an appropriate homepage for learning. In case of finding learning contents using a general searching engines, the searched site can exist an irrelevant contents against a student's request. Moreover the result of searched content fell into learning confusion, because the contents are difficult to apply at learning intact. In order to overcome this problem, an education portal site was constructed to gather only the address of education homepages that had been made several times before. An advantage of education portal site is that content can be used correctly and rapidly in learning because searching site was well constructed for learning. In addition student can easily get a suitable contents and information. For providing the education site to student and teacher, the education portal system, called Korean Education Portal System(KEPS), was constructed on the EDUNET homepage by the KERIS and Inchon National University of Education.(http://210.102.100.38)

While walking past a type of the gathered homepage in KEPS, we can see that almost learning sites and contents made by a teacher and a private person. As a result, characteristic of the homepages have to be petty and is frequently updated. Because the education homepage can disappear easily, portal site faces difficulty to maintain consistency of the site’s address. If a stored address of a portal site is not connected or the retrieval site is disappeared to user, then this portal site may bring discredit to student. In order to maintain consistency of portal, the administrator of portal site must validate all addresses of site. But this examination is impossible work that man completely manages and finds. Consequently, the filtering of dead sites can be process by an intelligent agent instead of human administrator.

A single agent needs comprehensive amount of time required for the filtering of a portal site. If a single agent examines a great many site addresses extremely, the filtering works may be inefficient or impossible. Because a mobile agent is possible with decentralization and a parallel processing, the filtering can be process effectively through a mobile agent(J. White, 1997). Accordingly, we designed and implemented a cooperative filtering system to filter off dead site using a mobile agent. For viewing efficiency of this system, we made an experiment that compared a cooperative filtering agent system with a single filtering system.
Related Works

The agent is a program with intelligent characteristics to help the users with the use of computers and take the user's place. The intelligent agent perceives any dynamic stimulation or condition and interprets the data collected for a solution to the problem and exercises reasoning for a final decision. It also acts to change the conditions within its environment in order to perform assigned duties (M. Wooldridge, 1995). Generally an agent divides a kind of two by the mobility, a stationary agent to be executed roles in single system, while the mobile agent is executed at various systems after moving through the networks. The research on an agent has been progressing by FIPA (www.fipa.org) and UMBC (http://agents.umbc.edu). And the research on the mobile agent has been studying many works by IBM and universities all over the world. The mobile agent has a specific characters compared with a stationary agent as reduction of the network load, the overcome of network latency, an encapsulation of protocols, asynchronously and autonomously execution, dynamically adaptation, naturally heterogeneous, robust and fault-tolerant and so on (Danny Lange 1998).

In the information retrieval, a filtering work ascertains the state of gathered site for the maintenance of data consistency. Generally, because the information of the web is changed frequently, a filtering job by human is an impossible or inefficient work. This filtering job can be processed by intelligent a computer program instead of a human. Such a program is called the web robot or an agent and searching site and portal site is certainly needed (R. Tolksdorf 1998). In case of examining many sites in the filtering work, if a single agent of a server processes filtering work, then it may be needed long time and overloading of a filtering server. The mobile agent has made possible cooperative and speedy filtering job from distribution and parallel processing (Ehab Al-Shaer 1997). This paradigm about a mobile agent contains data sharing as well as resources sharing as SETI@home (the search for extraterrestrial intelligence project) and information sharing on P2P.

Overview of Cooperative Filtering System

The overview of the KEPS system shows figure 1. The education portal system is consisted of four parts. These are the education portal server (EFS) and the filtering agent server (FAS), the temporary filtering server (TFS), and a mediator. For using educational portal service, user must be connected with the Portal web server. Gathered address of an educational homepage is supported searching service of an education contents to user through the Portal web server. The Portal web server has searching engine, site DB and a query processor. The filtering agent server has a stationary filtering agent and a cooperative mobile agent, error DB, a mobile agent server. Also the filtering agent server performs works as a creation and an allocation, a control, a gathering of the filtering mobile agent. For the mobile agent perform it's task fully, each server is installed the mobile agent server necessarily.

The temporary filtering servers are in existence out the KEPS system. In order to process a fast filtering work, the TFS have function of distributed and parallel processing. The number of TFS is not fixed but dynamic by amount of filtering job. Furthermore the TFS is used in temporary palace which mobile agent examines each a state of the registered site. At ordinary times, the TFS is not used usually for examining a
state of the registered site. However the TFS can be only used when is requested by the mediator agent server. The mediator is situated between the filtering agent server and TFS, and acts as the role of mediation with the mobile agent and servers. All agents and agent servers must be registered in the mediator.

The detail structure of the KEPS System shows figure 2. The portal web server is consisted of searching engine and query processor, is shared the gathering DB of portal site. The searching engine provides searching service about education content and the query processor is shown the result searching at DB. The filtering agent server is consisted of inference engine and agent manager, error DB. The filtering system in filtering agent server has a stationary agent and a mobile agent for distribution and parallel working. A stationary agent examines the state of gathering site and the confirmation of HTML documents through HTTP connection. If a failure sites is saved at temporary error DB, these will be deleted from site DB of portal web server. A permanent deletion of fail sites is executed by inference engine of the filtering agent server.

![Figure 2. Structure of the KEPS system](image)

**Cooperative Work of Mobile Agent**

When a filtering agent server is overloaded or the stationary filtering agent has difficulty processed by examination with many site, the filtering agent server requests to the mediator about information of the registered TFS. If the number of the TFS is lacking, the filtering agent server waits until the TFS becomes sufficient. Having sufficient number of the TFS, the mobile agent is created to divide as a suitable size of address by inference engine. And then the mobile agent has been created by a filtering agent server, will be cloned with suitable number. Each mobile agent is allocated a filtering work and will be dispatched to the TFS through the ATP(Agent Transfer Protocol). The mediator agent can grasp each work states of an agent by using the agent finder.

Each agent is moved to temporary filtering server and examines the allocated addresses of sites through HTTP. When a mobile agent is finished all checking of sites, it sends to the filtering agent server with the result of observation. If the job of the mobile agent is occurred some problem, filtering agent server creates a new mobile agent and re-dispatches to the TFS. All results gathers, result of examination saves at site DB and error DB. Finally, dispatching the agents retracted by the filtering agent. The job of filtering using the mobile agent has advantages that prevent an overloading of a single server and lessen filtering time by distribution and parallel processing. Because agents are not used stationary server but are dynamically used in other servers, all servers performed share resources of filtering system. Accordingly, each agent can do cooperative parallel processing using autonomous and society properties of agent.

**Implementation of Cooperative Filtering System**

The filtering agent system proposed in this study was implemented two types. The stationary filtering agent was implemented by using VC++ and CLIPS. Also the mobile filtering agent system proposed in this study was implemented using JAVA based Aglet API and JESS(Java Expert System Shell). Aglet is the java class library for that can easily design and implement all the properties of the mobile agent(Chang, D 1996). Moreover the Aglet provides with the Tahiti server and Agent finder for helping research of users.
The stationary filtering agent interacts with the mobile agent of Tahiti server based environment. Inference engine of the stationary filtering agent was used the CLIPS dynamic linked library and the mobile filtering agent system was used the JESS class library. The CLIPS and JESS are rule based inference engine and was used to infer planning and allocation of the mobile agent. SQL was used for the gathering DB of portal site. ODBC and JDBC were used to connect the filtering agent system and the gathering DB of site.

The stationary filtering agent was consisted of three parts mainly. The left screen of figure is represented list that the agent will examine site of DB. Also the center of screen is viewed results of a successful site and the right screen is represented results of a failure site.

Figure 3. Interaction between stationary filtering agent and Tahiti server

Figure 3 is shown screen that the mobile filtering agent is examining each site with distribution and parallel processing. If the numbers of sites are many in existence, the stationary filtering agent executes the mobile agents to interact with the Tahiti server as followed image. Above window of figure is represented the stationary filtering agent. Black screen below is viewed that mobile agent sever is executed by the stationary filtering agent. Small screen below is shown the Aglet viewer. The Aglet viewer perform an important role as a creation, dialog, dispose, cloning, dispatching, retracting of a mobile agent.

Figure 4. Interface of education portal site
To use the implemented filtering system in this study, we applied it at the educational portal system and the KEPS system in the EDUNET site. Figure 4 is shown the searching screen of the web browser using KEPS system. This portal site in the EDUNET was constructed for the Korean elementary student and teacher. Also this site contains all contents about the curriculum of the Korean elementary school.

Experiment and Considerations

For examining the efficiency of the cooperative filtering system using the mobile agent, we compared and evaluated a filtering time of each agent system. A comparative objective is the filtering work time of single vs. cooperative mobile agents. Also, the estimative items are the single filtering agent and the three, seven filtering agents and the number of site 10, 30, 50, 70, 90, 110, 130, 150, 170, 190. The experiment measures examination time of sites using a comparative and estimative items above. The estimative result is represented figure 5 with form of graph. The horizontal axis of graph is represented the number of site and the vertical axis of graph is represented filtering time of each agent.

In case of the number of an examine site is small, the result of experiment is viewed that the single stationary agent is faster speed of examination than the mobile filtering agent. Also, when mobile agent is dispatched to three servers, speed of examination is faster than is dispatched to seven servers. The reason is caused by overtime occurred because the many mobile agents are created, allocated, gathered.

However, the more the number of site increases, the faster the mobile filtering agent gets speed of checking than the single stationary agent. In particular, when the cooperative filtering system using many agents, experimental result is shown that a speed of examination is very fast. If a single stationary agent processes very many sites, the result of execution can be useless though the result is very accurate.

Consequently, the cooperative filtering agent can become higher execution speed by distributed and parallel processing and an overload of network by using a mobile agent can be decreased. If a server has an active environment of the mobile agent, the servers can be used with an active space of a searching agent and a filtering agent.

Figure 5. Result of filtering time

Conclusions

This study is on the efficiency of cooperative filtering agent using mobile agent for educational portal site. The filtering job has been getting difficulty processed by human. Thus, an intelligent agent can process the filtering of the portal site instead of human. A filtering work by using a single stationary agent needs
long time for checking of many sites.

To overcome the problem in this study, the mobile agent is used in filtering job. The filtering job of educational portal site can be processed by collaborative method of decentralization and parallel using the mobile agent. The filtering system was implemented by using the Aglet and Tahiti server. This system could execute cooperative filtering job through an intelligent interaction between the stationary agent and a mobile agent. Also the KEPS system is possible with the mediation and the registration of agents by using the mediator agent between the filtering server and the temporary agent sever. The temporary agent sever is not fixed with the number but can be dynamically changed. Therefore all servers are by resources of filtering job and each server can execute its role by inference.

More studies are required on research that constructs knowledge base for inference engine of the mobile agent. For effective portal site constructed, future work needs researches not only intelligent filtering but also intelligent searching and gathering of educational information based on P2P. Also, to interact between the mobile agents, we will make a plan the research on KQML, language for sharing and exchange of knowledge between agent and agent.

Because laboratory experiment in science education is essential for understanding the natural phenomena and principle related to a subject. Laboratory activity should be required even for distance learners providing vivid interaction between learners and nature. In this paper, we are proposing a noble experimental technique in physics education for distance learning and the regular school by introducing the remote control experimental system through Internet.
The Virtual Reality Science Museum of Kongju National University in Korea

We will present our recent developments of the virtual reality science museum (VRSM) of Kongju National University in Korea. Our group works together to build the VRSM covering many scientific areas. The purposes of the VRSM are (1) the development of new concept of science museum for the 21C science education, (2) the contribution to the popularization in science literacy for citizens, and (3) the development of new teaching and learning methods in science education, etc.

A virtual reality science museum (VRMS) is a new concept of the educational system using VR interface, which brings together a 3D model of some real scientific situation and a virtually real visualization of the natural phenomena. And clients control the virtual world in terms of their scientific understanding. There are many virtual show-rooms such as the experience of virtual reality, the exploration of the space universe, the exploration of the earth and its environment, the exploration of physical world, the exploration of materials, the exploration of life and human, the exploration of mathematics, and the exploration of high-technology, etc. The url address of VRMS is http://science.kongju.ac.kr/cyber_science/web/original/.
Model of Utilizing ICT in Teaching Information and Communication Ethics

Abstract: Korean society is currently overwhelmed by the digital trend and the various deviation phenomena through the cyber space are getting more and more serious. In view of this fact, we are urgently required to provide Netizen with the information and communication ethics education. The purpose of this study is primarily to survey the teaching of information & communication ethics in various levels of educations in Korea, such as primary schools, middle & high schools, colleges and private level. We suggest a certain teaching model of the information & communication ethics utilizing the information and communication technology. And based on the basic teaching strategy, we suggest the specific procedures of the teaching. The teaching procedures are divided by three different stages: preparing, implementing and completing courses. And the implementing course is again divided into three stages; Before-class, In-class, and After-class. We specify the missions of the teachers and the learners for each stage.

Introduction

Internet is spreading rapidly beyond comparison with any other media in Korea. Unfortunately, however, it is bringing a lot of negative impacts on Netizen(citizen using network) as the business concept is being involved, deviating from the original positive aspect sharing useful information between and within Netizen, leading to serious social problems.

Only education makes it possible to reestablish social conscious minds for Netizen since it is closely related to each segment of social groups and influences respectively on whole society as a fundamental. The mood of computer education has been growing up because of the conformed presidential messages at the beginning of the year 2000. But, we easily neglect to deal with information & communication education to Netizen.

In this study, we are going to discuss the educational solutions of information & communication ethics. It will be helpful to activate its ethical educations. Especially, as we get along with large scales of information sources, we overview the efficient solutions utilizing the ICT which is one of the most important factors in our lives at this Knowledge and Information Age on teaching the information and communication ethics.

The Information & Communication Ethics Education in Korea
The State of Primary & Secondary Curriculum

In 1997, the 7th educational curriculum was officially announced in Korea. It emphasized primarily on fostering information literacy and information ethics education (The Korea's Ministry of Education 1998a, 1998b). Unfortunately, however, specific guidelines are not included on the information & communication education in curriculum. Only teaching & learning methods are described a little in curriculum.

The State of College Curriculum

Still there is no information & communication ethics class for college students in Korea. They merely teach some portions of information & communication ethics, such as 'protection policy for program', 'Information Society', and 'information Ethics' in general Philosophy or introductory Computer classes. Computer Science(CS) curriculum in Korea hasn't tried to select information & communication ethics officially in its field. There are various efforts to include ethical issues in CS curriculum with ACM (Huff, Charles & Martin, C. 1995, Martin, C. Dianne et al. 1996); it suggests many things to CS curriculum.

The Education Trend for Citizens from the private level

Information Communication Ethics Committee was organized in 1992 from the private level and it has been actively spreading a sound awareness about information & communication ethics until now. The committee's main activities are preventing gutter information's distribution, spreading information & communication ethics, researching more about information & communication ethics, activating international cooperation, supporting parents' guards for information, and so on (ICEC 2000).

Direction of Information & Communication Ethics Education

In the first place, education needs to spread and settle the awareness of information & communication ethics. It is the most solid way even though it doesn't come out any result right away. Information & communication ethics education needs to be proceeded in following directions.

Early Education of Information & Communication Ethics

As ICT (Information & Communication Technology) has rapidly spread and generalized, users of computer age groups are becoming younger. For this reason, elementary school curriculum has to be occupied information & communication ethics in its early stage as elementary school teaches general ethics in low grades. It's better to practice from elementary to high school consistently and without interruption.

Establishing College Lectures about Information & Communication Ethics

It is time for college students to establish their life goals and clear guidelines on their future. Therefore, students need to continue to take information & communication ethics education even after Primary & Secondary schools. Information & communication ethics education requires students' initiative participation, and active discussions between students. In addition, students should have opportunities to listen lectures from specialists, who are good at ICT and have various computer experiences, so that they can broaden their knowledge and experience more. According to Diane Crawford, executive editor of Communications of the ACM, there were 300 computer ethics courses in 1995 and an estimated 400 courses in 1996 (Nancy J. Wahl 1999 quoted).

Integrating Curriculum & Developing Textbook

Curriculum is an important guideline providing teaching contents, teaching methods, and evaluation. Instructors depend on curriculum and textbook when they start teaching. Therefore, curriculum should include the contents of information & communication ethics quite obviously in any subject so that they can manage the lesson. Moreover, according to integrated curriculum, it is required to develop textbook which provides specific contents of teaching, teaching methods, and teaching strategies. It is desirable to be participated in this work those who are in the related fields, such as curriculum specialists, ethicists, computer experts, teachers, and so on.
Cases Focused Lecture with Discussion

Information & Communication Ethics has a practical feature coming from cyber space. Therefore contents of education should be focused on concrete cases that have happened before, and they should cause leading attendance and critical thinking of learners. Cases focused education seems to have strong educational effects because students experienced them or have possibility in experiencing them. Learners can be suggested concrete issues, search cases about them, discuss each other about them, and they can internalize consciousness of Information & Communication Ethics through evaluation. For example, learners search regulations and cases through internet, newspaper, CD-ROM, library, encyclopedia, etc. about illegal software copy, and share information with other learners. And then they will have a correct understanding of illegal software copy through mutual critical discussion.

Instruction Utilizing ICT

Instruction utilizing ICT provides new possibility to traditional instruction. ICT enables divergent instruction free from traditional instruction and has changed the existing roles of teacher and student to new paradigm. Students can perform leading roles in searching information and solving problems using ICT because it is the source of knowledge and information. ICT requires spontaneous, creative, and critical thinking ability of learners. The ultimate objectives of Information & Communication Ethics instruction is making learners have healthy ethical consciousness. We can't get desired effect of instruction if we emphasized one-sidedly only norms, netiquette, etc. because it decreases students' interest. The instruction method should be form that learners are able to aware consciousness of Information & Communication Ethics by themselves in process of instruction. Cooperative Learning and Problem Based Learning using ICT can be excellent instruction method.

Model of Utilizing ICT in Teaching Information & Communication Ethics

The ultimate purpose of information & communication ethics class is to help learners to have a healthy awareness of information & communication ethics. In the event teachers lead one-sided lesson, only focus on teaching regulation and netiquette, it causes boresome to learners, therefore, it doesn't bring any effectiveness. However, as ICT has been increasing in power, it provides a new possibility in this traditional teaching. The ICT uses computer, internet, every kind of information equipment, multimedia, and so forth in order to format, transact, analyze, apply and search information. The ICT enables students-centered classroom and transform roles between teachers and students. We suggest following teaching strategy and model that are from utilizing ICT in teaching information & communication ethics.

Basic Teaching Strategy

Utilizing Internet

Internet is an useful tool to increase the teaching effectiveness of information & communication ethics. Learners can easily find various multimedia resources through search engines and plenty of web data. They discuss and work on the project with other learners from different areas or countries by using e-mail, chatting, bulletin board, and news group. Moreover, they can receive advice from specialists outside. In addition to it, internet is also used as an appropriate tool which shows negative situations of cyber space.

Eric Roberts(1998) suggested a case of utilizing internet technology in teaching ethics. As he applied internet technology in teaching CS201 Computer Ethics class, he received positive results.

Utilizing Video

A well organized and systematic ethical video tape can be more useful than an instructor's lecture. One thing important is to find a video tape with appropriate theme for class. Teachers need to put efforts to find suitable videos through various media and contemplate to select one in advance. They also need to have full knowledge of video so that they can lead any perspective of discussion during the class. Kevin(2000) used a video aids in a Computer Ethics class. He suggested price, educational theme, and contents of video, such as whistle blowing, software privacy, freedom of speech, and safety-critical software he used for his lecture in South Florida. He also proposed a class model exercise from his paper.
Case Study—Small Group Discussion

Small group discussions brings effectiveness more than teacher-centered classroom(traditional way of teaching) in information & communication ethics class where talks about social issues. Information & communication ethics is similar to the practical ethics dealing with the various problems in cyber space. Therefore, lessons need to be focused on the real cases, a spontaneous participation of students, and guide them to have the thought of criticism. The tradition way of having a small group discussion class is to divide groups, and develop the discussion in prearranged time with the theme. After that each group presents their results. Using internet discussion can be continued even after class. Therefore, if a theme requires a long period of time of discussion, it's better to have internet discussion simultaneously. Tom Jewett(1996) emphasized that a careful group organization is the core of succeeding in small group discussion and suggested various strategies for organizing groups.

Model of Teaching Utilizing the ICT

The teaching model of utilizing ICT in this study is a model of mingling internet with video in a small group discussion classroom. Students at second class schools and colleges are subject for this study. This course focuses on applying internet and video in proper periods. The ICT can be an useful teaching tool not only in 'In-class', but also in 'Before-class' and 'After-class'. It is important for a teacher to determine timing for applying the ICT and the sorts of the ICT. They also need to do continual monitoring in order to find out effectiveness of applying results. This teaching model is divided into course preparation, course implementation and course completion. Each course is described as follow.

Step1: Course Preparation

In this stage, there are three things which teachers must do.
First of all, teachers need to understand students' background, tendency, and their opinions to reflect the whole course. It can be done by surveying and analyzing results. On-line and Off-line surveys can be conducted appropriately. Followings are showing contents of survey questionnaires.
- Subjects' background: grade, age, sex, using computer hours a day, period of using computer
- Ability to utilize computer
- Percentage of daily usage of computer
- Deviation from and harmful experiences through cyber space
- Awareness of traditional ethics vs. Awareness of information & communication ethics
- Theme wants to be included in course
The theme for lesson can be selected based on various backgrounds of students. Also, it can be reflected in organizing groups. Following topics are potential themes for lesson.
- General information & communication ethics
- Trespass of privacy
- Addicting to internet/computer
- Infringement of intellectual possession
- Distribution of unhealthy information
- Unhealthy intercourse through media
- Responsibility of the Computer Professional
Second, teachers collect, analyze and classify varieties of teaching and learning resources. They search, analyze, classify concepts, knowledges and cases about theme for lesson through internet, books, encyclopedia, newspapers, and CD-ROM; and then, they improve and store them. Besides, they download or purchase some videos(including streaming type) about computing and social issues through internet and other broadcasting media.
Third, teachers prepare bulletin board for announcement, teaching-learning resources, submitting assignment, and discussion. The board for announcement is only for teachers to post up information. The board for submitting assignment is where students freely upload but, only teachers have the authority to download.

Step 2: Course Implementation

In the basis of course preparation, proceeds the course in real at this stage. Each class module which composes the course is subdivided into three stages: Before-class, In-class, After-class. Before-class is to prepare necessary things before a real lesson. In-class is the stage when real teaching is proceeded. After-class is for evaluating the lesson and preparing for next lesson. Each stage is rotating. Followings are specifically described of each stage.

(1) Before-class
First, teachers need to announce reading assignment, next class theme, issues of discussion, and other assignments through internet bulletin board. Then, based on the analysis of survey, they organize groups and assign each member's roles. Roles of members can be group leaders and representatives etc. If teacher wants to use video in-
class, they need to watch the video several times in order to analyze the contents, and select additional discussion topics.
Second, learners need to read carefully for the class, research cases through internet, and write down their opinions about discussion issues.

(2) In-class
First, teachers take for 5 to 10 minutes to explain about reasons for choosing the topic and basic concepts and knowledge. When dividing the class into small groups, follow the announcement from 'Before-class' stage. Depending on situations, teachers can rearrange group members and their roles. They fix In-class time for about 50 minutes and announce portions of each time to students.
Second, when planning to use video, teachers watch the video with students. Teachers stop playing the video when providing discussion issues. Let students have time to think about the issues for about one minute. Then, guide them to participate in discussion by asking questions or suggesting discussion issues.
Third, if they do not to plan to use video, proceed to group discussions right away. When suggesting discussion issue, follow the announcement from 'Before-class' stage. It is not necessary to have same issue for each group. Group members are participated in discussion with prepared notes from Before-class stage. At this time, teachers often participate in each group's discussion and controls controversy. In other words, they activate the discussion atmosphere. It is also suitable for having discussion for 15 to 20 minutes.
Fourth, provide 5 minutes to finish up the discussion and summarize. After that, students present results of discussion and teachers give them some comments. Before finishing the class, announce about After-class and assignment.
Fifth, if discussion is not finished in a restricted time, postpone the discussion to 'After-class' step.

(3) After-class
First, if discussion is not completed in In-class, teachers arrange the due and have students notify the opinions on internet discussion bulletin. If due-time is over, let students upload discussion results by group as well as assignment. Second, conduct satisfaction survey of students about discussion. It is convenient to have on-line survey; and there are two ways of filling out. One is downloading the survey then fill out. The other is filling out on-line right way. The contents of survey include appropriateness of discussion issue, gaining through discussion, and satisfaction about group members.
Third, based on the satisfaction of discussion, choose next theme & issue, and arrange group members. Sometimes, discussion doesn't go well because group members are not harmonized with each other. So, it is needed to consider about Tom Jewett's(1996) strategy of organizing group.
Fourth, teachers need to consider various teaching methods according to theme of lesson besides discussion such as role-play, problem solving, and so on.
Fifth, proceed to Before-class stage. If any articles in Before-class is overlap with After-class, exclude them.

Step 3: Course Completion
Completing course, as the last stage of module, diagnose whole courses, synthesize contents and then publish it. In this stage, following are specifically proceeded.
First, after learners collect and organize their projects(assignment, contents of discussion, and so on), publish it on web by groups. The projects, which will be on web, can be good examples for teaching and learning materials to teachers and students later. Especially, reading and criticizing discussed contents about social issues of computing provides a basic philosophy to students to build up their own opinions and ethical values of information & communication.
Second, conduct a course evaluation to students. The questionnaires like theme of lesson, appropriateness of discussion topics, selection of group members, and appropriateness of dividing roles. In In-class stage, appropriateness of time portion, spontaneous participation of students, and appropriateness of utilizing ICT(applying period, kind, content, technical mistake) should be included in evaluation.
Third, do survey about effects and influences on students' awareness of information & communication ethics and tendency of using ICT through the course. It is convenient to use on-line survey system, and its results necessary to be announced on-line. Results of survey can become good sources to measure effectiveness and quality of course because the goal for this course is to have a healthy awareness of information & communication ethics and tendency of utilization among learners.
Fourth, Write an essay about completing this course. Students need to write their general opinions, which couldn't deal in the survey, about this course and things to be improved for the next learners.

Figure 1. is described when summarizing and organizing the above teaching model.
Step 1: Course Preparation
- Understanding the learners' background, tendency and opinion
- Selecting theme for class
- Collecting, analyzing, classifying teaching & learning materials
- Searching, downloading, purchasing videos
- Opening internet bulletin board (rooms for announcement, teaching & learning resources, assignment, discussion)

Step 2: Course Implementation
- Before-class
  - Instructor: announcing lesson information, organizing groups, assigning roles to each member, analyzing contents of video
- In-class
  - Introduction (5-10 min.)
  - Developing discussion by using video or by group (15-20 min.)
  - Summarizing discussion (5 min.), Presenting & comments (remaining time)
  - Announcing after-class & assignment
- After-class
  - Uploading results of discussion
  - Investigating satisfaction of discussion
  - Selecting theme & discussion topic for next class
  - Rearranging group members
  - Leading back to before-class stage

Step 3: Course Completion
- Collecting & synthesizing projects by group, web publishing
- Evaluation for course process
- Investigating change of awareness of information & communication ethics and variation of using ICT
- Writing an essay about completing this course

Figure 1: Model Flow of Utilizing ICT in Teaching Information & Communication Ethics

Conclusion

This paper investigates mainly the status and plan of information & communication ethics education in Korea, model of utilizing ICT in teaching information & communication ethics. Presently, Korea is experiencing an ethical crisis in information & communication fields. We only hope that our promoting education plans and teaching methods activate information & communication ethics education in Korea.

This developed teaching model will be applied in real teaching fields later on. Verifying validity of this instructing model is an important subject to secure reliability. From this standpoint, we are planning to refine this model more accurately, and then apply to students in Korea National University of Education who major in Computer Education at the second semester in 2001. The next goal of our study is to make a perfect teaching model through rectifying problems which will be derived from the real classrooms.

Technology Impact on Roles of Instructor and Students—Case Studies

Amy S. C. Leh, Ph. D.
Department of Science, Mathematics, and Technology Education
California State University San Bernardino
United States of America
aleh@csusb.edu

Abstract: The paper reports research conducted in an Instructional Technology course in which the instructor changed roles of an instructor and students. As a facilitator, the teacher guided the learners through the learning process and encouraged the students to be active in their learning. Data collection relied on class observations, interviews, and surveys. The results revealed that the new teaching methods and role of an instructor motivated students, fostered students' active, meaningful, and constructive learning, encouraged students' critical thinking skills, increased students' confidence, and had positive impact on students' learning.

Introduction

What is a teacher? Who is the teacher? Answers to these questions have been changing in the past few years due to technology advancement. Years ago, a teacher was the main information giver and center of a classroom. Lately modern technology has been shifting the education paradigm and providing students with information from a variety of resources via various channels. Consequently a teacher is no longer the center of a classroom.

According to the report released by the National Council of Accreditation of Teacher Education (NCATE) in September of 1997, teachers should develop a new understanding, new attitude, new approach, and new role (NCATE, 1997). Tom Carroll, director of Preparing Tomorrow’s Teachers to Use Technology (PT3) grants of the US Department of Education, vividly described the changing role of teachers at the annual convention of Society for Information Technology and Teacher Education (SITE) 2000.

Carroll (2000) advocated that a teacher should take the role of a learner. A teacher is an expert learner while a student is a novice learner. Novice learners may become expert learners as time progresses. As an expert learner, the teacher should facilitate learning for novice learners and let them become instructional resource providers. Creating a learning community that consists of expert learners, novice learners, parents, and members who may foster the learning process, a teacher’s responsibility is to facilitate interaction and learning within the learning community and to further expand the community by involving members of other communities.

Hence learning no longer refers to learning from a teacher. A student may learn from other students or any member of the community. A student who does not know one area may be expert in another area. Thus a student may be a receiver at one time while he (she) may be a provider another time. A student may also self-learn from available resources, for example, the Internet. Learning becomes multifaceted and dynamic, and resources become essential in the learning process.

In addition to Carroll, Oliver (2000), an invited speaker at World Conference of Educational Multimedia, Hypermedia, and Telecommunications (EDMEDIA), also supported the idea of using students as instructional resource providers. In his speech, he further explained how he treated his students as resource providers and how his students contributed to the teaching materials. Similar ideas were echoed at two presentations at the convention, Leh (2000) and Santema & Genang (2000). The author of the paper was one of the presenters and was pleasantly surprised to see the idea simultaneously spring up on three different continents, North America (the USA, Leh), Europe (Netherlands, Santema & Genang), and Australia (Oliver). This notion might be an indicator of a current global educational trend.

In this paper, the author will share her experience why the role of instructors in Instructional Technology has to change. She then will describe how she played the role of a facilitator and encouraged
her students as educational resource providers in an Instructional Technology course. She will also report her students’ opinions towards their learning in the course.

The Need for the Changing Role

The author is a university professor who teaches technology credential and graduate courses in Instructional Technology at the College of Education of a public university in the USA. The students of the course were K12 schoolteachers working on their master’s degree at the university. Due to state mandate, her students had to integrate technology into their classroom. In addition, because they were master’s students in Instructional Technology, they were also expected to help their colleagues in their schools to employ technology. These two forces generated their need to study use of technology, especially a variety of computer-based software applications and existing technology resources.

How could the author successfully and effectively help her students? She realized that technology advancement had changed how people learned and altered the role of the instructor. She could no longer be an information giver but had to become a learner learning with her students. For example, while she was a student, she learned HyperCard, a commonly used multimedia authoring program during that time. When she became an instructor, HyperCard was considered to be an out-of-date program and most people no longer used the program. Similarly, while she was a student, only professionals developed webpages. Now webpage development has become common knowledge and a necessary skill for many people. She could not depend on what she learned in school but had to learn new technology by herself when she entered the field. Likewise, her students would face the same challenges. They had to become self-learners of technology.

Technology integration requires people’s knowledge and expertise of subject areas. The author might be an expert of integrating technology into one subject area, like second language learning, but might not know how to effectively integrate technology into another subject area, for example, science. As a result, the author had to learn with her students who were experts of their subject areas.

Due to the two facts mentioned above, the author changed her role to be a facilitator and hoped to set a good teaching example for her students. She encouraged her students as instructional resource providers and trained them to be self-learners. She prepared a learning environment in which students could learn by themselves and from each other. The computer applications they learned in her classes might be obsolete one day; however, the learning skills, she hoped, might be transferred and applied to new learning experiences. Illustrated below are her experiences with teaching one of the graduate courses, “Advanced Computer Applications in Education”.

Students: Resource Providers and Self-Learners

The goal of the course “Advanced Computer Applications in Education” was to familiarize students with a variety of authoring multimedia software programs. Since this was the only course directly dealing with such applications in the academic program, the author structured the course as a multimedia survey course in which students studied a variety of applications rather than focused on a specific computer program.

She assessed students’ skills at the beginning of the course. On a survey, students identified their skills of using the following seven computer-based application software: Webpage development tool, HyperStudio, PowerPoint, PhotoShop, Premier, Authorware, and Director. The students circled one of the following—“don’t know”, “good”, “very good”, and “excellent”—which best described their skill level.

The author reported the survey results in class. She intended to help the students use the information to complete their course assignments: developing a HyperStudio project, creating a webpage, integrating PowerPoint in instruction, and offering a technology training session. Course assignments emphasized integrating technology into content areas, independent learning, and learning from each other. Described below is how the students learned from each other in the “Technology Training” assignment.

For the assignment, the students selected their team members (no more than three members in a team). Each team chose and learned one of the software applications mentioned above. Overview of software and step-by-step instruction of using some of the software were illustrated in a course textbook. Benefits of using such a book in a multimedia course will be described later.

After selecting the software program, the students constructed a training plan for a 60 to 90 minute training session. In the training session, they were supposed to teach their classmates the use of the application software they selected. The training plan had to contain (1) assessment, (2) time length, (3)
content outline, (4) evaluation, and (5) training materials like handouts or evaluation sheet if applicable. They met with the author to discuss their training. They had to be prepared to answer questions like their trainees' prerequisite skills, what they would cover in the training, which criteria they used to decide on the content in the training, and how they would evaluate the success of their training session. The students were aware that they could ask for help from the instructor (the author) at any point of time.

Finally they delivered the training to the entire class. The author observed the class and recorded classroom interaction. She also took notes how the trainers could make the training better. After the training, the author first asked the trainers to self-evaluate their training. She then asked the trainees to critique the training session by providing good points and suggestions for improvement. She asked the trainees to provide oral input in class so that the trainers could receive instant feedback and response. She conducted the discussion and concluded with her own critiques. The trainers also received written feedback afterwards from the trainees and the instructor.

Evaluation and Opinions of Students

During the quarter, the author observed the class and interviewed students about their learning experiences in the course. At the end of the quarter, the author interviewed the students and also had them fill in a survey expressing their opinions about the course. The responses were analyzed and categorized. The results revealed that the teaching methods used in the course were deemed to be successful.

The teaching methods motivated the students. The students were enthusiastic about choosing a training topic and being actively involved in the learning process. Some of them chose software they were familiar with but more than half of them selected software that they knew little about. When asked why they selected the software foreign to them, the students answered that this would be a good opportunity for them to learn new skills. One said, "I wanted to learn this software for a while. Selecting this topic may push me to learn it." They learned beyond the textbook. Two of them rented a videotape on Macromedia Director. Three of them bought a book and together studied Adobe PhotoShop. They mentioned that they enjoyed learning with their partners. They also expressed their frustration when they explored software. Despite the frustration, they cherished the learning experience and thought that they learned a lot from their peers and other resources, not only from the instructor.

The teaching methods generated students' meaningful, active, and constructive learning. For the training plan, the students constructed their own instrument to assess the trainee's skills, decided on training content, and determined how to evaluate their training. They mentioned that instructional design models, for example Dick and Carey's model, made much more sense when they went through the process. They expressed that they spent much time on the course, much more than what they spent on a regular course. However, they liked the experience. They felt that they were the masters of their learning and felt sense of ownership. They mentioned that this learning experience would influence how they learn and how they teach in the future. They would search for resources that could foster their learning, and the instructor would only be one of the resources. They would also try to play the role of a facilitator rather than an information giver in their classrooms when appropriate.

The teaching methods encouraged the students to think critically. The author required the students to critique their classmates' training sessions. She noticed that the students could easily say, "you did a great job!" Nevertheless, they had difficulty in addressing points of improving a training session. By requiring the students to specify good points and provide recommendations for improvement, they practiced to think critically. At the end of the quarter, the author noticed the improvement that the students made on critique.

The teaching methods increased the students' self-confidence. Before taking the course, the students often complained that they did not know how to use certain software, for example, webpage development tool, because the instructors did not teach them. The students seemed to count on the instructors and did not feel comfortable of learning by themselves. At the end of the course, the students expressed that the course increased their confidence in learning technology on their own. They mentioned that, if they could learn software with their partners and successfully provide training to their classmates in this course, they should be able to do the same elsewhere. They became comfortable of being self-learners.

The students also benefited from one of the textbooks used in the multimedia course. Many instructors could not include advanced multimedia software in their courses because institutions could not afford the expensive software. The textbook offered a possible solution to the problem that educators and students often encountered. The book included a CD of recent multimedia software—Macromedia Authorware, Macromedia Director, Macromedia SoundEdit 16, Adobe PhotoShop, and Adobe Premiere—and step-by-step instruction on the use of the software. The advantage of such a book was that users could
explore and learn the software at low cost, approximately $40 US dollars. They could also independently practice the software. The disadvantage was that saving of files was restricted. Several companies published books similar to the book mentioned above. Because of the opportunity of exploring a variety of advanced multimedia software at low cost, the author highly recommends using such a book to make students learning possible.

Conclusion

Technology advancement is shifting our education paradigm. The role of the instructor is changing from an information-giver to a facilitator. Students no longer passively receive information but may be instructional resources in class. Given opportunities, they may be self-learners and self-trainers.

In a multimedia course, the instructor employed teaching methods allowing her to be a facilitator and her students to be self-learners. It was found that the course motivated students, fostered students' active, meaningful, and constructive learning, encouraged students' critical thinking skills, and increased students' confidence. Class observations and students' feedback revealed that the new teaching methods and role of an instructor had positive impact on students' learning.

As a university professor in Instructional Technology, the author might have experienced the education paradigm shift and its impact on the role of an instructor earlier or faster than instructors of other subject areas might. However, the changing role is a trend. Every instructor should be open to the idea and explore the possibility and experiment with the opportunity.

As NCATE stated in 1997, teachers need to develop a new understanding, new attitude, new approach, and new role. Every instructor should be open to the changes and further create a learning community in which instructors, students, and community members may contribute, benefit, and generate meaningful learning experiences. One can only look forward to participating in the dynamic learning and expect its positive impact on our society.

Interaction in Online Courses – Case Studies

Amy S. C. Leh, Ph. D.
Department of Science, Mathematics, and Technology Education
California State University San Bernardino
United States of America
aleh@csusb.edu

Abstract: The paper reports action research on online courses conducted in 2000. The goal of the research was to investigate students' opinions toward online courses and to examine the need of converting more courses of the academic program to online courses. Data collection relied on online messages, observations, and surveys. The results revealed that students and the instructor were all in favor of online courses. Interaction and online community greatly contributes to the success of an online course.

Introduction

Technology advancement is changing our society and shifting our educational paradigm. In the last few years, the number of online courses has increased dramatically, and offering online courses is currently a trend in education. Some educators have high regards for online courses. They offer opportunities to people who cannot receive education otherwise due to large distance between home and school. Some view it as an alternative that provides learners with options of learning. Some even expect virtual classrooms to be the future of education. Meanwhile, other professionals doubt the value of such education and question its quality.

Due to its infancy, people interpret the expression “online course” differently. Some consider courses containing online features like synchronous or asynchronous communication to be online courses while others define online courses based on the frequency of physical meetings between instructors and students. In this paper, an online course refers to a course in which an instructor uses online features and only meets his/her students for half or less than half of the usually scheduled meeting time during a semester (quarter).

The paper reports action research on online courses conducted in 2000. The author is associate professor of Instructional Technology at a state university. The goal of the research was to investigate students' opinions toward online courses and to examine the need of converting more courses of the academic program to online courses.

Background and pilot study

In summer 1999, the author's university first offered grants that encouraged faculty to convert traditional courses to online courses. The author received the grant and converted one of her graduate courses to an online course. The participants of the study were the students in the course. They were in-service teachers who were pursuing their Master’s degree at the university, and they never took an online course before. They met four times throughout the quarter, at the beginning, in the middle, and at the end. Data collection relied on online messages, observations, and surveys.

The results indicated that students were in favor of an online course. The students felt that they spent more time on course preparation and that they learned more in an online course. They wished that more online courses would be offered in the academic program and they preferred an online course over a traditional course.
The study

Based on the preliminary results, the author converted two additional traditional courses to online courses. The characteristics of the participants of these courses were similar to the participants of the pilot study. The author employed similar research methods. Data collection relied on online messages, observation, and survey. The survey, containing 10 Likert scale (1-4) questions and two open-ended questions, was conducted at the end of the courses. The questions were guided to examine the following points: (1) Compared to a traditional class, did students feel that they learned as much as, or even more, in the online course? (2) Compared to a traditional class, did students feel that they spent as much as, or even more, time preparing for the web-based class? (3) Compared to a traditional class, did students feel that they were motivated as much as, or even more, in learning in this course? (4) While taking the course, did students have sufficient access to the instructor? (5) While taking the course, did students have sufficient interaction with other students in this course? (6) Given the choice between traditional courses and web-based courses, did students prefer a web-based course if the course content were suitable for a web-based course? (7) Did students wish that more on-line courses were offered in the master program? (8) Would students enjoy taking another on-line course? (9) Were students concerned about the quality of web-based or online courses? (10) How many sessions in which the teacher and the students meet are appropriate for an on-line course? (11) Did students like the delivery method of the web-based course? (12) What were benefits and barriers of an online course?

The results revealed that the students favored online courses. The table below reports students' opinions.

</table>

Table 1: Students' responses to the questions posted in the survey at the end of the quarter. For each question the mean for the 1st class, for the 2nd class, and the combined mean are given. The scale ranged from 1 to 4 with 4 meaning full agreement with the statement. WB = web-based.

Students listed several benefits of an online course. The schedule was flexible. They could work at any time and at any place. Since the participants were full-time in-service teachers, the author felt that these comments were very understandable. She had noticed in earlier traditional classes that the students often came to class tired, sometimes without having eaten dinner, and that they occasionally had to miss class because of commitments at school, for example, meetings with parents. The learning conditions of a traditional class were therefore not beneficial for these students. The responses of the participants show that an online course may allow students to choose their best learning conditions for their learning. The participants also mentioned that the online course saved them gas and time on commuting. They also expressed that they had more access to instructor and fellow students. They felt that meeting three to four times was appropriate for online courses.

Still, barriers exist in an online course. The participants missed face-to-face communication. Students with low technology skills felt pressured and anxious. Despite these barriers, students expressed that they would still choose an online course if they were given an option.

In general, students and the author were all in favor of online courses. Interaction and online community greatly contributes to the success of an online course. Instructors should employ a variety of strategies to build up and nurture an online community. The new delivery method, online courses, has its potential and may greatly benefit students' learning.
The Continuous Education Solution for a Country Wide Telecommunication Company

Marcelo Leifheit; Juarez Sagesbin; Daniel Fink; Candida Moraes
Training Center
CRT – Brasil Telecom
Porto Alegre – RS – Brazil
mleifheit@crt.net.br; jsagesbin@crt.net.br; dfink@crt.net.br; cpmoraes@crt.net.br

Abstract: Competition among companies has put up a challenge regarding training and development of human resources. In a country-wide company this challenge takes into account constant trainee traveling back and forth, so, generating costs. This paper presents a telecommunication development program that uses top of the available technology to broadcast synchronous classes, over a system with full motion images in real time. It uses a transmission rate as low as 2 Mbps, easily available almost everywhere, allowing training at remote sites with all of its advantages.

Introduction

Actually there are many education methodologies based upon new technologies, but a lot of them without satisfactory results evidences. The lack of knowledge about new applied education technologies and methodologies is one of the main problems among professionals who are not being prepared to use those tools to be competitive in this new globalized world.

Considering new education methods, associated to new technologies, one of the greatest challenges posted to instructors is keeping people motivated and using distance learning tools for actualization, focusing in the company business.

A decade ago, there were the first attempts in distance learning as a corporate tool [5], which means using various methods to reach and teach people who are widely dispersed geographically.

In practice, how is it possible ? What is the technology that can actually be counted on ? How is it implemented ? What methodology could be used for a Telecommunication Company environment ?

Methodology

This work refers to, as it is seen, the best-implemented solution until today in a Brazilian Telecommunication Company, that is seeking for continuous education for all of its employees scattered all over Brazilian ten states. The methodology used for this system, counts on WEBTV resources, chat-room, a Teleeducation system with full audio and video interactivity, which allows the participant a total interactive environment with the instructor, minimizing the discomfort caused by the non presentational situation.

As a solution for those challenges it was sought one that could put together management instruments, top of technology, new distance learning methodologies, allowing organizing culture dissemination and valorization of the enterprise human capital. PEN BrT, which is Brasil Telecom’s Extension Program is a technical and institutional knowledge-recycling program, focused in training employees on technical and administrative areas, wherever the professionals are, and they are spread out all over the Country.

The program issues were selected to provide a basic formation oriented to the Company’s core business and the main departments internal processes, searching the improvement of quality service benchmarks. At the end of the program, the participant is supposed to have a clearer idea of each activity importance in the company’s general context, reinforcing the value of cooperative work among involved areas.

The employees qualifying matrix, which was developed under training consultants orientation and their managers, showed training necessity.

According to the philosophy that the best Brasil Telecom’s company business specialists are their own employees [6], they themselves conduct the classes. This methodology increased competitive advantage that derived from having a well-trained workforce that is up-to-date on the entire latest trends, collaborating with one another and sharing information throughout the company. The classes are filmed, recorded and broadcasted through the auditorium’s television system.
Technology

The Teleducation system implemented at Brasil Telecom uses an audio and video network exclusively for training [1]. It is based on compressed video using a MPEG-2 algorithm that allows showing VHS quality images, in real time and using a bandwidth equivalent to an E1 channel at 2Mbps. This low transmission rate allows using the public telecommunication network for this task. This bit rate is nowadays easily available and the backbone access can be made through a variety of means. It can be pointed out, as examples, coaxial cable, HDSL modems and twisted pair.

Distance Learning System

For those students who do not have a TV reception point nearby, it is possible to participate in classes through the WebTV system, since the web connection has a bandwidth larger than 300 KBPS with the main server so having an excellent audio and video quality. Through the WebTV class, students can watch the instructor, presentation slides, interacting with others participants and making questions through a chat-room.

For distance learning classes, the interactivity with the instructor happens by e-mail, phone call and a chat-room provided in the course home page [2]. An instructor assistant receives questions and forward them to the instructor during classes. At the beginning of each class, presential participants receive the training material which was made by the instructor in advance. For distance online learning participants, the slides can be downloaded directly through the PEN home page – http://www.ade.crt.net.br/pen, for watching, printing, or online consulting during the class as well as afterwards. Recorded classes remain stored at the Company’s library for future references. Participants who could not watch a class can request the video tape through an online library service. The video will reach the participant desk in less than three days, for home watching. After this, he proceeds to the PEN home page to fill out the on-line evaluation and reaction forms for attendance registration in a training database [3]. Questions will be answered by e-mail or phone call directly by the instructor, who is a company employee too, during work time. Distance learners fill out the registration participation form directly on the PEN site. There is a suggestion box, where the students can leave messages for the organizing team who manages the program.

Conclusions

The results obtained up to this date can be considered satisfactory; some questions have been pointed out such as new technology equipment handling and a little delay pertaining to the information flow in this system. With some practice instructor and students were able to overcome these characteristics of communication. Through the reaction and opinion evaluation and interviews with students and their managers, it was indicated that this teaching methodology has reached an efficiency of 82 percent considered through the question tasks applied under the PEN web page after classes and acceptance of 98 percent measured by a reaction evaluation. The low cost associated to commuting and also, the fact that the employee does not leave his post to go to classes, contribute to validate the investment in this methodology.

Actually, the on-line learners can, not only access their studies from remote locations using multimedia, but they can also build online communities [4], swapping questions and answers with their tutors, and fellow students via e-mail and a chat-room. This online learning methodology can add up to presential learning to build a successful knowledge management system and using technology to leverage the intellectual capital of the entire company, which in turn, leads to increased productivity, shorter time to access new knowledge to the company, and a superior competitive advantage.

Abstract: The purpose of this paper is to describe pedagogical background and design rationale of ITCOLE (Innovative Technology for Collaborative Learning) software. The ITCOLE software is a highly scalable and easy to use modular environment that supports students' joint efforts to build knowledge together, whether they are primary, secondary, or older students. The central metaphor of the ITCOLE system is that of shared electronic workspaces which students and teachers use for asynchronous and synchronous collaboration. The system will provide tools for community building as well as include awareness tools that help users to manage their joint knowledge building by providing real-time information on various aspects of collaboration. It is intended that the ITCOLE software will become available free of charge and mostly under open source terms for educational institutions. A downloadable pilot version of the ITCOLE server software under title Future Learning Environment 2 (Fle2) with some of the basic functionality is currently available (http://fle2.uiah.fi).

Introduction

According to international assessments, innovative learning technology based on the new information and communication technology (ICT) promises to lead to a new decade of the learning revolution (Roschelle & Pea, 1999; Pea, Means, Hsi, Tinker, Bransford, Brophy, Linn, Roschelle, & Songer, 1999). Collaborative knowledge building is one of the most promising innovations to increase quality of education with the help of modern collaborative technology. This pedagogical approach emphasizes the importance of engaging students and teachers in coordinated efforts to build new knowledge and to solve problems together (see Dillenbourg, Baker, Blaye, & O’Malley, 1996; Scardamalia & Bereiter, 1994). Several empirical experiments offer evidence
ITCOLE - Innovative technology for collaborative learning and knowledge building

that collaborative technology designed according to innovative pedagogical ideas facilitates higher-level cognitive and social interaction and deeper understanding (Pea et al., 1999).

The key objective of the present project is the design and development of a modular knowledge-building environment (working title, the ITCOLE software) that supports students' joint efforts to build knowledge together, whether they are primary, secondary, or older students. The system will be designed to provide tools to facilitate the development of the students' skills of collaborating, engaging in various networked activities, solving increasingly complex problems in different domains of knowledge, and working productively with knowledge. The central metaphor of the ITCOLE system is that of shared electronic workspaces which students and teachers use for collaboration. Such workspaces are provided in a number of different ways since the functionality and the interface of the system will be derived from pedagogical considerations and can be adapted to the different school environments and contexts as well as used in conjunction with other pieces of software.

Even if there are hundreds of networked learning environments available, most of the available applications are not designed to facilitate in-depth learning or genuine collaboration between students (Stahl, 1999; Stahl, Hoadley, Slotta, Guzdial, & Suthers, 1999; Roschelle & Pea, 1999). Most of these systems have been designed to manage and deliver study materials or provide tools only for unstructured chat-like discussion rather than facilitate advancement of knowledge and understanding. From these environments, knowledge-building environments differ substantially; the latter, from the beginning, were designed to facilitate collaborative knowledge building within a local or virtual learning community (Scardamalia & Bereiter, 1994). Characteristic of knowledge building is to go beyond individual learning by pursuing together students' own questions and problems of understanding, generating, elaborating and discussing students' own explanations for the problems being addressed. An engagement in knowledge building focus on articulating, elaborating, and extending knowledge objects created by the participants (Bereiter, 1999). Various innovative tools and facilities are to be developed into the ITCOLE system that enable the users to construct, illustrate, share, analyze and synthesize their understanding while building knowledge together. Moreover, ITCOLE software will be an awareness-oriented collaboration system that provides users real-time information on several aspects of collaboration and helps them to manage the process of knowledge production and build their social community.

Extensive studies in authentic school environments reveal that practices of knowledge building have not yet been disseminated to European schools; teachers and students are currently not using the new technology intensively as a tool of learning (Lehtinen, Sinko, & Hakkarainen, in press). To successfully promote educational use of the new learning technologies, and at the same time implement new pedagogical and cognitive practices of learning and instruction, appears to demand the utmost of both teachers and students (Lipponen, 1999). The problem is that technical tools do not themselves provide teachers with adequate models of pedagogically meaningful ways of using them in various pedagogical situations. Educational researchers need to further crystallize and concretize pedagogical models of collaborative learning and knowledge building; implement these principles in highly scalable and easy to use learning environments; and make these environments accessible to teachers and educational institutions (Lehtinen et al, in press).

The project focuses on crossing boundaries between software developers, pedagogical researchers, and the users of knowledge-building technology - teachers and students. It represents a plan to integrate in an innovative way software development with pedagogical research and intensive field testing. The present project is based on a contention that through co-evolution of the technical tools and pedagogical practices, solutions are likely to emerge that really contribute on pedagogical change at school.

Description of the ITCOLE software

The research and development project of ITCOLE software is a part of European Community's Information Society Technologies (IST, Schools of Tomorrow) program 2000-2002. The design principles will be specified by piloting of the first working prototype of ITCOLE software as well as the participants' benchmarking experiences of other pieces of collaborative technology (CSILE, Future Learning Environment, Knowledge Forum, Telecommunicado, Virtual Web School, WorkMates and so on). Many challenges of designing ITCOLE software's user interface has been preliminarily solved in the design of Future Learning Environments (see Leinonen, Raarni, Mielenon, Hakkarainen, & Muukkonen, 1999). A downloadable pilot version of the ITCOLE server software under title Future Learning Environment 2 with some of the basic functionality is currently available (http://fle2.uiah.fi). The Fle2 server software has been developed in the Nordic Nodunet2 project (http://fle2.uiah.fi/project_plan.html). The Fle2 server software itself works on Unix/Linux systems, but for end-users (students, tutors and administrators) it is totally cross platform, usable with any computer or other device (palmtops, mobile phones), for which there is a HTML 3.2 compatible webbrowser and Internet connection. Although only some aspects of the learning environment have an adequate technical im-
ITCOLE - Innovative technology for collaborative learning and knowledge building

plementation, this environment can be used to evaluate and test pedagogical characteristics of ITCOLE software in different educational settings. The pilot studies will allow developers of ITCOLE software to go beyond current understanding of CSCL design principles and creating a next-generation pedagogical design for ITCOLE. In order to facilitate scaling up of good pedagogical practices of using innovative learning technology, it is intended that the ITCOLE software will become available free of charge and mostly under open source terms for educational institutions.

The specification of the ITCOLE System is focused on providing a shared multi-user environment to carry out computer supported collaborative learning. The system will be accessed through the Internet (TCP/IP) with any HTTP/HTML compliant browser such as Microsoft Internet Explorer or Netscape Navigator so that users normally will not have to install any software locally. In this way, access to the system will be platform independent and it will be usable across Microsoft Windows, Macintosh, Unix, Linux, TV Set-Top Box (Internet on TV), and palmtops, e.g., Nokia Communicator or Windows CE systems. (The system functionality is implemented through extensions to servers, primarily Web servers.) Thereby, it will provide seamless support for co-operation in heterogeneous environments often typical of educational institutions. The environment will contain several tools:

- **Virtual WebTop** module (with folders and wastebasket). In the virtual WebTops the users may create documents, bring documents from the www and upload documents from local disks. With the Webtops the users may store and share these documents with fellow users. The Webtops may also contain several small educational applications (Java applets), such as calculator, simulations.

- **The Knowledge Building** module facilitates between-user interaction and provides means for conducting multiple discussions simultaneously within a course. Notes posted to the database are labeled with 'Category of Inquiry' reflecting a step in inquiry process.

- **The Jam Session** module encourages free flow of ideas and allows experimentation with different ways of representing knowledge. The Jam Session is a shared environment for collaborative construction of digital artifacts.

- **Meeting Rooms** is an avatar world where avatars (pupil, tutors, and teachers) can immerse themselves in a 3-D experience and use the collaborative multi-user applications (whiteboards, chat, presenters and so on).

- **The Library** module is designed to store, publish, and browse different learning materials (see the Tutorware) and student's works.

The ITCOLE software will be designed to provide external structures that help a student to participate in expert-like processing of knowledge without the increasing cognitive processing load. This kind of external support provided during the process of inquiry appears to enable students to solve more complicated problems than they would otherwise be able to do.

- **Participation in in-depth learning** will be facilitated by ITCOLE software's system for entering thoughts and ideas: the ITCOLE environment guides (scaffolds) the users in categorizing their computer entries and cognitive activity in a way that corresponds to fundamental aspects of inquiry learning; for example, Problem, Working Theory, New Scientific Information, and Comment. Furthermore, several sets of scaffolds will be designed for assisting learning of different subject domains (e.g., sciences and humanities) and specific purposes of a study project.

- **ITCOLE** will provide tools for students to record and visually represent their activities as they participate in inquiry learning. By using the tool, teachers and students can track and reflect on the progress of a project together as well as plan how to go ahead.

- **A further challenge is to design** such a kind of interface that helps the users to manage the knowledge they are producing (Muukkonen, Lakkala, & Hakkarainen, 1999). Frequently, relatively large number of messages in a learning environment's database makes it very difficult for the users to follow lines of argument or advancement of ideas. An important challenge of ITCOLE is to design tools that help to represent progress of discussions by graphical means, such as reaching milestones, reflecting activity, highlighting chosen items or summarizing prior work.

**Design Objectives of the ITCOLE Software**

The objective of the Interface Design is to build, for the ITCOLE system, a pedagogical interface for educational use. This objective can further be divided into three main aims: scalability, usefulness and usability. The three aims for interface design for the ITCOLE system are as follows:
ITCOLE - Innovative technology for collaborative learning and knowledge building

1. Building a working interface that scales to various client platforms representing 80% or more of those used in typical educational, home and work environments (n.b. a set of minimum requirements for a client are a HTML standard capable browser, on-line internet connection and typical input/output device combination). This ensures universal access for different user/browser configurations.

2. Incorporating a full set of features to enable collaborative knowledge building over the Internet into the interface, and coupling that with the functionality of the System implementation. This ensures the usefulness of the system for the major target groups in the field of collaboration.

3. The interface design process will place a strong emphasis on creating user-friendly and attractive graphical design and a graphical style, which is flexible and customizable by the user. This ensures that the level of usability in the system is high enough to support and sustain actual learning situations in a typical school environment.

For the development of the various components, strong emphasis will be put on modularity, so that it is possible to compile individual components for the various application scenarios to be used for testing and evaluation. In terms of increasing content sharing and future co-operation among different partners, the platform specifications will enable us to remove technical barriers of collaboration between applications. This objective will be achieved by adapting powerful standards, such as XML.

The ITCOLE System Architecture

Shared workspaces are the primary means of collaboration to be provided by the ITCOLE system kernel that relies partially on the BSCW system kernel (see http://bscw.gmd.de). The shared workspaces contain the persistent objects, which are needed for or created by the collaboration processes and support the construction and reconstruction of collaborative processes within specific work groups. The overall system architecture is shown in the following figure.

![System Architecture Diagram]

Objects in the workspaces can be accessed and manipulated, e.g., users may upload, download, edit or publish information. Around this kernel will be a set of additional features and tools, in particular tutorware, collaboration tools, assessment tools and comprehensive awareness features as described below.

Shared Workspaces

The primary features built into the shared workspace component of the ITCOLE system are as follows:

- The system allows the joint production of multimedia information in distributed environments. The system will provide tools for the users to collaboratively create, develop, discuss, and publish (hyper-) documents, or more generally, knowledge.

- The system provides information about what the individual persons of a group have done or are currently doing with respect to the collaboration processes supported by the workspaces. Towards this end, the system will provide comprehensive information about activities within workspaces, capturing various types of activities (events) and using various ways of promoting these events to recipients.
ITCOLE - Innovative technology for collaborative learning and knowledge building

- Besides the textual representation of information, the system will provide graphical representations, e.g., for visualizing cross-relations between documents or lines of arguments in discussions, shown in varying stages of complexity, providing features such as “zooming in/out” of details.
- The system will support the publication of the results of collaboration processes, i.e., a read-only copy of (parts of) a workspace will be anonymously accessible over the Internet.
- The system will include components for organizing and managing the collaborative learning process similar to features found in workflow systems, e.g., the appointment of (one or more) moderators for particular tasks, the time scheduling of tasks, and the allocation of duties.

Synchronous collaboration tools

- The shared workspaces are primarily targeted for asynchronous modes of collaboration; cognitive research as well as practical experience indicate that this form of collaboration provides the best support for extended and sustained working with shared ideas and knowledge objects in the context of a study project. Frequently, however, synchronous collaboration and co-operation is also needed to coordinate efforts of participants or members of a virtual team as well as to support building of a social community within the virtual learning environment.
- Synchronous communication provides a means for participants, who may not know each other very well beforehand, to interact socially, learn about each other, and engage in social bonding, thus creating the sense of community needed for engaging in intensive knowledge building. Applications as whiteboards, presenters, and chats are important elements for the communication within a group of people. These applications are based on the concept of data transmission to all collaborators. Combinations of these applications can result in a powerful tool with all the advantages of each single application. The following applications will be integrated in the ITCOLE tools:
  - **Whiteboards** allow users to draw in a shared area, which can be visualized by all collaborators simultaneously.
  - **Presenters** (or presentation software) facilitate the transmission of sequential images to all participants, for example, the presentation by slide show or a sequence of HTML pages. In addition, these tools must contain features that permit the highlighting of particular objects.
  - **Chats** permit the written communication between all participants of a study group. They must indicate the name of the user that wrote the message, so other user can know who is talking.

To simulate conversational meeting, real-time applications must include features that offer characteristics similar to such meetings, for example presence awareness and activity awareness is the sense of the presence and general activity of group members. For instance, it is very important that a whiteboard, a chat or a presenter show the list of the actual collaborators. The tools for synchronous communication can be located in avatar-world. In general the scene represents a Meeting Room which avatars (pupil, tutors and teachers) can immerse themselves in a 3-D experience and use the applications (whiteboards, chat, presenters, and so on) available in the Meeting Room. Also some external tools, such as the Virtual Room Videoconferencing System (http://vrvs.cern.ch/) developed in CERN can be embedded to the Avatar-world.

Assessment Tools and Tutorware

In addition to the previous features which are directed towards collaborative learning environments, the ITCOLE system will also support more instruction based learning scenarios. Assessment tools will allow self-evaluation of students with respect to their learning progress and will enable feedback between students and teachers in this process. The assessment tools will be built on top of the awareness system and thus create a suitable infrastructure for progress tracking and learning improvements based on feedback information. These tools will use technologies developed in the field of artificial intelligence for the identification of students who are not actively participating, or who produce only fragmentary, episodic notes, instead of sustained dialogues of knowledge building with their fellow students. The assessment tools function simultaneously as a means for the tutor or teacher to monitor participation of students, to identify students and discussion that do not appear to advance, and to detect groups that are not sufficiently interacting or communicating among themselves.

Teaching courses are usually a collection of individual learning modules which have to be traversed by the students in a particular order. **Tutorware** will be used to create such courses materials to the system's Library. The tutorware to be developed will allow the adaptation to the requirements and interests of each indi-
ITCOLE - Innovative technology for collaborative learning and knowledge building

Individual student, depending on progress and performance during the visualization of the contents, i.e., the content will be made up both of the information that will be presented to the pupil in each single learning module and of the control mechanisms that tell the system how to guide the student individually through the courses. Tutorware will also support teachers in collecting and creating educational objects like simulations, problem-solving tasks or other teaching materials available on the Internet or through other resources.

Pedagogical Evaluation and Testing

In advanced pedagogical practices, the use of information and communication technology becomes an integrated part of the whole learning environment and the culture of learning. As such, technology is used to build up social structures that encourage learning and reflective discourse, and to help students and teachers gain knowledge as well as to deepen their understanding of different domains (Dillenbourg et al., 1996). The evaluation process focuses on assessing how the ITCOLE software specifically facilitates learning in various educational settings, European countries and educational cultures. Field tests focus on developing and analyzing innovative ways of using ITCOLE software for facilitating in-depth learning from elementary to high-school level education. Case studies will be used to assess ITCOLE software's technical as well as pedagogical usability and functioning. The case studies will be carried out by setting up pilot versions of ITCOLE software in several classrooms in each participating country to be used alone or in conjunction with other pieces of software. Results of the field tests will continually provide feedback for the on-going design and development of ITCOLE software. The second part of field test involve experiments in scaling up networked learning, i.e., the investigators will examine and demonstrate, in collaboration with national school authorities, to what extent innovative models of networked inquiry learning can be scaled up beyond individual well-supported experiments across normal schools and teachers and students. The scaling-up experiments will involve a relatively large number of primary and secondary schools, several teachers from each school, and hundreds of students in several participating countries.

Student Directed Generation of Word Clusters with “Hikari”: Utilizing WordNet in an Intelligent Vocabulary Tutoring System for Adults Learning English on the Web

Juan Leon, Ph.D.
Department of Language and Culture
Graduate School of Human and Environmental Sciences
Kyoto University
Kyoto, Japan
e-mail: L50005@sakura.kudpc.kyoto-u.ac.jp

Introduction

Adult students of English working to acquire vocabulary beyond the lower-intermediate levels can be well served by Intelligent Tutoring Systems (ITSs) that offer both broad coverage and principled approaches to the knowledge domain, contemporary systems that facilitate personalized learning through guided exploration while providing required information, measuring performance, and monitoring progress (Levy, 1997). The need that such complex and flexible systems have for sufficiently rich and structured databases of English vocabulary poses a major challenge to their would-be designers, however, and the challenge is especially daunting in the case of applications intended for deployment over the web, where high loads and unpredictable user demands necessitate the adoption of extraordinarily large and fast databases.

“Hikari” is a web-based ITS for use in English language vocabulary study that addresses this challenge by incorporating the WordNet electronic lexical database. The product of over a decade of collaboration by cognitive scientists at Princeton University and elsewhere, WordNet is a freely available “electronic dictionary” that remains, to date, a resource surprisingly underutilized by educators involved with English language instruction despite its clear and impressive potential: In its present version, WordNet contains over 168,000 English words, each linked to detailed information about word senses and frequency. More importantly, a word’s location within a variety of interconnected semantic networks can be quickly recovered by computer-based queries against WordNet.[1]

As discussed below, one of the most rewarding ways of exploiting WordNet for computer-assisted language instruction may be to draw upon not only its vast lexical scope, but its unparalleled richness of quickly accessible relational data. The “Hikari” project pursues this approach at present by offering students the tools with which to run specialized queries against WordNet. Building upon a key word determined by the student, “Hikari” encourages learners to discover a variety of semantically related words and word groups for themselves, prompting students to compose study lists of word “clusters” of particular personal interest.[2] Because these clusters are based upon WordNet relationships, relationships which are themselves derived from widely accepted findings in cognitive psychology and psycholinguistics, the composition of word clusters tends to reflect adult cognitive structures.

Pedagogical Considerations

In recent years, computer-supported learning environments have been designed so as to provide guidance and to add limited structure to the learning process, offering students tools rather than predetermined curricula (De Corte, 1996). “Hikari” has been designed in this spirit. At the same time, “Hikari” seeks to accommodate adult learners by taking into account their special (i.e. non-childlike) cognitive standing. While all learners must accommodate new materials to preexisting conceptual structures, adult students of non-native languages bring an especially rich conceptual apparatus to the task of acquiring new vocabulary (Coady and Huckin, 1997). (In contrast, a child’s conceptual structures are
relatively underdeveloped.) Unlike both children and adult students approaching new subject matter, adult language learners are often masters of the concepts for which they lack only the foreign-language words. This pre-existing structure, then, can be exploited by supplying such learners with words organized by adult conceptual relations.

Equally important, adult language learners are often interested in learning the language of a particular area of knowledge, such as that of economics, politics, medicine, or law. In a traditional classroom all of the class members are typically asked to use the same textbook or other resource, so that students beyond the early stages of language study who do not enjoy the luxury of choosing from highly-specialized courses must work through vocabulary that is either irrelevant or, at best, of secondary importance to them. In contrast, an ITS combined with a broad and deep lexical database such as WordNet allows these students to generate word lists that closely match their needs and interests, promoting more efficient, productive, and satisfying study.

Running Queries Against WordNet

WordNet and its categorical relationships can be efficiently searched by means of browsers supplied with the database, custom software that makes use of the APIs also provided, or utilities developed by third parties. Hikari processes queries on behalf of students by first soliciting key words from them via custom ASP pages available over the web. The heart of the system lies in the algorithms, implemented as COM objects in Visual Basic, that generate a series of queries against WordNet and return results to the student users. Students then choose from among the result sets the word clusters they would like to add to their permanent study lists, and Hikari then takes care of presenting students with periodic quizzes and reviews based on those lists and on performance on past quizzes (if any).

In its present phase of development Hikari only allows for the creation of noun clusters, returning terms linked to any given key word by relations of hypernymy and hyponymy. The goal for the near future is to broaden the choice of parts of speech and vary the search algorithms, moving through a series of refinements that will optimize the search menu available to students with various learning preferences or aptitudes. Searches could be extended, in principle, to include queries returning term + antonym pairs for students who tend to think antithetically, searches that center on basic concepts, searches that isolate cause-effect relationships, and so on.

[3] See the WordNet homepage for a very helpful guide to third party tools and projects.
[4] Once generated, queries are run against WordNet database records via a COM object utility supplied with the "WordNet TreeWalk" created by Bernard Bou.

Exploring Roles for Intelligent Agents in a Language Learning MOO

Juan Leon, Kyoto Univ., Japan

The free-form, collaborative, highly interactive and user-directed quality of the MOO gives it much of its pedagogical value. However, these qualities can become liabilities for educational MOOs because learners run the risk of distraction, of wandering in a chaotic information space, and of receiving and repeating misinformation.

As teachers cannot be made available at all times to all MOO users, there arises a role for software agents that can assist human teachers by continuously monitoring student activity, selectively providing information from database stores, administering diagnostics, and productively engaging students. One of the chief challenges in the development of such intelligent tutors lies in designing and deploying them so that they complement (or construct) teaching that incorporates sound instructional designs.

The “Conversational”, “Administrative”, “Knowledge”, and “Secret” agents discussed in this presentation may help bring foreign language educational MOOs into greater harmony with sound instructional design principles for computer assisted learning.
Course Material Model in A&O Learning Environment

Abstract: One of the problematic issues in the content development for learning environments is the process of importing various types of course material into the environment. This article describes a method for importing material into the A&O open learning environment by introducing a material model for metadata recognised by the environment. The structure of metadata in A&O material model is defined and encoded using XML (Extensible Markup Language) vocabulary. To motivate our work, we briefly introduce basic ideas of structured documents and reflect our work with some learning standards related to this field. Finally, we illustrate our work with a simple example of using the material model in the A&O learning environment.

Introduction

The article discusses the problems in producing interactive learning material to learning environments. As an example, we introduce the material model designed for the A&O learning environment. A&O is a learning environment produced in the Open Learning Environment (OLE) project in the Hypermedia Laboratory of the Tampere University of Technology. The main features of the A&O learning environment are: possibility to accommodate any number of courses and their materials, user identification, tools to assist the learning e.g. communication and constructive tools, and connectivity to databanks. Technically, A&O is mainly a Java technology based distributed application. [Pohjolainen, S., et al. 2000]

In the first chapter we discuss about different ways of creating learning material to WWW-based learning environments and define the context to which the A&O material model design was based on. Then we introduce the concept of structured documents and XML (Extensible Markup Language), and the notion of metadata which constitutes a big part in the A&O material model. We also take a look at some learning-related standards that can have great affect on the evolution of the learning material production. We describe the A&O material model with some examples and definitions. Finally there we draw some conclusions about producing learning material and the A&O material model.

Constructing Interactive Learning Material

There are many ways in constructing learning material to various learning environments in the World Wide Web. Some people like to use HTML (Hyper Text Markup Language) while others prefer traditional publishing programs to create PDF-files (Portable Data Format). There is also a possibility of defining rigorously typed documents by using XML or SGML (Standard Generalized Markup Language) like Solvig Norman [2000] has done in Open Learning Agency. In addition, what would be the correct way to produce interactive elements such as exercises and various other constructive tools? Faced with a bundle of pedagogical questions to consider in creating learning material, it seems that we should be able to use the tool that we feel most comfortable with. Of course, sometimes we have to make compromises in favouring our own and the learners’ convenience. For example, the technical constraints imply that we can’t use very large pictures even if they would be easy to produce and pedagogically appropriate. However, this is something we must all live with.

Fortunately, some of these restrictions can be hidden, simply by choosing the right tools. Selecting to use a specific tool, however, tends to limit our possibilities to import learning material into learning environments. This is not really the fault of the learning environment; there simply exists almost uncountable number of different kind of
formats to multimedia documents to deal with. Although some of these formats are very suitable in describing the material, not all of them provide the right kind of information, e.g., to be used as a basis for the search engines of learning environments. Even if the format did contain the appropriate information, e.g., based on a global standard, there is the risk that it would eventually be a limitation for producing material utilising the latest technology. This implies a need for two levels of standardisation.

Structured Documents

The idea of describing the structure of course material presupposes the concept of a structured document. To put it simply, structured document is a text document consisting of two kinds of characters: data and markup. Markup is mainly used to organise content into hierarchical element structures. The ultimate goal is to provide a unique and simple syntax for representing relations between different types of elements in a document. The approach of structured documents is usually used for two reasons: to describe abstract data structures and to separate the content of documents from their appearance.

The first major mechanism for describing and writing classes of structured documents was SGML (Standard Generalised Markup Language). SGML received the status of an ISO standard in 1986. SGML is not a markup language itself but a metalanguage; an open-ended industry level standard for defining logically structured information. The key idea of SGML is to provide standard means for the construction of hardware and software independent document encoding schemas, called SGML applications. The most famous SGML application is by no doubt HTML. The complexity of SGML, and the success of the simplicity of HTML, led to the development of a markup language that would combine the best parts of both worlds in a modern networked computer environment. This work culminated in XML (Extensible Markup Language) 1.0 recommendation published by W3C (World Wide Web Consortium) in 1998 [W3C, online]. XML provides both a metalanguage for describing document classes consisting of logical element structures and an actual markup syntax for writing documents. The basic idea is to markup text documents into logical element structures in a specific machine-readable form. It is also possible to declare a type (including the vocabulary of documents) for an XML document, providing a basis for automated validation of the logical structure of documents. The meaning of logical XML structures is not stated in XML, but can be globally fixed using Namespaces names prohibiting collisions of names of different applications.

As such, XML 1.0 is sufficient only for very abstract tasks such as describing data exchange formats between applications. Other practical applications of XML require also, e.g., agreements of specific vocabularies. With this in mind, W3C introduces a whole family of XML-related standards, including XML Namespaces, XML Schema, XLink, and XSL (some of which have not received a status of W3C recommendation yet).

Metadata

In principle, standardising all document encoding using specific document schemas and vocabularies would provide a powerful way to promote interoperability of documents, e.g., for transferring educational content between learning systems with different architectures. In reality, however, this is too much for a requirement since majority of authors wants to produce their material with a wide range of different techniques, aimed to radically different Web client configurations. Fortunately, from the practical point of view, the question whether the internal structure of documents can be formalised and interpreted by different learning systems or not, is not as important as the question whether meaningful descriptions of documents can be shared and successfully applied among them. This is where standardised formats of metadata come into the picture.

As the term puts it, metadata is information about data. The basic idea is to provide short, informative, and a useful description of a large amount of related information whose internal structure is to too complicated or even irrelevant to be used as such. Most metadata structures deal with taxonomic systems characterising information some sort of queries in mind. Given an application, the question what is good metadata, is answered by evaluating the intended usage of it. For instance, considering educational course material, a good metadata description might provide a standard format for stating the topics of the material, the intended organisation of the material when taught as a course, and the list of exercises or quizzes prepared for each topic.
Learning-related Standards versus Reality

There are two major levels of standardisation of metadata to be considered. First, the intent and format of metadata within a specific learning system (say, A&O), and second, the intent and format of metadata between two or more different systems (say, between A&O and WebCT). The application area of the former is to provide a mechanism, e.g., for uploading diversified course material into a specific learning system, while the latter deals with interoperability standards, e.g., transporting course material between different learning system architectures.

It might be tempting to assume that an ideal solution would automatically combine these two objectives in a form of a universal learning standard. Unfortunately unified standardisation only comes with a price, either by accepting overwhelming complexity of such a standard, or allowing oversimplifications in descriptions of learning objects and concepts. We will not address this issue further here; for a more detailed discussion about the pitfalls of "fossilisation", see, e.g., (Robson, 2000). Of these two levels of metadata standardisation, we shall first consider the latter more general case, and then return to the first, in which this article will mainly be focused on.

It is obvious that in order a metadata format independent from learning systems to be applicable, it must be both well standardised and agreed among vendors of different (major) learning systems. Without a mutual commitment and a concrete specification, the abstract idea of metadata doesn't carry too far. This implies that an influential forum for developers and system vendors is required. At the time of writing, there exists several groups promoting learning technology standards. According to [Robson, 2000], general interoperability standards are developed by IEEE LTSC, the IMS project, and ADL. Standard development is done, e.g., in IMS, Ariadne, Gestalt, and AICC. These organisations have actively participated in the development of LOM (Learning Object Metadata), developed by the IEEE learning technology standards committee [IEEE, online]. LOM aims providing an abstract data model for describing educational material. Abstract LOM is implemented via LOM bindings, concrete implementations of data structures proposed by it, e.g., using XML document schemas.

There are, of course, general metadata standards applicable also to describing learning material. A good example of a general approach towards a practical metadata standard is W3C's RDF (Resource Description Framework) candidate recommendation (see, e.g. [W3C, online]). According to the specification, "...RDF is a foundation for processing metadata; it provides interoperability between applications that exchange machine-understandable information on the Web." In principle, provided that a suitable vocabulary is agreed upon, RDF provides a way to describe any Web resource from the viewpoint of learning in the same fashion that LOM would do. Another example of a suitable general metadata system is Dublin Core metadata, a short and concise set of properties developed for classifying Internet resources [Dublin Core Metadata Initiative, online].

However, from the viewpoint of a specific learning system, interoperability standards come with at least two major shortcomings. First, much of the standardisation work is still experimental or under development, and second, the standards do not necessarily provide support for the information that is crucial for the specific features of the learning system at hand. A practical learning system is faced with the evident problem of content production that can't be postponed until the grand standards are settled. In order to be able to upload content here and now, some proprietary format for accepting material is needed.

There are two basic approaches for solving this problem. The first solution is to define, introduce, and essentially fix, a range of authoring tools allowed in the authoring process. The second is to define an exact model for the core structure of the material, acting as an interface between the learning system and the process of content production. In this article, we're promoting the latter line of working since we believe that it has three major advantages to offer. First, it gives authors freedom of using any tool appropriate, as long as material is described correctly via the material model. Second, the complexity and behaviour of the material is not unnecessarily constrained; material may contain components outside the scope of the model, as long as the learning system doesn't have to be aware of them. Third, provided that the mode is rich enough, rigorous modelling of the material creates a concrete basis for future applications of interoperability standards.
The Material Model in A&O

The new A&O material model was designed in team-work in the Hypermedia Laboratory in the Tampere University of Technology by the authors of this article and the other members of the A&O technical development team: Tuukka Arola and Vesa-Matti Hartikainen.

The Realisation of the A&O Material Model Project

The main reason for designing a new course learning material model for A&O was the fact that the old model was only implemented to work with one specific tool which didn't quite meet the new requirements set by material authors [Nykanen 1999]. The new model was designed to be as open and general as possible because there seemed to be quite large number of tools for creating material for the WWW-environment, none of which being significantly better than the other. The decision about selecting the authoring tool was left to the author, and the material model was designed so the author could use his or her favourite authoring tool, bearing in mind that the material produced will be accessed via the WWW. We also wanted to leave room for the considerations of the upcoming standards concerning learning environments and the material.

The A&O learning environment provides many useful services for the learning material, for example, the annotation tool which allows the learner to write and attach notes to certain places in the material. One of the main concerns in the design of the material model was that we wanted to create an easy way for authors to take advantage of the services of the A&O while developing the material. Another major reason for the new material model was the awareness of the increasing need for security in the Internet. The previous implementation didn't explicitly favoured storing course material in a protected and private storage. However, if security issues are not taken care of, course material in a public directory accessible through the Internet to anyone knowing where to look for it. The new model allows situating the material to a private directory in the file system of the server and the material is only accessible to a user when he or she is actually using the system with right privileges. This is achieved by using Java Servlets as gatekeepers for all the material. The identification of the user is done with the comparison of the cookies, client IP-addresses (Internet Protocol), and active user sessions.

The Material Description Document

The A&O material model is based on the idea of collecting metadata from the material and the author. We decided to describe the material with an additional description document, in a similar manner to some proposed interactive learning material standards. The metadata or description document uses the vocabulary listed in Table 1 to describe the course and the material as generally as possible (from the viewpoint of the learning system).

Table 1. The terms defining the structure of the A&O material model.

<table>
<thead>
<tr>
<th>Course</th>
<th>The term course refers to the actual course, metadata of which we are describing. One course description element contains general information about the course such as name, code and description, authors, and material.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Author</td>
<td>The term author refers to the producer of the material. In addition to the personal information, author element may contain, e.g., contact and copyright information.</td>
</tr>
<tr>
<td>Material</td>
<td>The material is the learning material as a whole. It contains general information about the material and it’s presentation and components.</td>
</tr>
<tr>
<td>Component</td>
<td>The component term refers to one material topic or a page. It contains general information about the topic, keywords and relations to other components, and references to meaningful subcomponents.</td>
</tr>
<tr>
<td>Subcomponent</td>
<td>Subcomponents are smaller bits of learning data identified by the model, for example the image files linked to a HTML page.</td>
</tr>
<tr>
<td>Tool</td>
<td>The tool elements describe course dependent tools that can be accessed through an URL (Universal Resource Locator).</td>
</tr>
<tr>
<td>Relation</td>
<td>The relation element models an actual relation between two components. The relation includes information about the target of the relation and information about the type and meaning of the</td>
</tr>
</tbody>
</table>
Logical structure of the description document providing metadata of a course is defined using an XML document type definition, which, in our case, is stored in a file COURSE.DTD. COURSE.DTD defines the metadata document in a form easy to interpret and validate. The ability to validate metadata descriptions implies that the correctness of the created description documents (and hence the approximate correctness of the material itself) can be checked before importing course material to A&O.

Writing complicated XML documents by hand is tedious. This is mind, we have created a visual tool called Material Descriptor that analyses the given concrete material and asks all the predictable right questions from the author. Material Descriptor visualises the material as a tree of components and subcomponents, with the intention of easy description and construction of the metadata.

Example

Listing 1 provides an example of using the COURSE document type. The course material described in the example is a simplified description of the Matrix Calculation course held in Tampere University of Technology, Autumn 2000. Due to lack of page space we included only two examples of components in the description. In practice, the components would occupy a major part of the document. Note that the second component is actually a PDF-document, the structure of which cannot be interpreted as an XML or HTML document as such.

Listing 1. Example of an A&O material description document.

Conclusions

The A&O material model defines an open and effective method to describe learning material. In a world where authoring tools and document formats are developing fast, we feel that the openness of the material and the format independence of the model are very important. The key point is to separate the metadata from the actual material formats of material used in learning environments. This separation has other advantages as well. For instance, it enables editing the course material after importing it to the learning environment, allowing adding information to the description document without having to change the existing learning environment. Using XML in describing and encoding description documents makes it also possible to effectively reuse metadata in a form of interoperability standards in the future. This can be achieved, e.g., with appropriate XSL transformations, one for each interoperability standard or document type. The material model introduced in this article is actually used in developing content for the A&O learning environment. Future experiences will evaluate our work in revealing the hidden gaps and gems of design. The initial work, however, seems promising.

Abstract: The Educational Technology Development Group at the University of Washington creates and manages innovative projects that integrate teaching with technology. Through a network of collaborative partnerships with campus teaching practitioners—learning, technology, and teaching research centers, libraries, and departments—the group leverages resources and spreads promising practices throughout the university. From this unique position as the intermediary between educators and technical support staff, the group is able to facilitate diverse projects from the Web-based Catalyst Initiative which supports innovation in teaching through technology for all UW faculty to managing and facilitating a cutting-edge distance learning projects that utilize Internet 2 connectivity.

Partnerships as a Support Strategy

In 1994, three top-level administrators at the University of Washington were charged by the Provost to “do something about technology.” They redirected resources from their respective units and worked with faculty to launch a small pilot project to provide 65 freshmen with laptops and training in technology and information literacy. Collaborating with other faculty, librarians, technologists, and students, they quickly moved beyond this initial pilot, rounding up more partners and gathering resources from wherever they could to focus on bringing technology into the service of teaching and learning in a more systematic way through the Center for Teaching, Learning and Technology (CTLT), established in 1996.

The CTLT served as a drop-in center where faculty could work and receive one-to-one assistance in a uniform and familiar environment of standard software and hardware. The Center tailored custom solutions to faculty needs, often working closely with support staff from a client’s home department. Staff also gave frequent workshops on basic applications and technology skills. This support model required significant staff time and created the expectation of continued, intensive support (for relatively few clients). By 1998, drop-in visits to the CTLT had increased dramatically, seriously taxing staff resources. At the same time, however, the absolute number of instructors assisted by CTLT staff was relatively small, a few hundred early adopters over the course of the academic year. The need to expand support to a much wider audience—and to do so without a major infusion of new staff or relocation to a larger facility—was clear. How to do so was not.

At this point, staff entered into an intense period of assessment and wide ranging conversations with the major partners behind the CTLT, campus stakeholders, faculty focus groups, and campus support staff.
What emerged from these conversations was a clear set of requirements for supporting wary adopters: (1) the initial foray into educational technology must be smooth and easy; (2) flexibility is critical to meet the both the changing needs of instructors as well as evolving technologies; and (3) campus-wide, scalable resources are a must. Not only did these conversations forge a consensus among campus educators about what needed to be done, but the new support framework that resulted—the Catalyst Initiative—explicitly met the needs expressed by faculty, librarians, instructors, and teaching assistants.

What has proven critical to UW's success in supporting educational technology is that all the units that should have been shaping technology integration were shaping technology integration. The initial partnership established an ethos of multi-unit, results-oriented collaboration that has persisted, producing a support strategy owned by all the players. This intense collaboration also resulted in the creation of a permanent staff for the CTLT, now called the Education Technology Development Group, who understands the needs of faculty and the units on campus with a stake in teaching with technology. Ed-Tech staff is thus perfectly situated to arrange collaborations and bridge gaps between educators and other units on campus. This position as an intermediary and a change agent has allowed Ed-Tech staff to not only develop a scalable support strategy for all UW professors—the Catalyst Initiative—but to participate in high level experiments that push the boundaries of innovation.

The Catalyst Initiative

By now all institutions of higher education are grappling with instructional technologies, in part spurred by the explosive growth of Internet technologies in everyday life. To support technology in teaching, many campuses have established a faculty technology center, offered training to interested educators, supported faculty technology projects and the transformation of particular courses, and/or implemented off-the-shelf courseware. These efforts have generally targeted early adopters who are eager and willing to teach themselves how to use and implement new technologies. Most support staff, however, now face the challenge of moving beyond the small core of early adopters to the wary adopters, the vast majority of faculty who look for easy ways to bring technology into their teaching but are unwilling to match the time commitment of the pioneers.

As noted in a recent National Learning Infrastructure Initiative white paper, this second wave of wary adopters shares a commitment to quality learning with the early adopters but is much more risk averse and unwilling to experiment or invest significant amounts of time to integrate technology. Moreover, there is no magic-bullet solution that will meet the needs of all or even most wary adopters. To reach its own second wave of wary adopters, the University of Washington chose to forego courseware or unitary solutions in favor of a support strategy, the Catalyst Initiative, grounded in partnerships and collaboration with campus teaching practitioners—learning, technology, and teaching research centers, libraries, and departments. Just 18 months old, the Catalyst Web site is widely used by UW faculty. On an average day, approximately 600 instructors use the original content on Catalyst to help them integrate technology with their teaching but are unwilling to match the time commitment of the pioneers.

Scaling Innovation through the Catalyst Initiative

The concept was simple: provide examples, promote good teaching practices, build technology skills, and make technology easy for instructors to use. These are the tenets of the three-tiered Catalyst Initiative, a support framework that provides anytime-anywhere resources via the Catalyst Web site. Catalyst places good teaching and student learning at the forefront, treating technology as a means to these ends. The resources on the Catalyst Web site shape and inform the other two tiers of the Catalyst Initiative: redesigned workshops and one-on-one consulting delivered through the CTLT. This interlocking support strategy ensures that campus educators receive clear, consistent help for integrating technology into their teaching.
A great deal has been written about the creation of the Catalyst Web site, but it is worth reemphasizing here that its homegrown content is built solely through collaborative partnerships with campus teaching practitioners—learning, technology, and teaching research centers, libraries, departments, and faculty. A look at the six major content categories on Catalyst makes clear the close connections to campus practitioners:

- **Profiles** tell the stories of educators who are using technology in teaching—the challenges they face, the pitfalls they encounter, and the successes they achieve. This section allows faculty who use technology to share what they are learning and doing with their colleagues from across campus, breaking through traditional disciplinary boundaries.

- **Teaching** lets instructors explore the ways that technology can help achieve specific teaching and learning goals. These pages were created input from teaching research centers and point faculty to these centers.

- **Action Plans** are "road maps" for particular tasks, such as creating a class web site or setting up electronic discussion. Many of these draw on existing campus computing resources or rely on information gathered from technology centers.

- **How-to** pages take users step-by-step through specific tasks needed to make technology work. The range of applications covered here mirrors the range of applications available in the many different computing environments throughout UW. Indeed, numerous How-to documents were created in collaboration with department of unit support staff.

- **Learning** offers information on CTLT workshops and other campus activities related to teaching with technology.

- **Web Tools** is a gateway to Web-based software and also links to innovative uses of Catalyst Web tools by UW educators, again helping to spread good practice beyond disciplinary boundaries.

These resources easily meet the three requirements for supporting *wary adopters*. First, the varied stories of teaching with technology, the step-by-step instructions, and the best practices make an educator's initial foray into educational technology smooth and easy. Second, Catalyst is extremely flexible; faculty needs and wants vary markedly across departments, disciplines, and course types, but Catalyst allows them to pick and choose support options that suite their environment and needs. Finally, Catalyst is a campus-wide resource, available 24-7, which scales local solutions throughout the campus teaching community.

Excellent support resources and exciting teaching practices using technology are found all across campus. Very few people, however, have knowledge of resources and practices beyond their own departments. The Catalyst Initiative was created exactly to make these resources and practices visible, scaling innovation across campus through collaborative partnerships. Not only does this strategy leverage resources, but it also forges both a sense of ownership and a measure of comfort with educational technology among faculty and support staff who come to see themselves in the offerings on Catalyst.

**Co-Branding Innovation through Catalyst**

Last February, the Catalyst Initiative celebrated its first anniversary, having survived initial growing pains to produce some very formidable gains in campus technology support. Ed-Technology Development staff was now ready to make use of use the results-oriented, multi-unit collaborative ethos critical to the formation of Catalyst to help grow the initiative. Co-branding efforts focused on formalizing existing but piecemeal partnerships with campus teaching practitioners—learning, technology, and teaching research centers, libraries, departments, and faculty—to generate new ideas, content, and tools for the Catalyst Web site. Resources and materials generated from these partnerships are placed on Catalyst and co-branded, giving credit to the partners who helped create them.
Co-branding allows staff to maintain current and innovative resources on Catalyst, while alleviating the burden of generating new materials whole cloth. Among the most notable results of these co-branding partnerships are:

- **MyClass**: C&C has recently created MyUW, a personalized Web portal for UW students and is working on portals to meet the needs of each segment of the UW community. C&C is currently working with the Ed-Tech Development Group to create MyClass, the personalized teaching portal for UW instructors. This portal will integrate Catalyst Tools with course and student information systems, online grading capabilities, and applications that let instructors post content directly to the Web. In part, **MyClass** is designed to reach *wary adopters*, bringing useful Web-based course administration tools together with a simple interface for creating online course materials.

- **CONTENT**: With its Digital Initiatives Program, UW Libraries is building an online multimedia collection that showcases print, photograph and textual materials through the **CONTENT** digital asset management system developed at UW’s Center for Information Systems Optimization (CISO). Librarians, working with scholars who wish to digitize their own materials, design the individual **CONTENT** databases within the Digital Initiatives collection. The CTLT now houses two **CONTENT** digitization and acquisition stations, and the Ed-Tech Development Group is working with CISO staff to create instructions and support materials which, once housed on Catalyst, will permit faculty to create **CONTENT** databases themselves.

- **Task Consultant**: This Catalyst Web Tool, currently being co-developed with the School of Library and Information Science (SLIS), meets a need frequently voiced by faculty—how to guide students in the formation of research papers and projects. Building on a core strength of the SLIS program, models for information problem solving, the interactive **Task Consultant** will help students sharpen research topics, structure arguments, determine appropriate levels bibliographic information, and create a project timelines.

- **Turning Your Course into an Online Course**: This new workshop series, co-developed with Educational Outreach, aims to help faculty create courses that have distance-learning or online components. After the first series of workshop materials, Ed-Tech Development staff will transform workshop materials into new Catalyst content, making these resources available to all instructors.

Not only do these partnerships lead to new Catalyst resources and Web Tools, but they also scale resources that might otherwise remain underutilized, like **CONTENT**, or spark exciting new campus-wide developments in educational technology such as **MyClass**.

**Partnering to Push the Limits with Internet 2**

The Ed-Tech Development Group’s understanding of faculty technology needs and its position as an intermediary among a network of partners also allow it to provide technical and pedagogical support for innovative projects that create a new generation of technologies to be used by *wary adopters* for teaching. In September of 2000, the group began facilitating a variety of distance learning projects that utilize Internet 2 broadband connectivity. These partnerships were arranged by the office of the Provost and included key players from Computing and Communications, the organization that creates and maintains the campus technology infrastructure, UWTV, the campus television station, and representatives from various academic departments.

The first of these projects is the creation of a $5 million distance-learning classroom for case-based, synchronous learning, currently under development by the UW School of Public Affairs. The classroom will use video, sound, document cameras, and simulations to connect students to expert speakers from all over the country while facilitating the group interactions of case-based learning. In the initial needs assessment phase, staff determined that the project leaders in Public Affairs had a mastery of both the subject matter and teaching methods but required additional support in design, planning, and assessment of the needed technologies. After an initial meeting, Ed-Tech staff has played a key role in documenting the process of
building the classroom and facilitating a series of pedagogical experiments that will help solidify the curriculum design. Ed-Tech staff has also continued its traditional intermediary role by inviting participation from other partners. To provide research about distance learning and develop an assessment strategy, the Program for Educational Transformation Through Technology (PETTT) and the Office of Education Assessment have now joined the effort.

Ultimately, the campus teaching and learning community will benefit from these projects. Initial lessons from the Public Affairs experience are already being carried by Ed-Tech staff to a new synchronous, distance-learning project where students in Seattle will learn the Hawaiian language from instructors and native-speakers based in Hawaii. Once distilled, all of the lessons from these pilot projects will be disseminated as teaching guides and how-to resources via Catalyst, helping wary adopters move from asynchronous to synchronous uses of technology for teaching. These partnerships will allow us to share experiences and findings with other institutions connected to the Internet 2 network, and will help us create recommendations for equipment and standards while reporting on best practices.

---

2 Indeed, this partnership has been so successful that it received the 2000 EDUCAUSE Award for Systemic Progress in Teaching and Learning.

Can technology be effectively used in the classroom to deliver consistently high quality training while reducing the costs of faculty and administration? The College of Business at Colorado State University has designed and implemented an on-screen e-learning and assessment Essential IT Skills classroom model that achieves the goal of consistent delivery with reduced costs. The course utilizes existing industry e-learning and assessment software as the primary delivery vehicle, and employs CIS students as the classroom learning mentors. This course covers the topics of: Basic IT Concepts, Operating Environments, the Internet and Search Engines, Wordprocessing, Spreadsheets, and Presentation Graphics.
The **ActiveMath** Learning Environment in a Nutshell

**ActiveMath** (Melis et al., 2001) is a web-based learning environment that dynamically generates interactive mathematical courses adapted to the learners' goals, preferences, capabilities and knowledge. **ActiveMath** is realized as a client-server web-architecture that can be accessed using standard web-browsers. When learners use the system for the first time, they have to complete a registration form in which they indicate their preferences and abilities and may estimate their mastery levels of the course's domain knowledge. From this information, an inspectable user model is generated which is constantly updated when the learner acts in the course. The learner can choose between predefined courses (defined by a teacher) or let the system generate a new course according to the goal concepts (mathematical definitions and assertions) and the scenario the learner chooses. One possible scenario is exam preparation in which only the mathematical definitions of concepts and corresponding exercises are provided. Another scenario is the guided tour in which complementary information such as motivating texts, examples and elaborations etc. is selected.

**ActiveMath** integrates mathematical service systems. Currently, these are Computer Algebra Systems (CAS) and the proof planner of MEGA (Melis & Siekmann, 1999). They can be called to demonstrate an example, to interactively solve an exercise, and to take over certain routine tasks.

The learning material is encoded in the XML-based knowledge representation language OMDoc (Kohlhase, 2001). OMDoc encodes mathematical objects and items such as definitions, theorems, proof methods, proofs, examples, exercises, and remarks. Each item has its own meta-data that can contain additional information such as dependencies or pedagogical data, e.g., difficulty level or abstractness level of an exercise.

A demo of the **ActiveMath** system is available at [http://www.mathweb.org/activemath/demo](http://www.mathweb.org/activemath/demo).

The Presentation Planner

The central component of **ActiveMath** is the presentation planner. It is responsible for generating a personalized course in a three-stage process:

1. **Retrieval of content.** Starting from the goal concepts chosen by the user, all concepts they depend upon and corresponding additional items (e.g., elaborations, examples for a concept) are collected recursively from the knowledge base. This process uses the dependency metadata information contained in the OMDoc representation. The result of this retrieval is a collection of all concepts and information that the user needs to learn in order to understand the goal concepts.
2. **Applying pedagogical knowledge.** Then, the collection of content items is processed according to the information in the user model and in the pedagogical module. This results in a personalized instructional graph of the learning material. This process is detailed below.
3. **Linearization.** Then, the instructional graph is linearized.

The result of the presentation planning is a linearized instructional graph whose nodes are OMDoc items. This collection is eventually transformed by XSL-transformations into HTML pages.
Applying Pedagogical Knowledge

The goal of the application of pedagogical knowledge is to select from and transform the collection of items that was gathered in the first stage of presentation planning into learning material. ACTIVEMATH employs pedagogical information represented in pedagogical rules. It evaluates the rules with the expert system shell JESS (Friedman-Hill, 2000). The rules consist of a condition and an action part. The condition part of a rule specifies the conditions that have to be fulfilled for the rule to be applied, the action part specifies the actions to be taken when the rule is applied.

The presentation planner employs the pedagogical rules to decide: (1) which information should be presented on a page; (2) in which order this information should appear on a single page; (3) how many exercises and examples should be presented and how difficult they should be; (4) whether or not to include exercises and examples that make use of a particular service system. Since the work with service systems requires a certain minimal familiarity with the systems, ACTIVEMATH presents those exercises only if the capability is confirmed. Moreover, pedagogical rules may restrict the available functionalities of a service system. For instance, a student learning about integration and derivation should not use a CAS to solve his exercises completely, whereas using the CAS as a calculator for auxiliary calculation is acceptable.

The application of pedagogical rules works as follows. First, information about the learner retrieved from the user model (e.g. what kind of service system the learner can use) is entered as facts into Jess' knowledge base together with the OMDoc items (annotated with the learner’s mastery level) collected in the first stage of presentation planning, her goals, and the chosen scenario. Then the rules are evaluated. This results in adding new facts in the knowledge base and eventually generating the sorted lists of items the pages of the course will consist of. In the following, we provide examples of pedagogical rules for two different types of decisions. The rule

(defrule PatternForExamPrep
(scenario Exam Prep) => (assert (definitions assertions methods exercises)))

determines the kind of items and in which order they will appear on the course pages, here for the case that the learner has selected to prepare for an exam (indicated by the fact (scenario Exam Prep)). When this rule fires, then the facts (definition ... exercise) are asserted, i.e., added to Jess’ knowledge base. This implies that these items will appear on a page in the specified order.

In turn, these facts will make other rules fire, e.g., those choosing exercises with an appropriate difficulty level:

(defrule RequireAppropriateExercise
(exercise)
(definition (name ?definition) (userKnowledge ?user-knowledge))
(test (< ?user-knowledge 0.3))
=>(assert (choose-exercise-for ?definition (0.3 0.5 0.7))))

This rule determines that if exercises should be presented at all (indicated by (exercises)) and if there exists a definition d in the knowledge base of Jess, then d’s name is bound to the variable ?definition and the learner's knowledge of d is bound to ?user-knowledge. Jess allows to specify Boolean functions (indicated by test) that are evaluated and whose value determines whether a rule fires or not. The above rule fires when the learner's knowledge is less than 0.3. Then the fact (choose-exercise-for ?definition (0.3 0.5 0.7)) is inserted into Jess’ knowledge base and this triggers the selection of examples for d with difficulty levels 0.3, 0.5, and 0.7 in a row.

Abstract: Technology is changing every aspect of our lives. We now access information instantly on multimedia CD-ROMs and via the Internet that less than five years ago would have taken hours of research. We use computers for communication, analysis, learning and entertainment. Our children and students are growing up in a world where they will live a computer dependent lifestyle. Technology itself is changing at a tremendous rate, and one industry that has to keep up with this pace is IT training industry. The Computer Education and Training are one of the main national objectives, keeping in view the rising need for quality computer professionals. A nation must develop new ways to educate this ever-changing work force by developing the best technologies to meet the unique needs of educators, students, professionals and support academic achievement. A strong partnership between educators and technology innovators is essential to achieve this. The age of information introduces new demands and requires reorganization. To reorganize the working methodology is to reorganize the process of learning.

Education Components:
Computer education is very imperative today because of the advances in technology and the sophistication and complexity of our society. No one can survive if they lack the skill of knowledge to deal with today's problems. Only a dynamic and progressive education system will produce a competent informed citizen, who is capable of realizing his/her full potential in the new world that awaits.
The three broad technology trends are:
> Networking
> Application development
> Internet / Web technologies.
A gamut of comprehensive computer courses to provide training in these trends related to Software, Hardware and Networking are available throughout the country. The outcome of any IT training Institute is to churn out good quality professionals who are ready to deal with the latest technologies of the world. In Universities and Educational Institutions, providing the technology infrastructure, increasing the access to technology, and integrating the technology into the classrooms can produce skilled professionals who can substitute the demand for human resource in IT.
Communication is the essence of all our interactions. Due to the enormous development in technology, computer has become an essential tool for communications. Communication is multidimensional and it has become richer today due to the addition of video, sound and animation. Multimedia communication which started as an authoring and presentation system allowed people to create and deliver matter, which created a good experience by the end user.
Multimedia
Multimedia technologies empower professors to create interactive and exploratory classroom experiences. The integration of text, voice, photography and animation offers a revolution in the art of instruction and the joy of learning. Audio, Video technologies enable the students and teachers to use the learning technologies of today (Speech, Video conferencing etc.) from the convenience of single location on their desktop. Electronic courseware has also become a reality, including CD-ROM textbooks and customized electronic textbooks developed by professors in on-campus labs. Internet and Intranet technologies enable students, teachers and educators to communicate, collaborate and create media rich content using digital media in new and powerful ways. Internet also provides access to incredibly vast information resource and offers a course of communication opportunities.
including the ability to publish work and participate in worldwide collaborative projects. Publishing on Internet or setting up a local Intranet at campus wide level is easy and affordable.

Distributed Learning
Distributed learning environment is an extension of a classroom where people with common learning interest engage in conversations, sharing of information and work together anywhere and anytime. Mobile computing technology can motivate learners to explore, create and communicate out in the field as well as inside the classroom. This model supports lifelong learning and requirement of knowledge workers in global economy that places a premium on information access.

Internet
The Internet offers all of us possibilities to expand our horizons, pursue our dreams and create a truly interactive community of learners in e-classrooms. The objective of the e-class room is to eliminate the barriers of time and distance. Students are able to hold on-line threaded discussion with their team members in addition to having access to their class files 24 hours a day.

E-learning
E-learning centers that provide interactive web-based training are coming up fast that offers training for technical certifications, web development and other professional courses. Virtual universities are set up that connect student’s world wide to the training they need and provides search for authorized training resources.

Training:
Every walk of our life is marked by penetration of the computers and its applications. This has lead to the increased demand for training in computers for all. The industries are also facing these challenges everyday. Even small and medium industries need to be modernized with the latest computers and their applications for speedy operations and customer satisfaction. So there is the necessity to train the employees of the industries too. The banking sector is also revamping their system to provide easier and faster transactions with computers. Efforts are taken to replace staff with young computer trained employees.

Institutions
These days there is a mushrooming of software training institutions in India. These institutions offer regular training on software and also certified training programs that provide self study training and certification the industry needs - whether that is with Microsoft, Novell, Sun, Cisco or other certifying. These centers need to be committed to always be on the leading edge of new computer environment training products.

If computer training Institutions have to do well they need to concentrate on the following issues:
- Provide quality product to the customers at a price that is within reach of most computer professionals.
- Committed to always be on the leading edge of new computer environment training technology and products.
- Strive to provide training programs & tutorials that far exceed the expectations of our customers with 100% customers’ satisfaction
- Mission to include practical applications of real world and give up-to-date training.
- Provide training that extends opportunities to students by offering certificate programs, comprehensive enough to enable graduates to qualify for careers in their field of study.

These are the key elements in educating and improving the lives of our society and in specific the student community today. Continued success rests with our commitment to offering individual attention, intensive hands on training and intensive career support services.

Conclusion
What we aspire today is a global community of learners who view technology as the means through which we transcend any barrier - including geographical, temporal and physical limitations, to acquire, enjoy and provide unlimited education opportunities and information access. Several technologies and products are available that has enhanced today's learning opportunities.

torriero@eco.unibs.it

Abstract: We present a project for an introductory course in Mathematics (the so called pre-course). The pre-course is designed for first year students of economic faculties, in order to provide them of the necessary basic mathematical tools, preliminary to take Calculus I. Even more important is the use of the pre-course for last year high school students willing to apply to economic faculties, so they could "anticipate" conveniently their mathematical background. The innovation of the project is the framework in which the project originates: this is the first step toward a homogeneous formative offer in the field of economics in North Italy and tries to establish a link between high school and University.

The project TEOREMA

The Italian university system is undergoing a radical change with the introduction of credits, as it has been done in the majority of other European countries. The credits evaluate, based on time-units, the work really done by the student towards the exam preparation and thus, in their assessment, one has also to give due importance to the "homework" study as well as to other learning activities completed outside the classroom.

In this context, we have developed TEOREMA for an on-line Mathematics preparatory course: it is an innovative tool not so much for its technological aspects but rather because it is the first Italian project of university teaching which will be applied by the major universities of Lombardia, a northern Italian region.

This project is mainly aimed at freshmen (or students who wish to enroll for the first time) in our Economics Faculties. Its main objective is to give the basic skills and preliminary knowledge necessary to benefit from the attendance of the regular course of Calculus I. The admission to the Calculus I Course will be subject to an evaluation test to be taken at the end of the preparatory course.

It should be noticed that almost all the universities adhering to the project offer similar preparatory courses, but very often a problem with the timing arises. These prep-courses are generally given very early in the calendar, long before the beginning of the regular academic year; therefore, many students either may not have finished their enrolment phase or they may not attend classes on a regular basis. The access to the preparatory on-line course directly from one's home may remove these discrepancies.

The extension of the on-line preparatory course to the last year Secondary School (Senior High School) students could bring even more remarkable results. In this way, the Secondary School students could verify, and if
necessary, complete or supplement their mathematics knowledge in the perspective of a future enrolment in an Economic Faculty, thus anticipating the mathematical requirements needed to successfully profit from the Calculus I Course.

The contents of the traditional mathematics preparatory course are standardised. This peculiarity has contributed to make the same preparatory course a well-gauged tool to be applied to many Faculties.

The basic topics of the preparatory course – whose knowledge should be considered as a necessary pre-requisite for all students who want to enroll in an Economics Faculty – are derived both from the contents of the current preparatory course offered by the Faculties participating in the project as well as from the Mathematics Syllabus published by UMI (Association of Italian Mathematicians). The contents include: Mathematical logic, Set theory, Arithmetic, Elementary Algebra, Analytical Geometry, Trigonometry, Functions (*).

Some of the participants do not share the subjects in italics. The asterisk indicates a subject that is covered in Calculus I Courses. Therefore, it is not a real pre-requisite.

TEOREMA is based on the co-operation among the Departments of the following northern Italian economic faculties and CILEA:

- University of Bergamo [http://www.unibg.it](http://www.unibg.it) (E. Allevi)
- Bocconi - Milano [http://www.uni-bocconi.it](http://www.uni-bocconi.it) (M. Cigola)
- University of Milano- Bicocca [http://www.unimib.it](http://www.unimib.it) (S. Stefani, R.Pini, G. Carcano)
- Catholic University of Sacred Heart of Milano - [http://www.unicatt.it](http://www.unicatt.it) (M. Bianchi, F. Vassallo)
- State University of Brescia [http://www.unibs.it](http://www.unibs.it) (A. Torriero)
- University of Pavia [http://www.unipv.it](http://www.unipv.it) (G. Giorgi, E. Caprari)
- LIUC, Castellanza [http://www.liuc.it](http://www.liuc.it) (C. Rossignoli, A. Lissoni)
- University of Insubria [http://www.uninsubria.it](http://www.uninsubria.it) (A. Guerraggio)

CILEA (Consorzio Interuniversitario Lombardo per l'Elaborazione Automatica, [http://www.cilea.it](http://www.cilea.it)), a neutral institution which provides computer services to the Lombard universities, will supply general coordination services, site administration and all the technical skills required to develop, set up and put online the final course prototype.

CILEA is connected to GARR backbone with a 6 Mb/s direct connection. TEOREMA works on a NT4.0 platform, Pentium III 500 Mhz 512 Mb RAM dedicated server. This machine is connected to a switched LAN at 100 Mb/s speed.

**Student profiles and course structure**

This course is addressed to two different kinds of students: the High School's last year students who are interested, and perhaps wish to enroll, to an Economic Faculty and the Freshmen, students of the first year of one the Economic Faculties involved in this project. Therefore, from the very beginning, the entire project contents are conceptually divided into two parts: a common, public (or semi-public) one for the first kind of students and a more specific one, tailored upon the needs of the specific Economic Faculty and restricted to its students.

This double target reflects on all the aspects of our course. Regarding the way to connect to it, we suppose users will access its public part mostly via domestic dialup connections, whereas for the ones already enrolled to university courses, from dedicated PCs in some computer rooms, getting of course a better quality of service.

The course is conceived according to the following modules: **Self-learning, Self-evaluation, Tutoring.**

**Self-learning:** it will exploit to the utmost the characteristics of the tool. In particular it will be based on a standard hypertext, animations and algorithms. Periodical live sessions will be performed by an audio or video conference (once a week or twice a month).

**Self-evaluation:** to give a student a way to measure his/her progress, the course will propose self evaluation tests for each topic, to be completed in a given time. The more common technique used will be a multiple choice quiz, randomly chosen in appropriate database. At request, a complete explained solution of the test will be given. The student's course history is tracked down in a central server database.

**Tutoring:** this service is offered solely to the students who have access to the customised Web sites of each university. This will be done at least via synchronous moderated chat-room with the teacher as a moderator. Asynchronous tutoring will be offered via standard e-mail, for longer and maybe more complex questions and answers. A forum will allow students to ask questions on the course topics and to find or give answers to the questions raised by other students. A many times answered question goes immediately into a FAQ list, maintained by the forum administrators and available at once to every forum member. Finally, a mailing list is a simple way for the teachers or course authors or administrators to get in touch with all the students via a single message. Free and
partially checked chat is always available to students to openly discuss at any time and on any subject either related or not related to the course.

Software packages

After a thorough review of standard available software, we have turned to Learning Space V4 (by Lotus) for the framework, the course structure and the tracking system (Windows SQL Server 7.0 database). For the authoring part we have chosen Toolbook Instructor (by Click2Learn) for text and HTML as a text editor. Both packages are able to communicate via AICC public CMI Standards.

Abstract: MathCAL is a tutoring system designed for learners to practice mathematical problem solving. It is capable of offering guidance and proposing remedial tutorials automatically. MathCAL uses Petri-nets as its knowledge representation model. The static domain knowledge as well as a learner’s dynamic problem-solving steps in each interactive session is represented as Petri-nets, which may be used effectively for diagnosing a learner’s problem-solving difficulties. The database maintained by MathCAL is consulted to decide on a suitable guidance for the learner. Math problems, solution paths and learners are three major entity sets modeled by the database. This paper describes the implementation details of MathCAL’s database and its distinctive features.

Introduction

MathCAL has been designed for learners to practice mathematical problem solving. In our previous papers (Lin et al. 1999, Lin et al. 2000a, Lin et al. 2000b) we have described the functions provided by MathCAL, its design considerations, system architecture, knowledge representation scheme, and its diagnostic mechanism. In this paper we focus mainly on MathCAL’s database design.

To use MathCAL, a user first logs onto the system with a Java-enabled WWW browser. MathCAL may be operated in two different modes: the practicing mode or the editing mode. The practicing mode is for students to practice problem solving, and the editing mode is for teachers to insert or edit a problem set and input expert knowledge pertaining to solving the problem.

In the practicing mode, the student begins an interactive session with MathCAL by selecting a problem from the system’s test bank. S/he should first analyze the problem statement to identify the given conditions embedded in the statement, and then enter those conditions to the system by selecting appropriate objects from the input condition menu. An insert window associated with each input condition object will pop up for the student to assign values to related attributes of the object. For example, a student may select the circle object and fill in the coordinates of the center of the circle, the measure of its radius, etc., or s/he may select the line segment object and assign A and C as the names of the two end points and 12.5 as its length. With the initially given conditions properly entered, the student may then proceed with the problem-solving procedure step by step.

As in ordinary mathematical problem solving, a student needs to search his/her knowledge base for some mathematical concept and rule that can be applied to the currently known conditions and use it to transform the problem from the current state to a state closer to the desired solution state. In MathCAL we have identified the concepts and rules related to a certain topic and collected them into a set of transitions, and these transitions are organized as a pull-down menu for easy selection by the user. Each transition has its corresponding input and output arguments. The input arguments are
the necessary conditions for firing a transition and the output arguments are the results to be generated by the transition when it is fired.

The user provides the input arguments by ticking the appropriate items from the set of current known conditions shown on the screen. The system will reject a user's request for firing a transition if the input arguments ticked by the user are incorrect. This ensures that the users know what a concept or a rule, as embodied in a transition, is really about and discourages them from trying blindly. Firing a transition results in addition of new facts, as represented by the output arguments, to the set of known conditions. This select-and-fire step repeats until the desired result is derived. A user's thought process is truthfully reflected in this sequence of select-and-fire steps, as such it is considered the most useful data on which the system may base its analysis about a user's comprehension level and problem-solving difficulties. MathCAL records this sequence by constructing and storing a corresponding Petri-net dynamically. In MathCAL's database, we also store all possible solution paths about each problem. Therefore, when the user requests system's help in the middle of solving a problem, MathCAL is capable of providing expert guidance by matching the learner's partial solution path with all possible solution paths about that particular problem. A closest match is identified and used to guide the user through.

The editing mode is provided for teachers to insert new problems into MathCAL's test bank. Besides typing in the problem statement, the user may choose to illustrate the statement with a graph by importing a separate file containing the graph. The teacher then informs the system of one or more solutions about the problem by activating the practicing mode and solving the problem using each different method. The problem-solving procedures demonstrated by the teacher will then be automatically recorded by the system and stored as the correct solution paths. While the teacher is demonstrating a problem-solving procedure, the editor also allows the teacher to enter guiding message associated with each step. These guiding messages will be used in providing feedback to users when they ask for help with a particular problem. It is possible that a teacher may enter a new problem which requires the use of some transitions that are not already included in our set of transitions. Under such circumstances, the system kernel need be modified to incorporate the new transitions.

To capitalize on the communication capabilities made possible by the Internet, MathCAL also implements both the chat function for synchronous communication among on-line users and the e-mail function for asynchronous communication. That is, a user may ask for human help instead of requesting system guidance. Petri-net representation also plays an important role in this respect because it allows efficient transmission of a user's current problem-solving status to the helper side. With the Petri-net representation of a user's problem-solving procedure, MathCAL is able to transmit the Petri-net and use it to re-produce user's screen mage at the helper side. This considerably reduces the amount of data transmitted.

MathCAL's functions as described above are realized with the help of a well-designed database module. In the following section we present the schema of our database and elaborate on how we model such important entity sets as math problems, problem solutions, problem-solving procedures, and the learners. Specifically, we present the entity-relationship diagrams (Date 1995) to show the details of our database design. We then summarize MathCAL's distinctive features, which is followed by our concluding remarks.

MathCAL's Database Design

Modeling Mathematical Problems

A typical mathematical problem consists of the problem statement and possibly a geometric graph which illustrates the problem. In addition to this basic information, MathCAL also stores the following attributes about a problem: (a) ID: a unique ID to identify a problem in the database, (b) Difficulty level: an integer (1 to 5) to indicate how difficult a problem is, and (c) Attribute: remarks about a problem. (Fig. 1) shows the entity set of the math problems.
Modeling Problem Solutions

As mentioned previously, MathCAL uses Petri-nets as its knowledge representation scheme. Both the static domain knowledge and the dynamic problem-solving procedures are represented as Petri-nets. There are three essential symbols in a Petri-net graph, which are transitions, tokens and places (Peterson 1981). Each transition represents a mathematical concept or rule, e.g., the 180 rule, the Pythagorean theorem, etc. Places represent facts, which are input conditions for a transition. The outputs resulted from execution of a transition are also places. For example, a problem statement may contain a number of given facts, including, say “a tangent touched a circle at point C” and “the diameter of the circle is AB with a measure of 26.” These facts will be modeled as places by MathCAL. A transition may be fired only when its input places are all enabled. Tokens are usually used to indicate whether a place is enabled. However, tokens need not be modeled explicitly in MathCAL’s implementation because all places are considered enabled. That is, if there exists an arc from a place to a transition and the transition accepts the place as its input conditions, then the place is automatically treated as enabled. In the following we focus on how we model places, transitions and arcs in our database.

The Entity Set of Places

There are three attributes associated with each Place entity: Place_ID: a unique ID to identify a place, Statement: the meaning of this place, e.g., “the diameter of a circle,” and Value: the value of this place if any, e.g., 26 (the measure of the diameter). (Fig. 2) shows the entity set of the math problems. The underlined attribute represents the key.

The Entity Set of Transitions

We model the transition entity with two attributes: Transition ID: a unique ID to identify a transition, and Description: A description for this Transition. The diagram for this entity set is similar to the previous two figures and is skipped to conserve space.

The Entity Set of Solution Paths

The entity-relationship diagram of (Fig. 3) illustrates how we model the data involved in a mathematical problem-solving process using the place entities and the transition entities defined above. As shown in (Fig. 3), each solution entity has a unique ID for identification. Since each solution path typically consists of a number of problem-solving steps, there is another entity set called solving-step which has a many-to-one relationship with solution. It also has a many-to-one relationship with the transition entity set, indicating that each solving-step is mapped to one
transition and that every transition entity may map to one or more solving-steps. In terms of object-oriented design (Booch 1994), the transition entity set corresponds to a class, whereas a solving step is one of its instances. Relationships Input and Output mean that every solving step may have one or more place entities as its input and also one or more place entities as its output. A place is an instance of the place-type class, as indicated by the is-a relationship between them.

There also needs to be special mechanism for determining if a rule may be fired at a certain step. For example, transition TI can be fired only if places P1 and P2 are present. We thus create a satisfy relationship between transition and place type to record this type of information. It is a many-to-many relationship, meaning that each transition requires the presence of one or more places in order to be fired, whereas a place may be used for firing several different transitions.

<table>
<thead>
<tr>
<th>TI</th>
<th>Given the three sides of an isosceles triangle, find the top vertex of the triangle.</th>
</tr>
</thead>
<tbody>
<tr>
<td>P1</td>
<td>Three line segments</td>
</tr>
<tr>
<td>P2</td>
<td>The top vertex of an isosceles triangle</td>
</tr>
</tbody>
</table>

Figure 3: Mathematical problem solving modeled as an entity-relationship diagram

Modeling Learners

In order to identify each learner and also to maintain information about his/her learning history, MathCAL requires a login process and keeps a record for each learner. The record includes (a) Full name: a user’s full name, (b) Username (c) Password, (d) Attributes: additional information about the user, and (e) E-mail. Such data is used by MathCAL in such situations as:

1) when MathCAL is requested to suggest tutorial and/or exercise problems appropriate to a learner’s comprehension level;
2) when MathCAL attempts to guide a learner by reminding him of some previous experiences that the learner has which are related to his current problem-solving activities; and
3) when a learner requests help from other users by activating system-supported synchronous or asynchronous communication functions.

The Database as a Whole

The three entity sets described above may now be put together to construct MathCAL’s database module. Two more relationships, provide and has, has been added to indicate that a problem may have more than one solution paths associated with it, and that a learner may provide new solution path for a given problem. The entity-relationship diagram of (Fig. 4) shows the complete model of
MathCAL's distinctive features:

1. MathCAL’s step-by-step recording of a user’s problem-solving procedure reflects the user’s thought process. With the availability of this handy information, the system need not employ complex mechanisms to guess where the user has got stuck when he requests system’s help.

2. MathCAL’s student module maintains a separate record for each user. In addition to such static data as user names, the passwords, e-mail addresses, etc., it stores a user’s profile as well as his learning history, including which problems the user has solved before, which transition rules he has used before, the user’s comprehension level as determined by the system based on his past performance, etc. Such information is useful for MathCAL to make correct diagnoses and prescribe suitable corrective measures.

3. MathCAL has been designed in such a way that it is capable of updating the solution procedures about a problem. That is, if a user solves a problem successfully but the solving procedure is unknown to the system, MathCAL will add the new solution path to its database dynamically. Furthermore, as mentioned before, MathCAL allows users to add new problems to its test bank. The solution path(s) of each new problem need be provided to the system at the same time.

4. With MathCAL as a learning aid, users can concentrate on the application of concepts and rules during problem solving without being distracted by tedious computation. This also makes it possible for MathCAL to be used as an effective teaching aid in the classroom to demonstrate problem-solving procedures to the students.

5. Whenever MathCAL establishes a communication channel between a helper and a learner, it allows them to look at the work of each other. Namely, their screen displays are synchronized.
Such synchronization allows the helper to see the steps performed by the learner up to that point. The helper can also demonstrate to the learner how to solve the problem from that step on. Similarly, when a learner sends an e-mail message to another user asking for help with the problem, MathCAL transcribes the learner's problem-solving process from the Petri-net representation into text form and attaches it to the e-mail message automatically. This relieves the learner of the burden of lengthy explanation in describing his problem-solving difficulties.

(6) MathCAL provides a number of auxiliary tools to enhance its user-friendliness. For example, there is a notepad function for users to make remarks about a particular problem, which may later provide useful hints to the user when he tries to solve a similar problem. In addition, as a visualization aid to users, MathCAL also implements a Petri-net graph generator which can dynamically generate a Petri-net graph corresponding to a user's problem-solving process.

(7) The current version of MathCAL has been designed to solve trigonometric problems, but the system model underlying MathCAL's implementation can certainly be enhanced to solve problems of other topics. More importantly, the same model is not limited to solving mathematical problems. It can be used to model problem solving in any knowledge domain.

Conclusion

In this paper we describe how a user may interact with MathCAL to practice mathematical problem solving. We especially elaborate on MathCAL's database design and summarize MathCAL's distinctive features. Interested readers may refer to our previous papers (Lin et al. 1999, Lin et al. 2000a, Lin et al. 2000b) for other details about MathCAL. A working prototype of the Chinese version of MathCAL has been implemented using Java. Due to space limitation, we were unable to provide screen dumps of MathCAL in this paper. The prototype has proved that the Petri-net representation model supplemented by a carefully designed database does enable the system to exhibit a certain degree of intelligence in offering guidance to the learners. We are currently undergoing major design rework to bring a cleaner system structure to MathCAL and to improve its user-friendliness.

A Network Learning Environment to Support Control Engineering Learning

Juha Lindfors
Control Engineering Laboratory, University of Oulu
P.O. Box 4300
90014 University of Oulu
juha.lindfors@oulu.fi

Abstract: This paper presents some findings of a study conducted on the Control Engineering Laboratory at the University of Oulu. The study concerns analysis of enquiries and exam results of a control engineering course that deals with experiment design. Since 1994 new learning methods were taken into use on the course. Projects, collaborative learning, hypermedia and WWW were used to support lectures. The results of enquiries and the exams show that the new methods were adopted well among the students. The students who used the network learning environment passed the course as well as the students before. The exam results have improved from the beginning.

Introduction

Traditionally lectures and exercises of control engineering courses were carried out both in classrooms and laboratories. Along the traditional methods, hypermedia, network learning and other new methods were taken into use on the control engineering courses in 90's. Student feedback was collected when the new methods were taken into use. Special interest has been focused on the course Control Engineering Course II. Both open and closed, LCProfiler (Unknown, 2001), web environments has been utilised on the course.

The Study

An aim of the study was to find answers how the new methods affected to the motivation of the students. Moreover, an answer to the question if the students concerned the course important and interesting was looked for. In addition, grades of the students in the exams were studied in order to find out how the students learned on the course.

The data for the study was collected from the student feedback sheets. Additional data concerning the use of web in years 1999 and 2000 was collected using a questionnaire along the normal feedback. The grades given in exams from year 1993 to 2000 were analysed and frequency distributions were plotted. An average grade distribution was also calculated. The comparative presentations can be seen in Figures 1 and 2. Figure 1 shows the frequency distribution of courses lectured in years 1993 (no new methods used) and 2000 (new methods used.) In the Figure 2 the grade distributions of an average and the course in the year 2000 are presented.

Findings

Fails have decreased from the year 1993 to the year 2000. This can be seen in both figures. Moreover, the amount of higher grades has increased. If the students on the course in year 2000 are compared with the average year, the difference in the distributions can be seen in Figure 2. The students performed as well (or better) than the average. The development from the year 1993 when conventional learning methods were used is very clear, see Figure 1. The percentage of fails is lower and the percentage of highest grade is higher.

The effect of network learning environment to the learningmotivation was twofold, some considered the new methods motivating some did not. The following sample comments represents the attitudes. "Nice addition, but does not affect very much on learning" and an opposite comment "New things increases the interest."
Conclusions

The use of new methods on the course have affected to the performance of the students: the amount of fails have decreased and the amount of higher grades in the exam has increased. The affection of the Web cannot be seen in the results because several factors have been changed at the same time. Although, the use of web is one of the main factors on the course. There is also a variation between the courses (Jaako 2000), therefore additional studies will be needed. More data from a longer period will be needed. Besides, a change be it positive or negative, can affect positively to the results.

Abstract: In this research, we examined the impact of a cognitive apprenticeship-style learner-as-multimedia-designer environment on middle school students' cognitive skills development. The findings showed that engaging students as designers could increase their understanding of the importance of the cognitive skills involved. The skills mostly affected in this study included planning, presentation, collaboration, and testing. Following a design model used in the multimedia industry, the middle school students created multimedia projects for a real audience using state-of-art multimedia tools, and learned such design tasks as storyboarding, designing, and evaluating.

Theoretical framework

Promoting higher order thinking has been an issue of critical importance to educators. Research shows that appropriate uses of technology such as using computers as cognitive tools to extend human minds and help learners to construct their own knowledge can have potentials to enhance students' thinking skills (Jonassen, 1994). Engaging learners as designers is an instructional strategy that implements this constructivist idea. In a learner-as-designer environment, learners, instead of merely receiving information from computers, become an intellectual partner with the technology and engage in a constructive learning process (Salomon, Perkins, & Globerson, 1989). The emphasis is on using multimedia tools to assist in processing information meaningfully and in integrating new knowledge with prior knowledge. As designers, learners are given the opportunity to be creative and pursue actively their own intended goals. According to Seymour Papert, "better learning will not come from finding better ways for the teacher to instruct but from giving the learner better opportunities to construct" (Papert, 1990, p.3). Because of its nonlinear and associative characteristics as well as its use of various media, interactive multimedia is considered to be capable of assisting information presentation, representation, and construction, and capable of facilitating this learner-as-designer process (Jonassen, 1994; Lehrer, 1993).

Designing interactive multimedia programs is a complicated and challenging task. This designer role calls for many critical thinking skills. Sixteen major thinking skills have been identified that form five categories: (1) project management, (2) research, (3) organization and representation, (4) presentation, and (5) reflection (Carver, Lehrer, Connell, & Erickson, 1992). Each skill in these categories has its own place in the entire development process, and is needed for producing a successful program. The development process, from the inception of an idea to the finished product, involves not only exercising the aforementioned thinking skills but also learning various multimedia tools, working with team members, working against a deadline and, more importantly, making a strong commitment. As the practice in the real world suggests, multimedia development relies heavily on various talents in a team (Liu, Jones, & Hemstreet, 1998). Whether a team member is a
programmer, a graphic artist, a designer, or a manager, collaboration among team members is crucial. Although each member will have his/her distinctive role, the success of a multimedia program depends on constant communication and understanding between team members and their working together to reach the goal. Such collaboration and group interaction provides a concrete and meaningful context for enhancing cognitive development through social negotiation. It is the development of these cognitive skills (skills concerned with analysis, interpretation and decision making processes) that is the focus of this research. Specifically, we are interested in designing a learner-as-multimedia-designer environment to facilitate the development of such skills.

A number of studies have already documented the promising results of engaging students in the role of a designer. Some earlier studies were conducted using the Logo programming language. Harel (1991) engaged fourth-grade students as software designers in their Instructional Software Design Project (ISDP). Students used Logowriter to create instructional software on the topic of fractions for other students to use. As a result, students improved in their ability to work on fractions and learned more about Logo programming than the control groups. Qualitative data showed that students have developed problem-finding skills and increased their awareness of strategies to solve a problem. Kafai (1996) worked with students in designing games using the Logo programming language and discovered that students not only acquired design skills but also reached a high level of reflection beyond the traditional school thinking.

Spoehr’s study (1993) showed that students developed more complex knowledge representations and various thinking skills through the design of hypermedia programs. Similar results were found in the study by Lehrer and his colleagues (Lehrer et al., 1994). In their study, ninth-grade students used a program called HyperAuthor to develop hypermedia presentations about a topic in American history for their peers as an educational tool. As a result, students significantly increased their time on-task behavior and internalized some design skills over the course of their design projects. Students’ responses indicated their increased understanding in such areas as: (1) mental effort and involvement, (2) interest, (3) planning, (4) collaboration and (5) individualization.

Liu and Rutledge (1997) worked with a group of at-risk high school students as they designed multimedia projects for a children’s museum. In their project, student learning was scaffolded in several ways: (1) explicit design instruction, (2) learning state-of-art multimedia tools, (3) coaching by the teacher, and the clients, and (4) interaction with various multimedia experts. The result showed that students have significantly increased their interest and involvement throughout the project. Students steadily increased their time spent on the project and became more motivated in learning than the control group. Moreover, their self-efficacy was enhanced and they obtained a more positive image about themselves. Many students have reset their goals for the future—to work in multimedia design profession rather than working in fast food restaurants. In terms of the production and design knowledge, students have recognized the importance of storyboarding and collaborating with team members.

Designing such a constructivist learning environment is not easy. It involves the learners, the tasks, the context, the process, the coaches/teachers and the outcome. While initial studies on this topic have given us a good picture of what is possible through engaging students as designers, more research is called for to understand how to construct such an environment effectively and study various factors contributing to a successful environment. While studying how elementary, middle and high school students were involved in creating multimedia programs, McGrath and her colleagues (1997) suggested that there may be an age difference in readiness for design—with the sense of responsibility absent at the elementary level, very mixed at the middle school level and very impressive at the high school level. They raised the hypothesis that novelty may be the factor for student motivation. Other research showed that while students were highly motivated in many respects and were on task, the critical design skills of planning, and time management were not easy for them to acquire (Liu & Rutledge, 1997).

Given the benefits of the learner-as-designer approach, it is obvious that to achieve the goal of enhancing cognitive skills, much depends on how such an environment is constructed and various factors (learner, tasks, the context, the process, the coaches/teachers and the outcome) interact with each other. This present study is designed to understand the impact of a cognitive apprenticeship-style learner-as-multimedia-designer environment on middle school students’ cognitive skills development.

**Research question**
The purpose of the research is to examine in what way a learner-as-multimedia-designer environment affected middle school students' cognitive skills acquisition. The research question is:

Are the middle school students' cognitive skills affected by engaging in the role of being a multimedia designer? If so, to what extent?

Design of the study

Participants

The participants were students in an elective multimedia class (N=16) from a middle school in the southwestern part of the United States. Eighty percent of the student population was white and 20% was of a minority race. There were five female and eleven male students. To get into this multimedia class, students needed to have a GPA of B and above, recommendations from two teachers and an essay describing why they wanted to take this class. These seventh and eighth graders had fairly high computer skills. Many had used software such as Clarisworks, Hyperstudio, Photoshop, and internet. Four students were in the multimedia class for the second year. The class was co-taught by an art teacher and a multimedia teacher. Students spent roughly two-thirds of their time in using computers and one-third in learning art using a non-computer based art curriculum.

The Learner-as-Multimedia-Designer Environment

The study took place during the spring semester of 2000. The multimedia class met every day for forty-five minutes for a total of eighteen weeks. This school offers a multimedia class as an elective for its seventh and eighth graders (which is not common for most of the middle schools) and the curriculum is in existence for the second year. At the time of the study, the class had access to five Power Macintosh computers, 15 Dell computers, a color scanner, a digital camera and a video camera. Professional multimedia software were also available for use such as Adobe Photoshop, Adobe Premiere, and PowerPoint. However, not all computers were equipped with all the software and zip drives. Students needed to share the resources, and transfer files from one platform to another, or one computer to another (as some computer were more powerful than the others). The PC and the Mac labs were quite a distance away from each other. With a very tight schedule in the middle school, it was challenging for students to make full use of the 45 minutes while transferring files or waiting for their turn to get onto a computer with some specific software.

The organization of the class consisted of three phases. Phase I (approximately five weeks) was devoted to learning software and creating a small presentation file as practice. The goal for this phase was to learn the tools and be able to use state-of-art multimedia software. Phase II (approximately eight weeks) focused on working in groups and creating a large presentation program for use in the upcoming teacher job fair. Students followed a 4-phase development model used in the multimedia industry (Liu, Jones, & Hemstreet, 1998) and created a project for a real audience. Students assumed the role of a researcher, a graphic artist, a programmer, a project manager, and audio/video specialist, depending on his or her preference. Cognitive aids such as storyboard and flowchart samples were presented to students to provide guidance on their planning of the project. Students also provided feedback to each other, and received feedback from their peers, teachers, researchers, and the client. During the course, students made a field trip to a local multimedia company and got first-hand experience of what it was like to be a multimedia designer.

In Phase III (approximately three weeks), students used the skills they acquired and worked on creating a web site template for their school. While students received direct instruction and much guidance during phases I & II, such instruction and guidance were gradually faded in Phase III. Students were very much on their own, applying the skills and making their own decisions. Guidance and assistance were provided as needed. While the goal for Phase II was to provide needed scaffolds for the middle school students and helped them acquire important design skills, the goal for Phase III was to see if the students could apply what they learned on their own in a new situation.

Data Sources & Analyses
Multiple data sources were used. The triangulation of the data was to provide a better picture of the process under study.

**Project Design Questionnaire.** A 20-item questionnaire based upon Lehrer and his colleagues’ work was used to assess learners’ various cognitive skills needed in producing multimedia projects (Lehrer, et al., 1994). Each item used a five-point Likert scale with one being "not true of me" and five being "very true of me." The 20 items addressed six categories: audience (3 items), presentation (2 items), planning (3 items), interest (5 items), mental effort (2 items), and collaboration (5 items). Sample statements included "I often ask myself about the best way to present an idea, like should I use a graphic or just write about it," "I think having other students look at my project is important," and "Doing projects sure beats listening in class." The KR 20 for the questionnaire was .82. Students completed the instrument at the beginning and the end of the project. Paired-tests were conducted.

**Task Ranking.** Students were given a list of ten tasks relevant to their project development, and were asked to rank the tasks according to their relative importance. Some of the tasks were "Making the graphics very colorful," "Have someone to try out the program," and "Plan and write down on your index card what your card will look like." This instrument has been used in a number of research studies on the same topic (Lehrer et al., 1994; Liu & Rutledge, 1997). Students were given this instrument at the end of the project. Descriptive analysis was conducted.

**Concept Map.** Students were asked to complete a pre-concept map and a post-concept map on the concept of “multimedia development.” Students were given the core node “creating a multimedia project” and were asked to create a concept map of any concepts they would link to the core node and label the importance of each link. At the beginning, a brief tutorial on creating a concept map was given and each concept map generation took about 15 minutes. The differences in the two concept maps were analyzed descriptively in terms of the depth and breadth of the nodes listed.

**Reflection Logs and Interviews.** Students were asked to reflect on their learning experiences after phase II as well as Phase III. For each reflection, students were given some questions. Sample questions included “Of all the things we have done this semester for this multimedia class, what activities do you like the most? Why?,” “What activities do you like the least? Why?”

Interviews were conducted with the students on their design and thinking process at the end of the research. Following Miles and Huberman's guidelines (1994), the data were transcribed, chunked, and coded using themes emerged from the data. These qualitative data together were to provide richer and more detailed information, and were used to substantiate the results from the statistical analyses.

**Results and Discussion**

The paired-T tests showed that there were no statistically significant differences between the pre-test and post-test scores. However, the mean scores for the posttest were slightly higher than those of the pre-test for the categories of (1) audience, (2) presentation, (3) planning, and (4) collaboration (see Table 1).

<table>
<thead>
<tr>
<th></th>
<th>Mean_{Pre-Test}</th>
<th>Mean_{Post-Test}</th>
<th>T-value</th>
<th>p-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Audience</td>
<td>3.88 (.104)</td>
<td>4.15 (.68)</td>
<td>-1.13</td>
<td>.27</td>
</tr>
<tr>
<td>Presentation</td>
<td>3.84 (.83)</td>
<td>4.0 (.67)</td>
<td>-.55</td>
<td>.59</td>
</tr>
<tr>
<td>Planning</td>
<td>3.25 (.56)</td>
<td>3.40 (.61)</td>
<td>-.85</td>
<td>.41</td>
</tr>
<tr>
<td>Interest</td>
<td>4.16 (.51)</td>
<td>3.90 (.67)</td>
<td>1.39</td>
<td>.19</td>
</tr>
<tr>
<td>Mental Effort</td>
<td>4.0 (.86)</td>
<td>3.6 (1.11)</td>
<td>1.35</td>
<td>.20</td>
</tr>
</tbody>
</table>
Though not statistically significant, the T-test analyses showed the post scores were a bit lower than the pre-scores for the categories of (1) interest, and (2) mental effort. The interview and observation data also showed that these middle school students grew a bit bored of the same development process used for Phases II & III, and became less interested toward the end. Multimedia design skills such as brainstorming, storyboarding, designing and testing/evaluating were new skills for the students to acquire. It was intentional that Phases II & III followed the same 4-phase model so as to provide multiple opportunities for the students to acquire and practice these skills. During the each phase, a considerable amount of time was spent on the apparently “boring” tasks of planning, designing, and testing. The data showed that the students became aware of the importance of these tasks, but they may not like doing them as much as learning software programs (also see below). This finding seemed to be in line with other research showing novelty can play a role in middle school students’ motivation (McGrath et al., 1997). The challenge for the teachers and researchers is to keep the students interested while engaging them in the more important, but less fun, tasks such as planning, designing and evaluating.

Students were given a list of ten design tasks to rank their relative importance. The more important tasks in the students’ opinion included “Discuss with your group what info to include,” and “Research and find relevant information.” “Plan and create a storyboard of what your program will look like” (see Table 2). The less important tasks included “Making animation,” and “Making sounds.” It is interesting to notice that the important five tasks were all related to planning and designing. Four out of the five less important tasks were related to the mechanics of creating the media.

</table>

* The lower the mean, the higher the importance.

There is a significant difference in the number of concepts accurately listed by the students from their pre-concept map to the post-concept map: t(1,14) = -3.14, p <.01. Students listed significantly more relevant concepts in the post-map. In the pre-concept map, most of the nodes were about the production and only twelve nodes were about some aspects of planning, or designing. This number increased to 41 in the post-concept map. More importantly, the concepts of “storyboarding,” “designing,” or “testing/evaluating” were not mentioned at all in the pre-map while they were listed for 27 times in the post-map. The concepts listed in the pre-map were less concrete and to the point.

The interview and reflection data provided more information to show that students had acquired some understanding of the importance of planning and testing, and the need to work well in groups. One student said, “If we have another project, I’d suggest everybody have fun doing it and do it faster and have time to revise it. And plan ahead so that we have time in the end.” Another commented on the process: “I think working in a group
has its advantages as well as working on it by yourself. You can overcome obstacles together. Our group worked well together. If somebody in our group didn’t participate and contribute as much, then we go and talk to the person and tell them: ‘Look, we need your help and we need to finish this project on time, or we will get a bad grade. You should help or you should come after school and finish your part by yourself.’ It usually worked.”

Being a multimedia designer is often associated to a professional job. Middle school students do not usually get an opportunity to be in that role. The results of this study showed that engaging middle school students in being a multimedia designer can have positive impact on their cognitive skills acquisition. Though promoting higher order thinking is an educational goal, it is usually a challenge for twelve and thirteen year olds to realize their importance and to develop such skills consciously. The learner-as-multimedia-designer environment provides a structure and an opportunity for the development of such cognitive skills. In this environment, the students had a multimedia development model to follow, a concrete project to work on, a deadline to meet, and a client to be responsible for. All these provided necessary scaffolds to the middle school students. The findings showed that the middle school students began to acquire an understanding of the important design tasks such as storyboarding, designing, and testing, though they may not often like these activities.

Learning a piece of software and creating a program with it is a typical way of multimedia authoring in a classroom. Engaging students as multimedia designers, on the other hand, extends multimedia authoring by placing students in a designer position. Instead of merely learning the technical skills and creating a project, the designers need to consider other issues such as the needs of the audience, the distribution of work in a group, the management of time and resources, and the deadline. They need to implement steps such as planning, designing, evaluation, and discussion. The authenticity and complexity of the design tasks provide students a learning environment where they can develop cognitive skills and skills of high value to the work place. This study investigated the effect of being multimedia designers on middle school students’ learning of design knowledge, and showed that such an environment can facilitate the development of cognitive skills for the middle school students.

Abstract: Web based curriculum development allows students to develop their learning portfolio and interact with peers on a web learning system. This system contains web portfolios that record in detail students' learning activities, peer interaction, and knowledge progress. However, teachers can not easily diagnose students' learning processes and regulate effective strategies according to student activity performance without the model of activity performance on web learning systems. This investigation proposes a novel methodology that employs Bayesian network software to assist teachers in efficiently deriving and utilizing the student model of activity performance from web portfolios in an online manner. Teachers can assess and diagnose performances with the model of learning activity on web learning systems. The model of activity performance also allows teachers to manage various activity performances in web learning systems so that desired strategies can be achieved to promote learning effectiveness.

Introduction
Teachers normally assess and diagnose students' learning activities based on the student model developed from teachers' experiences. The student model includes all aspects of the student's behavior and knowledge that impact their performance and learning (Wenger et al. 1987). For instance, Burton et al. (Burton 1982) constructed a student model of learning procedural skill to diagnose students' misperception in the learning skills. Fletcher et al. (Fletcher 1975) also developed a student model in computer-based instruction to understand students' learning status in computer aid instruction. Similarly, teachers can understand the model of activity performance on web learning systems by analyzing web portfolios because these portfolios record in detail students' learning activities, peer interaction, and knowledge progress.

Related studies (Burton 1982, Chi 1982, Conati 1997, VanLehn & Martin 1997) have explored how students think and behave in order to diagnose and maximize the learning effect in intelligent tutoring systems. Teachers can know how individual students learn concepts or skills via the developed student models. The student models of intelligent tutoring systems focus on the states of knowledge and skill of individual students. However, a web learning system allows many students to learn and interact with peers on the Internet. Teachers may enforce group learning strategies such as collaborative learning (Johnson 1993) and peer support (Baker & Dillon 1999) to promote learning effect. In doing so, a teacher can intervene in the student learning process by closely observing their behavior in peer interaction. Therefore, in addition to domain knowledge of the learning concepts addressed in individual student models, teachers must know from the student model how students behave and perform in portfolio development processes and how they interact with peers on web learning systems to effectively interact with their students on the Web.

Teachers construct a student model by closely monitoring students' learning processes. For instance, Mitrovic et al. (Mitrovic 1996) proposed a methodology to develop a student model of problem solving by engaging students in explicit dialogues about problem-solving decisions. However, teachers can not develop the students' activity model via interactive observation in a web learning system. Although the web learning system can log many behavioral records in web portfolios, inducing the relationship structure among various activity records and how these records affect each other is extremely difficult. Such difficulty is owing to that these activity records contain a large amount of various types of complex data and interweave with each other. Consequently, teachers can not easily derive the model of learning activity on web learning systems that impact learning performance.
**Student modeling from web portfolios**

Deriving the student model of activity performance on web learning systems for diagnosis and strategy regulation involves collecting portfolios, discovering causality structure among activities, as well as inferring students' performance from the observable activities. While using web-based learning systems, teachers have difficulty in obtaining and using the student model for strategy regulation and diagnosis purposes. These difficulties are summarized in the following problems.

The first problem is the lack of support for analyzing the causality relationship among various learning activities and performances. Teachers can predict student learning performance and adapt proper strategies at an early stage by analyzing available learning factors. To derive a student model that impacts student learning performance, teachers must answer questions such as “What behavioral factors affect student learning outcomes with respect to various types of activities in a Web learning system?”, and “How do various types of learning activities affect each other? Does a student who often answers others' questions tend to submit homework on time?”. Therefore, a teacher requires convenient support for inducing the causality relationship and impact factors that can explain how various student learning behaviors and performances are related. This is commonly referred to as the causality discovery problem.

The other problem teachers have is answering probability questions such as “If a student often answers others' questions, what is the probability of that student achieving a good learning outcome for a particular learning concept?” and “If students achieve a poor learning outcome for a particular concept, how will they behave in the discussion activity?” To answer these questions, the teacher must compare the learning records of web portfolios for current students with similar web portfolios of previous students. Teachers can also apply the student model developed from previous web portfolios to accurately predict the behavior and outcomes of current students. However, as the available records in web portfolios have a sophisticated causality structure, teachers have difficulty in inferring student performance, commonly referred to as the performance inference problem, because estimating a student's behavior or performance involves complicated computation of probability.

**Purpose of study**

This investigation presents a novel methodology to assist teachers in deriving and using a student model in a web base learning system. Bayesian network software (Pearl 1988), a data miming and machine learning technique, is employed herein to facilitate teachers not only in reasoning the causality relationship among various activity performances in web portfolios, but also representing the relationship in probabilities for estimating students' performance. Such probabilistic reasoning can analyze student performance because it provides a mathematically sound means of handling an uncertain situation in assessment. With this methodology, teachers can go online and efficiently use web portfolios to derive and apply the model of students’ learning behavior in web learning systems. Teachers can assess and predict student learning performances with the model of students’ learning behavior. Doing so allows them to diagnose learning processes and closely monitor strategies to enhance learning.

**Web portfolio system of using Bayesian network**

In the learning programs, teachers identified ten essential concepts in C programming language: input/output, data types, arithmetic operations, switch control, iteration, if-than-else alternations, functions, message passing, array, and recursions. Students must develop portfolios for each concept and discuss it with other students on the web learning system. Meanwhile, teachers utilize the web portfolios to diagnose students’ learning activities and fulfill the peer support (Baker & Dillon 1999) strategy. The peer support strategy entails recommend experts to students proposing learning questions. The expert must be willing to answer other students' questions. Analysis of students' portfolios can help a teacher diagnose student activity performance and enforce the peer support strategy. Analysis involves the following portfolios:

- Portfolio development activities, including the behavior associated with submitting homework, notes, experiences, and self-reflection.
- Discussion activity and learning behavior in the web portfolio system, including frequency of using the learning system, reading behavior, posting and replying in the discussion activity.
- Portfolio content assessments, including teachers’ assessment of students’ learning outcomes of the ten learning concepts by examining the products developed by students and quizzing them to assert their self-reflection.

To efficiently diagnose students' learning activities and fulfill peer support, teachers must know how portfolio development behavior, discussion behaviors, and learning outcomes are related in various learning concepts. For instance, teachers must diagnose students’ learning processes and recommend proper students to answer other students’ questions by asking the following questions:
- Which student is willing to answer others' questions and excel in a certain concept? What are the behavioral characteristics of the student in observable learning activities such as developing homework, experience reports, and self-reflection?
- If students overestimate their learning outcomes during self-reflection, can they effectively grasp learning concepts?
- What are the behavioral symptoms when students fail to grasp a specific learning concept?
- How are the ten learning concepts related? That is, does any concept heavily influence the learning outcome of other concepts?

![Diagram](image)

Figure 1. Student modeling of learning performance with Bayesian network software

Figure 1 illustrates how teachers analyze and use student model by using Bayesian network software from web portfolios. Students initially develop learning portfolios and discuss with peers in the web learning system. Meanwhile, the web learning system automatically records students' portfolios development processes and discussion behavior in the web log. After student portfolios, learning process and discussion records, as well as assessment results of students' portfolios are accumulated in a database, Bayesian network software enables teachers to induce the student model of activity performance in portfolios in a Bayesian belief network. The belief network clarifies the relationship among various activity performances in probabilistic rules. Hence, teachers can go online for utilizing the experienced rules to diagnose students' learning processes and regulate strategies.

![Diagram](image)

Figure 2. Belief network of student learning performances
Bayesian network technologies for performance modeling

Teachers can use the Bayesian network software to reason how various activity performances are related. For instance, VanLehn and Martin (VanLehn & Martin 1997) applied Bayesian network to discover the causality among 230 physics rules to diagnose students' learning status. Bayesian Knowledge Discoverer (BKD) is used herein to discover the causality relationship among performance of portfolio development activity, discussion activity, and learning achievement in various learning concepts. BKD analyzes the students' portfolios and produces a belief network to explain the causality relationship among various activity performances, as illustrated in Fig. 2. The Bayesian network analysis includes the following activity performances:

- **Reply**: the performance of answering others' questions which is classified into Y (ever answered others' questions) and N (never answered others' questions).
- **Post**: the performance of proposing new issues or questions which is classified into Y (ever posted issues or questions) and N (never posted issues or questions).
- **Read frequency**: The frequency that students read articles in discussion activity which is classified into classes H (high), M (middle), and L (low).
- **LA of previous concept**: the learning achievement in previously learned concepts which is classified into classes A, B, C, D, and E.
- **LA change of previous concept**: The change of learning achievement in previously learned concepts which is classified into classes prog (progressive), same (the same), and regre (regressive).
- **LA**: The learning achievement in the learning concept which is classified into classes A, B, C, D, and E.
- **Self-reflection**: The accuracy of students' self-evaluation of learning achievement on the learning concept which is classified into classes OVER (over estimate), FIT (fit estimate), UNDER (under estimate), and N (absent).
- **Experience report**: the time require for students to submit their experience reports which is classified into classes F (on time), L (delay), and N (absent).
- **Notes**: the time require for students to submit their notes which is classified into classes F (on time), L (delay), and N (absent).
- **Homework**: the time required for students to submit their homework which is classified into classes F (early), M (on time), and L (delay).
- **Homework Self-reflection**: the time required for students to submit their homework self-reflection which is classified into classes F (early), M (on time), and L (delay).
- **Reading Self-reflection**: the time required for students to submit their reading self-reflection which is classified into classes F (early), M (on time), and L (delay).
- **Login**: The frequency students login the learning system to develop portfolios which is classified into classes H (high), M (middle), and L (low).

The belief network illustrates how various activity performances in portfolios with respect to cause and effect. For instance, the learning achievement (LA) in previously learned concept (A, B, C, D, or E) and the learning achievement change in previously learned concept (Progressive, Regressive, or Keep in the same) dominate the learning achievement (LA) (A, B, C, D, or E) in the current learning concept. In addition, the learning achievement of the learning concept also dominates the students' replay behavior (Ever or Never) in discussion activity, student self-reflection accuracy (Over estimate, Under estimate, Fit estimate, or Absent), and the submission time of experience reports (on time, delay, or absent). The bar chart beside each node represents the probability of student performance without any prior condition. For instance, without any available observable phenomenon, a student has a probability 0.24730 to attain learning achievement (LA) A, 0.19235 learning achievement B etc. A student has a probability 0.87348 not to reply others' questions or issues and 0.12652 to reply others' questions or issues.

Bayesian network software discovers not only the causality relationship, but also the impact factors among various learning performances. The impact factors are represented as a conditional probability notation. Restated, under an observable activity performance, a student has a certain probability to achieve a specific activity performance. For instance, a student has a probability of 0.37 to attain learning achievement B in a learning concept, but has only a probability of 0.04 to attain learning achievement A, if the student has learning achievement A and has been regressive in a previous concept. Table 1 lists the impact factors of learning achievement of a previously learned concept on the learning achievement of a learning concept. Table 2 summarizes the impact factors on reply performance by conditional probability in the web learning system.

Using the discovered causality relationship and impact factors, Bayesian network software also facilitates teachers to estimate students' learning performance from observable conditions. For instance, Figure 3 estimates students' learning achievement (LA) from learning achievement in a previously learned concept. A student has a probability of 0.5 to attain learning achievement A or B if the student with learning achievement B has been progressive in a previously learned concept. Figure 7 estimates learning achievement from the performance of discussion activity. A student has a probability of 0.65087 to attain learning achievement A and a probability of 0.34913 to attain learning achievement C, if a student replied to others' questions. Therefore, use of Bayesian network software allows teachers to accurately predict students' activity performance and, hence, to diagnose learning processes or fulfill strategies from observable phenomenon.

Figure 3. Estimation of students' learning achievement (LA) from performance of discussion activity with a discovered belief network

In sum, the web log and Bayesian network technology satisfy a teacher's requirement of effectively diagnosing student learning processes and managing teaching strategies because they overcome the difficulties in
obtaining and utilizing the student model of learning performance in the web learning system online. First, the web log mechanism of web servers automatically records students' learning activities to help teachers obtain behavioral portfolios. Second, Bayesian network software facilitates teachers in inducing the belief network and impact factors among various learning performances. Third, teachers can utilize the belief network obtained from historical data to estimate various activity performances.

**Conclusion**

As students learn and develop learning portfolios on the World Wide Web, web portfolios completely record student learning processes, learning products, and interaction history. Although such web portfolios are collected in an electronic format, teachers lack computational support in deriving and utilizing student model of learning performance to utilize web portfolios. This investigation has described how teachers should effectively assess activity performance and fulfill pedagogical strategies by using portfolios. A web log methodology is proposed herein to accumulate the students' behavioral portfolios. This investigation also illustrates the experience of using Bayesian network technology to help teachers derive and utilize a student model of activity performance. Bayesian network technology can help teachers discover a belief network that not only impacts student performance from web portfolios, but also allows teachers to utilize the belief network to diagnose or intervene in students' learning processes at an early stage. Electronic web portfolios enable teachers to assess activity performance and analyze pedagogical strategies in an online and efficient manner. Therefore, teachers of a web-based learning system can also extend the use of web portfolios and Bayesian network technology for other pedagogical purposes with relative ease.

Abstract: Cartography is a discipline that focuses on the visualization of geographic data. In the cartographic classroom, students learn how to gather, measure, manipulate, and represent (using a map) data. Emphasis is often placed on different types of maps, specific methods of mapping, and map design guidelines. Nearly all cartography courses are taught in a traditional classroom setting and include both a lecture and a hands-on lab component. However, distance learning is permeating all disciplines, including geography. As a result, a research study was designed to evaluate the potential impact of a virtual, distance learning, cartography laboratory. This paper will present the research design, including the design of the virtual lab and accompanying course web page as well as the study results, including student and instructor impact.

Introduction

Cartography is a discipline that focuses on the visualization of geographic data. In the cartographic classroom, students learn how to gather, measure, manipulate, and represent (using a map) data. Emphasis is often placed on different types of maps, specific methods of mapping, and map design guidelines. Nearly all cartography courses are taught in a traditional classroom setting and include both a lecture and a hands-on lab component. However, distance learning is permeating all disciplines, including geography. Even courses that are taught on campus in a classroom have a distance-learning element, as many instructors create course web pages, which may include syllabi, announcements, lecture notes, study guides, and student grades. While course web pages serve as useful resources and even contain instruction-related material, they usually are not designed to serve as a substitute for classroom instruction. But, the demand for more course scheduling flexibility continues to push the envelope towards including more distance teaching/learning in many curriculums.

The reasons for the expansion of distance education are varied. Maybe the two most significant factors are the changing student population and the improving technology. As a national trend, student populations are getting older and are less interested in full-time, resident education. In fact, 40% of students claim to be part time and the percentage is only expected to increase (Chute, Hancock and Balthazar, 1991). As a result, students are demanding flexibility in time and geography; they want to take classes that adhere to their schedule and they want minimal (if any) travel. Technology is a driving force behind the boom in the number of distance education courses conducted. The correspondence course of the past had made way for technology-enhanced methods of instruction delivery (Moore 1986, Beller & Or 1998) including, television courses, teleconferencing, computer-conferencing, and most recently Internet delivery.

Distance education, in its purest sense, is not geographically constrained; the students and the instructor do not meet for instruction. In fact, students may not be located in the same town, the same state, or even the same country as the instructor. As a result, most distance education courses are designed to serve students who rarely or never visit
the actual campus. However, on-campus students are also beginning to demand more scheduling options as a result of a national trend in increased student employment. The number of students who maintain full-time or part-time employment along with a full course load continues to rise. In 1996, over 40% of freshmen reported that they would work in some capacity to help pay for college, while only 34.7% of freshmen reported working in 1989 (Furr and Elling, 2000). The increase in college students’ employment responsibilities results in less time available not only for studying but also for attending class. Colleges currently attempt to meet these students’ needs by offering a variety of time options, but adopting a distance-learning component into a campus-based course may provide more flexibility, while maintaining high academic standards. How to incorporate distance-learning components into course has not become a standard procedure though. Presently, the design of these courses is very dependent on the technology available to the instructor and students (Wells 2000). But as technology pushes forward, opportunities become available for educators in all disciplines to explore and offer distance-learning courses in their fields.

The research presented in this paper focused on incorporating distance education into a classroom-based cartography class. The objectives were not to design and evaluate a pure distance education course; rather the goals were to determine how on-campus education may be enhanced in terms of instructional flexibility and educational effectiveness. Two primary research questions were addressed. How should a virtual cartography lab be designed? Can cartography, a graphics-oriented discipline, which has traditionally included a very hands-on instruction format, be effectively taught with a virtual lab component?

Methods

The educational impact of utilizing a virtual cartography lab was tested using two Introduction to Cartography classes. One class (Class 1) met Mondays and Wednesdays, while the other (Class 2) met Tuesdays and Thursdays; both classes occupied the 2:00pm to 3:50pm time slot. Class 2 functioned as the control group and was taught using a traditional method, which comprises 2 hours of lecture and 2 hours of lab per week. A virtual lab was introduced to the curriculum of Class 1, whose students completed most labs through a distance education format. A two-sample difference of means test was conducted on both the exam scores and the lab scores from each class to determine whether a statistical difference existed between the two groups. The design of the virtual lab along with the curriculum differences is discussed below; results are presented and discussed in the following section.

Designing the Virtual Cartography lab

Computer mapping often requires specific software that is not commonly installed on most computers, including university computer labs that are accessed by students. As a result, availability of the specialized software needed for mapping exercises was a critical factor of this experiment. The software, ESRI’s ArcView 3.2, was made accessible in two ways. First, the main university computer lab offers 24-hour admittance to all students with a current identification card. A university-wide license of ArcView was obtained and all PCs in the main university lab were equipped with the software, making it available to students 24-hours per day, 7-days per week. Second, a Microsoft Windows 2000 Terminal Server (an internet server) equipped with Citrix Metaframe software was installed in the geography department. This server allows the network administrator to make a selection of software running on the main department server accessible via the Internet to anyone with a valid username and password. Therefore, students are able to access the fully functioning version of software with the same interface as though it were running on their home computer, which in reality, functions merely as a host. Only two programs housed on the main department server were selected for Internet server accessibility. Both programs, ESRI ArcView and Macromedia Freehand, are utilized in the introductory cartography course.

In addition to making software available, the actual laboratory exercises needed 24-hour accessibility. A course web page was designed specifically for Class 1 (the virtual lab group). The page was created using the BlackBoard program, Internet course management software. This program allows instructors to create course web pages onto which students logon using an assigned user-id and password. The page maintains course documents, including the laboratory exercises in Microsoft Word format, student grades, and an announcement page primarily used to remind students of the due dates of the virtual laboratory assignments. Also, because communication is an important element of any distance education (Wells 2000), the course web page included a chat room in which students could post questions to the instructor or to other students. The chat room was designed so students could ask questions in text format or post a graphic (such as a map) accompanied with a question. The class was regularly encouraged to visit the web page to check for assignments and due dates.
The lab component of both classes included 11 assignments, most of which were map-making exercises. Class 2 completed all assignments during scheduled class time, while class 1 (the virtual group) completed 7 entire assignments and part of 3 others through the distance education format. One assignment required aerial photographs and was, therefore, completed in class (in the future, however, the photographs will be scanned and made available on the internet server). For three assignments, students needed to collect position readings using a Global Positioning System (GPS) and then complete mathematical calculations in two exercises and create a map in the other. The positions were collected during class and the remainder of the assignments was completed outside of class.

Students in both groups were given the same assignments and were allowed at least one week for completion. The traditional group (Class 2) received the assignment instructions on lab day and worked on the exercises in the lab with the instructor and a teaching assistant (usually present) available for help. The virtual group, however, was informed in class when the week’s assignment had been posted to the course web page; they were encouraged to e-mail either the instructor or the teaching assistant with any questions regarding the lab, but, otherwise, completed the assignment independently.

Because the virtual lab group completed most assignments outside of class, more in-class time was available for review of lecture material. No additional material was introduced to this group that wasn’t introduced to Class 2. In fact, all lectures were accompanied by PowerPoint presentations, which were identical for both groups. Instead, the extra time in Class 1 was devoted to more thorough discussion of the material presented. In addition, in-class worksheets that address famously troublesome topics such as locating positions using the Universal Transverse Mercator (UTM) coordinate system, calculating standard deviation, or determining distance and azimuth between UTM positions provided reinforcement of the subject as well as “self-checks” of student understanding. The same worksheets were made available to Class 2, but, because time did not permit completion in class, they were advised to work on them outside of class.

Results

Data were gathered in two areas. First, a log of time spent by both the instructor as well as the teaching assistant was kept to evaluate time spent outside of class with each group and second, student performance was assessed through exam grades and exercise grades.

Outside Class Help

All time spent helping students outside of scheduled class time with both lab assignments as well as lecture material related questions were logged. However, no distinction was made between time spent answering lab questions as opposed to lecture questions. Initial attempts to document time spent in each area failed as sometimes questions and answers permeated both areas of the course; therefore, a categorization of time proved impossible. Instead, the total amount of time spent with each student in each class was recorded and summed over the course of a week. Following meetings with students, a brief summary of questions addressed during the meeting was recorded. From the total time spent per week, a mean number of hours per week was calculated for each class. The results reveal that 2.4 hours per week were spent helping the virtual lab group, while only .8 hours per week were spent with the traditional group. While time spent on lab questions was not distinguished, the summary of meeting questions revealed that most of the out of class time spent with the virtual lab class was devoted to answering exercise-related questions and most time spent with the traditional lab group was devoted to answering lecture-related questions. However, this analysis is qualitative and was made through reviewing the log; no statistical summary is available.

Student Performance Assessment

Two-Sample T-Tests were conducted to assess student performance in two areas, laboratory assignments and exams. For both analyses, a significance level of 0.05 and a critical value of 1.684 were established. The analyses were conducted using the SPSS software program. The null hypothesis developed for the laboratory assignments analysis stated that the two classes were the same (had similar assignment grades). The calculated value was 1.608; because
this value was lower than the critical value, the null hypothesis could not be rejected. The null hypothesis for the exam grades was that the two classes maintained equivalent exam scores. The calculated value was 1.679, which was also lower than the critical value and again the null hypothesis could not be rejected. Overall, the analyses indicated that no statistical difference in either laboratory assignment grades or exam scores existed between the two classes. The inclusion of a virtual lab component in Class 1 could not be proven to be beneficial in the area of student grades.

Implications

One of the most significant limitations of the virtual lab was student uncertainty of lab expectations. More instructor time was spent outside of class answering lab exercise related questions for students in the Class 1 than in Class 2. The virtual lab students seemed less certain of expectations than did those students in the traditional group; frequent questions were “am I doing this right” or “does this look right.” Possibly the reason for the reservation on the part of the virtual group was due to the fact that most students worked independently, as opposed to the traditional group, who completed the assignments during class time, allowing for peer as well as instructor input. Although a method of virtual communication was provided (the chat room on the web-page) for Class 1, a map looks very different on a screen than it does printed; in fact very different design techniques are applied to virtual as opposed to printed maps. In addition, when reading a map and providing feedback, the reviewer often draws arrows indicating where to move objects, inserts text, or re-draws map symbols as suggested changes. Reviewing a map posted to a web page is more difficult for the reviewer (and therefore less likely to occur) and probably less informative for the map designer since suggested changes would be textual only.

One way to help alleviate the uncertainty could be to include high-quality examples of what the final map should look like for each assignment. However, peer or instructor input would still be absent and feedback is crucial in the map design process (Dent 1998), without it, the designer may feel uncertain about the effectiveness of the design or about the map’s overall communication. Including a “feedback session” in class, in which students share their maps-in-progress, may provide an opportunity to include the critical feedback into the students design process, although the labs would then cease to be virtual.

Overall, the research presented revealed three significant implications of including a virtual lab component in an on-campus cartography lab. 1. Providing 24-access to the computer programs along with basic lab instructions is not sufficient; students are denied the input necessary during the map-making process. 2. The additional class time in the virtual lab class did not significantly improve student exam grades. 3. The virtual lab class required more instructor time spent outside class with students, trouble-shooting computer hardware/software/printer problems, and designing the necessary course web page.

In conclusion, distance education has been shown to be an effective teaching method in select cases. However, cartography is a field, which necessarily requires instructors to develop artistry and creativity in students. The cartographic “eye” is often developed through hands-on mapping exercises, which requires a significant amount of feedback and a virtual lab, by design, results in map-making in near isolation.

Distance education may be shown to be an effective educational delivery method in many disciplines. However, just because it is technologically possible to construct a distance-learning course doesn’t mean that it will be effective. The results of the research presented here indicate that some types of courses, including the cartography lab and the map-making process, in general, may not be delivered as effectively as others through distance instruction.

Give It A Go! - Using Interactive Digital Television To Help Passive Viewers Become Active Learners

Matthew Love

Sheffield
England
m.love@shu.ac.uk

Abstract: Significant number of adults have problems with basic literacy, numeracy and communication skills. Interactive digital television is currently being developed to meet commercial and entertainment needs, but educationalists may be able to use it too, to deliver active learning opportunities directly to the home, workplace or place of viewing. The paper describes the use of DVD, satellite and cable systems to deliver interactive learning, citing experience drawn from the Upgrade2000 project.

Introduction

Seventeen percent of European adults are unable to calculate the change they should expect to receive in a simple shopping purchase. Ten percent cannot pick out the time and venue of an event from a publicity poster. People with significant difficulties with basic numeracy, literacy or communications face a bleak future: in the UK they are five times more likely to be unemployed. If they do find employment it is twice as likely to be officially classified as lowly paid. Sixty percent of the prison population have basic skills problems. At any time only five percent of adults with basic skills problems will receive formal assistance (All figures from Moser, 1999). The UK government is co-ordinating attempts to address these issues through the Basic Skills Agency (BSA).

This paper outlines why television, and especially interactive digital television, is an effective medium for reaching people with basic skill learning needs. It describes the Upgrade2000 project, which developed a series of interactive television programmes for use in the home, workplace and training environments, together with a supportive learning surround. The development phase of the project is complete and programmes are scheduled for UK national broadcast in March 2001 under the series title "Give It A Go!" The paper particularly focuses on the pedagogic design framework for the interactive elements of the educational programmes and how these relate to the television technologies of digital versatile disk (DVD), satellite/aerial broadcast and cable narrowcast.

What is digital television?

Most television today uses analogue broadcasts, where the image and audio signals are transmitted more or less in proportion to the levels they are to be displayed/played on the consumers' TV sets. However, if consumers install additional hardware, usually Set Top Boxes (STBs), the signals can be sent in digital format. Digital transmission usually gives better picture quality, but perhaps more importantly each channel takes less spectrum space. This allows many more channels to be broadcast.

To reach all households, transmission companies currently have to output their signals in both analogue and digital formats. However, as soon as sufficient numbers of households have suitable Set Top Boxes, governments intend to raise huge revenues (billions of Euros) by selling off the analogue channel space for further digital tv channels, mobile phones and other wireless applications. Many European governments intend to end analogue broadcasts between 2006 and 2010. In the UK consumer access to satellite and terrestrial aerial digital reception was
considerably aided when the main rival broadcasters, Open and ONdigital, started to distribute their STBs at zero-price rental.

An alternative to 'through-the-air' broadcasting is cable transmission. In some European countries, Germany for example, this is the dominant form of reception. Most existing analogue cables could already take digital signals, but cable companies must still invest in complex transmission equipment and replace the STBs in each home. The marketing opportunities offered by interactivity, though, mean that most cable companies will convert well before the dates given above.

To allow broadcasters to monitor the use of pay channels, the satellite and terrestrial technologies usually require the consumer to plug their STB into the home's existing telephone line. This is often referred to as a "back channel", but the wire is actually bi-directional and can be used to carry personalized interactive services such as home banking, home shopping, email and designed-for-TV-display information pages. Digital cable technology has a significant advantage: as well as making use of the cable itself as the back channel, it can use the cable's higher capacity for delivering to the viewer full web access and possibly video-on-demand services. The combination of video-on-demand and full web access is very attractive for educational programme providers and is discussed below.

Why use interactive digital television for education?

People with basic skills problems are notoriously hard to attract back to formal learning opportunities. Many perceive themselves as having "failed" at school and are highly dismissive of traditional adult education provision. Television, though, offers a different approach. This section of the population watches more hours of television than the average viewer, and their households have been amongst the early adopters of subscription-based multi-channel satellite and cable services (BSA).

Television can reach the masses: in the 1980's the BBC attracted weekly audiences of 100,000s for a basic skills tuition series "On the Move". It can also stimulate follow-up action: in 1999 the UK's open learning initiative Learning Direct took over 10,000 telephone enquiries after the Channel 4 soap "Brookside" series showed characters facing up to and overcoming basic skills problems.

From a logistics point of view, distributing learning materials through the television rather than via CD-ROMS or other media is relatively simple. There is no need to register to receive materials, and no need to follow complex instructions to install them on PCs (which can be a circular problem for basic skills learners). However, in a multi-channel world, bringing the programmes to the attention of the viewer and tracking their subsequent progress will still be a problem. We discuss this later.

The Upgrade2000 project

The Upgrade2000 project developed an integrated set of interactive television programmes, a web site and CD-ROM materials for further learner support, and instructor guides to enable non-specialist educators (mentors in small organisations, for example) to tailor the materials for individual situations. This paper concentrates on the television component of the project. The programmes were produced between January and June 2000, and the content was tested via DVDs. They are scheduled for broadcast via satellite in March 2001 as described below.

Interactive programmes for basic skills learners – design structures

People with basic skill needs are notably more receptive to learning if it has a clear link to their immediate occupational or leisure needs (BSA). With this in mind, we designed each programme to have a main theme section showing practical and applicable occupational, with in-context branches to the basic skills materials. Fig. 1 shows the structure of the programmes.

Many occupational tasks, such as wallpapering a room or planning exercises at a health clinic, can conveniently be explained though a naturally sequential development. The vocational skills section of each programme was designed to be watched in a linear / sequential route. However, viewers have different Basic Skills learning needs and interests. We use interactivity to allow the viewer to branch to "Learning Encounters", and then choose their own
route though the basic skills content. Examples of Learning Encounters are how to estimate the area of paint needed, communicating with customers, and skills in scan-reading.

Figure 1: Structure of the main programme and learning encounters

The first item within the Learning Encounter is a bridge, which explains the link between the work skill and the underlying basic skills. It is motivational in tone.

Basic skills learners often have a very fragile confidence in their own abilities. It is important that we do not place them in positions where they believe they will fail again. The confidence check outlines a problem and asks the viewer if they believe they could solve it. The viewers may opt to attempt to solve it, request help, or return directly to the occupational theme (the Learning Encounter may be too easy, too hard, or not in their area of interest).

The skills check builds on the confidence check and sets a problem encompassing all the learning points of the Encounter. The viewer may select an answer from a multiple choice menu using the colour or arrow keys, or the 0-9 keys for some mathematics problems, on the remote control. We chose not to use alphabetic keyboard input at this point for some of our viewers.

If the skills check is answered correctly the programme gives positive confirmation and summarises our approach to the task. Perhaps they had a lucky guess at the right answer, or to go to the supporting web site (discussed below) for further practice, or to return after the correct confirmation they are led through the solution a little at a time. There can be further branching scan reading, for example.

Learning Encounters also offer information about other sources of help, including the UK's government's on-learning provider Learning Direct, launched during year 2000. They also provide a selectable link to the Upgrade2000's learner web site especially designed for viewing on the domestic television set. Here the learner could have further practice, and take practice assessment with formative feedback. An advantage of the web over current television is that the web server can be programmed to keep detailed records of answers and interactive inputs made by the user, so it could – if authentication of identity could be resolved - be used for building portfolios.
of work leading to summative assessment. The technology for TV access of web sites (see Green, M 1999) was not

The project drew several conclusions about the style and suitability of the interaction as described above. A key point is that basic interactive television technology – as opposed to computer technology – cannot 'remember' upon events later. Interaction is largely restricted to actions based on the last input only. More advanced facilities do exist, but they vary between the different types of transmission technology, and if different platforms programme makers have to restrict their use of interactivity to the lowest common denominator. Branching based on user selection is the most common approach.

that Basic Skills learners are comfortable with using the remote control keys to answer questions. The introduction to each programme showed on screen how to use the remote control. To assist poor readers we also arranged that all menus had voice over instructions, with one of the on screen buttons replaying the audio on demand. Together these approaches were found to be sufficient instruction our learners did not need paper or human instruction to use the technology. Horsburgh (1999) reports similar fin equipment.

Digital television technologies

Digital Versatile Disk sometimes referred to as Digital Video Disk (DVD)

DVDs look like CDs, but are capable of holding 1½ to 2 hours of television quality programmes, menus and instructions that control the interactivity. The disks can be viewed either through devices that plug into standard players will leap in November 2000, when the games console Playstation II which also shows DVD Video on tv screens, is launched in Europe.

At the time of the Upgrade2000 project no commercial systems for interactive television were installed in the interim solution. However, we met a number of problems similar to those listed by Fritz (1999): the expense of authoring systems meant that production had to be outsourced (with its + Euros to press, meaning that we could not give them away for home trials by learners; we found notable differences in playback behaviour between made second versions as necessary.

We also surveyed learner and mentor reactions by interview and by questionnaire. However, we are reluctant to the DVD equipment and interest in their progress may have an effect on learner perceptions. Our pedagogic

consumer's Set Top Box picks out a selected channel and passes this to the television set for viewing.

Many consumers already have videocassette recorders. These can record the output of STBs, but because they are -in recording media are becoming configured for use with the (satellite) system will be available from January 2001.

The main commercial motive for transmission companies to support recorder-

revenue- For example, a range of adverts could be 'downloaded' by nighttime broadcast to the STBs, and shown at prime time as appropriate. If linked with a device who is watching (FutureTV use a card for viewer identification) adverts can be targeted individual's past home shopping purchasing habits.
The technology for downloading programmes can also be used by educators. The components and "master
controller" program of interactive programmes can be broadcast when off-peak schedules permit, to be available for
later viewing. The viewer may then skip sections or rewatch sections as many times as they choose. This gives the
equivalent experience of watching a DVD.

Through a partnership with Coleg Digidol (the Welsh Digital College), the Upgrade2000 programmes will be
broadcast on the Open platform in interactive format in March 2001 on the S4C2 channel. The broadcasts will be
receivable, free-to-view, throughout the UK and some parts of northern Europe. Open's channel-usage tracking
systems will be able to provide accurate figures on household viewing levels (including use of recorded copies).
Learning Direct should be able to track the number of viewers who proceed on to recognised courses.

Narrowcast

Narrowcasting is where each viewer signals, via the cable, to the transmission company which channel they wish to
watch. This is then transmitted over the same cable back to the house. The technology, though more complex at the
transmission end, allows video-on-demand services. If quick enough (not all current systems are) it can replicate the
DVD experience by showing short sequences of video separated by menus to select the next component. A second,
strong advantage that narrowcasting is also the way that web browsing works. A number of cable companies are
now offering full web browser access to the tv screen, including video streaming at far better quality levels that is
possible over standard telephone lines. This gives the possibility of "hooking" a viewer's interest through interactive
television, then passing them on as "learners" to web sites that can track and fully adapt to the individual's progress,
without the learners changing physical media.

Having already invested heavily in their technology, existing cable companies are likely to try to maximise their
revenues by using the switch to digital communications to create the space for broadcasting extra channels whilst
leaving just a small capacity for narrowcasting Web access. Television by narrowcasting may well come from a
different source: Asynchronous Digital Subscriber Line (ADSL) is a technology that allows telephone companies to
use existing telephone lines to carry television signals. The approach is not certain to work: each programme has to
be highly compressed to meet ADSL's bandwidth and this may over-compromise picture quality. Also, ADSL can
only be transmitted a few kilometers over copper wire (i.e. the type of cable telecoms companies use between the
last exchange in the chain and the home). Many rural households are likely to be outside this range.

Conclusions

The possibility of using interactive television for education has been postulated for a number of years (eg Bascish,
1996; Bates, 1999). The Upgrade2000 project has identified a particular use to reach the basic skills audience. This
group watches more television than average. They have also been amongst the earliest adopters of home-based
digital audio-visual products. The cost of acquiring digital receiver equipment is, in any case, falling and for some
systems is now free.

Bates notes that is the transmission companies that are financing the development of interactive digital television,
and that their commercial interests are leading them to target the greatest revenue-generating markets of blockbuster
film rental, shopping channels and advertisement-bearing information services. They are tailoring the hardware they
distribute to suite: the Set Top Boxes are designed to support the above functions but do not yet have the built-in
memory that could hold downloaded programme components to be watched interactively at a later time. Likewise,
the current viewer tracking methods can record what programmes were watched, and can even recommend follow-
ups in a similar genre, but the systems are orientated towards the needs of billing functions rather than offering
learning material matched to learner progress.

Even though educational programmes must rely on systems developed for commercial markets the technology is
moving in useful directions. The Upgrade2000 programmes are scheduled for satellite broadcast interactive
programmes to disk-based STBs in March 2001. This paper has also shown how ADSL might provide a seamless
environment for interactive television leading on to web pages with streamed video. Overall, the Upgrade2000 has
developed and is testing a new pedagogic model that uses interactive television to 'hook' the viewer's attention and
-building practice, and then pass them to the web site for more detailed learning. We summarise this rase "moving passive viewers to active learners".

Accreditation of home-identification cards into the STBs. It is a parent's responsibility if they let the child use the card to watch something. We know who actually answered questions, and whether they were receiving help from others in the room. Perhaps the different adverts in breaks between programmes depending upon the individual's profile as recorded by the tracking slot but the whole family is watching. However, this may be more of an issue for health or personal relationship.

Abstract: This paper discusses how a web-based course in calculus is created using a Computer Algebra System and delivered to the students who are studying for their diploma course at the Polytechnic using an in-house developed e-Learning portal named e-CAMPUS system. The e-CAMPUS is an in-house developed portal for lecturers to deliver their course materials and other purposes. It has the necessary features to support an online course completely. The system was developed to support the campus wide mobile computing initiatives that see the Polytechnic helping students to own their personal notebook PC. The initiatives hope to cultivate a learning culture in both students and staff to fully exploit the new development of Information and Communication Technology for life-long learning. The paper will emphasize on showing how teaching and self-learning materials in calculus were written using a Computer Algebra System and placed on the web using the e-CAMPUS to support the students in learning anytime and anywhere. Students are able to carry out investigation, exploration and much more, with the online materials. The paper will also show the many features like online assessment, online discussion that are built within the e-CAMPUS to support virtual learning.

Introduction

The advancement in the information and communication technology has greatly affecting many aspects of our lives including the education. In an educational institution like Ngee Ann Polytechnic, it is believed that the technology can be used to improve the learning environment for both student and staff. Through many initiatives, the Polytechnic hopes to use the technology to cultivate and promote a life-long learning culture in all who comes into contact with the Polytechnic.

The polytechnic places great effort in creating an environment allowing both students and staff to learn anytime and anywhere. One of the initiatives is to help all students to own their notebook PC. The mobile computing initiatives hope to enable students to have easy access to the information provided whether they are on or out of the campus.

The initiatives also provide an opportunity for many courses of study to go online. In this paper we share the experience in creating a course in calculus taken by all first year students who are studying for the Diploma in Mechatronic Engineering. The teaching and material in mathematics has been created using a Computer Algebra System, Scientific NoteBook. An in-house developed portal, e-CAMPUS is used to deliver the course material.

e-CAMPUS

e-CAMPUS is an integrated virtual learning environment that allow students to learn at anytime and anywhere. It makes uses of the latest state-of-the-art Internet Technology for effective delivery of courses and management of
learning experiences. The environment was developed based on modular approach and it can be customized or scaled up or down to meet the different needs and aspiration of different organization. Additional functionalities can be easily added as the learning infrastructure grows. It supports the ASP(Application Service Provider) service model for cost effective implementation.

Biometrics Technology that allows the use of thumb print to recognize individual learner can be incorporated into the system as an option to provide more accurate performance tracking and measurement capability. The use of Biometrics Technology also enabled course contents and sensitive information to be protected and restrict access to only authorized end-users.

The system provides web-enabled use interfaces to manage the environment and to participate in on-line learning activities. It manages the learning communities by providing access to only the contents and data for which they have privileges and permission. It provides multiple levels of security according to the role of the users. The use of biometrics solution as a middle tier between the web server and the database server and biometrics device at client-end will further enhance the authentication mechanism of the system.

Providing an online course in calculus

Learning of Mathematics is often associated with calculation, investigation, exploration and many other tasks. In providing an online course in mathematics, it is important for the users to have access to a Computer Algebra System (CAS) on their PC. The users can use the CAS to perform the tasks of calculation, investigation, etc, without any additional tools. The system can be used to carry out tedious tasks and laborious calculation that otherwise difficult or impossible. With careful planning and correct instructions, the system can also be used effectively to explain many concepts that would help understanding.

The materials of the online course in calculus were created using a Computer Algebra System called Scientific NoteBook (SN). SN has the functionality of a word processor that enables all instructions to be typed conveniently. It also has the functionality for the user to type mathematical expression that is alive. The Maple Engine enables the users to perform a series of mathematical function without the need to learn any syntax.

All students taking the course are given individual account to access to the course materials and other related information on the web. They are presumed to have their own NoteBook PC loaded with the correct version of the SN.

The materials divided into a list of independent sub-topics for easy updating and easy access by the students.

Besides the learning and instructional materials, other facilities supported by the e-CAMPUS can be made available to the students.

Conclusion

The facilities in the e-CAMPUS open up many new dimensions and possibilities to the learning community. It is hope that with this platform, the benefit to both students and staff who are involved in this calculus course can go beyond the learning of mathematics. It is hoped that they are able to see a new paradigm in borderless learning.
Developing Generic Skills through On-line Courses

Abstract: Developing generic skills for students in higher education institutions has become a priority issue. Higher education institutions are experiencing continual pressure from government, industry, funding bodies and students, to place greater emphasis on developing generic skills that are currently delivered through the "hidden curriculum". This paper explores ways of developing students' generic skills in higher education through on-line delivery. By investigating the nature of generic skills and contemporary methods of teaching and learning, it proposes a framework for learning designs within higher education contexts to prepare students for the workplace by helping them develop generic skills as well as subject-specific knowledge.

Introduction
Over the past decade there has been a growing concern about the role of higher education institutions and how they are meeting the needs of employers. Increasingly, higher education institutions are being asked by industry, government and higher education funding bodies to produce graduates with versatile workplace skills, as well as subject-specific skills. This is causing a major reappraisal of higher education institutions purpose, learning outcomes and research activities. (Australian National Training Authority, 1998; Bennett, Dunne, & Carre, 1999; Candy, Crebert, & O'Leary, 1994; Dearing, 1997; Mayer, 1992).

As higher education institutions struggle to implement strategies and courses to promote the development of generic skills across different courses, they must firstly define what "generic skills" are. It currently has several synonyms including key, core, life, competencies, work, employment, transferable, personal and others. These terms usually refer to "skills that are common to more than one work site, more than one occupation or more than one field of knowledge" (National Board of Employment Education and Training, 1996, p. 17). The Finn Review (1991) and the Mayer Committee (1992) were both commissioned by the Australian government to identify key generic skills considered fundamental to performing tasks in a wide range of occupations and needed by graduates from higher education institutions. These reports considered being able to work in teams, communicating clearly, personal and interpersonal skills, problem solving, understanding technology and using mathematical concepts efficiently, all as important skills required by employers in the workplace. This is in consensus with the Australian Council for Educational Research (2000) which found that the most frequently mentioned and desired generic skills by employers include communication, problem solving, critical thinking, interpersonal skills, ethics, life long learning and information and technology literacy.

Strategies Used to Develop Generic Skills
As promoted by Biggs (1999), Candy, Crebert & O'Leary (1994), Gibbs (1992) and Ramsden (1992), an emphasis on process, rather than subject content is needed to develop generic skills. Learning environments with a focus on the learner activities, rather than creating "excellent" lecture notes are needed. This approach is in contrast to traditional didactic methods of teaching in higher education institutions, which emphasise subject specific content and the transfer of knowledge from lecturer to student, which must often be memorised for examination purposes. This is also supported by Oliver (1999) who proposes three elements are needed when designing learning environments: course content; learning strategies, which determine how the learners engage with course materials; and learning supports or scaffolding, which is needed to guide learners and provide feedback on their progress.

Through a broad review of the literature, it was found that the three elements of self-regulation, reflection and authentic context are the central tenets of instructional design needed to create learning that can develop students' generic skills. As shown (Fig. 1), these learning strategies provide a framework for developing...
suitable learning activities that in turn determine the required learning resources and supports needed for effective learning environment.

On the basis of the above framework, an on-line learning environment was developed for a final year project management unit (multimedia based) at Edith Cowan University. It incorporated a heavy group-work component, with a strong focus on peer-assessment (student contracts and weekly journals). Learning activities were developed using self-regulation, authenticity and reflection, activities with an emphasis on collaboration and self-directed learning. As part of a team, students were required to access necessary information needed to complete weekly tasks and then use self/peer assessment and journals to reflect about their progress, and that of their peers (Fig. 2).

Catherine McLoughlin
Teaching and Learning Centre, University of New England, Australia
mcloughlin@metz.une.edu.au

Abstract: This action research presents a description of how an on-line E-commerce business-planning unit was developed. Initially, an intensive ten-day E-commerce course was developed in collaboration with government, industry and university sectors with a view of raising awareness and promoting electronic business planning issues. The course utilised a range of learning approaches, including peer teaching, in which participants were trained as team leaders to facilitate group learning. Based on the evaluation of this course, a full semester course for final year tertiary students was developed and evaluated. An overview of both case studies is given with recommendations for future developments.

The Need for E-commerce Training and Awareness

The rapid increase of Internet usage is demanding that businesses update their skills and re-engineer their organisations, products and services to meet new competitive demands both locally and globally. This is not only providing immense opportunity and threat for small, medium and large businesses at a micro-economic level, but is posing similar opportunities at a macro-economic level (Turban et al. 2000). Training is needed to support these changes that require equipping business operators with new skills and forms of information literacy. These demands raise some critical issues for educators, such as how to structure “rapid” training while at the same time keep pace with technology and business issues. How can large numbers of business operators be quickly trained in on-line technology? How can E-commerce strategies be quickly implemented by business to take advantage of this new revolution?

University courses spanning over three years duration will not provide the body of knowledge or skills needed by Australian business to compete in this rapidly changing marketplace. Training and development courses need to have ongoing collaboration and mentoring with industry to ensure the knowledge acquired is current and relevant (Mitchell, 2000).

Case Studies – Intensive and Semester Based Training Courses

In September 1999, a group of ninety, second year multimedia degree students from Edith Cowan University completed a two week intensive E-commerce business-planning course. They had no previous instruction in business planning and minimal understanding of E-commerce issues. Participants were required to develop an E-commerce business plan,
which could be sustained economically by a business to sell products in an on-line environment. The course was subsidised by the Office of Information and Communications (OIC), which is part of the Department of Commerce of Trade, a Government department in Western Australia. Dow Digital (an e-commerce and on-line services consultancy and development company) developed the course and was subsidised to run it at Edith Cowan with a view of evaluating its effectiveness for university graduates in Australia, as well as how it could be implemented in third world countries.

In order to ensure relevant, authentic content, there was daily input by e-commerce experts and local business representatives that had established e-commerce as part of their business. "Just-in-time Learning" principles were used to deliver the course that focused on integrating students’ knowledge base into real life contexts and engaging learners in collaborative project work (Erhaut, 1994; Ben-Jacob & Levin, 2000). This is supported by constructivist learning principles which emphasise social interaction, communication, exchange of views, collaboration and support for learners to take more responsibility for the learning process through learner-centred tasks (McLoughlin & Luca, 2000; McLoughlin & Oliver, 1998; Collis, 1998). Learning tasks required students to work collaboratively to create an e-commerce business plan and share the expertise of the group. Thus, collaborative learning, peer communication and negotiation were key elements of the learning approach. The course culminated in the students presenting their plans to a panel of e-commerce experts, members of local industry and their peers after the 10 days of intensive instruction.

A questionnaire was designed to elicit student and industry views on the value of the course. Results of the questionnaire were very positive, showing that students and industry representatives considered the course to be very worthwhile which was strongly reflected in point 8 of the questionnaire (“Overall, I thought that the course was very worthwhile”), which rated 3.9 out of 4. From feedback gained, a number of conclusions were made: a two week intensive course is too short; the course is better suited to final year, final semester students; teams should be involved in developing more authentic business plans; team size should be no greater than four and students needed more help on creating budgets using spreadsheets.

On the basis of the two week intensive program, a full semester e-commerce business planning course was developed and implemented for final year, final semester multimedia students. A web site was set up for students to obtain the syllabus, chat on bulletin boards, download weekly notes/PowerPoint slides and contribute to an on-line "URL catcher". Students were given the opportunity to enter a business planning competition promoted by the Software Engineering Association of Western Australia (SEAWA) and sponsored by the Western Australian government. Successful teams were given four days of free training as well as notes and advice about how to build their business plans. All students were encouraged to use "real" business clients who wanted to move their businesses on-line. At the end of the semester, students presented their plans to peers, staff and industry representatives. (see http://www-scam.ecu.edu.au/projects/Business_Plans/BusinessPlans.htm).

Students were interviewed and questionnaires given to all participants in an attempt to evaluate the course. There was unanimous agreement that the course provided information
and ideas that would help students gain employment, and also generate ideas for their own businesses. They also enjoyed the tutorial discussion sessions were contemporary E-commerce topics from newspapers, magazines and the textbook (Turban et al, 2000) were discussed by students and tutors. On the negative side, students felt the course did not integrate business-planning concepts with the weekly content well enough and would have preferred structured tutorial activities each week that would have contributed to the overall development of a business plan, with the E-commerce knowledge derived from the book tied into the business-planning structure.

Conclusion

The E-Commerce business-planning course was developed through a joint venture with business, government and Edith Cowan University. On the basis of a subsidised two-week course, a full semester-based course was developed for final year students. Overall, the course was well received by students and industry but was found to be deficient in structured business planning concepts.

Fostering Higher Order Thinking through Online Tasks

Joe Luca,
Edith Cowan University, School of Communications & Multimedia, Western Australia
j.luca@cowan.edu.au

Catherine McLoughlin,
Teaching and Learning Centre, University of New England, Australia
mcloughlin@metz.une.edu.au

Abstract: Increasingly higher education institutions are being asked to be more pro-active in delivering instruction through on-line facilities, while at the same time being more effective in fostering higher order thinking skills for students. This action research case study considered the effects of tertiary students working in teams to collaboratively solve ill-defined problems in an on-line environment. The framework adopted for analysis of higher order thinking investigated types of talk that were indicative of reasoning processes. Results indicated that the students' capacity to display higher order thinking increased as a result of the students collaborating and communicating through the custom built on-line problem solving environment. The implications of the study are that on-line collaborative environments can facilitate the development of higher order thinking skills that are increasingly expected of graduates.

Introduction – Integrating higher order thinking and on-line technology

The ultimate educational goal for all educators that cannot be disputed must be enhancing students’ ability to think and reason (Paul, 1993; McPeck, 1990). Research and interest at all levels of the educational system is promoting an increased emphasis on higher order cognition and lifelong learning (Australian Council for Educational Research, 2000; Candy, Crebert, & O’Leary, 1994; Brown, 1997). At the same time, students are increasingly being required to become familiar with using technology as a means of collecting information, and also as a means of communicating, collaborating and value-adding to their jobs.

Tinkler, Lepani & Mitchell (1996) propose that in a knowledge economy, where data and information are raw material, value-adding will require higher order thinking skills not only to convert information to knowledge, but also to convert knowledge into insight, foresight, and ultimately wisdom. This is supported by Candy, Crebert & O’Leary (1994) who also promote that access to and use of information technology is absolutely vital to lifelong learning and accordingly “no graduate – indeed no person – can be judged educated unless he or she is information literate” (p. xii). This view is supported by other reports which suggest that graduates must be technology literate in the new economy (Mayer, 1992; Finn, 1991; National Office of the Information Economy, 1998).

In Australia, as in many other countries around the world, this push toward technical literacy, generic skills and higher order thinking has resulted in formal testing being developed. The Department of Education, Training and Youth Affairs (DETYA) has funded the Australian Council for Educational Research (2000) to develop a “Graduate Skills” survey instrument and is being implemented in 2001 across all universities in Australia. This will enable universities to compare the variance in students’ generic skills over the course of study, differences in student profiles between fields of study, and differences between universities. So the move to develop student generic, life long and higher order thinking skills must be taken seriously by all tertiary institutions. They can no longer just deliver content and ignore the importance of these skills.

However, the term “higher order thinking” is not clearly defined in the literature (Resnick, 1987). Talk of higher level cognitive processes evokes different views and perspectives from researchers, and this has been
referred to as the great debate (Weinstein, 1993). Nevertheless, there is some consensus that when we speak of higher order thinking processes, we refer to thinking which is complex, multi-faceted and self-directed, and that the learner plays an active role (Resnick, 1987; Coles, 1995; Nastasi & Clements, 1992). In this study, we document the design and learning processes that took place in an on-line learning environment that aimed to promote the development of higher order thinking skills. Through the design of tasks that are authentic, collaborative and self-directed, students were engaged in solving ill-defined problems and self and peer assessment of others. Teamwork as facilitated by enabling students to give and receive feedback as well as comments on each others' work.

Context of study

Final year students enrolled in the Interactive Multimedia course at Edith Cowan University are required to develop skills and expertise in project managing the development of multimedia products, such as web sites. These skills are taught through the IMM3228/4228 "Project Management Methodology" unit where students practice developing web sites using project management models, performing needs analysis, developing design specifications (storyboards, concept maps and rapid prototypes), conducting formative and summative evaluation.

The unit consists of thirteen, three-hour class sessions and runs over a full semester, or thirteen weeks. Each session consists of a one-hour lecture followed by a two-hour group-based activity. Team skills and collaboration are continually promoted and reinforced throughout the unit with teams of four students working together to build the web site. Learning outcomes include:

- communicating and collaborating in a team-based environment to effectively problem solve, resolve conflict and make appropriate decisions
- making a significant contribution to the development of a team-based web-based product
- developing a suitable project management model
- documenting and reporting on QA procedures, communication strategies, timesheet estimates, overall costs, proposal, legal, design etc which are representative of industry expectations
- evaluating the quality and effectiveness of the product

Students are required to complete three assignments that consist of a project proposal, design specification and final web site. Each assignment contains four assessment components. A team mark for the quality of documentation, final web product, and solving of the on-line problems. Individual marks are gained for reflective reports, which are designed to encourage students reflecting on their and others contributions. Peer assessment is encouraged and negotiated with the team at the end of each assignment (team members who are not performing lose points that are added to the score of other team members).

There were 73 students involved in the study, which was delivered through a web site in order to make the learning resources available to both internal and external students. The site include problem solving software, a Listserv, anonymous bulletin boards, time management tool, syllabus and assessment materials, lecture notes, legal/QA templates, relevant URL's, web sites developed by previous students and a student details database (see http://www-scam.cowan.edu.au/ and go to IMM3228).

Designing the learning environment

Group based project work (building a web site) and problem solving were chosen for their relevance and congruence to the learning outcomes that were sought. Project work and problem solving are advocated for their capacity to support the development of generic skills and professional expertise and are successful as instructional strategies in many contexts (Collis, 1998; Klemm & Snell, 1996; English & Yazdani, 1999). Learner activities were undertaken in teams, and the on-line problem-based learning activities involved a number of activities and tasks that appeared to provide strong support for the development of a number of key skills. The students were required to undertake the following activities each week:

- Problem solving - the tasks required students to seek information from appropriate sources in order to solve problems that reflected state-of-the-art knowledge about project management. The students are able to use the Web as an information source but had to select from the many resources available, those that were relevant to the task.
Peer evaluation - having solved the problem, student teams were then required to develop criteria to apply to others solutions. The students had to examine the information given by other students, consider the scope of their inquiry and decide on the parameters which they were going to assess with, and also give feedback on.

Collaboration - each group consisted of four students and required them to organise themselves into productive teams and share the workload, undertake separate tasks and maintain tight deadlines and schedules each week. Such activities demanded that students consider the requirements of others, be adaptive, responsible and flexible.

Personal reflection on task and process - each student created reflective notes in which personal views of self-progress was recorded. Students considered the skills and competencies they applied, noted the skills that needed to be developed and developed learning goals that carried over to the next task. This provided a strong framework for the development of personal and process knowledge.

The on-line problem solving process is illustrated below (Fig. 1). From the figure it can be seen that it allows for communication, peer assessment and finally individual reflection on how successful the whole process was. Students post their solutions and then view, assess and give comments to other teams solutions in an anonymous fashion. This enables students to view others solutions and perspective's and also pass comments within the 'safety' of the on-line environment. So students can comment on the overall process and see how the efforts of their team compared to that of others as suggested by both peers and tutor feedback. To help student teams develop an approach to the problem solving process, the "Stair-Step" problem solving process developed by Lynch, Wolcott & Huber [, 2000 #133] was explained and illustrated to the students.

![Figure 1: The on-line problem solving process](image)

For the group project, students were required to complete three assignments that consisted of a project proposal, design specification and a web site. Each assignment contained four assessment components: a team mark for developing the project, a team mark for solving the on-line problems, an individual mark for personal reflections and intra-team self/peer assessment mark. Students were given three problems to solve as follows:

- **Assume that you are building a web site for a difficult client who thinks they know lots about multimedia design and development! Outline how you will scope the project, collect the content, develop acceptance criteria, control scope creep and cost the overall project. (Consider issues such as client objectives, feasibility, end users, hardware/software, use of sound/graphics/video, potential difficulties, evaluation (formative), implementation issues, maintenance issues and content collection issues).**

- **If the client asks for changes in design or content after you have commenced production, what should you do? How can the design specifications be tied into the legal contract? How will the prototype, formative evaluation process or storyboards help with this? What other considerations should you bear in mind?**

- **If you were the developer how would you ensure that the final product met the original objectives? If you were the client how would you ensure that you had satisfied the original objectives to the letter of the original contract?**
Working on-line gave students the opportunity to access multiple forms of peer support through shared tasks, teamwork, collaboration, feedback and peer review. It was hoped that this environment would create an effective climate of support in which students could practice developing generic and higher order thinking skills. To test the effective gain of this on-line environment in developing skills, key-word indicators were used to monitor instances of higher order thinking, as explained in the following section.

Methodology

A discourse analysis approach was used to identify instances of higher order thinking in student responses developed by McLoughlin & Oliver (1998). This approach used a taxonomy of key-word indicators to signal instances of higher order thinking using the categories of cognitive accountability, critical inquiry, interpretation and reflection. This is based on a collection of words used in the English language which signal a statement is serving the function of reasoning or higher order thinking. For example, inference indicators such as “because” or “whereas” signal that what follows is a reason being given for the statement (Thomas, 1981). Key-word indicators for each of these are based on the following:

- **Cognitive accountability**, in which students explain or justify a concept, is evidenced when their language use includes “because” or “cos” to link a reason to a claim. Or, when they say “so”, “then” or “therefore” to signal conclusion or inference drawn from preceding evidence.
- **Critical inquiry**, in which students challenge, inquire, clarify, investigate or question a concept, and is evidenced through their language by questions such as “what if?”, “why” or “you mean” in order to challenge or make deeper inquiry. Also, students can draw a hypothesis through the use of “if...then”, “would”, “maybe” or “perhaps” to link conditions to inferences.
- **Interpretation**, in which students express opinion, suggest ideas, make rules, generalize, compare/contrast and give examples is evidenced when their language use includes “it means”, “that means”, “it says”, “I think”, “always”, “never”, “in comparison” or “for example/whereas” in order to express understanding or interpretation of text, activity or concept.
- **Reflection**, in which students evaluate ideas when their language includes “I think” or they make some form of metacognitive statement. Also, when their language includes some form of self evaluation or awareness of learning.

Using these key-word indicators to find instances of higher order thinking provided an effective means of substantiating improvement in students’ dialogue. By counting the number of key-word instances for each response in each problem solution demonstrated how student language changed over time, which illustrated whether the intervention had been successful in promoting higher order thinking. This type of analysis is supported by a number of studies (Thomas, 1981; Means & Voss, 1996; Tishman & Perkins) which also suggest that reasoning can be assessed by analysing how the discourse is structured.

The study used a computer based text analysis approach (NUDIST, 1994) which enabled the researchers to search for instances of the on-line text that contained keywords which represented higher order thinking. The corpus of data used was based on feedback responses given by teams to peers’ solutions ie student teams were required to assess and give comments (up to five hundred words) justifying the given mark to four other teams. As there were three problems to complete during the semester, we were able to collect three discrete compilations of responses in order to monitor changes.

Results

Because of the large amount of data generated for each problem, it was decided to investigate only a portion of the whole corpus. One of the four classes with twenty students was used over the full semester and their responses for each problem was coded. As shown (Fig. 2), a clear increase in the number keyword indicators used can be seen over the development of the three problems. A closer analysis in the second diagram shows that the main increases resulted from keyword indicators promoting critical inquiry. Keyword indicators for cognitive accountability, interpretation and reflection showed no significant increase.
The system of coding keyword indicators was useful in gaining an understanding of trends in the data. However, it was still necessary to examine the data manually and make decisions about how best to code some elements which didn't fall into any of the specified categories.

It was evident that as the semester progressed, and students became more confident in giving feedback, they became more direct and critical with their comments. Some examples of the comments made by students follow.

- "If you were the developer, how would you ensure that you satisfied the original objectives to the letter of the original contract"
- "It would be very interesting to see an expanded explanation from this group"
- "Who, what etc? What does this exactly mean? You should have expanded this more, it just doesn't make sense the way it is"
- "We feel that you have significantly missed the point of the question. The question asks how would you ensure that you HAD satisfied the original objectives not how you would ensure...."
- "We found your teams solution unclear and were not sure what you mean. You start talking about the developer then suddenly start talking about the client again. It would be better if you tried to stick with one idea before discussing the next one"

Summary and conclusions

The on-line problem solving application provided an infrastructure for the students to post solutions to ill-defined problems, and then view, assess and critique other solutions. Not only did this provide multiple perspectives on how to solve the problems, but it also encouraged students to reflect on solutions, challenge and question each other and revise their own ideas. Using a discourse analysis approach with keyword indicators to represent occurrences of higher order thinking, showed that there was a clear improvement over the duration of the semester. Our research indicates that online problem solving tasks have the capacity to foster inquiry skills, collaborative dialogue and critical thinking. Furthermore, the analytic approach of discourse analysis applied to online transcripts of tasks provided an indicator of the levels and types of thinking that occurred online. Our research will continue to refine the types of tasks that can be applied in online environments to support higher order thinking processes.

Abstract: The mutual plan/objective of this project is the construction of an Educational Portal—the EduKBr Portal—for a virtual Internet community that values education, quality of information and the process of knowledge-building. The EduKBr Portal Project is an educational product idealized, developed and implemented by EduWeb with the participation and partnership of Kidlink Project in Brazil's multidisciplinary team. During 1998, Kidlink and Kidlink Project in Brazil were awarded and/or received governmental aid. Nowadays, the KBr Project coordinates the Kidlink in Brazil Project and is ahead of all activities and national socio-educational projects that support the development of the global Kidlink Portuguese Language Forum. The main goal of the new KBr Project and its Portal is to "spread the word" about the Internet mentality and support the Brazilian Educational System, with activities, cooperative projects, own educational web sites and communication/interaction in Portuguese to schools, youngsters and parents and professionals in Education.

The objective of the EduKBr Portal Project is to be an integrated, cooperative environment for learning and a space for coexistence and exchange of experiences, where knowledge can be shared among peers in the Brazilian cultural socio-historical context. It will be an open environment for learning and will be permanently under construction. All the interactive activities suggested by kids, youngsters and adults will be continually stimulated and necessary for the development of the community and of this environment.

The EduKBr Portal will be a collective workplace with the following objectives: (a) to apply the information technology, communication and cooperation found on the Internet in teaching-learning process in a consistent and innovative way—either pedagogically or technologically speaking, (b) to motivate the Cooperative Distant-Learning based on the Internet, applying inventive learning methodologies that serve different users, (c) to create a Brazilian multicultural community whose interest be directed to Internet in Education, (d) to disseminate the environment among various segments of society, aiming support of people interested in cooperating and participating in this virtual community, (e) to stimulate the mentality of collective and cooperative construction of learning among the participants of the environment, (f) to evaluate results obtained during the teaching-learning process.
