This 13th annual ED-MEDIA conference serves as a multidisciplinary forum for the discussion of the latest research, developments, and applications of multimedia, hypermedia, and telecommunications for all levels of education. This document contains papers from attendees representing more than 60 countries, with keynote speakers representing both academia and industry. Approximately 450 long and brief papers were selected for presentation at the conference. In the papers, there are several common threads along a number of dimensions: discussion of technological tools varying from presentation of a new tool through the application of a commercially available system; new applications of technology varying from neural networks through assistive devices; using technology to support different educational methods from collaborative knowledge building through developing individual thinking skills; and applications of technology in various disciplines. There are 7 panel sessions, 11 tutorials and workshops, and 180 poster sessions. (AEF)
Steering Committee

Chair: Erik Duval, Katholieke Univ. Leuven, Belgium
Betty Collis, Univ. of Twente, The Netherlands
Rachel Heller, George Washington Univ., USA
Gary Marks, AACE, USA
Ron Oliver, Edith Cowan Univ., Australia
Ivan Tomek, Acadia Univ., Canada

2001 Program Committee

Program Co-Chair: Craig Montgomerie, Univ. of Alberta, Canada
Program Co-Chair: Jarmo Viteli, Univ. of Tampere, Finland
Panels Chair: Ron Oliver, Edith Cowan Univ., Australia
Tutorial/Workshop Chair: Samuel Rebelsky, Grinnell College, USA

Alan Amory, Univ. of Natal, South Africa
Philip Barker, Univ. of Teesside, UK
Alfred Benney, Fairfield Univ., USA
Jacqueline Bourdeau, Universite du Quebec a Chicoutimi, Canada
Peter Brusilovsky, Univ. of Pittsburgh, USA
John Buford, Verizon Technologies, USA
Dale Burnett, Univ. of Lethbridge, Canada
Patricia Carlson, Rose-Hulman Institute of Technology, USA
Depover Christian, Universite de Mons-Hainaut, Belgium
Betty Collis, Univ. of Twente, The Netherlands
Ross Dewstow, UNITEC, Institute of Technology, New Zealand
Michael Dobson, Lancaster Univ., UK
Erik Duval, Katholieke Univ. Leuven, Belgium
Allan Ellis, Southern Cross Univ., Australia
Jorma Enkenberg, Univ. of Joensuu, Finland
Yoram Estet, Tel Hai College, Israel
Kurt Fendt, Massachusetts Institute of Technology, USA
Tony Fetherston, Edith Cowan Univ., Australia
Brian Fisher, Univ. of British Columbia, Canada
Gail Fitzgerald, Univ. of Missouri-Columbia, USA
Yoshimi Fukuhara, NTT-X, Inc., Japan
Barry Harper, Univ. of Wollongong, Australia
Rachelle Heller, George Washington Univ., USA
Lyn Henderson, James Cook Univ., Australia
William Hunter, Univ. of Calgary, Canada
Michel Jacobsen, Univ. of Calgary, Canada
Tricia Jones, Univ. of Michigan, USA
Sanna Jervell, Univ. of Oulu, Finland
Mills Kelly, Texas Tech Univ., USA
Brian King, Harvard Univ., USA
Dr Kunishik, Massey Univ., New Zealand
Joel Klemes, The Open Univ. of Israel, Israel
Piet Koomers, Univ. of Twente, The Netherlands
Georgios Kouroupetroglou, Univ. of Athens, Greece
Chul-Hwan Lee, Inchon National Univ. of Education, Republic of Korea
Min Liu, Univ. of Texas-Austin, USA
Lori Lockyer, Univ. of Wollongong, Australia
Brian Mackie, Northern Illinois Univ., USA
David Mappin, Univ. of Alberta, Canada
Gary Marks, AACE, USA
Hermann Maurer, Graz Univ. of Technology, Austria
Catherine McLoughlin, The Univ. of New England, Australia
Carmel McNaught, RMIT Univ., Australia
Christina Metaxaki-Kossionides, Univ. of Thrace, Greece
Maria Teresa Molino, Consiglio Nazionale delle Ricerche, Italy
Craig Montgomerie, Univ. of Alberta, Canada
Tomasz Muldner, Acadia Univ., Canada
David Murphy, Monash Univ., Australia
Graham Oberem, California State Univ., San Marcos, USA
Ashok Patel, De Montfort Univ., UK
Jan L. Plass, New York Univ., USA
Samuel Rebelsky, Grinnell College, USA
W. Michael Reed, New York Univ., USA
Thomas C. Reeves, The Univ. of Georgia, USA
Geoff Ring, ICUS PTE Ltd, Singapore, Singapore
Robby Robson, Saba Software, USA
John Rogers, DePaul Univ., USA
Malcolm Ryan, Univ. of Greenwich, UK
Jaime Sanchez, Univ. of Chile, Chile
Nick Scherbakov, IICM, Graz Univ. of Technology, Austria
Louis Samrau, Arkansas State Univ., USA
Rod Sims, Deakin Univ., Australia
J. Michael Spector, Syracuse Univ./Univ. of Bergen, USA
Karen Swan, Univ. at Albany, USA
Michael Szabo, Univ. of Alberta, Canada
Akira Takeuchi, Kyushu Institute of Technology, Japan
Ivan Tomek, Acadia Univ., Canada
Jarmo Viteli, Univ. of Tampere, Finland
Yoneo Yano, Tokushima Univ., Japan
Alison Young, UNITEC, New Zealand
Duan vander Westhuizen, Rand Afrikaans Univ., South Africa
Invitation to Join

The Association for the Advancement of Computing in Education (AACE) is an international, non-profit educational organization. The Association's purpose is to advance the knowledge, theory, and quality of teaching and learning at all levels with information technology. This purpose is accomplished through the encouragement of scholarly inquiry related to technology in education and the dissemination of research results and their applications through AACE sponsored publications, conferences, and other opportunities for professional growth.

AACE members have the opportunity to participate in topical and regional divisions/societies/chapters, high quality peer-reviewed publications, and conferences.

Join with fellow professionals from around the world to share knowledge and ideas on research, development, and applications in information technology and education. AACE's membership includes researchers, developers, and practitioners in schools, colleges, and universities; administrators, policy decision-makers, professional trainers, adult educators, and other specialists in education, industry, and government with an interest in advancing knowledge and learning with information technology in education.

Membership Benefit Highlights
- Gain professional recognition by participating in AACE sponsored international conferences
- Enhance your knowledge and professional skills through interaction with colleagues from around the world
- Learn from colleagues' research and studies by receiving AACE's well-respected journals and books
- Receive a subscription to the Professional Member periodical Educational Technology Review [online]
- Receive discounts on multiple journal subscriptions, conference registration fees, proceedings books & CD-ROMs
Abstracts for all journal issues are available at www.aace.org/pubs

Educational Technology Review
*International Forum on Educational Technology Issues & Applications (ETR)*
ISSN# 1065-6901

AACE's member journal is the focal point for AACE members to exchange information between disciplines, educational levels, and information technologies. It's purpose is to stimulate the growth of ideas and practical solutions which can contribute toward the improvement of education through information technology. ETR is an online publication beginning with the spring 2001 issue.

WebNet Journal
*Internet Technologies, Applications & Issues (ETR)*
ISSN# 1522-192X Quarterly

Focused on WWW, Internet, and Intranet-based technologies, applications, research, and issues, the WebNet Journal is an innovative collaboration between the top academic and corporate laboratory researchers, developers, and end-users. Columnists offer how-to articles and expert commentary on the latest developments.

Journal of Educational Multimedia and Hypermedia
*(JEMH)*
ISSN# 1055-8896 Quarterly

Designed to provide a multidisciplinary forum to present and discuss research, development and applications of multimedia and hypermedia in education. The main goal of the Journal is to contribute to the advancement of the theory and practice of learning and teaching using these powerful and promising technological tools that allow the integration of images, sound, text, and data.

Journal of Computers in Mathematics & Science Teaching
*(JCMST)*
ISSN# 0731-9258 Quarterly

JCMST is the only periodical devoted specifically to using information technology in the teaching of mathematics and science. The Journal offers an in-depth forum for the exchange of information in the fields of science, mathematics, and computer science.

Journal of Interactive Learning Research
*(JLIR)*
ISSN# 1093-023X Quarterly

The Journal's published papers relate to the underlying theory, design, implementation, effectiveness, and impact on education and training of the following interactive learning environments: authoring systems, CALL, assessment systems, CBT, computer-mediated communications, collaborative learning, distributed learning environments, performance support systems, multimedia systems, simulations and games, intelligent agents on the Internet, intelligent tutoring systems, micro-worlds, and virtual reality based learning systems.

Journal of Technology and Teacher Education
*(JTATE)*
ISSN# 1059-7069 Quarterly

A forum for the exchange of knowledge about the use of information technology in teacher education. Journal content covers preservice and inservice teacher education, graduate programs in areas such as curriculum and instruction, educational administration, staff development, instructional technology, and educational computing.

International Journal of Educational Telecommunications
*(IJET)*
ISSN# 1077-9124 Quarterly

IJET serves as a forum to facilitate the international exchange of information on the current theory, research, development, and practice of telecommunications in education and training. This journal is designed for researchers, developers and practitioners in schools, colleges, and universities, administrators, policy decision-makers, professional trainers, adult educators, and other specialists in education, industry, and government.

Information Technology in Childhood Education Annual
*(ITCE)*
ISSN# 1522-8185

A primary information source and forum to report the research and applications for using information technology in the education of children—early childhood, preschool, and elementary. The annual is a valuable resource for all educators who use computers with children.
The exchange of ideas and experiences is essential to the advancement of the field and the professional growth of AACE members. AACE sponsors conferences each year where members learn about research, developments, and applications in their fields, have an opportunity to participate in papers, panels, poster/demonstrations and workshops, and meet invited speakers.

ED-MEDIA 2002
World Conference on Educational Multimedia, Hypermedia & Telecommunications
JUNE 24-29, 2002 • DENVER, CO USA
ED-MEDIA - World Conference on Educational Multimedia, Hypermedia & Telecommunications
This annual conference serves as a multidisciplinary forum for the discussion of the latest research, developments, and applications of multimedia, hypermedia, and telecommunications for all levels of education.

WebNet 2001
World Conference on the WWW and Internet
OCTOBER 25-27, 2001 • ORLANDO, FL USA
WebNet - World Conference on the WWW & Internet
This annual conference facilitates the exchange of information in these major topics: Commercial, Business, Professional, and Community Applications; Education Applications; Electronic Publishing and Digital Libraries; Ergonomic, Interface, and Cognitive Issues; General Web Tools and Facilities; Medical Applications of the Web; Personal Applications and Environments; Societal Issues, including Legal, Standards, and International Issues; and Web Technical Facilities.

SOCIETY FOR INFORMATION TECHNOLOGY & TEACHER EDUCATION 2002
MARCH 18-23, 2002 • NASHVILLE, TN USA
SITE - Society for Information Technology and Teacher Education International Conference
This conference, held annually, offers opportunities to share ideas and expertise on all topics related to the use of information technology in teacher education and instruction about information technology for all disciplines in preservice, inservice, and graduate teacher education.

Co-Sponsored Conferences
ICCE—International Conference on Computers in Education
ICCE is an annual event focusing on a broad spectrum of interdisciplinary research topics concerned with theories, technologies and practices of applying computers in education. It provides a forum for interchange among educators, cognitive and computer scientists, and practitioners throughout the world, especially from the Asia-Pacific region.

NOVEMBER 12-15, 2001 • SEOUL, KOREA
**Membership Application**

Join today and keep up-to-date on the latest research and applications!

*If you selected a Student Membership rate above, you must be registered full-time in an accredited educational institution and you must provide the following information:

- Expected graduation date: 
- Educational Institution: 

Non-U.S. postage: add $15 for shipping EACH Journal outside the U.S. $ 

**Library/Institutional Subscriptions**

- [ ] WebNet Journal: Internet Technologies, Applications & Issues $115
- [ ] Jrl. of Computers in Math and Science Teaching (JCMT) $115
- [ ] Jrl. of Interactive Learning Research (JILR) $115
- [ ] Jrl. of Educational Multimedia and Hypermedia (JEMH) $115
- [ ] Intl Jrl. of Educational Telecommunications (IJET) $115
- [ ] Jrl. of Technology and Teacher Education (JTATE) $115
- [ ] Information Technology in Childhood Education Annual (ITCE) $85

Non-U.S. postage: add $15 for shipping EACH Journal outside the U.S. $115

**Method of Payment (US Dollars)**

Membership extends for 1 year from the approximate date of application. Please allow 6-8 weeks for delivery.

Enclosed:  
- [ ] Check (U.S. funds & bank, payable to AACE)  
- [ ] Purchase Order (PO must be included)  

Credit Card:  
- [ ] MasterCard  
- [ ] VISA  

(sorry, no others accepted)

TABLE OF CONTENTS

Dialogic Knowledge Construction as the Crucial Issue in Network-Based Learning in Vocational Education
Helena Aarnio, Hämie Polytechnic, Vocational Teacher Education College, Finland; Jouni Enqvist, Hämie Polytechnic, Vocational Teacher Education College, Finland

A tool for practicing formal proofs
David Abraham, Univ. of Sydney, Australia; Liz Crawford, Univ. of Sydney, Australia; Leanna Lesta, Univ. of Sydney, Australia; Agathe Merceron, Univ. of Sydney, Australia; Kalina Yacef, Univ. of Sydney, Australia

Integrating a course delivery platform with information, student management and administrative systems
Anne A'herran, James Cook Univ., Australia

Preliminary Results Of A Pilot Project Internet Based Subject Registration System
Norhayati Ahmad, Univ. Teknologi Mara, Malaysia; Wahidah Mansor, Univ. Teknologi Mara, Malaysia; Nor'aini Abd Jalil, Univ. Teknologi Mara, Malaysia

The Effects of Strategies Instruction via Computer on Student Attitudes toward Mathematics Problem-Solving
Dohee Ahn, Dong-Eui Univ., South Korea

Capturing Communication and Interaction Needs of the Users -Building Better ICT Based Learning Environments
Raila Aijó, Helsinki University of Technology, Finland; Johanna Leppävirra, Helsinki University of Technology, Finland; Sigrún Gunnarsdóttir, Iceland Telecom, Iceland; Deborah DiDuca, BT, Great Britain;

OrtoWeb - Instructor Networking over Internet for Orthodox Religious Education
Risto Aikonen, Department of Applied Education, University of Joensuu, Finland

Improvement of University Classes Introducing Topics-based Discussion Using the Web Bulletin Board
Kanji Akahori, Tokyo Inst. of Technology, Japan

Promoting best practice in information and computer science education through the UK national subject centre
Sylvia Alexander, Univ. of Ulster, Northern Ireland; Tom Boyle, Univ. of North London, England; Mike Joy, Univ. of Warwick, England

The Evaluation of Multimedia Encyclopedia “Encarta 97”
Ahmed Al-Hunaiyyan, College of Business Studies (PAAE), Kuwait; Jill Hewitt, Univ. of Hertfordshire, UK; Sara Jones, Univ. of Hertfordshire, UK; David Messer, Univ. of Hertfordshire, UK

Intelligent Online-Knowledge-Resources for Intentional Learning
Heidrun Allert, Univ. of Hanover, Germany; Hadhmi Dhraief, Univ. of Hanover, Germany; Wolfgang Nejdl, Univ. of Hanover;

Multimedia in Concept Maps: A Design Rationale and Web-Based Application
Sherman Alpert, IBM T.J. Watson Research Center, USA; Keith Grueneberg, IBM T.J. Watson Research Center, USA

Web-Based Notes is an Inadequate Learning Resource
Alan Amory, University of Natal, South Africa; Kevin Naicker, University of Natal, South Africa

The Educational Process in the Emerging Information Society: Conditions for the Reversal of the Linear Model of Education and the Development of an Open Type Hybrid Learning Environment
Panagiotes Anastasiades, Univ. Of Cyprus, Cyprus; Simos Retalis, Univ. Of Cyprus, Cyprus

Secure & Credible E-Learning Systems
Dennis Anderson, Pace University, USA; Sabah Jassim, University of Buckingham, UK

Algorithm Visualization using QuickTime® Movies
Jay Anderson, Franklin and Marshall College, USA

Web-based strategies for improving undergraduate commitment to learning
Malcolm Andrew, De Montfort University, England
Development of Technology Based Distance Learning: A Case Study of the Centre for Commerce and Administrative Studies at Athabasca University .............................................................. 59
David Annand, Athabasca University, Canada

How Faculty Develop and Deliver Online Courses: A Task Analysis ................................................. 61
Anne Archambault, Technical Univ. of British Columbia, Canada; John Nesbit, Technical Univ. of British Columbia, Canada; Louise Allen, Louise Allen & Associates, Canada;

Enhancing student access to the University: The integration of online and course-based material for the visually impaired .......................................................... 63
Ray Archee, Univ. of Western Sydney, Australia; Monica Whitty, Univ. of Western Sydney, Australia

Measurement and Modelling for Dynamical Human cognition motion .................................................. 65
Noboru Ashida, Osaka Electro-Communication Univ., Japan; Atsushi Tsubokura, Osaka Electro-Communication Univ., Japan; Kagemasa Kozuki, Konami Co., Japan; Katsunori Nakamura, Heian Jogakuin Univ., Japan; Katsuji Higashio, Heian Jogakuin Univ., Japan

Learning Style Theory and Computer Mediated Communication ......................................................... 71
Hilary Atkins, Leeds Metropolitan University, England; David Moore, Leeds Metropolitan University, England; Dave Hobbs, Bradford University, England; Simon Sharpe, Leeds Metropolitan University, England

A multimedia gate to Museum of Astronomy ....................................................................................... 76
Anna Lina Auricchio, Astronomical Observatory of Capodimonte, Italy; Enrica Stendardo, II Univ. of Naples - Faculty of Letters, Italy

Need for Intelligent Web Server with Powerful Authoring Functions: No More Stress on Web Authors ...................................................................................................................... 77
Junichi Azuma, Univ. of Marketing and Distribution Sciences, Japan

Genesis of a CD-based Authorware application: Lessons learned from six years of design and development ................................................................................................................. 79
Patricia Ryaby Backer, San Jose State Univ., USA

Educational Applications of Conversational Agents ................................................................................ 80
Jeremy Baer, Univ. of Washington, USA; Chenoah Morgan, Counting Stick Software, USA

The Internet Shared Laboratory Project ................................................................................................. 82
Andrea Bagnasco, Univ. of Genova, Italy; Marco Chirico, Univ. of Genova, Italy; Anna Marina Scapolla, Univ. of Genova, Italy

Interactive multimedia web-based testing tool ....................................................................................... 84
Kazys Baniulis, Kaunas Univ. of Technology, Lithuania; Vytautas Reklaitis, Kaunas Univ. of Technology, Lithuania; Emilis Stupys, Kaunas Univ. of Technology, Lithuania

Constructivist Instructional Design and Development of a Networked Learning Skills (NICLS) Module for Continuing Professional Education Distance Learning .................................................. 86
Miguel Baptista Nunes, Univ. of Sheffield, UK; Maggie McPherson, Univ. of Sheffield, UK; Mariano Rico, Univ. of Sheffield, UK

Creating and Supporting Online Learning Communities ......................................................................... 92
Philip Barker, Univ. of Teesside, UK

Networking Schools: What Services do we Need? ................................................................................ 98
Patrick Barrett, Catholic Education Office - Parramatta, Australia

Reflections on the Use of an Integrated Computer-based Collaborative Learning Program in a Curriculum Design Course for Science Teachers ..................................................... 100
James P. Barufaldi, The Univ. of Texas-Austin, USA; Victor A. Zinger, The Univ. of Texas-Austin, USA

Meeting Teacher Technology Competencies in the Classroom with a Focus on Writing/Communication Skills .................................................................................................................. 102
Martha Beasley, Lees-McRae College, USA

The New Digital Civilization: The Best of Times, the Worst of Times ................................................. 104
Melissa Roberts Becker, Ed. D., Northeastern State Univ., USA; Donna G. Wood, Ed. D., Northeastern State Univ., USA

Tools To Create Time and Place-Independent Modules .......................................................................... 111
Scott Beckstrand, Community College of Southern Nevada, USA
Towards More Independent Learning: A Southern Nevada Perspective
Scott Beckstrand, Community College of Southern Nevada, USA; Philip Barker, School of Computing and Mathematics, University of Teesside, United Kingdom; Paul van Schaik, School of Social Sciences, University of Teesside, United Kingdom

De Bono’s Six Thinking Hats Technique: A Communication Metaphor in Computer Mediated Classrooms.
Karen Belfer, Technical Univ. of British Columbia, Canada

Flexible Delivery Damaging to Learning: Lessons from the Canterbury Digital Lectures Project
Tim Bell, University of Canterbury, New Zealand; Andy Cockburn, University of Canterbury, New Zealand; Bruce McKenzie, University of Canterbury, New Zealand; John Vargo, University of Canterbury, New Zealand

Urania, the new technologies for information and education in Science
Leopoldo Benacchio, Astronomical Observatory of Padua (Italy), Italy; Federica Guadagnini, Astronomical Observatory of Padua (Italy), Italy; Luca Nobili, Astronomical Observatory of Padua (Italy), Italy; Melania Brolis, Astronomical Observatory of Padua (Italy), Italy; Caterina Boccato, Astronomical Observatory of Padua (Italy), Italy

The Virtual Planetarium: The use and improvement of a Website as a case study of collaboration between Scientists, School Teachers and Students
Leopoldo Benacchio, Padova Astronomical Observatory, Italy; Melania Brolis, Padova Astronomical Observatory, Italy; Giovanna Mastrolorenzo, Padova Astronomical Observatory, Italy

Education and Information of Architects - New Media for Innovative Solar Architecture
Stephan Benkert, Univ. of Siegen, Germany; Joachim Clemens, Univ. of Siegen, Germany; Frank-Dietrich Heidt, Univ. of Siegen, Germany

Developing Web-based Courses on Computing Using a Hypermedia Model
José V. Benlloch-Dualde, Escuela Universitaria de Informática, Spain; Félix Buendía-García, Escuela Universitaria de Informática, Spain; Manuel Agusti i Melchor, Escuela Universitaria de Informática, Spain; José A. Gil-Salinas, Escuela Universitaria de Informática, Spain; Angel Rodas-Jordá, Escuela Universitaria de Informática, Spain

Learning About Multimedia Design Through Real-Life Cases
Sue Bennett, Univ. of Wollongong, Australia; Barry Harper, Univ. of Wollongong, Australia; John Hedberg, Univ. of Wollongong, Australia

Creating An Active Learning Environment Using Digital Video: What I Did and How I Did It
Alfred Benney, Fairfield Univ., USA

Satellite Home Tutorials vs. Satellite Classroom Tutorials
Ruth Beyth-Marom, The Open Univ. of Israel, Israel; Edna Yafe, The Open Univ. of Israel, Israel; Meira Privman, The Open Univ. of Israel, Israel; Hamutal Razi Harpaz, The Open Univ. of Israel, Israel

The Essen Learning Model - A Step Towards a Representation of Learning Objectives
Markus Bick, Univ. of Essen, Germany; Jan M. Pawlowski, Univ. of Essen, Germany; Patrick Veith, Univ. of Essen, Germany

A Scripting Language for Multi-Character Presentation Agent based on Multimodal Presentation Markup Language
He Binda, The Univ. of Tokyo, Japan; Santi Saeyor, The Univ. of Tokyo, Japan; Mitsuru Ishizuka, The Univ. of Tokyo, Japan

Electronic Portfolios in Tenure and Promotion Decisions: Making a Virtual Case
Kristine Blair, Bowling Green State Univ., USA

Building comic strips in a cooperative way: an interdisciplinary experience
Elisa Boff, PUCRS, Brasil; Lucia Giraffa, PUCRS, Brasil

E-Learning: Challenges and Inhibitors
Hans Boon, Univ. of Pretoria, South Africa

Supporting Developers By Building-Block Methods: The Case Of The Templates
Eddy Boot, TNO Human Factors, The Netherlands

Using Databases in Teaching Advanced Mathematics Courses
Mikhail Bouniaev, Southern Utah Univ., USA

Preface

Tervetuloa Tampereelle, Suomeen ja ED-MEDIA 2001!

Welcome to Tampere, Finland and ED-MEDIA 2001!

This is the thirteenth annual ED-MEDIA conference. While 13 is supposed to be an unlucky number in some societies, we believe that we don’t need luck to promise you the best ED-MEDIA conference ever. We have been successful in attracting outstanding keynote speakers who represent both Academia and Industry. The papers are of widely varied interest AND all are of excellent quality. The industry tours will show you what the future holds, and the social program is exciting and novel – especially for those of us who are attending from outside of Finland. We hope that by the end of the conference you’ll agree that you don’t have to be lucky to be outstanding.

ED-MEDIA is routinely held in a different country with Finland being the 5th country to host the conference. This emphasis on being an international organization, the quality of the presentations, and, most importantly, the quality and diversity of the attendees has led to ED-MEDIA being considered the best of many such conferences in the world with attendees coming from more than 60 countries this year.

We are very proud of the program that we have put together this year. This, of course, has nothing to do with us, but is a product of the many excellent papers, panels, workshops, tutorials and poster sessions that were proposed. Each of these went through a rigorous review based upon: relevance to the conference, originality, clarity/quality of English, references, length of the paper, and the potential value/impact of the research or the development presented. We selected approximately 450 long and brief papers as being of high enough quality for presentation at this conference.

As you review the papers, you’ll see a several common threads along a number of dimensions:

- discussion of technological tools varying from presentation of a new tool through the application of a commercially available system;

- new applications of technology varying from neural networks through assistive devices;

- using technology to support different educational methods from collaborative knowledge building through developing individual thinking skills and; of course,

- applications of technology in almost every discipline one can imagine.

Similarly, there are 7 panel sessions, 11 tutorials and workshops, and 180 poster sessions. In each of these areas, there is a wide range of topics covered, but the quality of the presentations is uniformly high. Finally, due to the international reputation of ED-
MEDIA, we have been able to attract Keynote and Invited speakers who really are representative of the best our various disciplines have to offer.

This year we are awarding Best Papers in both student and "open" classes. Selection of these best papers was extremely difficult. In the "open" class, we considered only those papers that received an average mark of 4.67 (out of 5) or greater by review teams of (usually) three members of our international Program Committee. Twenty-six papers met these criteria. We (the Program Chairs) then undertook a blind review of these papers and rated them independently. When we compared our evaluations, we had achieved a virtual match on the best papers. A similar process was followed to evaluate the student papers.

If you have any fears about the quality of the students in our field today, we challenge you to perform a blind review of the best papers in both classes, then attempt to divide them into student and "open" class.

ED-MEDIA is organized by the internationally respected Association for the Advancement of Computing in Education (AACE). The work of the Program Committee, the reviewers and the Program Chairs is greatly eased by the tremendous work that the AACE staff performs. This year, we received over 1100 presentation proposals from 60 countries. The submission, review and evaluation process is handled by AACE's technically advanced Web-based system. This year saw the introduction of the next generation of this system, which was designed to make the submission, review, and notification process even easier. As professionals working in this field, you are well aware that no new process works perfectly when it is first implemented. We were very pleased that the new system worked extremely well, but if you were one of the few people who did encounter a problem, we know you understand, but we still offer an apology. Be assured that any problems are being corrected and additional useful features are being incorporated. Also, while this conference was being organized, AACE moved their headquarters office. Again, it was amazing that this move occurred with almost no visible effect on the organization of this conference. We would also like to thank the technical and administrative crew who work behind the scenes (and sometimes in front of a restless, yet appreciative, audience) for their tireless efforts in coordinating and managing the huge number of administrative functions and technical requirements that a conference like this necessarily involves. On behalf of the Conference committees and you, the conference participants, we wish to thank Gary Marks and the AACE staff including Marianne Williams, Jennifer Gwaltney, and Jerry Price for their support in this massive endeavor.

As Conference Program Co-chairs, we have been aided considerably by a number of volunteers and helpers who have given tirelessly of their time. In particular, we must thank the Conference Steering Committee of Erik Duval (Chair), Betty Collis, Shelly Heller, Gary Marks, Ron Oliver, and Ivan Tomek who led and coordinated the conference this year. We would like to thank the Chairs of the various Program Sub-Committees: Ron Oliver, Panels Chair; and Sam Rebelsky, Tutorials/Workshops Chair. Finally, we would like to thank the 71 members of the international Program Committee who provided timely and insightful reviews without complaint and little credit.

The University of Tampere and its Hypermedia lab are more than proud to host this
year’s ED-MEDIA. We thank all of you for being here and, of course our partners and colleagues for making this all possible. Ms. Carolina Pajula and her planning team in Tampere have done a great job to make ED-MEDIA 2001 an enjoyable event for all of us. As you will notice during the conference, a good number of e-Learning experts from Finland are working with us. They are more than happy to share ideas and experiences with you. As you now are visiting “Nokialand,” we hope that you also have time to look around this lovely city and country. The city of Tampere has announced that it will be a leading city of information society development in the world (www.etampere.fi) together with its partners the University of Tampere, Technological University of Tampere, City of Tampere, and others. Challenge us, cooperate with us, and especially enjoy your time as our honored guests.

We look forward to meeting with you during the conference. Remember to spend time talking to colleagues from previous ED-MEDIA conferences and make some new friends – the informal program sometimes can have greater rewards than the formal program.

Perhaps you will develop a new collaboration that you can report on at ED-MEDIA 2002 in Denver, Colorado, June 24-29, 2002 or, if you wish to plan further in advance, at ED-MEDIA 2003 in Honolulu, Hawaii, June 23-28, 2003.

Finland
helena.aarnio@hamk.fi  jouni.enqvist@hamk.fi

Abstract: The VETO-project is part of the National Strategy's goals in order to provide good learning opportunities through the use of networks in vocational education in Finland. The methodological strategy is action research. This paper presents some essential results of the ongoing project. The main idea in this project have been to construct a dynamic dialogic model for learning and knowledge construction on the net. In this paper, the basic grounds of the model are described and a tentative model is introduced. The results already available of this project show that it is necessary to develop further pedagogy for dialogic knowledge construction on the net in vocational education. Vocational teachers and learners need cognitive tools in order to be competent on the net. The new learning platforms on the Internet are technically fairly good and versatile, but teachers and learners do not know yet, how to use them pedagogically adequate.

Introduction

The VETO-project is part of the National Strategy's goals set out by the Ministry of Education to develop an Information Society Program in Finnish schools. The goals of the national strategy are to provide basic skills to everybody and life long learning opportunities through the use of networks in studying and teaching. Vocational education has an important role in Finland, and the high level of the technological infrastructure in Finland is utilized effectively in vocational education. Learning environments are extended outside the classrooms, and this demands new pedagogical models of teacher action. Learners will engage in and become inspired by learning activities if they think it makes sense (Enqvist 1999).

Many researches show that teachers should be trained both in information-communication technological (ICT) competence and in how to use the network-based environment in a pedagogically skilful way (Hakkarainen, Ilomäki, Lipponen & Lehtinen 1998). The traditional methods of teachers are so deeply ingrained in their minds that it is difficult for them to learn to construct active and workable situations and processes for learning. Network-based learning environments provide a forum for authentic learning and interpersonal interaction with members of the learning community (see e.g. Lave & Wenger 1991; Harasim, Hiltz, Teles & Turoff 1995; Wenger 1998;), peers, and experts. What must a teacher do and how does she or he achieve the competence to allow the worlds of teaching and learning to meet one another? According to many researchers (Harasim et al. 1995; Warschauer, Turbee & Roberts 1996; Anderson & Kanuka 1997), making good use of the possibilities of interaction and learning on the net produces positive learning experiences.

Producing and Sustaining Authentic Learning in Learning Communities

How can we arouse a real desire of learning and joy of working in the students? The process of passion for learning can proceed, according to Enqvist (1999, 275-277), from an interesting, authentic assignment involved with problem solving and inquiring learning. In vocational education, it is really not difficult to find authentic assignments connected and involved with vocational training.

The significance of social interaction and dialogue in learning, emphasized by Vygotsky (1962; 1978), is crucial in this research. The social interaction is essential to construct knowledge and mastery as well as to get comprehensive and in-depth processed learning outcomes in ICT learning environments (Scardamalia, Bereiter & Lamon 1994; Brown & Campione 1996; Salomon & Perkins 1996). Especially when studying and training vocation and profession, it is important to take into consideration a number of implications derived from Vygotsky's pedagogical thinking by Wells (2000, 60-61). These are: 1) The classroom is seen as a collaborative community; 2) Purposeful activities involve whole persons; 3) Activities are situated and unique; 4) Curriculum is a means, not an end; 5) Outcomes are both aimed for
The notion of a zone of proximal development (ZPD) presented by Vygotsky (1978) is crucial in learning and through that the support of learning can be made adjustable. On the net, this means that it is possible to make learners’ thinking transparent so that the teacher can see what kind of tutoring students require in problem-solving situations just at a certain time. The scaffolding metaphor arises from the notion of ZPD (Dillenbourg 1996). A teacher has a big challenge in scaffolding: she or he has to search an optimal model of action, by means of which she or he can promote the learning processes. The opportunity exists, but in order to succeed, in learning collaboration much interpersonal interaction is required (e.g. Bullen 1998; Harasim et al. 1995). Teachers need a model in order to manage learning / teaching situations on the net.

The participants in the learning collaboration can be thought of as cognitive apprentices (Brown, Collins & Duguid 1989), who may increase their knowledge and competence with the assistance of the teacher, peers, and the experts at their disposal. Cognitive apprenticeship supports the learning of professionalism by developing students’ "conceptual understanding through social interaction and collaboration in the culture of the domain, not of the school" (Brown et al. 1989, 40). It is especially interesting when the learner can be justified to participate in the activities of some community of experts on the net. Then, one can talk about "legitimate peripheral participation" (Lave & Wenger 1991).

Dialogue in Network-Based Learning

An accepted fact is that in network-based learning, teacher, other experts, and learners form a community where, hopefully, conversation is purposeful, relevant, and fruitful. Dialogue is a type of conversation to achieve these aims (Aarnio 1999). Dialogue as a concept is very complicated and the lay opinion of dialogue is not enough to develop conversation in a network-based environment. According to Bohm (1996, 6), dialogue means "the flow of meaning between or among us". Isaacs (1996; 1999) emphasizes that dialogue does not mean just talking. It is important to distinguish dialogue from the general types of conversations.

Jenlink & Carr (1996) speak of four types of conversations common in educational settings, viz. dialectic, discussion, dialogue, and design. Discussion conversation is the forum in which many of us advocate our own individual position. Dialogue conversation is a conversation where meaning is constructed through sharing. Dialectic conversation focuses on framing a logical argument for distilling the truth. Design conversation focuses on creating something new. Lave and Wenger (1991) believe that an experience can be pedagogically valuable only on one condition: the experience does not consist of individually stored memories, but is primarily comprised of complex interactions and dialogue in the community. A network-based environment is good for this kind of work, where the participants are able to share their knowledge and at the same time contribute to each other’s construction of knowledge and competence (Comstock & Fox 1995; Stacey 1999). According to Bohm (1996), it is worth remembering that the word “pa
meanings: “to partake of” and “to partake in”. Receiving is as important as contributing.

Responsiveness is very important in the construction of dialogic knowledge and the construction of the meaning happens collaboratively in the act of speaking following one each other (Wells 2000). Bereiter (1994) proposes the word "progressive discourse" in describing the process in which sharing, inquiring, and checking of opinions will shape new understanding.

According to Bohm, Factor & Carret (1991), dialogue is a powerful tool to understand what, actually, is thinking as a process. Factually, all of this knowledge that we have in mind, is transparent in a thought and this knowledge mediates in a thought. We need a tool that will make the process of thinking a little bit slower with the aim of being able to perceive the thinking process at the same time. The skill to find out how somebody is thinking and how she or he explains her or his action (Aarnio 1999, 20-22) could be one method to slow down the process of the thinking. If one has this skill, one can help somebody make her or his thinking process transparent, and at the same time, one is able, as a listener and speaker, to look at one’s own process of thinking, namely, what it is like and how it proceeds. In a network-based learning community, one has good chances to develop one’s thinking skills through dialogue.

If teachers have the competence to help the learner to open conversation, to inquire and to open so called ‘hot words’ and utterances, and to express the thinking process on her or his own, which is at that moment incomplete and just getting form, then they will find continuously new paths to promote dialogue. Aarnio (1999) noticed that the student teachers had plenty of difficulties in dialogue, especially in inquiring, in a network-based environment. The facilitators of the dialogue are needed in a network-based environment and participants are assisted at creating dialogue and knowledge construction collaboratively by facilitators. A skilful e-moderator (Berge 1995; Paulsen 1995; Berge &
Collins 2000; Salmon 2000) is able to take the participants into dialogue according to the situation and is also able to continue the dialogue appropriately. Senge (1994) points out that when one can perceive and experience the meanings flowing in a situation and one is able to find out just that thing, which has to put into words, it is an indication of the excellent competence of dialogue. That's why the e-moderator in network based learning should be very sensitive to activate and stimulate the dialogue.

Purpose

The National Board of Education, University of Tampere and Hame Polytechnic, Vocational Teacher Education College and several vocational pilot institutes located at different regions in Finland are involved with the VETO-project. The VETO-project was started 1.5.2000 and will continue until December 2001. The main goal of this VETO-project is to create the dynamic dialogic model for network-based learning to benefit the needs of vocational education and learning on the job. In this article we like to consider two important questions, which are part of our research problems of VETO-project: 1) What are the elements of the dynamic dialogic model for network-based learning in vocational education?; 2) What kind of competence teachers and teacher students have in inquiring as a part of dialogic knowledge construction? We describe some important results and implications we have found out.

Design and Methods

The background of the themes of the VETO-project is based on the results of our earlier researches (Aamio 1999; Enqvist 1999). We have noticed as teachers in vocational teacher education how difficult it is for teacher students, as well as in-service teachers, to construct learning situations that support problem solving, inquiring, and intensive dialogue in traditional learning and teaching, to say nothing of learning and teaching on the net (Aamio 1999; Enqvist 1999). The starting point of the VETO-project was the course called "Network-based learning environment as a field of dialogue and learning", and it was organized for 30 vocational teachers from different domain during 5.5.2000 - 9.9.2000. The whole research project was divided into three stages: 1) The orienting and planning stage for the summer and autumn 2000; 2) The applying and constructing stage for the spring 2001; 3) The applying and evaluating stage for the autumn 2001. One of the outcomes of the first stage was a tentative model of network-based learning for vocational education. In the second stage the model has been restructured and improved on grounds of the empirical data that have been collected during research process. The observations in this stage indicate that there is a need to investigate teachers' and teacher students' competence of inquiring as a part of dialogic knowledge construction. Just now the process is in the middle of the stage 2, and that's why the results are tentative.

The strategy of this research project is action research by nature. This research is involved with practical issues, the kind of issues and problems, concerns and needs, that arise as a routine part of activity in the real world. Specifically, practical orientation has remained a defining characteristic of action research. This research has the central features of action research (see Kemmis 1995). It is characteristic of action research that the data is collected by many various mixed methods during the process: e.g. questionnaires, interviews, observation, and documents.

Results

Main result 1

The course "Network-based learning environment as a field of dialogue and learning" was organized for 30 vocational teachers during 5.5.2000 - 9.9.2000. The open question for the course participants (n=30, full time teachers) after the course was: How has this course improved my understanding concerning of the dialogic knowledge construction?

The answers of the participants to the open question reflect widely the improved comprehension of this subject area. The participants reflected the importance of the competence of dialogue. Many of them told that they have not been able to think that dialogue is very demanding and learning of dialogue requires a lot of conscious training and great effort. One of the participants answered: "My understanding of the meaning and the practice of dialogue has been opened so that I am able to evaluate conversations in practical situations in a new way." His peer caught the point in another way: "This has shown to me how long the process to change myself as the teacher is with dialogue into e-moderator of the dialogic learning."

From the participants point of view it was very useful to learn to pick up so called 'hot words' or utterances as a critical skill of dialogue. One participant said that "it was very insightful to make inquiring questions and to open the 'hot
words' and the other one emphasized "the inquiring method with 'hot words' is a very crucial help in conversation on
the net..."

The contribution of dialogue makes the learning process different on the net. One participant formulated this idea:
"Learning and teaching on the net is entirely new to me. I advanced when I noticed the advantages, which follow after
the thinking process has been made transparent and public... On the net it is really possible to get authentic thinking
together instead of the change thoughts." The peer participant described the same thing in this way: "Collaboration is
possible on the net, the students are able to work out things together and to create new common understanding."
Dialogue also helps students on the net in general: "When the dialogue is going, it is easier to find out the difficulties of
the student and the results of learning are better." One participant had very interesting comment: "I earnestly believe
that the net is a possibility and an answer for many situations as a field of dialogic learning ... To my great surprise I
think the net as a human and warm friend, which helps me to mediate my thoughts, hopes, experiences etc. to my
peers."

It is professionally very demanding on the teacher to engage students in dialogic knowledge construction on the net and
to facilitate students in their learning processes. The participants reflected these aspects critically and here are some
examples of their reflections:
"In the learning processes on the net it is important to set realistic aims and to structure the course very clearly..."
"It is necessary to study to use dialogue with the students and to understand the nature of dialogue before a teacher can assume
that the process can start and is progressing well on the net....
"The meaning of the dialogue is really crucial on the net. How does the conversation start, how does it go on, how is it directed, and
how can you influence the dialogue as a conversationalist and as a tutor."
"The teacher's role in sustaining learning process in the group is essential... By means of dialogue on the net you can catch up with
the students very easily or loose them as well - you have to be attentive..."
"The course has facilitated me to get clearer idea how to use dialogue in order to solve problems together."

The students brought up also that learning on the net must not be a digital version of a correspondence course, and the
function of the net is not merely to give out material and many kind of tasks or assignments.

Conclusions 1

The answers of the participants indicate that dialogue has become a useful tool to carry out learning on the net. The
participants comprehended the nature of a text or other symbolic language; it is a source to joint comprehension and
knowledge construction. A text can be like a 'treasury', full of unfamiliar knowledge that leads you to new
combinations of issues or to new insights. So called 'hot words' help to open that 'treasury'. The val
words' can be seen by means of inquiring the meanings which are hidden back of the words. The participants
understood that dialogic knowledge construction brings along something that nobody knows before.

The participants were satisfied with the things they learned on the course. Their realized that the mastery of dialogue,
the construction of meaningful learning process and structuring the process on the net as explicit is possible, are skills,
which cannot be compensated with any other skills. The professional skill of a teacher as a facilitator of dialogue and as a
"scaffold" on the net, demands efforts in order to evolve. The traditional working model of teachers and the
monological style of conversational culture, cannot be relied. An attitude of inquiring and explorative talk that will
promote learning, was difficult to them.

To sum up, it was demanding for participants to act purposefully in WebCT-learning platform; they have to struggle
hard to catch the collaborative idea of dialogue; and they need a lot of help and tutoring in order to become good
facilitators of dialogue, "scaffolds", and constructors of meaningful and enthusiastic dialogic and inquiring learning
processes.

Main result 2

Because, as we have seen above, the inquiring dialogue is a difficult way to work for teachers, it was important to find
out what kind of inquiring questions the vocational teacher students (n=298) could bring up fairly spontaneously on the
net in order to help a case example, student (A), to continue her online learning. All these teacher students were
studying in Häme Polytechnic, Vocational Teacher Education College and the mail lists and WebCT learning platforms
were set up for them. Before sending the proper open question, one preliminary information message was sent to them
via e-mail, four days before the proper message. So the students knew to wait some important task message and they
knew that when they opened the proper message, they would have only 15 minutes time to perform the task and then
send their answers back to the researchers. So the situation was spontaneous enough. 80 reply-message answers were received via e-mail on time.

The teacher students were asked to imagine themselves as an online teacher of the student (A). In the task, there was given an example message written by the student (A): "The very first day in the world of Internet and e-mail. I feel myself chaotic. It seems that it is difficult for me to face things I don’t understand at all. I am distressed. I feel like crying and I feel depressed…. My student fellows have sent an e-mail message to me, but I cannot find it in my computer. I don’t know, where I find it. Otherwise, even the simplest operations in the Word- text processing program seem not to be coming to my mind at the moment. Just now, I would like to leave off that job. This feeling of mine has come out also in other awkward and difficult situations. I have to work with this feeling by myself. How is that?"

Now the teacher students were asked to make 5-8 questions to the student (A), so that the teacher students would find out the train of thought of the student (A) and in order to help the student (A) to make progress. It is very important to notice that the teacher students were asked to make only questions, interrogative sentences, not any piece of advice or something like that. The findings were interesting.

In the answers of the respondents (n=80), there were given 565 reactions and only 135 of them (= 23%) were pure, open questions, without any preassumptions or proposals for the arrangement of the matter. All the other reactions (77%) were either narration of teacher students’ own range of thought and world of experience, emotional support or closed questions. The closed questions lead us into ‘either-or’-type of answer giving, or they contain either a proposal of the questioner in order to work out the situation or an interpretation of the student’s condition or an interpretation of his/her way of doing things. Then, because the questions are not open, the student’s train of thought and starting points will not be found out but they will be stayed unknown. The answers contained a lot of instructions, own ideas or experiences in related situation and interpretations, in other words illusions about the condition of the student (A), although they were asked only to make questions to the student (A), who needed help. Only 2 respondents of 80 understood the idea that scaffolding will succeed when a teacher has patience to start from student’s train of thoughts.

Conclusions 2

The teacher students use either closed questions or questions which emerged from the expectations and assumptions of their own. They have also tendency to guide and tutor the student, who needs help, based on the teacher student’s own thoughts, experiences and illusions. However, the open problem solving requires the skill of collaborative thinking and thus it should be able to keep the situation appropriately open for the new collaborative thinking. The open and pure questions that familiarize with the train of thoughts of the other, would take in that collaborative direction.

Dynamic Dialogic Model for Learning and Knowledge Construction on the Net

Finally we will present our dynamic dialogic model for learning and knowledge construction on the net in vocational education. Our model is some kind of synthesis of long lasting action research processes since 1996, when we started our earlier action researches (e.g. Aarnio 1999; Enqvist 1999), and ending to the ongoing VETO-project. The model is formed as a result of 1) these earlier action researches; 2) interviews and discussions with teacher trainers in Häme Polytechnic, vocational teachers and students in the pilot institutes; 3) the course “Network-based learning environment as a field of dialogue and learning” for vocational teachers (main result 1); 4) e-mail open question for teacher students (main result 2); and 5) the theory of dialogue and dialogic knowledge construction. VETO-project will continue to the end of the year 2001, and the implementing and testing of the tentative model has been started up and will continue in vocational education.

This model includes the essential elements of the learning and dialogic knowledge construction on the net. The model is dynamic and the progress is cyclic. It helps teachers and learners to identify the critical points or stages in the learning process on the net. (In this paper, there is no room for more details and explanations.)

Learner activities on the net: 1. Becoming acquainted with the world of Internet and the learning platform; 2. Searching for and designing vocational inquiring (study) problems; 3. Exploiting sources of information; 4. Problem

The results already available in this project show that it is necessary to develop further network-based learning and pedagogy in vocational education. The new learning platforms on the Internet are technologically fairly good and versatile learning environments, but teachers do not yet know how to use them in a pedagogically adequate manner. Our aim is that this dynamic dialogic model promotes learning and knowledge construction on the net.

A tool to practice formal proofs

David Abraham, Liz Crawford, Leanna Lesta, Agathe Merceron and Kalina Yacef
Basser Department of Computer Science, University of Sydney, Sydney NSW 2006, Australia.
dabraham,lizc,llesta@ug.cs.usyd.edu.au / agathe,kalina@cs.usyd.edu.au

Abstract: This paper presents a Logic Tutor, a tool to support computer science students in their learning of logic, more specifically in their learning of formal proofs. The current tool is equipped with a deduction system for propositional logic. However its modular conception makes it easy to change to another logic. Preliminary evaluation shows that this tool has a high educational value, thanks, among others features, to its simple, attractive interface and its specific error messages. The Logic Tutor will be integrated in our Logic teaching course in 2001.

Introduction
For a few decades now, computers have played an increasing role in education. They provide a more or less personalised environment where the learners can practice at their own pace, have access to tutorial lessons, be given explanations and feedback on their performance and so on. Intelligent Tutoring Systems, which make use of Artificial Intelligence and Cognitive Sciences, are a popular target but also require a lot more effort to build. On the other hand, non-intelligent but well-designed systems can also be educationally excellent [1,2]. This paper presents the Logic Tutor, a well-designed program with an attractive interface. It has intelligent features such as the expertise to apply rules of inference and laws of equivalence, as well as a certain level of adaptability to the user.

Students learning formal logic have to understand how conclusions can be derived from a set of premises using logical rules [4]. The increasing numbers of students in computer science make it difficult to provide enough human tutors to assist students in this part of their learning. Existing tools for practicing Logic have not matched our expectations, mainly because their GUI had high barriers to initial use and did not provide enough feedback to the learner. This led us to design our own tool. The Logic Tutor presents exercises of formal proofs in propositional logic, checks students’ answers and provides step-by-step feedback.

Educational value in the Logic Tutor is achieved by five means. First the Logic Tutor provides step by step feedback. Each time a student enters a line of the proof, the line is checked for correctness. In case of mistake, extensive explanation is provided by the use of a `cascading mistakes' principle. Second, several levels of help are provided, ranging from a quick start button, to a handy reference to rules of inference, and a tutorial on proof strategies. Third, the history storage provides students not only with the exercises they have done or attempted, but also with statistics on their mistakes. Fourthly, files of exercises may be easily created with a possibility of comments, hints, and partial or even complete solutions. Last but not least, the Logic Tutor has a simple and attractive graphical interface. Simplicity means that the barrier of learning how to use the program is almost non existent. Attractiveness, enhanced by a possibility of changing the look and feel, means that students have pleasure in using the program.

Description of the tool
The Logic Tutor is written in java, which makes it a portable tool. The main modules are the user interface module, the student module and the logical system module. The interface module makes use of the java swing library. The student module stores information specific to the student’s use of the tool. It records all the attempted exercises along with mistakes. The logical system module is divided into two sub-modules, the verification module and the mistake module. The verification module has the logic expertise and checks the correctness of a student’s deductions. The mistake module is articulated to a database of mistake patterns, which is used to produce proper feedback when a student error occurs. This modular design makes it easy to change the logic, as only a few classes are affected. The plug-in of another logic has been successfully tested.

Handling of mistakes
Each logical system, presently the propositional logic system, stores a database of mistake patterns. Whenever the student uses a rule incorrectly, the mistake database is interrogated to find the type of mistake made. The code that checks for mistakes when deductions are entered is thus independent of the logical system the student is currently operating.
When students make mistakes, they have quite often made more than one error. This lead to the principle of cascading mistakes. First it is checked that all the fields in the answer are filled with the right type of data. Then the formula is checked for its syntax. Then the real cascade in the derivation begins. The lower level represents general mistakes like incorrect line number and invalid application of the rule. This level is illustrated by Fig 1: the expert module detects that Modus Tollens can be applied, using lines other than those provided by the user. The higher level of mistakes deals with more specific mistakes, like the use of Simplification without Commutation to deduce the right hand side of a conjunct.

All mistakes are context sensitive, which means that explanations are adjusted to the current exercise. Fig 2 shows the explanation provided when the student uses Simplification before Commutation. The student concludes R from ((P->Q) & R) giving Simplification as justification. However Simplification, in the present logic system, has the form ‘from (A&B) deduce A’. Thus commutation is needed before R can be deduced. The mistake module uses the original formula to construct an explanation detailing how only the left-hand side can be deduced by simplification.

A careful analysis of mistakes made by students leads to the organisation of the database mistakes according to patterns. Currently the database has 50 patterns. Two patterns are given as example below.

Incorrect Justification Pattern: this mistake looks at the deduction and can determine that the user meant to use, say, Commutation, but confused the name with Association.

Incorrect Line of Reference Pattern: this mistake picks up typing errors when the user enters the line number references. It will inform them of the correct line numbers by printing "Try using (1, 3) instead", for example.

Conclusion
Summing up, the Logic Tutor is a tool to support students in their learning of formal logic, and more specifically formal proofs. It cannot yet be classified as an intelligent tutor. However, it has intelligent characteristics. It can adapt to the user by the possibility of changing the look and feel of the interface. It possesses an expert module that enables it to apply rules of inference and laws of equivalence of propositional logic. Moreover its feedback takes into account the inputs of the user, and the explanations provided, in many cases, are as enlightening as the ones provided by a good human tutor. Preliminary qualitative evaluation, which was conducted with students who took the Logic course in 2000, provided a very encouraging feedback.

Immediate future work includes the extension of the database mistakes and the addition of a dynamic exercise generator. This will improve even more the educational value of the tool, both for the student and for the lecturer. The Logic Tutor already provides the learner with the possibility of consulting her/his history using the system. Building on that, a proper learner model, i.e. with insight in the knowledge level and difficulties of the student, is planned to be added the Logic Tutor. This learner model will make use of MOST, a skill acquisition model [5] and maintain the present “scrutability” as it can help the learner to learn better [3].

Finally, our present logic course is being redesigned to include this tool at the teaching level, the training level and the assessment level. Extensive qualitative and quantitative evaluation will be conducted then and meaningful results should be obtained as nearly 500 students enroll in this course.

Integrating a Course Delivery Platform with Information, Student Management and Administrative Systems.

Anne A’Herran
Teaching & Staff Development
James Cook University, Townsville, North Queensland, Australia.
anne.aherran@jcu.edu.au

Abstract: This paper describes the development of an interactive online teaching and learning system model. Built first as a scoping and costing instrument, it has been transformed through use into a tool for systems integration.

At JCU an initial project set out to answer the questions: Do we need a system to delivery learning materials? If so, what / what else do we want that system to do? Should we build or buy a system?

A system model designed to model user paths assisted in the decisions about architecture, and further, the decision to buy rather than build.

Following a recommendation in March 2000 to purchase the Blackboard system, the system model has been re-purposed as a tool for the next stage of the project, which is integrating the selected course delivery platform with information systems, student management and administrative systems.

This paper will be of interest to institutions engaged in or investigating integration of a course delivery system.

The search for an online system at JCU

In 1999 James Cook University’s Teaching and Learning Development Program conducted an evaluation of online teaching and learning systems with a view to selecting one to enhance course delivery at the university.

A comprehensive website describing that Research and Evaluation of Online Systems can be found at http://www.tsd.jcu.edu.au/develop/survey_re/. Throughout 2000 the website provided information about the search for a system, compiling in one place:
- a full overview of the project (context, review of the literature, project plan, resources)
- a survey tool for staff input
- a trial online course developed in a range of systems as a means of comparison of systems and
- a web database of gathered information about system features, sites, capacities.

In March 2000 a report and recommendations for the adoption of online delivery went to senior management. Beginning with the recommendation of specific software (Blackboard 5 Level II) it progressed to strategies for full implementation. The report and its recommendations can be found at the above URL. Through 2000 the website grew, updating the JCU community on the progress of the project. Although its use has passed, it remains a useful resource possibly of interest to other institutions engaged in a similar research and evaluation exercise.

Development of the interactive system model

One aspect of the project which has transformed over that period is the development of an interactive system model. Built first as a series of HTML pages, it was useful first as a starting point, for scoping and costing a home grown system. It has since been re-purposed as a tool for the next stage of the project, which is integrating the selected course delivery platform with information systems, student management and administrative systems.
Build or Buy? The model from scoping and costing tool

We found that systems, like any commodity, can be either home-built, built to specification by an agent, or bought off the shelf. At the research and evaluation stage of this project it was felt important to investigate costs of building a system using university resources. This was because although there are strong reasons for purchase of an off-the-shelf system for online course delivery, there are many successful instances where universities develop a system themselves. It was evident that home-grown systems are often more tailored to a university's specific needs.

It was seen as necessary therefore to scope construction of a system at JCU. Although the exercise excited interest in the IT Resources department, it was difficult when speaking to others including programmers to convey an idea of desired system ingredients without a graphic representation. To this end a system model was designed as an interactive diagram reflecting each part of the system, in prototype. This system model includes basic componentry, specifically what JCU would want in a system. It is a use-case that takes the user - portals users in fact - through a range of pathways to fit their needs. It can be found at http://www.tld.jcu.edu.au/general/survey_re/My_JCU/siteols.html It is a useful tool for estimating costs as it allows more accurate scoping of construction and therefore costing of components and the whole.

We decided not to proceed to build a system ourselves but to purchase Blackboard 5 Level II.

Transformation of the model to integration tool

The next level of purchase, Blackboard 5 Level III provides at additional cost the required APIs and consultancy for institutional tailoring: that is, integration with JCU systems of information, student administration and course delivery. We are now looking at the costs of that integration, whether to purchase the consultancy or to do the integration in-house. The system model is now a low-key but practical aid to assessing the scope of integration. At time of writing it describes generally - possibly inaccurately - some relationships between JCU systems.

Benefits of the system model

As an interactive use-case it expresses what each part would actually do. A number of different users with different needs can walk through the system and test the parts. Its interactivity is its validation as a system and will be a useful means of eliciting from all stakeholders an accurate view of what they want in their part of the system.

It will provide a context when working with reference groups from the main system areas, in fleshing out what we want in that integration. It will elicit feedback by inviting ideas about what the system should do at each point. It will provide a useful vehicle for technical and non-technical administrative personnel to describe the transactions that occur in universities, such as student enrolment flows. It highlights the need for focus groups to work in certain areas as sub-projects.

It is not entirely a descriptive model as it looks forward to what could be, rather than describe what exists. Information and student administration systems at JCU will be replaced and upgraded in the years ahead, and an accurate system model could never be static as it needs to reflect continual operational change and expansion. It already highlights existing work-flows and arrangements that will need to change and become more efficient.

It is a useful exercise for any institution. Each institution will come up with an entirely different system model, one which reflects its specific needs. Other stakeholders could be added as discovered to the dummy 'portal' - e.g. the business selling its product to the university, with its specific pathway and requirements.

Conclusion

As an innovative example of organisational design method and a useful means of testing user pathways through a system, with possible benefits to costing and project management, the system model may interest other universities engaged in the process of development and integration of a course delivery system that meets the needs of all - learners, academic staff and administration.
PRELIMINARY RESULTS OF A PILOT PROJECT INTERNET BASED SUBJECT REGISTRATION SYSTEM

Abstract: This paper presents the preliminary results of a pilot project on Internet based Subject Registration System. The system allows the students to register for their relevant subjects through Intranet or Internet via any web browser. The system was developed using web programming languages such as html, VB script and ASP (Active server page). The system has been tested successfully on Degree Students of Faculty of Electrical Engineering, Universiti Technology MARA (UiTM) for three phases. The first phase involves only semester two Degree students while the second and third phases involve all degree students. The Internet-based Subject Registration System has managed to ease out congestion and found to be very efficient as it reduces faculty’s manpower and resources.

1. Introduction

Rapid advancement in Internet based applications and the wide usage of World Wide Web (WWW) has led to many challenges in information technology (IT) globally. The dawn of the new millennium has seen the births of numerous internet based applications as people are more geared toward borderless environment and communication anywhere anytime.

The trend is of no exception to Malaysia. The IT growth is made more rapid by the government’s immense interest in promoting its advancement through the famous Multimedia Super Corridor (MSC) programme [1]. MSC becomes the nation’s catalyst to the multimedia industry so as to provide an efficient information service in business organisation as well as the general public. Organisations have invested millions of ringgit in upgrading the infrastructures and resources to be at par with their counterparts locally and internationally.

Educational organisations are also affected by this technological evolution. New IT techniques are incorporated in their learning methodology such as web based learning (WBL) where traditional classrooms are replaced with multimedia applications[2]. Besides the revolution in learning methodology, various on-line information systems are developed using internet based technology such as student information system, financial system and administration system [3].

Thus, the Faculty of Electrical Engineering of the Universiti Teknologi MARA (UiTM) has taken a bold step in embarking a pilot project in Internet based Subject Registration system for its Degree students.

This paper presents the preliminary results of a pilot project on Internet based Subject Registration System which has been run for three semesters. The system facilitates the students, lecturers and administration with user friendly interfaces and end-user requirement.
2. Internet based Subject Registration System Design

The system is a Web application, running on a Personal Web Server. It is developed using Hypertext Markup Language (HTML), Microsoft® Active Server Pages(ASP), VBScript, Microsoft Access 97 and Open Database Connectivity (ODBC). The database design was created based on four (4) main contents namely, subjects, student list, lecturers list and class schedule. All the databases were developed using Microsoft Access 97. The detailed contents of the design are shown in Figure 1.

The software is designed to offer a complete feature of registration package to the students and is accessible as follows;

i) Check students’ identification numbers (SID) and semester through Student Login
ii) Register Subject, where it displays list of subjects offered and corresponding groups
iii) View schedule after registration which allows the student to see their current semester time table
iv) Change password allows the students to change their password for security reason

The lecturers are able to get access to the student list for the respective subject and able to print the list upon registration. The administration is able to modify timetables, lecturer’s and students’ identification number and add

3. Interfaces

Figure 2 shows the student interface which is generated as the student selects the subject to be taken for a particular semester and previews his selection. The interface consists of the student’s new schedule indicating subjects being registered and subsequently highlight time clashes if there are any. Here, the student can check his selection and hence, proceeds or reenters his selection.

The administration interface is illustrated in Figure 3. This interface allows an administration to add or delete lecturers’ particulars that includes his/her identification number, subject code, number of students per class. Apart from this, the administration is also allowed to view and modify the lecturers’ particulars directly from database.
Figure 3 Example of administration interface

Figure 4 shows the lecturer’s display window that would allow a lecturer to view or print the students’ list. Here, the lecturer is allowed to enter or modify the students’ results which will be stored in the system for future reference.

Figure 4 Example of lecturer interface

4. Results and Discussion

This system has been tested successfully on Degree Students for three phases. The first phase involves only semester two Degree students while the second and third phase involves all degree students. The first pilot run was conducted during June-November 1999 session and the second pilot run was conducted during December 1999- May
2000. Both testing were carried out on workstations and the website can be displayed using Internet Explorer or Netscape. The third run was conducted during June-November 2000 session using personal computers.

Figure 5 shows the number of students registered in each semester and Figure 6 shows the number of successful connections used simultaneously for each semester. The graph illustrated in Figure 6 shows that the system is limited to less than 12 connections when running simultaneously. This is due to the limitation of the database used. Therefore, a research is currently carried out to modify the system database server to accommodate more users and enhance the capability of the system.

![Figure 5](image)

**Figure 5 Number of students registered in each run**

![Figure 6](image)

**Figure 6 Number of successful connections for each run**

### 5. Conclusion

The Internet-based Subject Registration System has been successfully tested for three semesters with increasing number of students subsequently. The system has managed to ease out congestion as students do not have to move from one room to another to manually register for their subjects. Its user-friendly menu driven web page provide students with information on the study plan, pre-requisites and time table with an added advantage of avoiding time clashes in their time-tables.

Note:
The Effects of Strategies Instruction via Computer on Student Attitudes toward Mathematics Problem-Solving

Doehee Ahn
Dong-Eui University
Pusan, South Korea
E-mail: <dahn@dongeui.ac.kr>

Abstract: This exploratory study, utilizing a general strategy, SPIDER, and two types of computer-based instruction (CBI) programs developed by the researcher, examined the effects of explicit strategies instruction on 105 sixth-grade students' attitudes toward mathematics problem-solving. An attitude survey was administered to investigate their attitude change toward mathematics problem-solving and the CBI program which they received. The findings indicated that students who were exposed to the CBI program either with or without explicit strategies instruction developed more positive attitudes toward mathematics problem-solving. Importantly, some students in the experimental group showed increased self-confidence toward mathematics problem-solving and self-esteem, whereas such comments were not observed from students in the CBI control group.

Rationale and Purpose of Study
In the International Commission on Mathematical Instruction (ICMI) study (1986), Howson and his colleagues noted the following teaching conditions which prevent teachers from implementing well organized instruction:

A teacher who has to teach 5 or 6 classes a day has little time to reflect on his or her teaching, to prepare instructional material, to inspect a variety of alternative approaches, or to work with colleagues in developing and renewing a coherent program. A teacher who lacks a work space, equipment, a budget for purchasing materials or traveling, discretionary time for working with colleagues or students, cannot be expected to develop far as a 'reflective practitioner' (p. 80).

The question that arises then, is how can the teaching of cognitive and metacognitive skills be effectively applied to a classroom setting in the face of all the factors described above? One possible way is to use a computer to teach these skills because the teacher can no longer rely solely on a chalkboard, chalk, paper, pencils, and textbooks (NCTM, 1989). Computers can provide greater degrees of flexibility to activate students' learning processes. For example, computers can provide well-structured, individualized, and user-friendly instructional presentations that can facilitate learning. Silver (1985) suggested, that the "computer can be used as a tool to create environments in which students can be given the opportunity to think mathematically and solve challenging problems,...can be beneficial in the teaching and learning of problem-solving,...can be designed to provide useful feedback or help sequences that focus not simply on the calculation of an answer but also on processes or heuristics generally useful in problem-solving" (p. 263). In addition, motivation will be enhanced since students can learn at their own pace without group competition and evaluation. However, teaching mathematics problem-solving in a computer-based learning environment has not been done in many research studies. Moreover, there is a paucity of literature on the effects of mathematics problem-solving strategies instruction via computer on attitudes toward mathematics and mathematics problem-solving. The purpose of this study was to explore the potential effects of general and specific strategies instruction via computer on students' attitudes toward mathematics, mathematics problem-solving, and the CBI programs which they received.

Research Method
This exploratory study, utilizing a general strategy, SPIDER, and two types of computer-based instruction (CBI) programs developed by the researcher, examined the effects of general and specific strategies instruction on 105 sixth-grade students' attitudes toward mathematics problem-solving. Of the 105 students in this study, 68 students in the experimental and CBI control groups completed the entire survey, consisting of 12 Likert-scale items and an open-ended question, whereas 37 students in the traditional control group responded to only the first three items in the survey. Quasi-experimental design was implemented to conduct this study. Students drawn from five public
elementary schools were divided into three groups (experimental, CBI control, and traditional control). An attitude survey was administered to investigate their attitude change toward mathematics problem-solving and the CBI program which they received.

Data Analysis
To examine students’ attitudes toward mathematics, mathematics problem-solving, and the CBI program (PSS-CBI and Control-CBI programs), data were analyzed using $\chi^2$ tests. An independent variable was three treatment conditions (experimental, CBI control, and traditional control). A dependent variable was the attitude survey.

Results
Attitudes toward mathematics, mathematics problem-solving, and computer use. A comparison was made among the three groups’ (experimental, CBI control, and traditional control) responses with respect to their attitudes toward mathematics, mathematics problem-solving, and computer use. Statistical significance levels using the Chi-square tests were found on attitudes toward mathematics ($\chi^2 (2, N = 83) = 16.81, p = .000$), and mathematics problem-solving ($\chi^2 (2, N = 75) = 12.69, p = .000$) among the three groups. The findings showed that a significant number of students in the experimental and CBI control groups reported that they favored mathematics (experimental = 74.2% and CBI control = 89.3%) and mathematics problem-solving (experimental = 79.3% and CBI control = 80.0%), whereas only 37.5% of the students in the traditional control group responded that they liked math, and 38.5% expressed that they favored mathematics problem-solving. These results indicated that students who received the CBI program came to like math and mathematics problem-solving better than students who did not receive the CBI program. Participating in the CBI program appears to have improved students’ attitudes toward mathematics and mathematics problem-solving. With respect to their attitudes toward computer use, however, there was no significant difference observed among the three groups ($\chi^2 (2, N = 102) = 3.44, p = .179$). Regardless of the group, an overwhelming majority of students responded that they were interested in using the computer (experimental = 94.7%, CBI control = 100%, and traditional control = 100%).

Attitudes toward mathematics problem-solving and the CBI program. To measure the effects of the explicit strategies embedded CBI program on attitudes, students in the experimental and the CBI control groups were given nine Likert-scale questions on attitudes toward mathematics problem-solving, and as well as the CBI program they received. It was observed that there was no significant difference on students’ attitudes toward the CBI program between the experimental and CBI control groups.

Comments on the CBI program. As part of the attitude survey, students in the experimental and CBI control groups were also asked for additional comments on the CBI program they received. Students in both groups often mentioned the CBI program as fun and helpful for understanding mathematics problem-solving. They also expressed that the CBI program allowed them to work at their own pace. Interestingly, some students in the experimental group described increased self-confidence in mathematics problem-solving, whereas comments from the CBI control group did not include statements about self-confidence. Generally, students described the CBI program as fun, self-paced, and helpful for understanding mathematics problem-solving.

Recommendation for Future Research
Some students who were exposed to explicit strategies instruction via computer (PSS-CBI program) reported increased self-confidence in mathematics problem-solving and self-esteem; however, such comments were not observed from those who received the Control-CBI program. In order to find a significant effect of explicit strategies instruction via computer on students’ self-confidence and self-esteem, future research should include a systematic measure of these affective attributes.

Capturing Communication and Interaction Needs of the Users
– Building Better ICT Based Learning Environments

Raila Äijö1, Johanna Leppävirta2, Sigrún Gunnarsdóttir3, Deborah DiDuca4
1,2 Helsinki University of Technology
Finland
{raila.aijo,johanna.leppavirta}@hut.fi

Abstract: The design of an ICT based learning environment should combine the communication and interaction needs of different kinds of users in varied situations. The purpose of this study was to explore how the needs of different user groups vary and how their needs could be captured in the design of an ICT based learning environment. The analysis of the user needs was carried out as part of a design process of an interaction and communication environment for community based learning. The results showed that the needs of the user groups vary, which should be taken into consideration while planning new ICT based communication and learning services.

Background

The quality of distance education is highly dependent upon the interaction and participation of the learners (McHenry & Bozik 1995). Holmberg (1989) has stated in his essential principles of distance education that the core of distance education is the interaction between the teaching and learning parties. Each user has multiple communication and learning needs, which affects the choices of media they would like to use. For example Neal's (1997) study showed that the students varied clearly in the preference for, and comfort levels with the different communication tools. The communication tools provided for the users should support both the formal and the informal interaction. Fowler and Mayes (1999) have elaborated Wenger's (1998) ideas on organisational learning in relation to an educational context, and talk about learning relationships as a way of becoming a full member of a society. Learning relationships vary according to the characteristics of the groups involved, the context within which they operate, and the strength of the relationships (Fowler & Mayes 1999). Fowler's and Mayes's study of real world learning relationships implies strongly that also the user needs for ICT based learning environments vary. The goal of this study was to identify the communication and interaction needs of different kind of users.

The Study

The key in user centred design is to use the information gathered in the users' own environments as a basis of design. Typical user-centred methods include observations, listening to the users and talking with them. (Hachos & Redish 1998.) Focus group was selected as the data collection method for this study. During the focus group session the users were presented with a storyboard scenario of an imagined communication and learning service. After the presentation the participants filled in a questionnaire independently and afterwards the group discussed about their needs and concerns related to ICT based learning services. The participants (N=22) were selected to represent different forms of learning relationships defined by Fowler and Mayes (1999) in their study of learning relationships in real life:

a) Peer relationship: A relatively small group of people who know each other personally, and have strong relationships (e.g. are good friends). They have relationships outside but although these are usually connected to one member of the group (e.g. a father), they are perceived as a collective asset.

b) Federal relationship: The entities do not normally know each other well, and can be very widely distributed. Each entity is viewed as an equal, trading knowledge or skills, to meet their own particular needs, but also recognizing the importance of maintaining the federation for purposes of mutual benefit.
c) Hierarchical relationship: A structured and formal set of relationships, where communication patterns are determined mainly by perceived or actual status. The status is however not always explicit but inherent within the community. Movement up the hierarchy is a major motivator. Outside links tend to come in at the pre-defined level reflecting that the hierarchical structure is apparent to external people.

Results of the Study

The study showed that the representatives of the peer group were interested in using an ICT based learning and communication environment for supporting their already existing social and learning relationships while representatives of federal and hierarchical groups felt that a possibility to build new relationships and communities over an ICT based service would be useful for them. The representatives of the peer group didn't mention an ICT based communication and learning service as a possibility to get new contacts or as a possibility to be in contact with experts and teachers. According to Fowler and Mayes (1999) the peer group members have stronger learning and communication relationships, which indicates that their need for new relationships is lower than for federal and hierarchical group members. Fowler and Mayes (1999) have also defined that the members of federal groups are more aware of their own needs and goals and that the group is a mean for them to reach their personal goals. An indication of the need of fulfilling personal goals is that the representatives of the federal group were highly interested in being able to tailor the service to their own needs. The results also showed that the representatives of the hierarchical group were more interested in having contacts with the experts, which slightly indicates their hope for upward movement. Both the representatives of the federal and hierarchical group were interested in having all their communication tools integrated into one learning environment, which was not mentioned by the representatives of the peer group. And they would like to have a possibility to store conversations and other materials for later use especially if they don't have a possibility to be on-line at the same time with their colleagues.

The study showed that the needs and concerns of the different user groups vary and that the distinctions between different groups made by Fowler and Mayes (1999) can be used as a guideline while segmenting the user groups of ICT based learning and communication services. The differences between federal and hierarchical groups should be further explored. Focus group as data collection method combined with independently filled in questionnaire was found suitable for the study. The focus group discussions allowed the participants to share their thoughts, which generated new ideas. The importance of group discussion was evident, especially in the federal and hierarchical groups. The role of the independently filled questionnaire was more important for the representatives of the peer group.

OrtoWeb - Instructor Networking over Internet for Orthodox Religious Education

Risto Aikonen
Department of Applied Education
Joensuu University
P.O. BOX 111
FIN 80101 Joensuu
Finland
Risto.Aikonen@joensuu.fi

Abstract: This paper is a description about an ongoing development project concerning Greek Orthodox Religious Education in Finland at the information technology based environment. In the project the university co-operates with the local school authorities. A project group has been established of the voluntary Orthodox religion teachers from different school levels. Under the supervision of the university the main tasks of this group are to develop their subject teaching by using digital learning materials during the lessons, to produce new learning materials for the network and to share out the network the new pedagogical knowledge with their geographically widespread colleagues.

Introduction

In Finland Religious Education is a compulsory subject for the pupils both at Elementary and Secondary Schools (Lower and Upper). The Finnish speaking Greek Orthodox Church is a minority religion in Finland. Every school year there are about 6000 Greek orthodox pupils in the country and they are taught by 300 teachers. Because of the historical reasons the members of this Church are spread out all over Finland making up 1% of the total Finnish population of about 5.5 million. The majority of the Orthodox Christians live in the eastern and southern parts of the country. During the decades the Orthodox religion education at schools has faced many problems and among them the main one has been the lack of proper and updated teaching materials.

Since 1996 the Finnish Ministry of Education has launched a program called "Finland as an Information Society". The main targets are to increase the benefits of the new information technology in communication and education, to adopt it in networking between different kinds of institutions, i.e. schools, and to raise the level of education and research by applying information technology.

Network in teaching is based on the idea that a teacher utilises the network services to diversify to multiform teaching. The net is used as teaching aid. At the same time one has to take into consideration the fact that usually a teacher has two roles. He/she can be both the subject and the object of the network working. The network services used in teaching can deal with distributing information or communication. Communication in this environment has many benefits. The information can easily be revised, stored and produced compared to the paper versions. After having material in the network the teaching itself can be planned so that new learning material can be produced from the information located in the net. Students can obtain information independently or they can produce information for the net (i.e. own www-pages). When using the net in this way a teacher always has to remember that the computer-based learning environment itself is not the absolute value. One also has to take into account the functional insecurity when using net in teaching.

Networking over OrtoWeb

With this kind of background described above the local educational authorities and the Department of Applied Education at the University of Joensuu have planned a co-operative project. The focus is to develop networking in Orthodox religious education, and especially its materials and methods, by applying the possibilities of information...
technology and the internet. The project is one of the 17 projects the Finnish National Board of Education that has started in 1999.

The main target of the project is by using the internet to develop and test a national learning (network) environment for Orthodox religious education, and its teachers to support it at Primary and Secondary Schools (Lower and Upper). During the project there has been for example formulated the technical base (www-site=OrtoWeb), and the teachers have produced visual and auditory learning material of the Orthodox Church for the needs of Religious Education (R.E). Teachers have tested the Religious teaching and learning and communication in general in this environment and given feedback (pedagogical knowledge) from the site. The digital materials made by Orthodox teachers themselves were the answer to a great demand in spite of the product’s slight deficiencies in technical level. The material was mainly produced during the workshop days and the teachers got both technical and pedagogical guidance during the working process. In the workshops the contact with the colleagues in small groups supported also their networking. This kind of peer couching or peer tutoring is a good way of learning from colleagues to promote new pedagogical thinking, teaching material and curriculum. During the process they noticed that they had something common to be shared in face to face situation and encouraged by that feeling started to communicate by e-mail, too. In spite of this finding within the project the communication over the network was not very popular in general (discussion group and chat). Only when the teachers had a common topic, which was related to everyone’s work, the text based conversation was activated for a while.

Networking among the Orthodox religious teachers has orientated teacher’s content and pedagogical knowledge. They have the common substance, but they teach about it without knowing how their colleagues are dealing with the same things under the guidelines of the curriculum. Next step during the networking process has been that this kind of common, but before more or less unshared information can be utilized when making new teaching materials and contents on the net. On the other hand one has to remember that the networking does not just happen by itself. A technical platform has to be chosen, decisions about the server solutions, their administration and programs and so on has to be made. Also the teachers have to be educated in content making and trained to use the network in their communication and teaching. Though the experiences about sharing one’s diversified teaching knowledge with the colleagues, about making peer consulted digital learning materials and after having tested these in the classroom situations one can say weather the networking is worth it. According to the teachers answers in the questionnaire the answer is: “To get something, just pay it forward”.

Improvement of University Classes Introducing Topics-based Discussion Using the Web Bulletin Board

Kanji AKAHORI
Graduate School of Decision Science and Technology, Tokyo Institute of Technology
2-12-1, Ookayama, Meguro-ku, Tokyo, 152-8552, Japan
Akaahori@ak.cradle.titech.ac.jp

Abstract: This paper describes improvement of university classes by introducing topics-based discussions using the Web Bulletin Board (WBB), as a tool for assisting discussion. Students can exchange their ideas or opinions before and after classes by writing and reading on the WBB. The log record, which includes indexes such as access frequency, referred frequency, and student names, and texts written by students on the WBB were analyzed. Results indicate the following research-findings: (1) WBB plays a role to facilitate positive participation to classes, (2) Contrary to the traditional instruction without the WBB access, students were able to deepen their understanding of the theme by accessing the WBB before and after classes, (3) The aforementioned indexes were used as students' evaluation measure.

Introduction
It has been pointed out that Japanese students do not prefer discussion-based classes and lack discussion skills in general. Under the current educational setting, it is very hard to change the traditional lecture-based instruction style to the discussion-based instruction style in universities as well as primary and secondary schools (Akahori, 1998; Ertner, 1999). The assumption is that integration of the WBB to classes promotes advancement in discussion skills and positive attitudes towards classes. Some papers have addressed advantages of Web-based instruction (Collins, 2000; Laffey, et al., 1998).

Method introducing WBB to class
The author gave lectures on “Educational Technology” for undergraduate students at a university in Tokyo and introduced the WBB to classes in the subject as following.
a) Textbook used: The author's book.
b) Discussion topics: Sixteen topics were selected by the author. For example, “What are the problems on promoting ICT education and making plans to promote teachers’ ICT literacy by examining related information.”
c) Subjects: Sixty-two undergraduate students were separated into 16 groups.
d) Discussion method: The discussion began by each group choosing one topic and subsequently presenting their opinions and solutions on the topic on the WBB. Other students from the class participated in the discussion by responding to the initial presentation of the opinions and solutions.
e) Privacy protection on the Web Bulletin Board: Students accessed the WBB by entering a password to protect their privacy.
f) Period: Three months from April to June in 2000.

Statistical analysis of the log records from the WBB
The following indexes of the log were analyzed.
(1) Access frequency according to days of the week (Refer to Figure 1)
The classes were conducted from 8:50 to 10:20 on Wednesdays. Access frequency, including both reading and written text on the WBB, showed a peak on Tuesdays. In other words, students accessed the WBB the most on Tuesdays to prepare for the class next day. In figure 2, the gray bars show access frequencies (722 in total) and the black bars show written text only frequencies. Traditionally Japanese students do not study during weekends, however, by using the WBB, results show that students studied even on Saturdays and Sundays. This suggests that students' participation was facilitated.

(2) Access frequency according to hours within a day (Refer to Figure 2)
Figure 3 shows two peaks; one is from 10:00 to 16:00, and another is from 20:00 to 24:00. The two peaks correspond to after class and studying time at home, respectively. This shows that students accessed the WBB frequently outside of class, and therefore, suggests that their interest in the topics presented in class was high.
(3) Log records from the main host server
By examining the log records from the main host server, 339 counts (or 48%) were from the university server, and 373 counts (or 52%) were from commercial servers. This corresponds to the aforementioned two peaks of the access frequency according to hours within a day.

**Analysis of text content written on the WBB**
The author analyzed features of text content written on the WBB using the following indexes; a) writing frequency by each student, b) text quantity (total byte) written by each student, c) depth of hierarchy tree structure, d) referred frequency (including accessing and quoting) by other students.
The quality of the written texts were also analyzed and scored (on a 5 point scale) from the following viewpoints; (a) awareness of topics understandings, (b) logical composition of text, (c) originality of ideas, and (d) references of related information including other written texts.
The following results were found by analyzing the text content:

1. **Total frequency of written texts and text quantity written by students depended on the content of the topic.** Students were more motivated to discuss about reality based contents such as authentic and realistic problems, planning, and policy making, and contradictory topics for debate.
2. **Referred frequency was not due to the quality of the content of the text.** It was due to merely the fact that students accessed the initial text more often than new text because students had to read the initial text to understand the flow of the discussion.
3. **The texts leading to more depth of hierarchy tree structure could not be concluded as high quality content.** The author analyzed relationship between text scores of the viewpoints of the contents quality and depth of hierarchy tree structure and couldn’t find any clear correlation among them.

![Access frequency by days of a week](image1)

![Access frequency by hours within a day](image2)

**Implication and future works**
The author found effective functions of the WBB, especially to bring students’ active participation and positive attitudes to classes. However, since the hierarchy tree may contain too much information, students took excessive amount of time to process the information. For this reason, in the future it is necessary to develop a system where the text content of the hierarchy tree can be summarized in order to grasp the total flow of the discussion with more ease.
The author would like to express a lot of thanks to Mr. Kikuchi and Mr. Shimogohri for their great cooperation.

Abstract: The Learning and Teaching Support Network (LTSN) has been established to promote high quality learning and teaching in all subject disciplines in higher education. The Centre for Information and Computer Sciences (ICS) is one of the 24 Subject Centres who supports the sharing of innovation and good practices in learning and teaching in both the information and computer sciences. The Centre will act as a catalyst for change providing both a pro-active and a responsive service to address the evolving requirements of the discipline community.

Introduction
In the UK, the Learning and Teaching Support Network (LTSN) has been established to promote high quality learning and teaching [See http://www.ltsn.ac.uk]. The Centre for Information and Computer Sciences (ICS) is one of 24 Subject Centres who together with a Generic Centre make up the LTSN. The network supports the sharing of innovation and good practice in learning and teaching including the use of communications and information technology (C&IT). The subject discipline focus of the LTSN recognises that for many in HE it is at the subject level where most networking and exchange of best practice and innovation takes place. By working with subject-based communities, the LTSN provides an effective means for dissemination of information and practitioner support. In recent years the services traditionally offered by the library and computer centre have converged in many HE institutions. The establishment of a Centre for ICS mirrors this change and constitutes a major strategic response to the challenges facing academic practitioners within the disciplines of Computer Science and Library & Information Science. By merging existing capabilities within the two disciplines the Centre aims to create a powerful new force for the development of products and services accessible to the entire learning and teaching community.

LTSN-ICS aims to make a rapid and far-reaching contribution to ICS education through:
- identifying and promoting pedagogical innovation and best practice;
- promoting the integration of appropriate C&IT techniques to enhance learning, teaching and assessment;
- building and supporting networks for exchange and dissemination of expertise in relation to developments in learning and teaching;
- opening virtual and regional access points to expertise and resources which will encourage and invigorate local, national and international special interest groups;
- maximising the opportunities for sharing knowledge and evaluating achievements amongst academics;
- creating opportunities for continuous professional development.

Priorities
The Centre is located at the University of Ulster with partners at Loughborough University, University of Warwick, Heriot-Watt University and University of North London. In order that the Centre can respond to the evolving
requirements of the discipline, an early priority was to identify the needs of the subject disciplines. A comprehensive on-line needs analysis survey was issued [http://www.ics.ltsn.ac.uk/needs.html] and the information gathered was used to identify national trends and emerging developments to direct the activities of the Centre. Based on these findings, the authors engaged in informal debate with the community in order to explore:
- requirements for best practice in the teaching and learning of ICS, especially the application of C&IT to support the teaching and learning process;
- the extent to which educators are forging strategic partnerships at local, national and international level to enable and support change in the content and delivery of information and computer science courses.

Results of the survey identified a requirement to promote quality practices in the following areas:

**ICT**
There is an urgent need to underpin the appropriate use of innovative techniques. Given the particular nature of the ICS community it is recognised that learning technology will play a particularly important role and can act as a driver for the transformation of teaching and learning practice. The Centre fully supports this driving role, while emphasising that such innovations must be deeply pedagogically informed. It provides information and advice on strategic approaches to C&IT based learning support, i.e. the traditional instructionist and the more modern constructivist and dialogic approaches. The Centre will foster and support innovative developments and will widely promote learning technology as a significant and valuable area of research within the ICS discipline.

**Collaborative learning**
Today's employers have articulated the need for students to improve their communication, project management and team-working skills. Small group project work, in particular inter-institutional work, provides an ideal platform for developing competencies in these areas. New network-based tools that facilitate Computer Supported Collaborative Learning (CSCL) are particularly useful for the flexible interaction required in distance learning. The Centre will provide for the exchange of expertise and appropriate protocols for collaborative learning.

**Distance learning**
The future demand for ICS education is unlikely to be fully satisfied by conventional courses. Flexible and distance learning is recognised as a vehicle for widening access to programmes of study. Imaginative use of educational technology has the potential to revolutionise the learning environments of our students and provide an opportunity to share resources on an international basis. Experience in areas such as work based learning and the development of a virtual university will be disseminated to the ICS community through the Centre.

**Networks of expertise**
ICS education is characterised by a rapid rate of change and the short shelf life of curricula and support materials. The Centre actively supports academics by establishing and maintaining practitioner networks providing a forum for innovators to discuss frameworks to guide the integration of innovations into dynamic local academic programmes. A particular requirement for the ICS community is the need to target an increasing number of newly appointed staff, so as to provide immediate opportunities for them to engage with networks facilitated by the Centre.

**Dissemination and collaboration**
Central to the operation of Centre is a comprehensive web service providing an immediate platform-independent route to current materials suitable for wide scale access and re-use [See http://www.ics.ltsn.ac.uk]. The website provides a ‘one-stop-shop’ to expertise, resources and world-wide exemplars of good practice. Traditional workshops and seminars are complemented by a programme of web-based video-conferencing events, enabling international participation and interaction. The Centre also supports specialist and emerging areas by facilitating electronic focus groups which are used to provoke debate on the enhancement of learning and teaching. Strategies will be developed to ensure that a valued service is maintained and services will continue to evolve and be amended in the light of ongoing monitoring and evaluation activities.

The Centre actively seeks academic opinion and will undertake a programme of measures to engage effectively with the teaching community. Academic staff from an international audience are positively encouraged to contribute to the activities of the Centre. Through collaborative working the Centre anticipates greater sharing of knowledge, thus enabling effective dissemination of new methods, tools and materials. The ultimate goal of the Centre is enhancement of the quality of learning and an increase in efficiency through the integration of innovative practices into curriculum delivery.
The Evaluation of Multimedia Encyclopedia “Encarta 97”

1 Introduction

The study presented in this paper attempts to evaluate Encarta 97, a Multimedia Encyclopedia (English Edition) in a university setting. Encarta contains the content of a traditional 29 volume print encyclopedia plus thousands of pieces of multimedia (text, sound, graphics, animation, and video) in one CD-ROM. An experiment was carried out in Kuwait University, and 17 students participated in the evaluation. A summative evaluation was carried out to investigate the package by looking at its Usability, Learnability, Enjoyability, and Media Capability. The objectives was to: examine some design aspects of the package; understand how Kuwaiti students perceive a well designed western multimedia package; and apply some alternative evaluation tools.

2 Experimental design

A sample of seventeen students (15 female and 2 males) from the College of Basic Education at Kuwait University participated in the experiment. The students' average age is 22 years and 15 students were final year. They also had little computer experience and did not use computers in their early education.

The evaluation tools used in this study were a questionnaire, and a direct observation. Summative evaluation was carried out measuring three aspects which have been identified in the Horizon Project (BARKER, 1996). These aspects are: Usability, a measure of the effectiveness of the interface, display, and functions; Learnability, a measure of the ease with which information, media, and knowledge are accessed and learned; Enjoyability, a measure of how interesting and enjoyable the learner thinks the package is. The researcher examined another aspect of evaluation which is: Media capability, a measure of the effectiveness of each media element used in the package. The second tool used was direct observation. It involved observing and monitoring students' behaviour and comments while using Encarta. This includes: “walking around in the multimedia lab”, observing students' screens to examine “what things they like”; “What problems they face”; and “What comments they make”.

An IBM multimedia computer laboratory was prepared for the experiment. Encarta 97 was installed in the PCs which were equipped with CD-ROM drives and speakers. The experiment lasted about 2 hours, the first half hour was used to introduce Encarta to the students, in order to familiarise them with the nature of the electronic encyclopedia and the basic functions of the package. After the introduction, a list of tasks was given to each student in order to ensure that they use most of the package’s functions and features.

3 Findings

The students indicated that the visual interface, format, and content of information displayed on the screen were appealing. They felt that they were in control using Encarta, and the package was easy to use.
The interactivity of Encarta seems to provide them not only with access to vast and varied information, but also with control over the way they learn. This control takes three ways: control over the structure, control over the media, and control over the working environment (MCKERLIE & PREECE, 1993). With regard to the learnability aspect, Encarta provides a good learning environment in which it enhances students' learning experience by the way the content is structured, the various motivational learning activities, and the use of media. Encarta provides exploratory learning and involves various learning activities. This sort of learning which incorporates problem-solving skills as suggested by Quinn, motivates the exploration of the environment (QUINN et al, 1993) and offers increased freedom and motivation to students (OREN, 1990). This view is strengthened also by McAteer and Shaw who stress that learning by performing tasks, making notes, and making conceptual links will provide a full learning experience for students (MCATEER, E. & SHAW, 1995).

Turning to the question of enjoyability, the students indicated that using Encarta is enjoyable. This may reflect the ease of use, content, navigation, access, and control over the package, and indicate that Encarta designers have incorporated appropriate human factors issues which seem to create an enjoyable and motivating learning experience for learners. Thus, the students felt that they wanted to use Encarta more often. This motivation and interest was not only because of the media and the content, but seems to be linked to structure and presentation. Jacques believes that good presentation style makes a good initial impression, and motivates students to continue working on the package (JACQUES et al, 1995).

In respect to the media capability aspect, media is used extensively throughout Encarta. Thousands of photos and illustrations, and hundreds of sound and video clips have been integrated along with text articles. The students indicated that text, graphics, speech, music, animation, and video were extremely well used and presented throughout the package. Research indicate that the effective integration of media in any application with consideration to students' cognitive constraints creates an exciting, creative and supportive system (MCKERLIE & PREECE, 1993). However, there weren't many video clips in Encarta. Vaughan refers the rare use of video in multimedia packages to the big storage space they require and to the absence of efficient compression techniques (VAUGHAN, 1996).

4 Conclusion

Encarta 97 Multimedia Encyclopedia, has been evaluated in this study. Four aspects of evaluation have been considered, Usability, Learnability, Enjoyability, and Media Capability. The finding suggests that Encarta is not only usable and enjoyable, but also provides a good learning environment in which it enhances students' learning experience through the way the content is structured, the various motivational learning activities, and the efficient use of media. Although there is a general positive high response to the package, most of the students suggested the use of an Arabic version of Encarta. This emphasise the need to investigate further to address the effect of culturally designed multimedia interface on students' learning and acceptance. Two evaluation tools were used to collect the data needed. Although the objectives of the use of these tools were clear, most of the data were collected from the questionnaire. It is apparent that the use of direct observation was not effective in this study, and it is suggested that the use of such a tool should be planned properly and used formally for similar studies.

Intelligent Online-Knowledge-Resources for Intentional Learning

Heidrun Allert, Hadhami Dhraief, Wolfgang Nejdl
Learning Lab Lower Saxony
University of Hanover
Germany
{allert, dhraief, nejdl}@kbs.uni-hannover.de

Abstract: This paper presents the instructional design of online knowledge resources. A project that was designed to meet an instructional need rather than to exploit the capabilities of technology. We will present the instructional needs, a solution that exactly matched the requirements and an evaluation. The project is theory-based rather than technology-driven. The guiding question was: How can the virtual part of a university project enhance classroom teaching and learning? Online resources as well as lectures are organized and visualized as concept maps.

The Project

"ifu - the International Women's University 'Technology and Culture'- is the first and, so far, only gender-specific university project of its kind in Europe. ifu is interdisciplinary in scope and methodology of academic work, and intercultural. Between July and October 2000 the ifu offered 900 female students from all over the world the opportunity to participate in a postgraduate research and study program in six project areas: BODY, CITY, INFORMATION, MIGRATION, WATER, and WORK. In a more long-range perspective, and supported by modern information technologies, the virtual ifu (vifu) supported and extended the ifu on the internet." (http://www.vifu.de). The Institute of Computer Engineering - Knowledge Based Systems (KBS), University of Hanover supported the project area WORK. The strength of this work was interdisciplinary collaboration. In order to evaluate the requirements and to face the needs we strongly collaborated with the Institute of Psychology and the Institute of Pedagogy, who made up the curriculum, provided content and organized lectures. They had no specific idea of the use of the internet in learning and on how the virtual part could enhance their teaching. We collaborated in figuring this out. The KBS developed technical infrastructure, support and training and constructed online-knowledge-resources (http://www.work.uni-hannover.de).

The Process

Guiding question: How can the virtual part enhance classroom teaching and learning?
Koshmann et al. argue that computer supported projects should progress through several steps: "(a) making explicit the instructional requirements that serve as design goals for the project" (Koshmann, 1993/1994, p. 228). First of all our interdisciplinary project group of human scientists (providers of content), computer scientists and media educators (providers of technical infrastructure) made explicit the instructional requirements. We faced the concept of the ifu which comprises five guiding principles: interdependence and interaction of science and society; interdisciplinarity; integration of science and other social practices including the arts, implementation of gender studies as well as an international and intercultural scope.

90 students from all over the world were going to study in the project area WORK: Postgraduated students primarily not from western countries. Most of them researchers, lecturers, assistant professors at universities and NGOs in their home countries. We did not want the students from Africa, America, and Asia to simply "learn from Europe". Even if this was a huge number of students we did not only want to lecture them as they came with a strong cultural, educational, and also working background. But we still wanted to present lectures by experts in the domain of Sociology and Psychology. The humanities are ill-structured domains – there is nothing like a unique ontology. Neither did we want to present given systematics nor taxonomies out of
context. Lectures wanted to afford an opportunity for fluent discussions on theories, methodologies, on interdependence and interrelationships of factors e.g. Information should be embedded in (cultural) context, by lecturers as well as by students. The students should be enabled to realize interdisciplinary projects, to acquire knowledge presented by experts and practitioners, to share knowledge, to develop communities, to organize their own learning. Presenting knowledge as well as students’ project work was supposed to be supported by technical infrastructure, which facilitates networking and integration.

"(b) performing a detailed study of current educational practice with regard to these goals," (ibid.). There was no comparable project of international and intercultural scope to evaluate and to draw experience from.

"(c) developing a specification based on the identified requirements/limitations of the instructional setting and the known capabilities of the technology" (ibid.). The project „Intelligent Online-Knowledge-Resources for Intentional Learning“ focussed on three aspects using concept maps to visualize context and topics: (1) The coordinator Margot Poppenhusen and the local dean Regina Becker-Schmidt of the project area WORK used concept maps to specify and structure the curriculum. (2) Online knowledge resources were organized and made in form of concept maps. Access was also provided in form of concept maps. (3) Lecturers visualized their talks in form of concept maps and presented them on the web. These concept maps guided lectures: they were shown during lectures on touch sensitive screens.

"(d) producing an implementation that allows for local adaptation to instructional practice" (ibid.). Two main virtual projects were developed, prepared and provided. Main focus was to visualize context and structure: (1) The term ‚gender‘ and the concept of gender studies was presented in the context of division of labour and diverse cultural realities. (2) The effect of information technology and its impact on women’s work was presented against the background of basic shifts and fundamental transformation of work and work context. Online resources for these projects were organized as concept maps. We helped lecturers as well as students also to organize resources this way. Step by step several projects became available on the web. Students had access to these resources in order to rework lectures and to use resources for their own project work. We offered computer training for the students based on their prior knowledge.

Evaluation

We evaluated the project along the instructional goals. The evaluation is based on qualitative interviews taped on video: The concept maps actually changed the role of teachers and students inside the classroom. Teachers were facilitators, students brought up their own experience. Concept maps supported discussion on structure, terminology, and content. This was seen as relevant in teaching postgraduate students with strong intercultural, educational, and working background. It brought up detailed discussions on interrelationship and interdependence of factors, and on diverse organization of society in different countries and cultures. It made explicit different situational realities and specific problems not experienced in Western countries. Making explicit structure and organization of knowledge enabled students to discuss, define, and mark the differences seen from different perspectives depending on culture and context. It even brought up discussions whether to structure things totally differently: students and lecturers shared different contexts and perspectives. During discussions they restructured subjects collaboratively. In these interviews students pointed out advantage over linear resources.

Abstract: A concept map is a graphical representation of a person's (student's) knowledge of a domain. Concept maps have been used in educational settings for some time and many computer-based implementations of interactive concept map building tools exist. These concept mapping tools often provide for a solely propositional, primarily textual, knowledge representation scheme and do not fully capitalize on the functionality offered by the computational medium. In this paper, we motivate the enhancement of "traditional" computer-based concept mapping tools with dynamic multimedia—sound, video, and animated images—which offer representational capabilities that are analogous to human knowledge representation mechanisms.

Concept maps
A concept map is a graphical representation of knowledge of a domain. A concept map consists of nodes representing concepts, objects, or actions, connected by directional links defining the relationships between nodes. A node is represented by a simple geometric object, such as an oval, containing a textual concept name. Inter-node relationship links are represented by textually labeled lines with an arrowhead at one or both ends. Together, nodes and links define propositions, assertions about the domain. For example, the nodes and link in Figure 1 represent the proposition "horses can gallop" and might be a portion of a concept map about horses.

Figure 1. Nodes: horses, can, gallop; Link represents "horses can gallop."

Concept maps have been used in the educational community for decades, in virtually every subject area. In educational settings, concept maps have filled many roles: they allow students to reflect on and demonstrate their knowledge of a domain, may be used for teacher assessment of students' knowledge of a topic covered in class, act as tools to aid study and comprehension of a domain or story, support idea generation and organization in preparation for prose composition, and are used as instructional materials for learning new concepts and their interrelationships.

This paper offers psychological and pedagogical design rationales for the inclusion of multimedia in computer-based concept maps. It also describes a concept mapping application named Webster whose goals include more comprehensively representing students' knowledge of a domain, providing facilities that make concept maps more pedagogically effective for students using them to learn new concepts, and in doing both, capitalizing more fully on the capabilities of the computational medium. There are a number of characteristics of Webster that attempt to achieve these desiderata but in this paper we focus in particular on Webster's use of multimedia to realize these goals.

Why Multimedia Concept Maps?
The purpose of concept maps is to visually represent knowledge of a subject or domain. Indeed, Jonassen (1992) claims that concept maps are accurate reflections of their authors' cognitive structures. But this argument is based on concept maps that portray text-based propositions only. Jonassen goes on to pose the question "What constraints does the software impose on the product?" (p. 20). Older concept map tools are indeed very good at representing text-based propositional statements—wherein concepts are described by verbal means alone—but not necessarily other forms of knowledge. However, if concept maps are to be used to externally represent one's (internal) knowledge, they should allow for nodes to be something other than of a verbal or textual nature. "It is important to note that not all nodes in a semantic memory system have names corresponding to words in natural language" (Rumelhart & Norman, 1985, p. 24). This notion is further supported by numerous researchers who have offered evidence or arguments for the notion that one's knowledge contains more than simply verbal propositional knowledge. Kosslyn (1980), for example, proposes a cognitive model that represents information about objects with both propositional properties and images. Johnson-Laird (1983) similarly asserts that mental models of a domain include both propositions and imagery. Baddeley adds there is "abundant evidence for separate visual and verbal coding" (1985, p. 212). Shepard (1967) has, furthermore, provided evidence that memory for visual imagery is more robust than that for purely textual information. And Paivio (1986) asserts information encoded both visually and verbally is more memorable. So, to begin with, we see a need for image-based nodes in concept maps if we wish to more comprehensively represent one's knowledge of a domain or use maps to convey information new to learners.
Intuitively, in addition to static imagery, temporally dynamic visual and auditory memories are also part of one’s knowledge of an object or domain. Here we’re speaking of images in motion and sounds, both of which occur over time. Indeed, this notion has been acknowledged by cognitive science researchers and others. Johnson-Laird (1983) asserts that some mental representations are of temporally dynamic nature. Numerous studies involving music cognition provide strong empirical evidence for long-term auditory memory (see, e.g., Dowling & Harwood, 1986). Even popular culture reflects these notions; for example, as Lennon and McCartney wrote and the Beatles sang, “Penny Lane is in my ears and in my eyes,” highlighting the reality that recollections involve long-term auditory and dynamic visual memories. Hence, one’s knowledge of horses might include not only what a horse looks like, but what a horse looks like when galloping and when trotting, the image of a jumping horse gliding over an obstacle, the sight and thundering sound of a group of wild horses stampeding across a sandy plain, the moving images of a wild bronco bucking in its attempt to throw a rodeo cowboy off its back, the sound of a horse “neighing.” Certainly these are parts of our long-term memories for horses, and we ought to be able to represent these memories in concept maps to demonstrate our own knowledge or to use concept maps as instructional resources.

Imagery in general also offers the important capability of reifying concepts described by text. The ability to represent concrete instances and link them to text-based concepts supports the learning and memorability of those concepts. For example, Moore and Skinner (1985) demonstrated that abstract textual information is better understood and learned when presented along with reifying illustrations. The ability to portray concrete instances of concepts adds significantly to the representational and instructional potential of maps. The ability to use dynamic imagery and audio significantly enhances this representational capability. For example, here is a definition of the trotting gait of a horse: “In this most diagonal gait, the diagonal hooves lift off from and hit the ground at the same moment. [Right hind, left front, alternate with left hind, right front.] To see this, focus on a front foot, then include the diagonal hind in your field of vision. You can clearly see them lift off and hit together, in a hard trot. The sound will be a 1-2 beat” (Ziegler, 1988). Compare a concept map that represents these ideas via text-only nodes to another map that accompanies this information with a slow-motion video of a horse actually trotting. Clearly, the latter not only makes the conceptual information concrete but also provides an additional dimension to the map, namely sense-based information the text alone cannot.

The incorporation of temporally dynamic visual and aural elements in a concept map knowledge representation tool enhances its “flexibility of expressiveness” (Heeren & Kommers, 1992). More semantic and aesthetic options are open for the user to decide upon. This may help to accommodate individual differences, that is, to better support students with different expressive or learning preferences or needs when using concept maps to demonstrate their own knowledge or acquire new knowledge. And, clearly, temporally dynamic content in concept maps will better support those using maps for learning new domains and concepts because these users will be presented with: what objects look like when in motion, what they sound like, how things move or sound in particular contexts or situations, instructional visualizations of how to perform procedural tasks, videos showing dynamic interactions between objects or people.

Lastly, the use of multimedia in an interactive concept map builder and viewer may provide for a more engaging user experience. Of course, engaged and motivated learners are a desirable effect of any educational environment or tool (Vroom, 1994).

If we are using the computer to represent students’ knowledge, we should more fully benefit from what the computational medium offers over more static media, such as pencil and paper. This includes the ability to incorporate dynamic content in concept maps, thereby more comprehensively representing the knowledge a person possesses. If we are asking students to represent their knowledge, we need to be cognizant of the fact that some aspects of a student’s mental model may be expressible only through visual or auditory media. And for students using concept maps to learn about new concepts, the enhancement of those maps with dynamic media has the potential to improve the maps’ pedagogical effectiveness. Of course, one’s knowledge of a domain may also contain tactile, olfactory, or taste memories. However, standard PCs are not currently capable of representing and “playing back” such sensory information, notwithstanding ongoing research in these areas. But they are capable of manipulating video, audio, and animation.

To recap, concept map tools should be able to represent multiple types or forms of knowledge, not merely text-based propositions. Specifically, incorporating multimedia in concept mapping software should (a) provide for greater cognitive fidelity in student-constructed concept maps, allowing students to more comprehensively represent their knowledge in ways similar to their own cognitive representations; (b) offer the illustrative advantages of dynamic visual imagery and audio to students learning new concepts and domains; (c) provide the capability of reifying concepts with concrete instances that can be seen and heard; (d) offer richer expressive power for concept map authors; (e) provide for a more engaging student experience; and (f) better capitalize on functionality available in modern personal computers.
Multimedia in Webster

On the basis of the preceding cognitive and pedagogical design rationale, Webster allows for the representation of dynamic media components as integral constructs of concept maps. That is, Webster provides tools for the facile incorporation of animated images, video, and audio in concept maps. In Webster, multimedia elements are first-class elements of concept maps with the same status and ease-of-use as textual concept nodes.

Figure 2 shows Webster running in a Web browser. Webster is implemented in Java™ and thereby runs as an applet in standard Web navigators, providing student access from anywhere they have access to the Internet. Along the left side of Webster’s user interface are tools for creating elements that may reside in a Webster concept map: concept nodes (of various shapes; the user may assign different semantics to different shapes as appropriate for each map), relationship links, image, audio, and video nodes, and other types of map elements. At the top of this toolkit are two mutually exclusive toggle buttons (“iconic radio buttons”) that determine whether the user is in author mode (the pencil icon) or viewer mode (the eye). A user can create or modify maps while in author mode; in viewer mode, the map’s knowledge elements may not be edited and it is in this mode that multimedia elements may be viewed. When a teacher reviews a student’s concept map, he or she has access to viewer mode only for that map.

Figure 2. A Webster concept map, in a Web browser window, with a static image (the horseshoes), an animated image node (the galloping horse), an audio element (represented by the radio node), three video nodes (the television nodes), and a hyperlink to an external Web site (equestria.net).
Figure 3. When a user clicks on a television node while in viewer mode, Webster directs its Web browser to download and play the node's associated video file. Radio/audio nodes are handled in the same fashion.

Continuing with our example domain, suppose a student is building a concept map to demonstrate her knowledge of horses. In addition to propositional assertions such as "a horse is an animal," "a horse can gallop," and "domesticated horses wear horseshoes" the student wishes to represent what a typical horse sounds like, what it looks like when galloping, and so on. She therefore requires the ability to incorporate visual imagery and audio in her map. To incorporate sound, she includes an audio node in the map; similarly for video and image data and their respective nodes. To add an audio node to a concept map in Webster, the user clicks on the "radio" tool button in the toolkit on the left and drops a radio (that is, audio) element onto the map. This is the same process used to add textual concept nodes (and other node types) to a map; multimedia nodes are not handled in any sort of special case fashion. Webster responds to the addition of the new audio node by popping up a list of available audio files (only audio files are shown for a radio node), allowing the user to select one to associate with the node. Image and video nodes are handled in the identical manner using the "portrait" tool and "television" tools, respectively. The multimedia file associated with an existing media node may be modified by double-clicking on the particular video, audio, or image node; Webster again displays a list of files of the appropriate media type for the user to select from. This is another example of how multimedia knowledge elements do not involve special case handling; double-clicking to edit a node's content is precisely how textual concept and Web-link nodes are modified.

To listen to an audio, the user (say, a teacher viewing a completed concept map) simply clicks on a radio node in the map (while in viewer mode). In response, Webster plays the associated audio file. Video playback is similarly invoked via TV nodes in a map (see Figure 3).

With regard to images, there are other concept map tools that allow the use of static images as nodes in a map (see Related Work). Webster goes a step further in that image-based nodes in a concept map may be animated-GIF images. Thus we may have animations directly within a concept map. For example, the animated horse image in Figure 2 appears to be galloping within the map. Image nodes may be sized (stretched) directly within the map by the map author to show or hide details or otherwise accommodate aesthetic and spatial considerations. If a user wishes to view an image in its originally-created size, she may click on the image node (while in viewer mode) and the full-sized image is displayed in the browser frame that exists below the Webster applet (not shown in Figure 2).

Webster also automates the conversion of concept maps to a different representation form, namely outlines. A common activity associated with concept map usage in the classroom is generating and organizing ideas in preparation for writing a report, composition, story, or, a more modern form of "composition," a Web page. Of course, a common representation for idea organization is an outline. Further, alternative representations support developing deeper understanding of a domain. Hence, as in the Inspiration® concept mapping product (more on Inspiration below), Webster can translate a map into an outline containing the map's semantic content.

In Webster, multimedia concept maps become multimedia outlines. The same static and animated images, videos, and audios that are part of a concept map appear in the associated outline representation, as shown in Figure 4. Webster converts maps into outlines as HTML documents that appear in a separate Web browser window. As in the concept map itself, the HTML generated by Webster embeds radio images for audio nodes and a TV for each video. Outlines incorporate the text labels that appear on relationship links in the map, so an outline item (a single line in the outline) might appear with the text "looks like:" followed by a TV image. In the HTML document, the radio and TV images are coded as hyperlinks that reference specific audio or video files. Hence, users simply click on embedded radio and television images to "play" them. With regard to static and animated images, they are handled much as they are in concept maps: images are embedded and visible directly within outline items, so, for example, once again the horse seems to be galloping within the outline. All images are displayed in the outline with the same default thumbnail dimensions. These thumbnail images are also encoded in the HTML as hyperlinks to the full-size image file, so to view the image in its original size, a user simply clicks on the thumbnail in the outline.
Outline for KnowledgeMap "Horses"

I. horse
   A. can gallop
      I. looks like: 🐴

II. Is a animal
   A. animals
      1. have skin
      2. etc.

III. Babies

IV. For more info see: http://www.equestria.net/

V. "Neighing" sounds: 🦋

VI. Images of running: 🦄

VII. Wild horse
   A. stampeding in a pack: 🦄
   B. is a kind of: horse

VIII. Domesticated horse
   A. Wears: horseshoes
      1. look like: 🦄
   B. is a kind of: horse

Related Work

There are many existing computer-based concept map tools, far too many for exhaustive description here. But, some bear mention. With regard to images, Inspiration and Axon®, two commercial concept mapping products, and SemNet™, a shareware tool (Fisher, 1992), do allow the use of static images as nodes in a map. Another mapping tool permits the association of static imagery with a concept node: Learning Tool™ (Kozma, 1992) has the provision for a "notecard" to be associated with each concept node, and this notecard may contain text and images. These tools certainly offer a step in the right direction beyond text-only representations. But we should be able to incorporate temporally dynamic content in concept maps as well. Further, there are significant differences in the outlines generated by Inspiration and Webster (we'll focus only on the multimedia aspect). Even though Inspiration incorporates only static image and textual nodes in concept maps, the images are absent in its outline translation of a map, whereas Webster's outlines incorporate all the media elements that appear in the corresponding concept map. None of these mapping tools is accessible from a Web browser.

HandLeR is a handheld computer running proprietary software which includes a conceptual mapping tool that incorporates multimedia elements (Sharples, 2000a). In HandLeR's "topic map" tool, topic nodes may reference the same types of media files as supported in Webster (Sharples, 2000b). There are a number of differences between HandLeR's map tool and Webster. Topic nodes in HandLeR are all identical ovals (with embedded text), connected by unlabeled links. Hence, static and animated images are not visible within the map itself. The further implication is that nodes are not "typed"—this is, different node types are not visually distinguished—whereas in Webster concept maps, nodes provide visual cues regarding their content, including the clear indication of the existence of media nodes (video nodes appear as "televisions" and audio nodes as "radios"). We refer to this as visually typing, that is, making each node's content type evident by its appearance. Unlike HandLeR, Webster provides an alternative outline representation that incorporates multimedia as well. Lastly, Webster is Web-enabled, providing broader student access to the tool in terms of location and time as well as eliminating the logistical problems of distributing software to individuals, while HandLeR operates on a standalone basis.

In the IHMC CMap toolkit (IHMC, 2000) users may associate resources with a concept node. Resources may include images, sounds, or video files. Again, images do not appear directly within the visible concept map per se—users must follow a hyperlink to view an image, and this tool does not incorporate outline translations (multimedia-based or not) of concept maps. There are no labeled relationship links between verbal concepts and media nodes; media resources are, in a sense, part of the concept nodes. We feel that labeled links showing the relationships between media nodes and other nodes represent additional knowledge thereby enhancing the semantics of a map. (Link labels can be omitted in Webster if desired; making labels optional and the possible enhanced semantics when links are included increase Webster's flexibility of expressiveness for knowledge representation—more options and decisions are left to the user's preferences and representational requirements.) Indeed, based on studies with learning disabled students, Griffin, Simmons, and Kameenui (1992) strongly recommend that concept maps and other graphical organizers explicitly depict (i.e., label) the relationships
among conceptual elements to better support the learning and memorability of the represented domain. Further, Webster attempts to make the representation of knowledge elements straightforward and simple, both conceptually and in terms of user interaction, in part by treating different types of knowledge elements in a uniform fashion. Multimedia knowledge is represented as distinct nodes which are manipulated in the same manner as are other nodes in a map. Plus, in our design rationale we stated that there are apparently distinct cognitive systems for the representation of verbal and imaginal elements; if we wish to reflect one's knowledge in a concept map, it seems to follow that knowledge elements of these types be represented by distinct nodes rather than bundled into a single node.

Conclusion

A concept map is a tool for representing knowledge. In asking students to construct concept maps, we are asking them to demonstrate and communicate to others their knowledge of a domain. We ought not limit those students by restricting the types of knowledge they can they can represent. Webster offers greater expressiveness and broader representation capabilities by incorporating multimedia elements in concept maps, thereby attempting to offer a closer match to cognitive knowledge representations. The incorporation of dynamic media also provides concomitant benefits to students using pre-constructed concept maps as tools for new concept learning, because they are exposed to a broader range of knowledge media. Lastly, a concept mapping tool should be able to translate maps into alternative representations, such as outlines which many students find useful or necessary for composing narratives. Webster outlines contain all of a map's content including its multimedia knowledge elements.

Abstract: Development of on-line courses requires the use of appropriate educational philosophies that discourage rote learning and passive transfer of information from teacher to learner. This paper reports on the development, use and evaluation of two, second year, Biology on-line software packages used by students in constructivist environments. The courses on carbohydrate and lipid metabolism were developed in conjunction with subject experts but were designed from different perspectives. The carbohydrate metabolism course provided diverse views of a single knowledge domain and included the ability to find information in different ways. The lipid metabolism course was designed as a 'notes-on-the-Web' module. Evaluations were conducted via paper- and electronic-based software evaluation; student interviews; and analyses of student performance (pre- and post-testing; examination results). Results showed that students enjoyed using the software, found the constructivist learning environments challenging, valued the permanent availability of on-line information, found the user interface of the software products easy to use and navigate. Analyses of examination results showed that students performed better than in the previous year (traditional lectures). Results for the carbohydrate course were superior to those of the other course. It appears that interactive components that foster constructivist-based learning skills are more important in on-line learning environments than presentation of information.

Introduction
Attempts in the 1980s to bring technology into the classroom involved the creation of computer literacy classes at secondary school levels (Moersch, 1995) where students learned about computer architecture, operating procedures, basic software applications and introductory programming. Technology carries an expectation that it will transform many aspects of learning including the content and body of knowledge taught, delivery, and the types of facilities required to support delivery (Kook, 1997). Learning environments are becoming more creative and diverse with educational institutions becoming, not only information centres for specific content, but also arenas for technology development and innovation (Kook, 1997). However, technology is not a process, mindset, or a global solution, but is merely a tool. With the onset of the 21st century, it is undeniable that the computer, as a tool, has made by far the biggest impact on human endeavour. "Technology, be it a writing system, a media system, or a computer system, has been proven to be an effective tool to realize the interrelated goals of learning, teaching and cognitive growth" (Chen, 1993). Moersch (1995) stated that computers are used as tools that support and extend student understanding of concepts, processes and themes. In addition to its inherent use as communication tools, technology can also play a direct role in educational activities. Richards et al. (1997) argued that the use of technology is two-fold: it accelerates skill and knowledge acquisition and enhances teacher and student abilities. McDonald and Ingvarson (1997) argued that computer applications free students from laborious tasks of rewriting and copying notes. Dorfler (1991), on the other hand, stated that cognitive software tools amplify human ability as "information re-organizational devices" that extend activity and reflection to a higher meta-level.

While the use of computer technology could provide an increasing student population with adequate resources, the focus should still lie with educational issues (Hämäläinen et al., 1996) and user needs (Brown, 1995). Collis (1997) stressed that technology should be used as a tool to make concrete an educational philosophy and Greening (1998) argued that theory should drive the application of technology within educational contexts rather than technology itself. Reeves and Hedberg (1998) defined constructivism as "...the process of how we construct meaning and knowledge in the world...", "...based on our previous experiences and how we organize those experiences into knowledge structures such as schema and mental modes, and the beliefs that we use to interpret the objects and events we encounter in the world". Constructivism is context dependent rather than content dependent (Greening, 1998) and focuses not on the content or its objectives, but on the diverseness and
richness of the learning environment and the skills and competencies in learning that may not be directly monitored via behaviouristic assessment methods (Reeves, 1992). Today, most commercial educational software takes little notice of educational models other than instruction. This presents educational developers with two possible options of technology use where either (a) technology is supplemental and rests on existing structures (enrichment) or and (b) it is mandatory and changes the course structure completely (re-engineering) (Collis, 1997).

This project was based on the concept that integration of software into learning environments will only improve learning when courses are re-engineered to support constructivist-learning models and include tools to find, explore and organise information. In other words, the power of technology lies not in the presentation of information, but rather in the ability of learners to navigate information in different ways to enable their own cognitive development.

Materials and Methods

Course Design and Development: Two second-year biochemical courses were converted into resource-based on-line educational material. The original instructivist courses included notes, diagrams and overhead slides developed by the subject experts, based in part on the prescribed textbooks. The re-engineering of these courses included the development of a workbook that posed a number of problems, or exercises, supported by on-line resources. The first course, carbohydrate metabolism, consisted of a number of pathways and reactions, and requires an in-depth understanding of the compounds involved (their relationships), as well as control and regulation systems of the metabolic pathways. Software developed for this course was based on the idea that multiple representation of a single knowledge domain would enhance the learning process. Analysis of the lecture course identified a number of content building blocks (molecules, reactions, biochemical terminology, processes and actual pathways). These knowledge units were individually constructed using Macromedia Flash 2.0 (figures and charts) and were stored, with relationship information, in a Microsoft Access database. These building blocks, accessed in different ways (using hyperlinks or through a built-in search tool) provided the material for students to construct their own representation of the pathways according to problems presented in the workbooks. In addition a glossary of terms was provided. The interface (constructed in HTML using Microsoft FrontPage and Macromedia Flash 2.0), provided students with a series of notes, which, although static in nature, contained links into the database bound knowledge units. Information was also dynamically accessible via the database, where objects (terms, molecules, pathways) could be immediately viewed in separate browser windows. The second course (describing lipid breakdown) was based on a number of essays broken into separate topics that included molecular data. Notes were prepared by the subject expert and converted into HTML (FrontPage 98) and graphics and diagrams (Macromedia Flash 2.0). These resources were grouped into essays, structures, processes, and transport mechanisms on the introductory page. No search or glossary was provided.

Learning Environment: Students worked in groups of three or four at a single computer (Intel Pentium 233MHz, running Microsoft Windows NT, with Internet Explorer 4.0 browsers and Macromedia Flash plug-in installed) using the supplied on-line material and textbooks to answer questions posed in workbooks. Assistants and the subject expert encouraged group communication and collaboration, provided support and guided learners when asked for help.

Evaluation: A number of different instruments were used to evaluate the courses and included: paper- and electronic-based course evaluation; student interviews and analyses of student performance (pre- and post-testing; examination results). Paper based evaluations were conducted to measure student attitudes with respect to enjoyment of and benefit from the course, types of skills learned, as well as the suitability and feasibility of integrating technology into the classroom. Students were asked specific questions pertaining to: content structure; environment and learning activities; software usage; course structure; and skills and competencies. These evaluations were conducted at the end of the courses and were analysed qualitatively using QSR NUDIST (Qualitative Solutions and Research). Students used the on-line Educational Software Evaluation Tool (ESET) to assess the design of the user interface, pedagogy and interactivity of the software. These results were further analysed using the Wilcoxin Signed Ranks tests (SPSS, SPSS Inc). Thirteen students, who volunteered and represented each group, were informally interviewed to probe more deeply student opinions related to the use of on-line courseware and their use of the learning resources. Students answered questions in the following categories: personal use, perspectives of higher education, the learning environment, and learning outcomes and understanding. Interviews were recorded using a tape recorder, transcribed and analysed using QSR NUDIST.
Anonymous pre- and post-tests were constructed by subject experts and took the form of short questions (one word and short paragraphs) that tested the understanding of the course content. These tests were administered prior to, and after, each of the courses. The Mann Whitney tests (SPSS) were used to evaluate these results. Performance data (examination results) was analysed using Wilcoxin Signed Ranks (SPSS) tests to identify significant differences between computer based and non-computer for the current year. A combination of the Mann Whitney and Wilcoxin tests (SPSS) was used to compare results of the two computer based topics with the previous year’s results, as well as comparing each of the computer based course performances to the rest of the course.

**Figure 2.**

**Results**

Conventional paper based evaluations were conducted to determine student opinion with respect to the learning environment and use of the software. The questionnaire was divided into six categories (content structure; course structure; software usage; environment and learning activities; and skills and competencies) and included statements that students ranked (4-point scale) and short paragraphs answers. Students rated both courses in a similar manner; the content structure higher than any other category; the carbohydrate course content structure higher than that of the lipid metabolism course; and the course structure lower than any other category (Fig. 1).

For the carbohydrate course the highest rated statements for each category were: content structure - “It was easy to find relevant information” (3.2); course structure - “I enjoyed working with Internet-based courseware” (3.2); software usage - “I found the glossary very useful” (3.0); environment and learning activities - “I felt comfortable working with the material presented” (2.8); and skills and competencies - “I enjoyed using the software” (3.1). Similarly, for the lipid metabolism course the statements ranked highest per category were: content structure “Development of Internet-based courseware is a good idea” (2.9); course structure printed notes should have been provided” (3.1); software usage “I found the visuals very easy to understand” (2.8); environment and learning activities - “I felt comfortable” (2.8); and skills and competencies - “The course improved my computer skills” (3.1). Statements that scored the lowest included “I would prefer to work on my own” (2.2) for both courses, “I found the relevant information easily” (2.3) for the lipid metabolism course, “I found the time allocated for computer usage adequate” (2.2) both courses and “The course required a lot of problem solving exercises” (2.2) for the lipid metabolism course.

Using ESET students rated the user interface, design, pedagogy and interaction of the carbohydrate metabolism course software higher that the software used in the lipid metabolism course (Fig. 2). For the carbohydrate courseware students rated screen appearance (fonts -78.6%; choice of colours - 82.1%), layout (text flow -76.2%; consistency - 76.2%), instructions (73.2%); presentation (72%); reading (80.4%); and the search facility (100%) highly. For the lipid metabolism courseware students rated screen fonts (71.9%) and colours (72.5%) high, and screen consistency (66.3%), picture layout (69.4%), intuitive interface (66.3%) and text flow (61.9%) low. Ease of reading was amongst the highest rating components (73.8%) but students found that there were insufficient links (59.4%). A Wilcoxin signed ranks test indicated that the User Interface section and Pedagogy and Interaction for carbohydrate metabolism software was rated significantly better than the lipid metabolism
package (asymptote significance < 0.005, z = -3.845a and asymptote significance = 0.006, z = -2.726a respectively).

Students were interviewed to further probe their opinions regarding the two courses. Eight students (62%) said that they have used computers before (between one and two years) and five said that they had not previously used computers. Four of the students reported that they had access to computers at home. Those that had not used computers before stated that they soon became familiar with the software. When asked if they were aware that the computer-based courseware was part of a research project, nine (69.2%) responded positively and four said no (30.8%). Those who responded positively felt that the initiative was new and exciting, with them being the first to tryout this new form of learning. Students also felt that it was an improvement over conventional lecturing since it made learning easier. A few students thought that the approach was experimental and they had no reference to previous years and that the results of such initiatives are unpredictable since the use of technology is new. Students were asked if the change in learning environment was comfortable to work in. Seven students (53.8%) felt that they were comfortable, while three students (23.1%) maintained that they were not comfortable at first, but got used to the course after a while. Two students responded that they were initially lost and attributed this to their lack of computer knowledge as well as the wealth of information presented. However, they reported that they quickly adjusted to the new teaching method. Most of the student comments centred around interactions in the classroom and listed being able to work individually and at their own pace as an advantage. This was further probed by asking questions related to group work. Positive responses included division of labour (two responses), rich social experience (two responses) and ability to discuss problems with peers, tutors and the subject expert. Students did however maintain that group interactions often broke the flow of concentration, decreased the work rate and this caused them to work individually. Other problems identified were a lack of equal contribution, lack of self-discipline and "discussion led by one person". Despite these problems, seven students indicated that their understanding within the group was greatly improved. The key supporting features included: group explanations and discussion of key concepts (five responses); helping one or more students with problems and misunderstandings (four responses) and development of shared understanding amongst participants (two responses). Students were asked to comment on the difficulty of the content. Eleven students (84.6%) regarded the content as simple and easy to understand, even though it may have been difficult to work with the software at first. Although the software was well received, the lipid metabolism software was found more difficult to use. Students were asked to comment on how they felt using technology compared with previous or conventional modes of learning. This question provided the most insightful and varied responses amongst students. Students described different ways in which the technology affected them and made many references to lectures, which they considered as the conventional mode. Working with software was more fun, challenging, much better than lectures, encouraged learning, was interactive, allowed one to find information quickly and easily, made one more responsible, built confidence, improved understanding and made visualization easier. Students were requested to identify the difference between understanding concepts and memorization of content. They clearly understood that there was a difference between understanding and memorization, and that understanding took place before memorization. Students maintained that they did not remember much of what they learned (five responses), but could understand nearly all of what they covered (eight responses). Students also felt that their initial experience with the software mentally prepared them to study for examinations.

Figure 3. Comparative analysis of average student scores between two consecutive years (◻ - 1998, n=39; □ - 1999, n=47; bar = SE).
Pre- and post-tests were used to determine student understanding of the basic course content before and after using the developed materials. Students received no prior warning before sitting these tests and had therefore not
prepared themselves for testing. In the carbohydrate metabolism course, students \( n=49 \) scored an average of 15.8 ±1.4% that increased to 34.7±1.4% in the post-test \( n=44 \). Using a 95% confidence level, there was a significant difference between the pre- and post-test (asymptote significance < 0.005, \( z=-6.841 \), Mann-Whitney test) indicating that students had gained knowledge during the course. In the lipid metabolism course students \( n=39 \) scored an average of 26.1±1.6% for the pre-test and 34.0±2.2% in the post-test \( n=30 \). The Mann-Whitney test showed a statistical difference between pre- and post-test (asymptote significance = 0.009, \( z=-2.596 \)) indicating that students had gained knowledge during the course.

Examination results from the previous year (all lecture based) were compared (Fig. 3). There was a 4.8% increase in the current year (66.5%) for the carbohydrate metabolism course and a 5.04% decrease for the lipid metabolism courseware (55.5%). Students appeared to perform similarly in both examinations. However, the pass rate for the carbohydrate metabolism course increased from 78.4% to 93.6% (1999) while that for the other course on lipid decreased from 81.6% to 71.1% (Fig. 4). A comparison (Mann Whitney test) was made between 1998 examination performance and 1999 exam performance using the following sets of scores (1998 carbohydrate and lipid metabolism) - (1998 other courses) versus (1999 carbohydrate and lipid metabolism) - (1998 other courses). Although no significant difference was indicated (asymptote significance = 0.054, \( z = -19.925 \)), the results can be seen as marginal. The 1999 examination performance results were further analysed using the Wilcoxin Signed Ranks test: the carbohydrate metabolism examination results were significantly better than either the lipid metabolism (asymptote significance = 0.003, \( z = -2.948 \)) or the traditional lecture-based courses (asymptote significance < 0.005, \( z = -4.525 \)). No significant difference was found between the lipid metabolism course and the traditional lecture course results (asymptote significance = 0.111, \( z = -1.594 \)).

Discussion

In order to gain insight into the use of on-line material in constructivist classrooms two second-year biochemical courses were redesigned. The carbohydrate metabolism course on-line resources included multiple views of the knowledge domain, a search tool and glossary. The lipid metabolism course included only text and graphical resources on the Web. Both courses used a constructivist approach where students, working in groups, used the resources to answer problems posed in workbooks. A number of instruments were used to evaluate the courses and included paper and electronic evaluations, interviews and analyses of student performance.

Jarz et al. (1997) stated that a user interface has a significant influence on the 'look and feel' of the system and its success and includes "symbols and colours" as basic but important components. Barker (1990) stated that one of the functions of user interfaces is to enable the learner to visualize what is happening within the learning domain with which they are interacting. User interface design should also make full use of technology rather than "transferring paper or previous non-graphic interfaces onto the screen" (Starr, 1997). Results from the paper- and electronic-based evaluations, as well as student interviews, clearly indicated that students found the interfaces easy to use and adapted quickly to the use of the software in the classroom. The carbohydrate courseware was more highly rated than that used in the lipid metabolism course. While the user interface of both on-line resources was rated highly, the lack of search tools, glossary and self-testing components, which could be viewed as cognitive development tools, in the lipid metabolism software resulted in problems in the use of the resources and made it more difficult for students to find relevant information. These results support the arguments that the inclusion of different navigational tools supports different navigation styles (Jonassen and Grabinger, 1990) and learners who are allowed to make choices, answer questions and solve problems, are more motivated and productive (Jih and Reeves, 1992). The inclusion of a wider variety of navigational, visualization and self-assessment tools in the carbohydrate package supports the idea that software that actively engages students in constructive activities biases students towards knowledge transformation activities and away from simple knowledge replication (Ward and Tiessen, 1997).

Gustafson and Branch (1997) argued that the construction of knowledge and skills occur while learners interact with peers, media, content and teachers. Berge (1997) introduced the term "authentic learning activities" that includes inquiry, problem-based activities, case studies, projects, peer critique and support and self-reflection. While some students would have preferred lectures they argued that group work supported the development of understanding and felt that group work encouraged learning.

Reiser and Kegelmall (1994) stated that together with student "attitude data", the pre- and post-test method is a way of improving courseware evaluations. Use of such a method here found that students gained some insight.
into the concepts of both courses. Evaluation of examination results show that students performed better in the carbohydrate metabolism course compared to the lipid metabolism and traditionally taught courses. While both courses used constructivist principles, performance was only increased in the course that included software that provided learners with a richer set of tools to interrogate information and thereby build knowledge. It is interesting that students would have preferred written notes for the lipid metabolism course as they are familiar and have developed skills in using such media. The carbohydrate metabolism courseware consisted of discrete knowledge units (molecules, terms, pathways) and processes (reactions and control aspects) that fit more easily into a constructivist model. The lipids metabolism courseware was essay-based and textual in nature. The level of interactivity differed significantly between both packages and information was not rigidly structured in the carbohydrate on-line resource. Another important feature that distinguished the packages was the ease of navigation: the carbohydrate metabolism software was much easier to navigate and far more intuitive than the lipid metabolism software. Finally, the carbohydrate metabolism software proved to be more motivating in terms of fun, graphics and student interest. The results presented here clearly show that the use of on-line resources to provide information only provides no benefit to learners while those that are richly textured and include different navigational paths, are built of small interrelated knowledge blocks and include cognitive development tools improve learning. Therefore, computer-learning resources that are just electronic textbooks offer little value in knowledge development.

Abstract: The introduction of communications and information technologies in
the area of education tends to create a totally different environment, which is
marked by a change of the teachers’ role and a transformation of the basic
components that make up the meaning and content of the learning procedure as a
whole. We could say that, despite any changes, the training process is subject to a
tayloristic linear model of production, which takes the student at childhood and
gives him back to society and the dynamics of the market with the hope that he
will be able to respond creatively to the constantly increasing demands. As the
student moves on the school assembly line, the teachers at the various levels give
him the knowledge that has been worked out for each level in a predefined and
uniform way. Is the introduction of training technology going to help reverse the
closed model of training process, as we have known it up to now, or is it just going
to modernize the ways and methods, keeping the main body of the training
assembly line unchanged?

1. Introduction

In an era that everything around us is changing at incredibly fast rates, the contemporary human being
as well as the social structures that he has built during the ages, are trying to cope with the new
demands that are being created. A peculiar technological environment covers the current borders of
conventional reality, which seems to retreat scared, yielding more and more vital space to the new
information age. Computer systems are at the peak of technological development, as they constitute the
most characteristic advanced party of the new age. From large, hard to use and complicated computing
systems, we passed to the era of the personal and easy to use PC which invaded our offices and became
an integral part of our daily working life. PCs were equipped with advanced communication capacities
and transformed from a medium for facilitating the management function of a business, to a
mechanism for interconnecting users with innumerable data and information sources with the help of
the Internet. The mass production of PCs at reasonable prices for the average consumer set the basis
for the penetration of new technologies into the everyday life of the contemporary human being.
Nowadays, the use of a PC not only in the office but also at home is so common, that many people find
it hard to distinguish the borders between their business and social life. A lap-top connected to the
internet with the help of a mobile telephone can accompany us wherever we go, whatever we do. The
basic relationship between the human being and information is reversed (Anastasiades, 2000). The information nowadays travels through networks towards people who are looking for it from a fixed geographical point via their personal computer. The same applies to merchandise, to consumer goods, to studies, training, work and even entertainment. Electronic networks will partly replace transport by land, air and sea and will further develop into information highways reaching every household. The Information Society does not lie in the distant future, we already live in and experience it through a many of its applications. The education sector is one of the Information Society's main priority, one of the most important pillars of the new digital age (COM (96), 471 final). The Information Society is based on the informed citizen, on the person who knows the advantages and the challenges of the new era, as well as the ways with which he will seize the opportunities which will be presented to him. The Information Society is based on the aware citizen, on the human being who will be aware of the negative consequences of the advent of the new electronic reality and who will seek ways to avoid or to reduce the possible consequences. The Information Society needs all the citizens without exceptions and exclusions, as it concerns all of us, and affects all sectors of human activity (COM (95), 590 final). The velocity with which new applications are transferred from a company's laboratory to our everyday life is incredible. The downgrading of the basic cognitive competencies of modern human beings, is taking place in a much shorter period of time than in the past, and as a result nowadays entire age groups are threatened by labour extinction if they do not adjust to the new circumstances within the shortest possible period of time. The demand for continuous adjustment to what is "new", is pushing an entire era to its limits, an era that tries with dismay to synchronize itself with the dictates of an entirely different reality. The educational process is presented as the most important tool in the context of transformation towards the Information Society, as its role is to ensure for the citizen all the necessary means in order to manage in a completely different environment, a characteristic feature of which is the continuous effort for creative integration in a rapidly changing world.

2. Characteristics of the conventional – linear model of education

In the existing educational model we can readily locate certain characteristics, which, regardless of the changes and modifications that were occasionally made, remained unchanged and were correctly labeled as the components of the traditional educational system. The first basic characteristic has to do with the role of the teacher, who for years used to be practically the only source of knowledge in the classrooms. The second component has to do with the role of the student, who, within the conventional model, was restricted to a more passive role (lessons attendance, study, taking exams etc.) The training tools (books, notes etc.) that for years formed the two poles of education remained unchanged as to their basic characteristics. One could say that the training process, the way it was established during the years, might be associated with the production line of a commercial product as part of the industrial model of evolution (More Ch., 1997). On the production assembly line we have the subject of the training procedure (the students) going through its pedagogical shaping and knowledge enrichment by the trainers, who play the role of the traditional industrial worker. Utilizing their knowledge and skills in due time and in a predetermined way depending on the production stages, they contribute to the production and development of a learning and pedagogical standard, which has been found to carry the basic characteristics imposed by the market or society demands in different time periods. The introduction of the new technologies of communications and information in the learning areas is a necessary factor for the modernization of the whole system. The question is whether the new training technologies will modify the linear model of education, as we described it above, or just contribute to the modernization of its components, leaving its hard core intact. The development of an open learning environment which will go beyond the linear model of education that was established in the industrial age should not be just a theoretical starting point but also a delimited starting point of efforts carefully planned.
3. The new hybrid type learning environment

3.1 The introduction of information and communication technologies into education sector

The introduction of information and communication technologies into education significantly changes its structure and operation as it has been until now. The basic relationship between educator – learner is reversed as through electronic networks the educational process is transferred to the learner’s private space, no matter how many kilometres separate his/her from the educator (DeLoach, 1995). The rapid development of new technological communication and information technology applications (teleconferencing, electronic file transfers, etc.), the electronic interconnection of learning units and the penetration of educational multimedia into the basic body of the learning procedure, establishing is distance learning as the indisputable pioneer of major and radical changes in the wider educational environment (COM (91), 388 final). Through teleconferencing (Retalis, Papaspyrou, Markakis, Skordalakis, 1998) learners can attend organized units of classes and lectures from anywhere they choose and are able to intervene, to ask questions, to exchange notes, reading lists, etc. With a PC and the necessary multimedia applications, a learner can participate in the educational process, acquire knowledge in which he is interested, evaluate his learning ability or even be evaluated from the distance learning centre which will be able to certify his/her knowledge. This living form of the educational process in combination with educational multimedia applications through electronic networks, are literally changing the educational map by offering immeasurable possibilities, which until now were to be found in the realm of desire if not that of fantasy (Rowntree, 1994).

3.2 The meaning and content of the hybrid learning environment

A hybrid learning environment is one in the context of which we try to combine in the best possible way new technological applications that set the educational process free from its constraints in time and space – and the respective pedagogical references to the basis of the traditional educational procedure school of thought (Anastasiades, 2000).

By the term traditional approach we refer mainly to three points of view.

- The relationship between the educator and the learner is unique and cannot be repeated.
- The educational area is an area for socialization, for promoting collective forms of organisation, an area of competition and noble emulation, an area where human and social bonds develop.
- In the centre of the educational procedure lies the human being and the major universal values.

Aided by the basic information society services, digitised information can be transmitted to the end user via his computer screen thanks to rapid developments in telecommunications and networks. The integration of all network applications and the basic services in the context of the international Internet makes it the integrated platform for implementing the new educational hybrid environment (Washington DC, 2000).

3.3 The components of the new hybrid environment – The example of a university

The basic characteristics of the new educational environment are the following:

A. Open and distance learning: Conventional educational programmes demanded that learners be present at the place of learning, a fact which used to make it hard for some categories of people to have access to sources of knowledge. The introduction of information and communication technologies in the education sector has significantly changed both the structure of education and the way in which it has worked up to now (Holmberg 1986). Through a networked computer and the necessary hypermedia applications, the learner can participate in the educational process, acquiring the necessary knowledge, evaluating his learning ability while he can also be evaluated from the distance learning centre which will be able to certify his/her knowledge. The application of intelligent teaching systems with the use of advanced tools -Intelligent Agents- (Tecuci, 1998) which recognise some peculiarities and difficulties of the learners and which guide the learner accordingly, create a peculiar personal communication relation between the learner and the teaching system. Through teleconferencing
learners around the world can attend a series of classes and lectures at American or European universities without going anywhere and are able to intervene, to ask questions, to exchange notes, reading lists, etc. Distance learning modifies the vital relationship between educator - learner, as it creates a virtual learning environment, in which the educator's role seems to be degraded as he/she does not retain the predominant role that he/she had in the conventional educational context.

B. Electronic interconnection between places of learning and universities: Until now Universities all over the world were independent units of educational and research efforts which communicated among themselves depending on the relationships developed between their members. The electronic interconnection of universities will contribute to the creation of a virtual area of collaboration and of development of the relations between the members of the university community as well as between learners from all parts of the world, encouraging mobility among academics, the joint development of numbers of research tasks, and the widest possible exchange of views and ideas and subjects of common interest. The failure to widely disseminate findings to other institutions inside or outside of the countries of origin makes inter-scientific cooperation more difficult while also contributing to the waste of human resources and intellectual effort expended by Universities. The creation of a network for Universities and research centres allowing access to their research, scientific announcements and in particular their libraries is considered an immediate priority. In this way directly interest parties can gain access to research in the fields of their choice, come into contact with other researchers and scientists exchanging view and promoting their subjects by encouraging collaboration or other forms of cooperation.

C. The meaning of lifelong learning: The rapid introduction of new technologies in the wider working and social environment, downgrades existing knowledge with incredible velocity resulting in the urgent need for the continuous improvement and upgrading of qualifications so that holders of qualifications can respond to new realities. Life long learning is one of the most important priorities of the new approach to education and implies the need for an ongoing dynamic adjustment of learning skills, and of changes occurring in the labour and social environment. This fact gives the learning process a permanent character since it is something which accompanies people throughout their whole professional and social life.

4. Speculation – Requirements for the development of an open learning environment

The introduction of new educational technologies really defines the conditions for the creation of a new learning environment. It would be wrong to say that the use of new technologies would be sufficient in itself to form an open environment of education, thus reversing the linear traditional model.

<table>
<thead>
<tr>
<th>Start of training procedure – Educational Assembly Line – End of training procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Students</td>
</tr>
<tr>
<td>Teachers</td>
</tr>
</tbody>
</table>

Figure 1: Illustration of the conventional linear model of education.

At this point, it would be useful to describe the most important facts which, combined with the introduction of the training technologies, form the concept of the open learning environment. The first
basic characteristic concerns the evolvement of the teacher's role, in the sense that he should now reconcile to the idea that he will lose the uniqueness of his role, since from an absolute authority of knowledge will evolve into a coordinator of many different sources of knowledge and the respective training tools. At the same time, he needs to get familiar with the idea that many times he will leave his traditional place (outside the assembly line) and will move through the new roles that will be developed either inside or outside the conventional imaginary production line of his educational work.

The second basic characteristic of the new model will be about the student, since he will now leave the passive position he was in on a permanent basis inside the training assembly line, and will alternatively take the role of an active factor of the training procedure. This can be achieved through the assignment and presentation of projects, the development of learning activities by the students and the connection of the training procedure with the social and production evolution as an integral part of the training procedure in its new form. The third basic characteristic is about increasing the efficiency of the learning tools that are now available for both the trainers and the trainees. The development of internet sites for the courses, the use of modern training material through the utilization of multimedia, the accessibility to countless sources of data, the use of synchronous and asynchronous communication between students and between teachers create in fact a different environment of incredible potential and alternate learning approaches, mainly at the level of the training methods that can now be used. Finally, the introduction of the philosophy of the lifelong training in the learning process also releases it from its temporal limitations, since education, in various forms and aspects, will be with us throughout our professional life. We could say that, under the above conditions, the training procedure in the new hybrid environment is changing its structural parts and particularly:

a) The relation between teacher and student, by establishing the principle of changing roles, either in the conventional classroom or the virtual one or its hybrid form. b) The relation of the teachers with teaching itself, since from a unique source of knowledge they evolve into coordinators of numerous sources of information, changing the learning objective from accessing information to the handling and processing of timely and reliable flow of information. c) The relation of the students with the new environment, where the two factors equation of course attendance – examinations is replaced by the three factors equation of active participation in the training procedure, creation of a personal hybrid learning area, multiple and two-way approaches of evaluation. d) The time frame of the training process, which quits the rationale of starting and ending and enters into the lifetime education.

All the above form the concept of the new hybrid type open educational environment, where the learning procedure is released from its traditional limitations in regards to time, space and methodology, allowing the formation of a new consideration, which on one hand will help abolish the linear model of education, and on the other hand will lay the foundation for new types of methodological approaches in the area of education.

![Figure 2: The components of the new hybrid type open learning environment](image-url)
5. Conclusions

In the context of the emerging Information Society the use of basic teleconferencing, email and electronic file transfer systems in combination with the optimum use of the world wide web are changing the educational landscape as we know it today. The basic characteristics of the new educational environment focus on the process of open, distance learning via electronic connections to universities and on life long learning. The hybrid learning environment is a conceptual and functional integration of traditional educational methods and new modern approaches. Nevertheless, the introduction of new educational technologies and the new hybrid learning environment in particular does not constitute in itself a sufficient and necessary condition to reverse the linear traditional model. The creation of an open learning environment requires the evolvement of the teacher’s and the student’s roles, as well as the optimum use of the training tools in the direction of changing the learning approaches and training methods, and finally the familiarization of all those involved with the fact that the training procedure will be with us throughout our professional life.

Secure & Credible E-Learning systems

Dennis Anderson
Pace University, USA
danderson@pace.edu

Sabah Jassim
University of Buckingham, UK
sabah.jassim@buckingham.ac.uk

Abstract: E-learning is a rapidly growing concept and activity that sprung up due to advances in media technology. We are concerned with the security and credibility of evaluation and assessment in e-learning. The aim is to discuss the essential aspects of assessment, that need to be addressed in a security model and policy for credible e-learning.

The case for and the concerns about E-learning

In 1990, there were 48 million people studying in institutions of higher education, according to a report by Merrill Lynch. By 2025, there will be 160 million people who want to study in universities. (Kelly, 2001). It is inconceivable that traditional systems will be able to meet these needs. Distance education will be required to satisfy this demand. Distance learning in the form of studying by correspondence has been around for a long time. But rapid advances in networked communication and the ease with which “hypertext” media can be created are revolutionizing distance-learning programs, and such programs are becoming a normal part of the education practices of many universities (Schar & Krueger, 2000).

There are still significant problems to be overcome, however. Some are technical. For example, the quality and speed of video transmission over the Internet is still inadequate. More serious are cultural issues related to teaching and learning. The Open University of the United Kingdom (OU) has found that its distance-learning students hunger for face-to-face tutorials (Technology Strategy for Academic Advantage, 1998). The challenge of achieving social involvement among students (virtual and real) and between students and teachers in the distance-education context will be the focus of research for many years to come (Schar and Krueger, 2000).

Perhaps the biggest challenge to the success of distance education is establishing that distance learning is a credible alternative to more traditional, classroom-based approaches. Academics are divided about the merit and reliability of e-learning. Some are enthusiastic and supportive, but many others are sceptical. Keys to this debate are a number of questions, including: How can the confidentiality and fairness of assessments be guaranteed? How can standards of qualifications gained by e-learning be maintained? We aim, through this paper, to discuss some possible answers to these questions and to open the discussion about how to develop a framework for assessment and evaluation in e-learning.

Assessment and Evaluation in e-learning

Assessments and evaluation of students' work are essential components of education. Examinations, essays and research papers are the main tools. Assessment is not only about ranking students and measuring their knowledge and comprehension. It also allows students an opportunity to rehearse skills and gain feedback. Over many years, a variety of assessment standards have developed around the world, and different certificates are compared according to their examination procedures. Developing a model for secure and credible assessment-and-evaluation systems for e-learning must be seen as an evolutionary process. However, an initial framework must address two closely related and complementary issues:

Perception improving measures: The credibility of any educational system in large part depends on public perception of the security and fairness of its evaluation procedures. To reassure the public, and employers, the assessment standards of e-learning programs need to be seen as comparable to those used by the most trusted traditional institutions. Independent advisory groups that oversee distance-education programs and assure transparency and adherence to high academic standards are essential for a trusted public image. Appropriate supervisory and auditing infrastructures should be a pre-requisite to funding for “virtual” institutions.

Methods of assessment: In traditional universities, assessment is based on a weighted combination of coursework and written and oral examinations. Systems that give less weight to examinations are perceived by
many academics and employers as less reliable. This view is hotly debated, but it must be taken seriously when thinking of standards for e-learning systems. In such a situation, it pays to be prudent and suggest that examinations account for a very significant part of a student's final mark. Traditionally, examinations are done under controlled conditions, and plagiarism and impersonation are a greater threat in distance-learning settings. Regional examination centers that are manned and monitored are one solution that could instil a good measure of confidence and fairness.

External involvement: Most degree programs in traditional universities, especially postgraduate programs, are regulated according to well established and fairly standard examination systems and procedures that involve trusted independent external examiners from other established universities. There is a need to establish a comparable system that draws on the experience and expertise of the global community, which must be regularly monitored and adhered to with rigour.

Security Model and Policy

The most difficult and crucial step to establish the credibility of e-learning could well be the development of an effective security system. Various models have been developed and refined to deal with the issue of security for different information systems. Examples include models for intelligence services, financial systems and health-information systems (e.g. Anderson, 1993 and Golimimann, 1998). E-learning shares many of its security concerns with other information systems, but it has some unique characteristics as well. Here, we will confine ourselves to the security aspects of assessment and evaluation for e-learning institutions.

A threat model: To construct an effective security system, it is first necessary to accurately outline possible security threats. This would consist of a list of threats that are supported by empirical evidence of actual attacks against similar systems. Here we are at a disadvantage, because there is, as yet, insufficient experience with e-universities and their nascent evaluation systems. Therefore, we must rely on the experiences of traditional universities in the Internet age, as well as the experiences of the OU and its sister institutions. The main threat to the coursework component of the assessment system is plagiarism. Universities are detecting the spread of plagiarism in students' work and the Internet is becoming a plagiarism-enabling tool. For examinations, the main threats are impersonation and cheating. Corrupt staff at regional testing centers could also threaten the examination system. The potential global nature of e-learning means that this threat has serious implications, even if it occurs infrequently or at a small number of sites.

Security policy: The intended policy should have a clear and uncompromising statement on the seriousness of plagiarism. It should also specify detection procedures as well as the consequences of breaches. Prevention of impersonation and cheating must be given a clear priority. It is crucial to have a policy of publicising breaches and the actions taken against their perpetrators.

Enforcement plan: Enforcement mechanisms must be clearly defined and publicized. Detection of plagiarism may require the use of textual profiling software. The use of non-local staff, security cameras and biometrics-based identification systems may all be appropriate ways to prevent fraud. Random inspection of test centers during examinations is a must. It also is essential that independent outside authorities be involved in the design, evaluation and enforcement of security measures.

Conclusions

In this short paper, we discussed the security aspects of e-learning systems. In particular, we outlined the elements of a strategy to protect assessment and evaluation for (virtual) institutions of higher education. This brief discussion is meant to initiate a more substantive work that could aid in the establishment of secure and credible e-learning systems.

Algorithm Visualization using QuickTime® Movies

Jay Martin Anderson
Department of Mathematics
Franklin and Marshall College
USA
j_anderson@email.fandm.edu

Abstract: The steady evolution in algorithm visualization increasingly favors student interaction with the visualization over the instructor's display of the visualization. Consequently, ease of delivery, support for multiple platforms, ease of use, interactivity, and protection of the source are important qualities of an algorithm visualization. Java applets and QuickTime® movies represent two ways of delivering algorithm visualizations to students via the internet which have some or all of these qualities. Visualizations of algorithms from computational geometry will be presented as illustrations of these techniques.

Introduction. The pioneering work in algorithm visualization (Brown, 1988) provided a rich, interactive graphical display to help a student understand the workings and properties of an algorithm. The essential characteristics of this technique (BALSA, etc.) included:

- tight coupling of the algorithm with the visualization;
- algorithm and visualization available for one platform;
- the algorithm visualization delivered on diskette or from a file server;
- interactivity included some choices of mode of presentation and size or nature of dataset.

The tight coupling of algorithm to the visualization worked against those institutions which had few fast, full-color monitors or display systems, and made it difficult for a student to work with the algorithm code alone. The decoupling of algorithm and visualization, with systems such as GAIGS (Naps, 1991) allowed a student to code an algorithm herself, and present the results of the algorithm to a visualizer which could run on another machine. This enabled the algorithm to be coded on any machine in any language; visualizers were provided for certain target machines. The communication between the algorithm and the visualizer was by means of a file which contained descriptions of important events in the life of an algorithm (for example, the comparison of two pieces of data; the interchange of two pieces of data).

Heretofore, the student could watch the visualization, but could not interact with it. Several reports suggest that easy access to the animation, textual annotations and questions in the animation, and interaction with the animation is important for student learning (Lawrence, et al., 1994; Byrne, et al., 1996; Kehoe, et al., 1999). It is to these issues that the present work is chiefly aimed. Our goals, therefore, include:

- rapid and convenient deployment of an algorithm visualization via the web and onto several platforms;
- some choices regarding the nature of the visualization, parameters of the algorithm, size and characteristics of the dataset;
- some interactivity by which textual messages can be presented to the student, including questions which the student should answer before proceeding.
The Java applet meets most of these characteristics: applets can be attached to most web pages, and Java virtual machines are available for many platforms and most web browsers. The applet can be constructed to permit student choice and can provide text which either explains the workings of the algorithm or asks questions of the student. Applets have relatively small download sizes, since most of the functionality is contained within the virtual machine on the student's platform.

But, not all browsers work alike, and therefore differences in applet appearance are beyond the control of the implementer. Although the author has constructed some applets for algorithm visualization, his work has primarily been the construction of QuickTime movies.

The QuickTime movie also meets most of these criteria: movies can be embedded in web pages, or streamed from servers. QuickTime players and browser plug-ins are available for many platforms and browsers. It is difficult to provide choice in data or presentation. Therefore the viewer must choose among several similar movies which span the data space or parameter space. Recent advances in QuickTime technology allow the presentation of text along with the moving picture, and allow for interactive control of the presentation by means of "sprites." The sprite "track" and text track are the mechanisms for student-instructor interaction.

The disadvantages of the movie are that one forgoes an element of interactivity: the student cannot, for example, choose a dataset; he must choose a movie. This means that the instructor must provide movies which provide a thorough examination of the data space. Another disadvantage is that movies are large, and even though they can be streamed, or fast-started, there can be a considerable waiting time before the student can use the visualization.

The algorithms. I chose to use algorithms from computational geometry to explore the possibilities of using applets and movies in computer science instruction because they are intrinsically graphical, and because existing treatments of these algorithms have rarely used a text accompaniment.

The QuickTime movie technique. Movies are constructed from a program written in C or Java. At each step of the visualization, a picture is drawn to an offscreen canvas; this picture then can be displayed on-screen, and can be conveyed to the codec which controls the movie track. The text track for the movie was developed in the same way: at each step of the algorithm, text was posted to a text track.

Finally, student interaction, in the form of question and answer, was implemented with a sprite track. The sprite track was not developed programmatically, but with the software Livestage Professional" from Totally Hip Software, Inc.

Movies were constructed using QuickTime Pro versions 4 and 5. Movies will run with Apple's QuickTime player or plug-in (the 'pro' version is not required for playback); most should run with QuickTime version 3 as well.

Demonstrations. QuickTime movies are available to illustrate several algorithms from computational geometry: the convex hull problem, the intersection of line segments and the Voronoi diagram. See http://www.fandm.edu/Departments/ComputerScience/compGraph/CompGraph.html\#VizCompGeom

Web-based Strategies for Improving Undergraduate Commitment to Learning

Malcolm Andrew
School of Pharmacy & Pharmaceutical Sciences
De Montfort University
The Gateway, Leicester LE1 9BH, UK
mhea@dmu.ac.uk

Abstract: Students need a variety of ways to encourage them to learn. Web-based learning can provide a platform for achieving this in a variety of ways, other than the simple provision of "flat" lecture notes. This paper describes a range of strategies used in a module to encourage on-campus, full-time undergraduates to learn and presents feedback on this approach from three cohorts of students. It represents the use of the Web to augment traditional face-to-face teaching rather than to replace it.

Introduction

Web-based learning is ideal for learners studying at a distance but also offers a range of learning opportunities for full-time, on-campus undergraduates (Ryan et al. 2000), many of whom may need help to increase their commitment to learning. A number of factors are driving the use of web-based learning in undergraduate curricula, including:

- the rising expectations of students to use this technology in their learning;
- the benefits that this form of delivery offers in providing an “always on” source of interactive learning that is easy for the tutor to keep current;
- the need to teach larger groups of students;
- the need to offer learning flexibility to the increasing number of full-time students with part-time jobs;
- the need to compete with other providers of higher education that are not necessarily traditional on-campus universities;
- the use of this new technology being implicit in the Dearing Report (Dearing, 1997);
- university strategic plans for learning and teaching where the adoption of this technology is explicit.

This paper describes a number of web-based programs produced by the author which he uses to augment, rather than to replace, traditional face-to-face delivery of a pharmaceutical microbiology module to second year undergraduates on a 4-year MPharm course. It also reports students’ feedback and attainment after using these programs.

Microbiology Practical Tutor

Students are required to work through a web-based practical tutor (Fig. 1) before coming to each laboratory class. Each laboratory session has its own set of web pages which explain, using high-quality images, the tasks to be undertaken in the class. Questions are posed about the underlying principles behind the techniques and links are offered to sites on the World Wide Web, such as the UK Public Health Laboratory Service site. In this way, students arrive for the class better prepared, the introductory talk session in reduced and the exercises are completed more efficiently. In addition, the students gain experience of using a range of resources on the Internet and are able to place their learning of practical skills into a practice context. To ensure that this web-based preparatory work has been undertaken, an open-book spot test is given at the beginning of each class, which contributes towards the students’ coursework assessment. This web tutor also provides examples of positive and negative results that can be expected in the experiments so that students know beforehand what to look for when they return to the laboratory in a subsequent class to read their results.
When you looked at the photo of the 3 objective lenses you will have seen that the 100x objective has a tiny lens. To increase the amount of light entering this objective, it is designed to be used only when it is in contact with special lens oil (see photo above). The refractive index of the oil is such that it bends the light rays from the lamp so that more light enters the lens - and eventually the eye - so that the image you see is brighter. The oil is placed directly onto the specimen on the...

Question 9 (of 10)
If 100mg of an antibiotic powder has a displacement volume of 0.35mL, how much water for injections would have to be added to 200mg of powder to make an injection with a final volume of 10mL?

Click in this box and type in your answer: 9.3mL

DONE HELP NEXT QUESTION

Your answer is correct.

This problem concerns the preparation of injections, where you have to take into account the displacement volume of powders in order to add the correct volume of diluent to achieve the required concentration of the drug in a specified...

Figure 2: A web page from the Microbiological Calculations Tutor
Microbiological Calculations Tutor

The ability to successfully undertake simple calculations is obviously important to prospective pharmacists, who eventually will have to correctly calculate drug doses. Yet, undergraduate students are notoriously bad at calculations. A web-based Microbiological Calculations Tutor has been written for them to improve their numeracy (Fig. 2). Students are given three weeks to work through this tutor in their own time and at their own pace before undertaking a time-constrained test without the use of calculators. Each time the test is run, the questions remain the same but the values are changed so students are advised to repeatedly use the package until they become proficient in each type of calculation. A HELP text box is provided for each question, which describes, in simple terms, a method for arriving at the solution. This package has proved popular with students (Tab. 2) and its use has improved their ability to perform the calculations (Fig. 4).

Interactive specimen examination paper

To give practice in answering the end-of-module written examination, an interactive specimen paper is provided, which students work through in their own time. Besides familiarising themselves with the format of the paper, students can attempt to answer the specimen questions provided and receive on-line feedback on their responses (Fig. 3). The second section of the exam paper consists of multiple response questions (MRQs) and a separate web tutor is provided to practise these. The MRQs are fully randomised and provide the opportunity for students to see the impact of the imposed “negative marking” on their performance. Questions are presented 10 at a time and students are encouraged to repeatedly use the tutor until they feel confident to answer the questions correctly. A different bank of questions is used in the real examination paper.

Question 1

Draw a diagram of a section through a typical bacterial endospore. Label the parts and indicate which structure is thought to be responsible for the chemical resistance of endospores.

You should be able to draw a diagram like the one below. Can you label the parts correctly, by inserting the appropriate number in each box? Click the DONE button when you have finished.

Figure 3: A web page from the interactive specimen examination paper showing the feedback given after the user has completed the question and pressed the DONE button.
Feedback on assessment and teaching

Part of good teaching is to provide adequate and timely feedback to students on their assessment. The author uses web pages to do this. Feedback is given in the form of general comments and as histograms of coursework marks and examination performance, so that students can place their own achievement within the context of the whole cohort. The data showing the improvement in performance after using the Microbiological Calculations Tutor was published on the module website (Fig. 4) to encourage students to perform as well in similar questions in the end-of-module written examination.

It is equally important to elicit students' views on the delivery of the module, to provide them with an analysis of the results and for the tutor to respond to their comments. This shows students that their comments are valued and also closes the quality loop. The results of all questionnaires completed for the module are published on the website, together with the tutor's responses to the students' comments.

Many of you liked the microbiological calculations tutor. The histogram below shows that, for most of you, it improved your performance in the spot test on these microbiological calculations. Remember to run this tutor again before the written examination since, as you know, there will be a short question on these calculations.

![Performance histogram](image)

**Figure 4:** A web page summarising student feedback on use of the module website, showing the tutor's feedback returned to students on their calculations assessment.

Putting their studies into context

In vocational courses, like Pharmacy, it is desirable to put the course into the context of the profession wherever possible, so that students can see the relevance of their studies and increase their commitment to the course. Students on our MPharm program are provided with PharmScape, which is an interactive website describing the profession of pharmacy (Andrew, 1998). It uses, as a contextual device, the story of the development of a drug from its discovery to its delivery to the patient. As the story unfolds, each of the modules in the MPharm program is introduced to show how they fit into the overall picture. Hyperlinks are provided to show the content of each module. Students are encouraged to refer back to this website regularly during their studies to help them relate learning to practice.
Other web pages for the module

Other learning material that is provided as web pages for the students studying this module includes:
- a list of learning resources, including links to the publishers’ websites of the recommended textbooks and to on-line bookshops for possible book purchase;
- lecture outlines and the assessment criteria for the module;
- Dangerous Microbes, an interactive tutor for learning the names of microbial pathogens and the diseases they cause;
- The lecture presentations (as HTML versions of the author’s PowerPoint presentations);
- Microbes in the News, links to relevant topical articles from UK newspapers and other media.

Student response to the web-based learning for this module

Student opinions of the web-based learning packages for the module were elicited by means of an anonymous questionnaire. Students responded to the statements using a 5-point Likert scale with the options: strongly agree, agree, neutral, disagree, to strongly disagree. Table 1 summarises the results from questionnaires completed by three cohorts of students.

<table>
<thead>
<tr>
<th>Statements</th>
<th>Percentage of students agreeing/strongly agreeing</th>
</tr>
</thead>
<tbody>
<tr>
<td>A) It enhanced my learning experience</td>
<td>95</td>
</tr>
<tr>
<td>B) It was clear and easy to use</td>
<td>96</td>
</tr>
<tr>
<td>C) It was of the appropriate intellectual standard</td>
<td>89</td>
</tr>
<tr>
<td>D) I liked learning in this way</td>
<td>56</td>
</tr>
<tr>
<td>E) It increased my interest in microbiology</td>
<td>47</td>
</tr>
<tr>
<td>F) It increased my confidence in using computers</td>
<td>63</td>
</tr>
</tbody>
</table>

Table 1: Summary of an evaluation of the module website completed by three cohorts of students.

The data show that a high proportion of students felt that the web-based material enhanced their learning experience, that it was clear and easy to use and that it was of the appropriate intellectual standard. Some students were less enthusiastic than others to adopt this technology (see statement D; Tab. 1), but this is not an uncommon finding (French et al. 1999). Face-to-face discussion with the students on their questionnaire responses revealed that the low score for statement F was because many of them felt sufficiently confident in the use of computers before undertaking the module (a tribute to a previous module in which this topic was taught). Generally, there is remarkable consistency between the responses of the different student cohorts.

As part of the questionnaire, the students were invited to add written comments if they wished. Over one third of all respondents chose to do so. All comments were positive; Table 2 shows a representative selection of them.
“I found the website very useful and easy to follow. The microbiology practical tutor and the dangerous microbes programs were very good. Study would be a lot easier if all lecturers had a website like this.”

“I use the website regularly and find it very helpful. Backs up the lectures and practicals successfully. Increases my confidence for the phar2404 module.”

“I think that the website is very good and has been very helpful to me. Also provides extra material to make the practical part of the course feel complete. Very useful.”

“Practical tutor helped in practicals a lot.”

“The practical tutor was excellent for information about the forthcoming practicals but gaining access to them was sometimes difficult and very time consuming if there was no Internet access at home.”

“The website was a different way to aid learning and encouraged more effort to be put in to preparation for the labs.”

“Computer program was very useful, especially the microbiological calculations tutor.”

“The calculations tutor was very good as the answers were given and explained in a very understandable manner. This was good as many modules expect you to excel in maths and not all of us do.”

“The website is an excellent way to receive information. The only problem being that the printers in the computer node are rubbish and therefore taking printouts is difficult.”

Table 2: Student comments on the web-based learning material used to deliver the module

Conclusions

Experience of delivering this module over three academic sessions, suggests that using web-based learning to augment traditional face-to-face teaching was successful, both for the tutor and for the students. The website was well used, with some hits even being recorded on Christmas Day on two consecutive years! Student performance in, and commitment to, the module was enhanced, as judged by the feedback questionnaires, attendance at classes and by achievement in assessments. It was clear from the student behaviour that, like many tutors, students find it difficult to shed the “hard copy habit”, feeling the need to printout most of the web pages. This has implications for the support provided for them to do this (see last comment; Tab. 2). Moreover, the amount of web-based learning that is expected of students needs to be carefully judged to avoid “screen fatigue” amongst learners.

It is felt that providing web-based material is an ideal way of augmenting learning in the traditional on-campus setting, although it is arguable whether the “sage on the stage” should be replaced by the “guide on the side” for this group of learners. Full-time students have a right to expect access to their tutors and, for this reason, the author has not yet provided a chat-room for this module.

Development of Technology Based Distance Learning: A Case Study of the Centre for Commerce and Administrative Studies at Athabasca University

David Annand
Centre for Commerce and Administrative Studies, Athabasca University, Canada
davida@athabascau.ca

Athabasca University, Canada’s largest open, distance-based university, was established in 1971. The University offers both graduate and undergraduate programs. Registrations in the 2000-2001 academic year totalled about 36,000. Though originally designed to serve the needs of Alberta adult learners, more than 50% of University’s students now reside outside Alberta. Students outside of Canada accounted for about 5% of 2000-2001 course registrations and this percentage is growing. The Centre for Commerce and Administrative Studies (CCAS) is the undergraduate arm of the University’s Open School of Business. Undergraduate business courses account for about 13,000 annual course registrations, or over 1/3 of the University’s total undergraduate registrations. At present, there are about 20 faculty members in the Centre.

Over the past several years, CCAS has introduced a fully integrated electronic learning system in addition to providing distance education by traditional paper-based instructional material and telephone support. The process started with the introduction of the Call Centre in 1994, designed to increase student access to administrative and academic support. Instead of the traditional one-on-one tutor-student relationship, students were able to call or e-mail front-line “learning facilitators” who are available approximately 60 hours per week. The Call Centre handles all initial academic, administrative or technical inquiries from students in CCAS print-based and technology-based distance learning (TBDL) courses. As well as improving student service, the introduction of the Call Centre has reduced overall delivery costs. The related financial savings enabled CCAS to develop an integrated Web-based learning environment using Lotus Notes. Group interactivity, audio/video streaming, simulations, electronic assignment submission, on-line exams, and related electronic student support services have gradually been introduced in various courses. Although this system was originally used to convert unpaced, paper-based homestudy courses to TBDL format, it has been modified as of September 1, 2000 to offer paced business courses in “e-class” format. These courses have cohorts of students instructed by an online academic, and commence every September and January for 14-week periods.

The design of this comprehensive electronic system has required the re-conceptualization of all course development and delivery processes within the Centre for Commerce and Administrative Studies. Relatively successful organizational and technological change has permitted the Centre to retain its traditional homestudy student base, work within largely unchanged institutional structures, and develop new online business programs for delivery around the world, while requiring minimal net new financial resources. However, the Centre is now at a crossroads. There are several internal and external factors that will affect the rate and extent of TBDL development within the Centre over the next five years—expectations for growth, prospects for funding and other economic factors, internal strengths and weaknesses, and external opportunities and threats.

Like the rest of the University, the Centre has undergone rapid growth in the last five years. Annual course registrations have increased over 100% in this period. This trend is expected to continue, particularly within business programs. As well, an e-commerce major is now being developed within the Centre’s online BComm program. This program commenced in September, 2000. The e-commerce major will require the development of about 20 new courses over the next three years. Finally, there are real prospects for collaboration with Canadian and international educational institutions over the next five years. These factors mean that the number of student registrations will likely continue to grow quite quickly. As a result, additional faculty and technical staff need to be hired and trained, and existing staff need to be retrained.

Fortunately, approximately $675,000 of ongoing funding has been obtained to finance development of the e-commerce major. However, it is becoming clearer that these delivery costs will be higher in the online environment than in the traditional independent study, paper-based courses because online learning increases instructor-student interactions (Annand 1999). CCAS has requested that the delivery allowance be increased from $120 per student to $150 for TBDL courses, though it is unclear how the university will fund this.

The Centre’s faculty and staff are generally supportive of new technology applications and online learning initiatives. Most faculty members who resisted the direction of the Center over the last few years have
moved on to other centers or institutions. Remaining staff have been able to streamline their work duties as a result of adopting Lotus Notes for a variety of Centre administrative functions, and a core of three technical staff in the Centre provides users with adequate technical assistance. These factors have increased acceptance of change and created overall satisfaction with the new operating environment. Also, research in distance and open education is recognized as a legitimate alternative to discipline-related research for purposes of faculty evaluations and promotion decisions. As a result, there are incentives for faculty to experiment with new TBDL features. A strategic plan for the Centre was adopted several years ago. This continues to inform the direction of the Centre, and provides a point of reference for new initiatives.

There are criticisms of the Centre's evolution to technology based distance learning, however. Some faculty members are raising questions about the andragogy informing online courses. The courses have generally been adapted from the existing paper-based distance learning materials. Although some interactive features have been added, behaviourist learning theory still underlies most of the online courses. Instruction is generally broken down into small units, and detailed learning objectives are used. The courses emphasize the attainment of pre-specified learning outcomes, and the measurement of how well these learning outcomes have been achieved. Though TBDL could support courses informed by constructivist learning theory - where knowledge can be co-constructed by drawing on unique personal experiences and knowledge of the participants, for instance - this has not been the case to date because of limited faculty time and financial constraints. Because traditional homestudy students must still be served, faculty members are reluctant to maintain two versions of essentially the same course. As a result of this and financial costs of increased interaction, collaborative and experiential learning processes, or other forms of online group interaction that can be facilitated by TBDL are used sparingly. This will likely continue.

There are several threats to the TBDL initiatives undertaken by the Centre. Historically and to spur innovation, the University executive has supported development of several TBDL platforms like Lotus Notes, WebCT, and Web Board in different university programs. These platforms are now well-entrenched. The executive now wants to explore the possibility of merging all university programs onto one delivery platform to use resources more effectively. A move away from the Lotus Notes groupware underlying the Centre's learning system would be disruptive to technology and curriculum development plans. The University in general faces criticism about its move to online courses. Even though recent data suggest that over 80% of current students have access to some type of computer equipment, some critics argue that online learning still limits access to students who are economically underprivileged. This contradicts the general mission of the University, which is to remove barriers that traditionally restrict access to university education.

Executive-level negotiations of collaborative arrangements with offshore institutions have resulted in unanticipated demands on CCAS faculty and staff. The decision by the University to join the Global University Alliance (GUA), a consortium of 10 North American universities offering programs by TBDL, has meant that students in the Far East will be able to enroll in the BComm program commencing in September, 2001. These courses need to be converted to Blackboard, the delivery standard for the GUA. Although most of this conversion process will be carried out by a GUA partner, it is unclear what implications this and similar collaborations will have on faculty and staff resources within CCAS. These collaboration projects, which invariably result from the top-down decision making processes within the University, could eventually conflict with the desire for CCAS faculty to set their own research and teaching directions.

Finally, an increase in the number of online courses and programs offered by traditional and private, for-profit business schools means that the Centre may face increased competition in the future. This may curtail or significantly affect present development plans. Competition also increases expectations of students, which implies the need for higher service standards and shorter course revision cycles, for instance. Over the next five years, enrollments in the Centre should continue to grow as students throughout the world exercise their preference for independent study. The increased acceptance of distance education as a viable university-level learning alternative, and the University's commitment and ability to fill expressed learning needs of adult learners should enable the Centre for Commerce and Administrative Studies to flourish during this period. To do this, though, external and internal threats must be managed, the relative costs of delivering various forms of distance education must be recognized, and lower cost alternatives need to be chosen.

Abstract: The institution-wide adoption of web-based learning technologies at the Technical University of British Columbia (TechBC) has led to a significant departure from traditional duties for faculty. This paper reports the study results of a task analysis of course development and delivery processes for faculty at TechBC. The study identified critical tasks for academic staff, the tasks most difficult to do, and why these tasks were a problem. Study participants reported a large proportion of course authoring is done off-campus and outside the web development environment. Participants also reported excessive time required for data management tasks associated with team management and assignment grading.

Each course at the Technical University of British Columbia (TechBC) has a substantial online component and is prepared over a 4-month period. Course development consists of 5 stages: planning, specification, design, production, and post-production. Development is carried out by academic staff (faculty and learning support associates) working with instructional designers, media developers, licensing specialists, editors, and technical staff. Throughout delivery and development, academic staff work within the TechBC Course Management System (CMS), an integrated suite of web-based tools built in-house to meet the specific requirements of the institution. Authoring is done in Macromedia® Dreamweaver™, an HTML development tool configured to edit centrally stored files over a local area network. At the time of the study, academic staff needed to be on campus to directly edit course content.

In fall 2000, the Educational Technology and Learning unit of TechBC conducted a study of the work processes of academic staff as they developed and delivered courses. The goal of the study was to provide better tools, support, and professional development for academic staff. The study was designed to identify barriers to academic staff working in TechBC’s CMS environment and recommend design improvements.

Methodology

Eleven academic staff participated in one-on-one interviews conducted at their primary workstations. All participants were developing and/or delivering courses. As shown in Table 1, the study comprised 3 stages: identification of high-level tasks, identification of task details, and usability testing of specific problems. The first 2 stages provided a framework for identifying frequent, critical, and difficult tasks, and for identifying problem areas of the CMS. The final stage focused on assignment processing, an area identified in the initial stages as highly problematic.

Results

Task model
An essential outcome of the study was a hierarchical task model that identified tasks of academic staff, and broke tasks into subtasks and steps. Too large to be presented here, the model is quantitatively summarized in Table 2.

Table 3: Subtasks or steps flagged as difficult by at least 4 participants

Most participants did a substantial portion of course development from home or other remote locations. They often transferred work to campus using floppy disks or email, then typed or electronically transferred content into Dreamweaver or the CMS text fields. These data management tasks were seen as unnecessarily tedious and difficult.

Recommendations
Based on the study results, these high-priority changes were recommended:

- Provide and support secured remote authoring access to the CMS. Ideally academic staff and other authors should be able to author and edit courses from any location through a browser.
- Provide dynamic content management throughout the CMS to reduce or eliminate the manual entry of the same data in multiple places. For example, when updating the due date for an assignment, the instructor should only have to enter the change once, even though the assignment date may show up in several places.
- Provide online secured spaces and systems for file sharing, collaboration, and storage and retrieval of course resources, including learning objects.
Enhancing student access to the University: The integration of online and course-based material for the visually impaired.

Ray Archee and Monica Whitty
University of Western Sydney
Australia
r.archee@uws.edu.au & m.whitty@uws.edu.au

Abstract: Access to information is a basic right of all students, but this entitlement is not always available to blind or visually impaired students at every Australian university. Our wish to remedy this situation has led to an exploration of alternate uses of technologies such as the Internet, multimedia CDs and assistive software. Through personal experience, and the innovative design of two University subjects, this paper highlights the pressing need for research in this area, and presents possible solutions to this inequitable situation.

There is a paucity of educational research that deals with the problems of sight-impaired students (Williamson, Shnauder & Bow, 2000). In particular, there is a dearth of essential services available to visually impaired students in most areas of Australian educational life. In current times, where course materials are increasingly being placed on the World Wide Web, the technology has the potential to democratise information, not only for sighted students, but also for a whole range of perceptually challenged students. Smith, Waby, Neville and Dalloway (1999) support this finding highlighting the importance of technology for helping the visually impaired.

As educators and researchers, we were inspired to undertake this research, after a profoundly blind student presented her difficulties to us having enrolled in two of our subjects at the University of Western Sydney: Interpersonal Interaction and Electronic Research Methods. Both of these subjects make use of the Web; for example, to display lecture notes, tutorial activities, mock exams questions and real exam questions, displaying announcements and utilising a discussion board. Although we do not rely solely on the Web to educate out students, like other educators, we have found it to be a useful addition to our lectures and tutorials. Moreover, students who find it difficult to attend lectures can access all the information they require on the websites. Despite the versatility of our subjects, our blind student explicated our subjects' limitations.

Each subject presented its unique problems for this student. For example, Interpersonal Interaction required the student to partake in ordinary class work, including reading handouts and the textbooks, and carrying out library research. In contrast, Electronic Research Methods required the student to be able to read the instructional material off the Web, as well as to navigate the web, locate references and complete online exercises. A most unusual event occurred in this subject when this student entered the computer lab with a guide-dog and proceeded to sit down next to a computer with the largest monitor. Given that she was profoundly blind, all she could do was to listen to the instructor explain to the students how to access the online tutorials. She left half-way through the class since she had no way of completing any of the class activities.

As with most other universities, this university has a Special Disabilities service; however, given the range of material the student needed to access and read, they were unable to adequately meet the student’s needs. Special Disabilities had alerted us to the existence of this student to which we replied that the subjects were accessible several months before the student needed to enrol. Whilst translation into Braille of all the online material was possible, the student wished to participate in real time. This prompted us to seek funding to carry out our own research into improving education for the visually impaired.

Currently, we are investigating the alternatives to typical classroom activities and online materials. We first wanted to develop multimedia authored CD’s and web pages that can support sound and speech. Our investigations, which are still ongoing include the following:

- Collaborations with the Australian Royal Blind Society in terms of usability and media design for blind and visually impaired persons will provide hands-on R&D of multimedia/Internet navigation;
- Rethinking alternatives to traditional Web site design with traditional peripherals such as the mouse and keypad are leading us to other input devices such as touchscreens, 3D mice, and virtual reality devices such as 3D gloves;
- Exploration and testing of the available software which cater for blind and visually impaired people;
- Facilitating maximal interactivity for blind and visually impaired students within our own courses.
Our investigations have revealed that the solution to this problem should be simple and within the reach of most students equipped with ordinary hardware. Special equipment such as special input/output devices are expensive and out of the reach of most students. We also understood that written subject matter could be translated into Braille, but we questioned whether this was entirely necessary.

Screen magnifiers, Braille printers, read-aloud Web connectors, and voice activated wordprocessors all have the potential to assist sight-impaired students. One of the most elegant solution we found was a program called JAWS from Henter-Joyce, a company which specializes in technology assistive products. (www.hj.com).

JAWS is a screen reader which can recite aloud almost everything encountered on a Web screen. The JAWS program 'sits' on top of the Microsoft Windows operating system, and uses an adjustable synthetic voice to give feedback in the form of aural translations of the user's keyboard commands and text/graphics depicted on the Internet. Any text, graphics or links are automatically recited at variable speeds and volumes.

Initially we expected that multimedia CD-ROM's would be an appropriate alternative to the Web. We had planned an elaborate, professionally authored multimedia CD which comprised our lectures and notes. However we discovered that multimedia CD's using software such as Director is a much more problematic solution, since most screen readers have difficulties translating multimedia formats. Multimedia, it seems, is designed mainly for sighted people, with visuals playing a large part of the success of the format.

Using the Web for coursework is also problematic, even implementing the JAWS solution, since much of the online material needs to be located and saved to disk for future reference by blind and sight-impaired students. Thus our solution was to redesign existing Web sites for real-time use by blind students who decided to use the Internet, and to additionally place those Web sites, including all the reading materials on to a HTML encoded CD-ROM. The CD-ROM could also include the screen reading software and would be a perfect facsimile of the real Website. We could additionally include recorded lectures via digitally stored formats such as mpeg or mp3.

The redesign process takes into account the W3C guidelines for accessibility, which include:
- images without alternate text;
- lack of alternate text for imagemap hot-spots;
- misleading use of structural elements on pages;
- uncaptioned audio or undescribed video;
- lack of alternate information for users who cannot access frames or scripts;
- tables that are difficult to decipher when linearised;
- and sites with poor colour contrast. (see http://www.w3c.org)

Our original websites were almost devoid of graphics, the main offending screen elements. We initiated a process of rationalisation whereby we placed the most used links at the beginning of the Web page, so that students would hear this information first, without having to unnecessarily wait. This meant that hypertext links could be chosen quickly. We also broke up long lists of links into logical units and regrouped these under sub-menus for easy navigation and retrieval.

Interactivity and participation are further issues of equity/accessibility affecting both disabled and non-disabled students. As a postscript, we are further exploring the ability of voice recognition software such as Dragon Dictate coupled with JAWS, to enable students to participate in interactive online sessions using chat programs such as ICQ and IRC. If we can generate a system to hold class discussions, without the need for reading and typing, not only would we help blind and visually impaired students, but also remove those inequities produced by distance, and by other perceptual/cognitive loss.

ktsushima@sannet.ne.jp

*Konami Co.
**Heian Jogakuin University

Abstract: The refinement of measurement of a behavior of a human testee with Eye Mark Recorder on who is playing a computer game or typing keyboard is reported. The new strategy of analyzing the measured huge data is developed by using nonlinear feature extraction method. And further, the dynamical process model of human cognition motion process about typing operation using keyboard and playing the computer game called modified Flipper Game is developed. It gives us the comprehensive understanding of a testee putting on an eye mark recorder and datagloves by analyzing the measured data.

Introduction

Educational Systems on the computer such as CAI, ITS and ILE have a long history. Some remarkable progress concerning such educational systems was made in 1980's. Student model, subject matter and instructional strategy were constructed on the computer explicitly using knowledge processing technology such as production system to assist a learner in his study effectively (E. Wenger, 1987). In spite of a great deal of effort put into intelligent educational systems, they don't seem so effective in the actual educational situation. Almost all the educational systems require many learner's answer to many questions given by the system, and they can conjecture the learner's understanding status using these many answers logically. Consequently, the learner are tired of answering these many questions in communicating with these intelligent educational systems.

In the actual education in a classroom, a teacher receives from a student not only an answer of a question which he gives but also information about nonverbal motion and some behavior of the student. The latter two informations are not so logical, but they are important to understand the student deeply in his learning process.

Educational system which can understand the learner using these informations is necessary to get rid of the above defect of the present intelligent educational system. It is desirable to give the educational system the capability to detect cognitive data such as eye movement and finger-arm motion of a learner who interacts with educational system. We introduced eye mark recorders and motion capture system for fingers and arms in our laboratory, and incorporates them with educational system on the computer (M. Ueno et al 1996), (T. Nisiki et al 1997), (T. Nisiki et al 1998)
The used Eye Markrecorders and measurement of eye movement

The two used Eye Mark Recorders (hereafter we use EMR for them), NAC EMR-600 and TAKEI T.K.K 2901 are shown in Figure 1.

The eye mark of a testee has been analyzed by a human researcher using VTR tape usually. The eye movement of a testee in the time range longer than 1/30 second can be detected and analyzed in this approach, but the movement of eye mark in the short time range from 1/30 Sec. to 1 mSec. cannot be detected by using VTR tape.

So, it is necessary to develop a new measuring system to detect eyemark data in this short time range. A new hardware memory board called CINDY and the software calibration system for EMR which can detect both 600 eye mark data per Sec. and another data concerning human behavior at the same time are developed to analyze a human visual cognition and motion.

Using the real time data obtained from this calibration system, the computer can respond to human eye movement and vary objects which are seen by a testee on the CRT very quickly.

As a result, some communication environment on the computer which can respond quickly to eye movement of a testee has been developed in our research. The following two preliminary measurements to have a clear grasp of the general features of the eye movement of a learner who traces moving object is prepared.

1) Tracing a moving point on the CRT (Figure 2) 2) Tracing of vibrating point on the CRT (Figure 3)

Figure 2: Eye mark for moving point

Figure 3: Eye mark for vibrating point
A point moves from the left to the right on the CRT with constant velocity in measurement 1). A testee is under order to trace this circle on the screen.

A point vibrates on the Sin curve on the screen in measurement 2) and this point crosses the screen about 5 Sec. Also in this case, a testee is under order to trace this moving point on the screen.

Three different sin curves which have different amplitude are used in our measurement 2).

The gross structure of human eye movement in tracing moving object is grasped from these two different measurements.

The used EMR can trace small variation of human eye movement up to size 0.7 degree when a testee gazes stopping object. But, testee's eye mark moves in large scale when a testee traces the moving object in measurement 1) and 2). It is difficult to identify the absolute position of learner's eye mark in this case. In other words, relative variation of eye movement can be detected easily, but it is not so easy to detect absolute position of human eye point. So, some correlation mechanism to infer the absolute position of testee's eye mark from the information about the seen object is necessary. It is discussed in chap. 5 in detail.

**Computer game using realtime eye mark data**

In almost all the researches about human eye movement, measured data are used for analyzing human behavior only after the measurements end. But, we want to construct the environment in which the seen object on the CRT varies according to the real time eye mark of a testee to realize dynamical interaction between a testee and an educational system on the computer by using eye movement. If this environment is developed successfully on the computer, we can have the chance to analyze behavior of a testee thrown into dynamical communication process with a system using eye movement. It is essential to use real time eye mark data to realize this communication environment on the computer. As CINDY board developed by us made it possible to detect several data concerning human visual cognition and motion in high speed simultaneously, we can use it for analyzing this real time communication process between a testee and the system. We have developed a computer game called modified Flipper game in which our testee can play using eye movement. The details of this game are shown in ref. 4 and 5. There is a computer game called Flipper (Figure 4). A player of this game moves a mouse to select the squares divided on the screen, and then he can vary the color of a selected square by clicking a mouse. Six colors are used in this game.

The color of a selected square changes in the cyclic sequence, when the player click the mouse. For example, purple, red, green, blue and so on. When the colors of all the squares coincide, then the game is cleared. On the other hand, the color of each square varies randomly at regular time intervals on the CRT. So, the player of this game
must vary the color of squares as fast as possible. The player can confirm which square is selected by seeing a mousepointer on the CRT controlled by himself in this original Flippergame.

We modified the original Flipper game into the game where a player can select and change the color of the selected square using eye movement. In this modified Flipper game, a player need not click the mouse to change the color of the square but he has only to gaze at the square in a short time interval. If the eye mark of a player stays in a square for 0.6 Sec., the system automatically changes the color of this square in the cyclic order defined beforehand. The length of this time interval can be changed easily. Several types of modified Flipper games are developed by us. These games have different division number of sub squares from 2 by 2 to 6 by 6, different number of color assigned to sub square from 2 to 6, and different length of time interval from 0.3 Sec. to 0.6 Sec. The general feature of human dynamical eye movement of a player confined in this complicated context of computer game can be measured and investigated. This measurement is designed to obtain the standard touchstone for more complicated dynamical human eye movement in playing computer game and in operating input devices. The detailed analysis of these new data will be shown somewhere. To explain these results in detail, we have to construct the model which can explain the cognition-motion process in human brain. This will be discussed in chap. 6 in detail.

**Measurement of human body motion and eye movement**

It is important to see human body motion such as finger, hand motion to understand the skill level of a testee typing text using a keyboard. More dynamical information about a testee is obtained by measuring both eye movement and finger motion. The correlation between eye movement and the time delay of motion from visual cognition bring us several cognitive features and parameters which our testee has. We have measured typing process of our testee who puts on data gloves, 3D motion censor and eye mark recorder. (A. Tsubokura et al. 1998)

In this case, 6600 data are obtained from EMR and 6160 data are obtained from data gloves per second. The mutual correlation of these data is used to identify types of tasks which are generated automatically in his manipulation. It gives us the general feature of our testee such as novice or expert, and we can get some cognitive parameters such as size of memory buffer of our testee from these measurements.

![Figure 5: Measurement of Human Body Motion and eye movement](image)
It is relatively hard to construct the experimental environment for this hard duty human measurement. We have succeeded in constructing this environment and DBMS for human measurement data. Some of our results are shown in ref. 5. We are interested in the process of acquiring skill of a learner in his typing. To explain these combined results concerning visual cognition and body motion in detail, we must improve the model which can explain the cognition-motion process in human brain. This will be discussed in chap. 6 in detail.

Strategy of data analysis

Eleven data are sent to the analyzing computer from EMR in each detection of an eye mark. The used EMR can detect eye mark 600 times per sec, so the analyzing computer receives 6600 data per second from EMR. On the other hand, the used data groves can detect 14 bending angles for fingers 230 times per second, so 6440 data are sent from data grove per second. Nonlinear data analyzing system for these complicated data is developed using knowledge information technology. It can extract features of both eye movement and finger motion automatically from the observed data by using prepared templates and some rules about matching strategy. These features are saved in the system as a feature extracted list.

Many templates are prepared in every sheet of this multi-step feature extraction, the higher features are extracted from the low-level feature extracted list. But there is a serious problem in extracting the higher feature from intermediate structures. For example, to identify data with higher feature the system must use not only other data which occurred in the past but also other data which will occur in the future shown in Figure 5. As is well known, human cognition-action behavior depends strongly upon context of cognition-action history and cognitive situation in which a testee is confined, and so it is inevitable to use this type of matching strategy. So, we cannot avoid designing this type of process dependent nonlinear analysis of visual cognition action behavior of a learner. This type of data analysis is very complicated and time-consuming on the computer. There are two ways to overcome this difficulty. One is to use a parallel computer to analyze feature extracted lists for lower levels. The other is to use a model for human behavior to cutoff links among intermediate candidates for visual cognition action motion behavior.

Dynamical model for human Cognition-Motion process

The construction of the system to measure eye movement and finger arm motion of a learner interacting with a computer are reported in the above. These communication processes are very complicated and depend on the knowledge which he possess about the object he sees and the situation a learner is confined to. As the behavior of eye mark depends on the situation and context strongly, ordinary data analysis is not so effective. The strategy to analyze these data is designed with the help of both nonlinear data analysis including chaotic data analysis and agent-like schema formalization of human processes. Some models for human cognition-motion mechanism are necessary to extract feature of the correlation of eye movement with finger arm motion from these data.

![Figure 6: Strategy of nonlinear data Analysis](image-url)
As is well known, there are several hierarchies of information processing in the human brain concerning visual recognition. The schematogy may be promising as a model of hierarchical visual cognition-motion system. So, we have developed the rule-based modeling of visual recognition. This model is quite general, so it may have the capability to explain different cognition processes reported in this paper because many local rule corresponding various experimental situations can be assembled. Parallel production system called SYMPASI (SYMBolic PArallelSIMulator) is developed by us to explain the behavior of our testee playing Modified Flipper Game. It is possible to set retardation time for each rule to fire in SYMPASI. So, recognition simulation is generated as a result of successive adaptation of rules. We can tune the system against the specialization by assembling and modifying various production rules in SYMPASI. Many phenomenological facts concerning visual recognition reported in this paper can be assembled in SYMPASI, then overall cognition-motion phenomena for a testee is generated by the successive adaptation of rules in working memory of parallel production system. The structure of the rule-based simulator SYMPASI is shown in ref. 7. A part of rules of SYMPASI tuned for modified Flipper game which is reported in chap. 3 in detail are shown in ref. 7.

We regard modified Flipper Game as the first milestone for all cognition motion process. The parameters obtained from the analysis of modified Flipper Game can be used other cognition motion processes such as text input processes using keyboard.

Abstract This paper looks at the low participation rates in computer mediated conferences (CMC) and argues that one of the causes of this may be an incompatibility between students’ learning styles and the style adopted by CMC. The main learning style theories are viewed through the use of Curry’s Onion Model. It is argued that Riding’s Cognitive Styles Analysis is the most powerful theory with which to examine educational CMC. A framework for conducting an empirical investigation using this theory is outlined.

1 Introduction

Computer mediated communication (CMC) is becoming a popular tool in tertiary education establishments for both distance and campus-based students. Whilst it offers many advantages, especially to distance students, there are concerns about the low levels of active participation in conferences (Little & Light 1999). Indeed, Mason (1994) proposes the ‘thirds theory’, which suggests that students fall into three distinct groups: those who actively participate, those who read messages but do not participate and those who take no part. More recently, the experience of many tutors, including the authors, is that participation levels are often much lower even than Mason’s estimates (Hewitt and Teplovs 1999).

Reasons for the low participation may relate to the subject matter and the approach of the individual or their learning style. For example, Romiszowski & Ravitz (1997) question whether CMC, which is primarily text-based, is equally suited for various subject matters, whilst Kaye (1989) notes that the pedagogic value of computer-based collaboration depends on “the educational perspective adopted, the nature of the specific discipline and the characteristics of the learners”. It is the last of these factors with which the research reported in this paper is concerned.

Each individual responds differently to a learning situation. This response will be influenced by the way the individual thinks, their past experience, the demands of the environment and the current task. This approach is generally recognised as the individual’s learning style. A successful learner will be able to adapt his or her approach to meet the needs of any task, but not all learners will have developed this skill. The ability to adapt approaches to learning has led some authors to use the term “learning strategy” rather than “learning style”.

CMC is essentially a medium of written discourse. Individuals with an incompatible learning style, who are unable to adapt, may find that CMC perpetuates the inequity of an education system that discriminates against students who talk and listen better than they read and write, disadvantaging the less-verbal students. (Light & Light 1999, Rimmershaw 1999, Mason 1994)

Visual versus Verbal style preferences are one of many learning style theories discussed in the literature. During the last century there have been many investigations into style; these have often been conducted in isolation and have given rise to a large number of different style labels. Curry (1983) proposed the ‘Onion’ model to group the main types of styles, which she suggested could be grouped into three levels resembling the layers of an onion:
"By this organisation learning behaviour is fundamentally controlled by the central personality dimension, translated through the middle strata information processing dimensions and, given a final twist by interaction with environmental factors encountered in the outer strata."

2 Main Learning Style Theories Viewed Through Curry's Onion Model

Curry's Onion Model provides a well established framework within which to view the main learning style theories (Riding & Rayner 1998). Here we use the model to review these theories and hence to determine the most powerful theory with which to examine educational CMC.

Using CMC requires students to work in a predominantly text-based, somewhat hierarchical environment, which may present them with little or no information, or alternatively proffer vast amounts of information, according to the responses of other users. Although responses are written, the atmosphere is usually fairly informal and often relatively unstructured compared to a classroom. If the conference is asynchronous there may be a long wait for a response. On the other hand, if the discussion is synchronous, everyone may try to 'talk' at the same time leading to confusion. This is the context, then, in which we need to consider the suitability of the various learning style theories.

2.1 Outer Layer – Instructional Preference

The outer layer of Curry’s model examines instructional preference. This layer is considered to be most observable, least stable and most easily influenced. Influences include learning environments, learner expectations, teacher expectations and other external features (Curry 1983).

The main theory of instructional preference is proposed by Dunn & Dunn (1978), who believe that learning style reflects the manner in which elements of five basic stimuli affect an individual’s ability to perceive, interact with and respond to the learning environment. These are:

- **Environmental**: noise level, light, temperature and class design
- **Emotional**: motivation, persistence, responsibility and structure
- **Sociological**: learning groups, presence of authority figures, learning in varied ways
- **Physiological**: perceptual, intake, time and mobility
- **Psychological**: global v analytic, impulsive v reflective, hemispheric domination

Dunn & Dunn’s theory, then, is concerned with stimuli that affect learning. However, although this may provide useful information to individual students in online education some of the stimuli cannot be controlled. Indeed, it has been proposed that the whole concept of a single common learning environment needs to be re-examined in a CMC context, as each individual may be working in a different environment. (Benigno & Trentin 2000) Some of the stimuli will still be relevant, but it is felt that as this level can be easily influenced, advice from the tutor and peers could overcome problems encountered in this area. It is therefore seen as a fundamentally important theory from the perspective of improving educational CMC.

2.2 Middle Layer – Information Processing Style

The middle layer of Curry’s model concerns an individual’s intellectual approach to assimilating information (Curry 1983) and encompasses many of the learning style theories currently popular. This layer is considered to be more stable than the outer layer because it does not directly interact with the environment, although it is modifiable by learning strategies. Five main theories fall into this layer.

Kolb (1984) offers an experiential learning cycle, based on the learning models of Lewin, Dewey and Piaget. There are claimed to be four modes of experiential learning based on the cycle, which are presented on a two-axis grid. The horizontal axis runs between active experimentation and reflective observation whilst the vertical axis runs between abstract conceptualisation and concrete experience. The four quadrants are used to identify different types of learners: converger, accommodator, diverger and assimilator. Kolb’s model has been used
regularly since it was introduced and has led to the development of further models such as Honey & Mumford's LSQ and McCarthy's 4MAT system (discussed below).

The Honey & Mumford model (Honey & Mumford 1992) was developed from Kolb for use in commerce. It is intended to explore the implications of learning style for management and is often used in training situations and to strengthen teamwork. Like Kolb, it is based on a learning cycle and offers four learning styles: activist, theorist, pragmatist and reflector.

McCarthy's 4MAT system (McCarthy 1997) is also based around a four stage learning cycle and offers four learning styles: innovative, analytic, common sense and dynamic. Unlike the other theorists, McCarthy does not provide an assessment tool, instead advocating that every lesson should provide students of all styles with a preferred task for both left and right brain.

Gregorc (1982) proposes that people differ in the way they organise space and time. Individuals are seen as having two significant types of mediation abilities: perception (the way in which information is grasped) and ordering (the way in which the information is arranged, systemised and deposited). Perception has two qualities: abstractness and concreteness. Ordering has two dimensions: sequential and random. As with Kolb, these dimensions combine to provide four learning styles: concrete sequential, concrete random, abstract sequential and abstract random.

Gardener (1993) suggests that each individual has seven distinct areas of intelligence: linguistic, logical-mathematical, musical, bodily kinesthetic, spatial, interpersonal and intrapersonal. Gardener believes that an individual's abilities will differ in each area as will their learning style.

With the exception of the 4MAT system, all learning style theories at the middle layer of Curry's model provide some form of inventory that could be used to study educational CMC. The dialectically opposed modes offered by Kolb (1984), Honey & Mumford (1992) and Gregorc (1982) could all provide interesting insights into contrasting approaches to conferencing. However, we argue that the differences revealed by these modes may be apparent only in extreme cases, and will be difficult to discern in individuals with a more rounded learning style (Atkins 2000). Similarly, although Gardener's multiple intelligences theory (Gardener 1993) may help to provide an insight into the effect of subject matter on the response to computer conferencing, it is not seen as addressing learning style in a way that would aid our current research (Atkins 2000).

In sum, while all the theories in this layer could provide an insight into approaches to CMC, all fail to examine the verbal-visual modality, which is felt to be an important aspect of learning style when looking at a medium that is predominantly text based.

2.3 Inner Layer - Cognitive Personality Style

The inner layer of Curry's model examines cognitive personality style, addressing an individual's approach to adapting and assimilating information (Curry 1983). This layer is considered to be an underlying and relatively permanent personality dimension. Five main theories fall into this category.

The Felder and Silverman Learning Style Model (Felder 2000) overlaps the middle and inner layers, classifying students on five spectrums: sensing/intuitive, visual/verbal, inductive/deductive, active/reflective, and sequential/global. Although students are classified on five spectrums, the assessment tool only provides a profile over four, omitting inductive/deductive. It is not clear why this is the case. Further, although it may eventually be able to provide a good profile of learners, Felder & Silverman's model is still under development and has no empirical evidence to support it.

Witkin (Witkin & Goodenough 1982) offers the theory of field-dependence and field-independence, based on an individual's ability to extract details from a context. The Rod and Frame Test and the Embedded Figures Test are used to provide a means of assessment for this theory. This approach is currently being used to investigate learning via hypermedia systems (Kim 2000). However, doubts have been expressed about the validity of both the style and the embedded field test (Riding & Rayner 1998, Sternberg 1997). In particular, the approach has been criticised by Sternberg (1997) on the grounds that the tests have correct and incorrect answers, and that field-independence is seen as preferable to field-dependence, suggesting that the approach is related more to ability than style.
The Myers-Briggs Type Indicator (MBTI) (Association for Psychological Type 2000) is based on Karl Jung's theory of psychological types. Preferences in the four dimensions of: extraversion/ introversion, sensing/ intuition, thinking/feeling, and judging/perceiving, are used to characterise people according to sixteen types. Work is already being in progress using the MBTI to relate personality type to performance in CMC (Ahn & Ahn 2000). Kiersey develops two questionnaires, the Kiersey Temperament Sorter and the Kiersey Character Sorter, aimed at assessing temperament using different methods. (Kiersey 2000) These are broadly similar (approximately .75 correlation) to the Myers-Briggs Type Indicator. As in the MBTI Kiersey uses four temperaments and sixteen variants. However, both the Myers-Briggs Type Indicator and the Kiersey instruments examine personality types rather than learning styles. Although these theories are sometimes linked to particular learning styles, their primary use is not in that area.

Finally, Riding & Rayner (1998) offer the Cognitive Styles Analysis (CSA), developed as a result of their research on style differences in learning and behaviour. Over 30 style labels were reviewed, including some of the theories reviewed above. Riding and Rayner believe that style is divided into two dimensions: wholist-analytic (the way in which an individual would organise information - in parts or as a whole) and verbal-imagery (the way in which an individual would represent knowledge - in mental pictures or words). This verbal-imagery dimension which would appear to be highly relevant to CMC, given the latter's predominantly text-based nature. Further, the model has been developed for electronic use, has been in use for a number of years and has considerable empirical evidence.

In sum, two models, namely those of Felder & Silverman and Riding & Rayner, offer an investigation of an individual's preferences on the verbal-visual dimension that appears the most likely to affect CMC. Felder & Silverman examine four dimensions, which would give a broader picture than the two dimensions examined by Riding & Rayner. However, given the lack of empirical evidence to support Felder & Silverman's model, we argue that the CSA is currently the best model to use to examine the effects of learning style in a CMC environment.

3 A Framework for Empirical Investigation of Learning Style and CMC.

Our argument is, then, that the CSA should be used to empirically investigate the influence of learning styles on the effective use of educational computer conferencing. Much of the current use of, and interest in, CMC involves higher education, not least because of the growing economic pressures in that sector (Skillcorn 1996). Consequently, we propose an investigation of undergraduate study as a useful starting point for such an empirical study, using the following framework.

We begin by giving the target groups basic instruction in the use of text-based computer conferencing. Next we ask them to complete the Cognitive Styles Analysis which will determine their preferred learning style according to the CSA model and an attitudinal survey regarding their prior experience and attitudes to group work and CMC. Half of the sample is then asked to work on a time-constrained collaborative exercise using computer conferencing and given a similar exercise to work on in a face-to-face context at a later date. The other half of the sample participates in the exercises in reverse order i.e. face-to-face followed by CMC. This is an attempt to counteract the learning effect inherent in conducting two similar exercises.

Data is collected in a number of ways. An attitudinal survey at the end of each session obtains the students' reactions to the exercises. The face-to-face sessions are taped. Records of the CMC sessions are obtained from the computer. Statistical and qualitative analysis can then be used to evaluate the contribution of individual students in each situation, and results viewed in conjunction with the attitudinal surveys and learning style profiles.

We are currently putting this framework into practice with computing undergraduates. A later study will carry out a similar exercise with a comparable group of students from a different discipline, to investigate the possible effects of domain of study. A subsequent cross-sectional study will be undertaken to examine the possibility that maturation may alter the results. We also propose to conduct similar investigations with distance learning students.
4 Summary

It has been noted that often less than one third of students actively take part in a computer conference, and we have argued that this disappointingly low level of activity may be due, in part, to a mismatch between the presentation of CMC and the individual’s learning style. Using Curry’s Onion Model the main learning style theories have been reviewed and discussed. Whilst all of these may have some relevance to CMC, we have argued that Riding & Rayner’s Cognitive Styles Analysis (CSA) is the theory that best addresses the issues that are fundamental to the successful use of computer conferencing. Finally, we have specified an approach to the empirical study of learning style theory for CMC.

We believe that the research outlined in this paper will lead to improvements in text-based computer conferencing and more active participation by a much higher percentage of conference members. This in turn should lead to important gains in the acceptability and usefulness of Computer Mediated Conferencing.

A multimedia gate to Museum of Astronomy

Anna Lina Auricchio, Astronomical Observatory of Capodimonte, Italy; Enrica Stendardo, Il Univ. of Naples - Faculty of Letters, Italy

The Astronomical Observatory of Capodimonte is strongly working in the design and realization of multimedia and hypermedia educational products, in order to spreading the Astronomical Culture over a wider public. At present, there is a popular interest not only towards the astronomical research, but even for the historical events and their protagonists referring to Astronomy. Why the Bourbon, in XVII Century, would an Astronomical Observatory in the chief town of their kingdom? Who were the protagonists, artists - architects - astronomer, of the magnificent projects? What is their inheritance, in the light of the present scientific activity? To satisfy these questions, it is in progress the realization of a CD-ROM about the history of the Observatory and of Astronomy through the Museum of Astronomy, that is the testimony of a long history of astronomical research, presenting a unique collections of scientific and astronomic instruments of the 19th and first decades of the 20th century.

The CD-ROM features a highly interactive user friendly program. The structure is based upon fast and simple links among the various sections. The scientific contents are adapted to a language (word-image-sound) of strong communicative impact, without any spectacular effect that are dominant in many multimedia products. The educational aim is marked.

It is in progress the test phase of the software tools and of the authoring program that will be used for the CD-ROM realization.
Need for Intelligent Web Server with Powerful Authoring Functions:
No More Stress on Web Authors

Junichi Azuma
University of Marketing and Distribution Sciences
Gakuen-nishi-machi 3-1, Nishi-ku, Kobe 651-2188, Japan
junichi.azuma@nifty.ne.jp

Abstract: If we consider the rapid development of the Web technology, it will not always be possible for Web authors to keep up with the dramatic change of the authoring environment. In addition, there are several serious internal problems of WWW itself that make the Web authoring task laborious, e.g., the hyperlink management problem. As the number of Web servers will still continue to increase, and as more and more educators will join in the Web authoring activities, the demand for an intelligent Web server like Hyperwave will surely increase greatly in the near future.

Introduction

In the mid-1990s, when WWW first came into being, people were glad and excited because they thought that there would be only one common platform for hypertext authoring. Before that time, there existed a number of authoring tools that were mostly "machine-dependent." Thus, the widespread dissemination of high-quality multimedia materials developed with a specific authoring program was quite difficult. The emergence of WWW at first meant the separation of content authoring and navigation programming, since in HTML, hyperlinks are easily implemented just by writing simple tags. Today, the situation is not so simple. Needless to say, HTTP is the base system that enables communication in hypertext format on the Internet, and in this sense it is just the physical "rail" of the railway system. However, as we can see in some parts of Switzerland or Japan, several railway companies are now sharing the same "rail!" There exist several versions of HTML now, and several different types of programming languages have been developed for Web browsers. Streaming is no longer the monopoly of RealAudio and RealVideo, and the emergence of MP3 has had a great impact on the distribution of multimedia content over the Internet. Such developments may be indeed necessary for industrial evolution, but in order to maintain the presence of a Website in the total world of WWW, we have to create a really cool and sophisticated homepage. This inevitably gives a tremendous stress to Web authors. In addition, most of the Web authors creating educational Websites at educational institutions are not experts in information processing, so it is quite difficult for them to keep up with the current rapid development of Web authoring environments.

Further Problems

When we get accustomed to publishing documents on a Web server, we will soon encounter the difficulty of managing a rapidly increasing number of documents and multimedia objects on the server. Generally speaking, the energy required for the maintenance of a Website increases dramatically in proportion to the number of the Web pages and other objects, and will vary exponentially according to the total number of these objects. If we have too many pages and objects on a Web server, it will become very difficult to modify the contents of the Web pages or the directory structure, since these manipulations will inevitably force us to rewrite all link information involved. This is a very difficult task, and the perfect management of the link structure will be nearly impossible. As a result, large Websites will be never free from missing or broken hyperlinks.

In creating a new Website, we normally try to make an effort to create the best possible site in the beginning. We tend to spend a lot of time and lot of energy to create the "first version" of the new Website. However, as experience often shows, laziness will suddenly overcome us, and we often tend to be quite reluctant to continue the updating jobs to keep the site fully ready and fresh. Some researchers argue that there is a common psychological tendency among Web authors in regard to this problem. However, this author believes that this problem has something to do with the evolution of the HTTP platform itself. Today we are accustomed to the cool design of well-known Websites, and when we visit such cool Websites, we often notice that navigation switches are created in a very sophisticated way. Some employ a bold and novel graphic image and some employ Java, so that a Web page including such navigation switches requires nearly a minute for all the contents included in the page to be downloaded. This produces unbearable frustration for dial-up Internet
users. The role of a navigation switch is "only" to lead the user to a certain URL and nothing more. The emergence of WWW seemed to have provided us with freedom from the complicated programming-like task involved in hyperlink implementation, and seemed to have let us concentrate on content when creating hypertext materials. In the course of the evolutionary development of WWW, however, Web authors have begun to totally confuse the navigation tools with content these days.

As we have seen, these problems arose in the course of the recent development of WWW, and the evolution of the total WWW system will go on regardless of the original philosophy of HTTP and WWW. Although Web authoring software will also undergo a dramatic development in the future, earnest teachers who are going to learn the authoring method of Web-based educational materials will inevitably encounter these internal problems of WWW.

Solution to Web Authoring Problems

The author has already argued that as the number of the Web pages stored on the Web server increases, the energy required for link management increases dramatically. It was also pointed out that a large Website would be never free from missing or broken links. One of the solutions to this problem, together with the above-mentioned authoring problems, is to use Hyperwave Information Server (HWIS), originally developed as Hyper-G, at the Institute for Information Processing and Computer Supported New Media (ICM), Graz University of Technology, Austria. HWIS is a next-generation Internet/Intranet server with powerful authoring functions and full-text search capability. The browsing and editing of the documents on HWIS requires no special client software, and Web authors can do almost all of the editing work and publication of objects just by using existing Web browsers. This is quite different from the system of Lotus Notes, where a special Notes client is necessary even just to browse simple documents. In addition, academic use of HWIS is basically free of charge.

On entering documents onto a certain directory of HWIS, hyperlinks with the name of each document will be automatically generated. When we access the same directory after publication, the document titles will automatically appear in the form of hyperlinks, and by clicking a desired title, we can easily open the necessary document. Basic navigation switches together with other switches used for editing works, authentication, preference settings, etc., are offered in the standard header automatically generated by HWIS. This will free us from the complicated task of link management and enable us to concentrate on the authoring of pure content material for of hypertext documents. Needless to say, it is also possible to embed hyperlinks in the contents themselves. The information about each hyperlink is stored separately from the object itself, as part of its "meta-information," in a special form by which the target of a link "knows" which documents or objects point to it on HWIS. Thus, the internal link structure is always kept intact even if some objects are moved to a different directory, or the directory structure is dramatically modified. In this sense, links are "bi-directional" within HWIS.

When an object is totally removed from the server, the relevant hyperlinks pointing to it will automatically disappear, and if a link is embedded in the contents of a Web page, it changes into a normal phrase in black letters, and the default blue color and the underline indicating the existence of a link automatically vanish away.

HWIS is also equipped with powerful access rights control. Access rights of every object published on HWIS can be easily controlled just by using ordinary Web browsers. The easy control of access rights is also useful when we establish a BBS, which is internally offered in HWIS under the name of "Discussion Forum," because very often we would like only a limited pool of people to be able to post messages so that "uninvited guests" will not be able to post inappropriate messages. Of course, we can easily establish a BBS if we use one of the Web authoring software products such as Microsoft Front Page, but the control of detailed access rights is quite difficult if we use a WindowsNT/2000 based system.

Conclusion

If we consider the rapid change of the Web authoring environment, there seems to be only two choices for Web authors and publishers. One choice is to manage to keep up with the rapid change of the authoring environment, always learning new techniques of Web authoring and the related technology. The other choice is to rely on a Web server with powerful editing functions like HWIS, and concentrate on the contents of the documents. Considering the rapid development of the whole Internet infrastructure, it will not always be possible to continue to train educators in the most recent media-literacy skills. As the number of Web servers will continue to increase, and as more and more educators will join in Web authoring activities, the demand for an intelligent Web server like HWIS will surely increase greatly in the near future.
Genesis of a CD-based Authorware application: Lessons learned from six years of design and development

Patricia Ryaby Backer, San Jose State Univ., USA

The current paper describes the design, development, and evaluation of self-paced multimedia modules that are used in an advanced General Education course at San Jose State University. The design and development cycle of these modules began in 1994 and encompassed four major revisions. The General Education course, Technology and Civilization (TECH 198), is designed to introduce students to the realm of history and usage of technology in society and to increase their awareness of both the uncertainties as well as the promises of the utilization of technology as a creative human enterprise. The most recent version of the software (version 4.2) is used in lieu of classroom instruction. This presentation will display the evolution and evaluation of these multimedia modules over time. A focus will be on the lessons learned from the years of multimedia development.
Educational Applications of Conversational Agents

Abstract: Conversational agents have historically been used for entertainment purposes. In this paper, we discuss new work that extends the capabilities of conversational agents.

Conversational agents, often referred to as “chatterbots”, have a long history dating back to the “Eliza” program written by Joseph Weizenbaum in the 1960’s. Eliza attempts to simulate a Rogerian a simple transformation algorithm to change user input into a follow up question (Weizenbaum 1966). Since that time, many chatterbots have been written and the basic techniques improved upon to include knowledge bases and logical inference mechanisms. This paper discusses the application of certain techniques from the domains of intelligent tutoring systems and pedagogical agents to chatterbots for the purpose of providing a natural language conversational partner to support online educational experiences.

Chatterbots do not perform general natural language understanding as of yet, which is a difficult open user’s natural language input. When a pattern or key word is recognized, the chatterbot crafts an and has not found a match in the user’s input, it “punts” and outputs a response not based on the user’s phrases such as “please go on...” More sophisticated chatterbots, including those we are developing, perform a certain amount of user modeling the conversation (likes and dislikes, etc.). These chatterbots bring this information back up in the form of a question when they encounter a problem recognizing input and are forced to pu continuity to conversations, these chatterbots do not typically provide significant intelligent direction to the conversation, relying instead on the user for direction. While this behavior is adequate for entertainment it is often incompatible with educational objectives, and is a main area that we improve in our educational chatterbot. In addition to conversational direction and focusing mechanisms, we can adapt intelligent tutoring systems to provide more individualized interaction.

To achieve a directed conversation, we must give the chatterbot an idea of a precise conversational ct in the conversation. The student dialog can include tangents initiated by the user. However, the chatterbot remembers where it is in conversation to meet its educational goals. This type of conversation lends itself to Socratic dialog in understand the reasoning given, then it can offer a possible line of reasoning (either correct or faulty) and provide a reason, or it can choose to back up to prerequisite material in this case. If the student does test that theory with. Students’ subsequent answers can be checked for consistency with their current theory. If an answer is not c student for a new theory. The most difficult part of creating this type of behavior is the design of the conversational transition network for the chatterbot so that it knows large knowledge base. This knowledge base can be specific to the instructional domain it is designed to
work with (mathematics, for example), or it may also include general knowledge (birds lay eggs, have feathers, can fly, are a type of animal, are thought by some to be the evolutionary descendents of dinosaurs, etc.) Knowledge can be organized according to a variety of conceptual hierarchies. Students may query the agent for information from this knowledge base, such as “Tell me about Pascal’s Triangle”, or “Is an integer a type of real number?” In addition, the agent may contain self-referential knowledge used to establish aspects of its personality.

In order for an educational chatterbot to tailor its conversation to best suit the knowledge of a particular student, we can employ student modeling techniques which attempt to give the agent an idea of what concepts the student either knows or has misconceptions about. The student modeling technique we employ is based on educational research described by Jim Minstrell and others, and is founded on an idea called a facet (Minstrell 1992). A facet represents a particular conception or misconception of a certain idea, which a student may or may not hold. For each important idea in a curriculum, there exists a cluster of facets, each facet representing a different level of student expertise. A chatterbot can be programmed so that certain things that the student says in the course of a conversation (particularly a directed conversation) can be interpreted as evidence that the student holds a particular concept or “facet”. When deciding how to respond to student input, the chatterbot may be designed to take into account relevant facets that it has inferred the student holds and alter its behavior accordingly. This student modeling technique has some similarities to the classic “overlay” techniques used by some intelligent tutoring systems (Carbonell 1970), but does not suffer from the lack of misconception information found in such models. It is currently being used in pedagogical agent development work being performed at the University of Washington (Baer & Tanimoto 2000). Chatterbots are not a replacement for teachers, but compliment teachers’ educational objectives. Using student modeling techniques, they can also do limited assessment of student knowledge and can provide assessment evidence and suggestions as an educational resource to the teacher.

Taken together, the techniques described in this paper offer a great deal of opportunity for chatterbots to be applied in educational settings, where their ability to interact using a natural language interface may be of value to students, particularly those who may feel put off or intimidated by other types of human-computer interactions. Even in an educational setting, a conversation with a chatterbot can be entertaining — sometimes they say rather amusing things — and this may contribute to the motivation of students to continue interacting with the system and learning. These agents can be implemented as either stand-alone conversational agents or as conversational pedagogical agents within the context of an interactive learning environment. As stand-alone agents, they can provide an entertaining method of delivering educational content in an interactive and conversational way, without requiring the development of a complete computer-based learning environment and accompanying agent for each topic that one wishes to teach.

We have begun a project to develop chatterbots for educational purposes. We began by initially building a basic framework for an entertaining chatterbot, and are currently in the process of building directed conversations around specific subjects for our chatterbot. The first of these will guide the user through a dialog to discover the relation that describes Pascal’s Triangle. We are also building a conversational pedagogical agent to support a language arts and word processing learning environment for 6th graders.

Abstract: In this paper we present the project of an Internet shared instrumentation laboratory for measurement on electronic circuits. The main project goal is to perform experiments driving real instrumentation and controlling the real operational conditions, working from any node on the network in a multiuser environment. We realize a virtual presence into the laboratory since it is obtained through software interfaces that remotely allow instrumentation control. The interaction with real devices overcomes the typical limitations connected with simulation and leads to an effective learning by doing educational environment. A measurement testbench prototype has been implemented following the proposed model.

Introduction

Virtual reality has been successfully used to build experimental environments mainly addressed to the reproduction of the aspect and the behaviour of physical systems. Complex models have been developed and a high level of realism has been reached. We believe that virtuality is well suited to the "learning by doing" approach of technical disciplines where the experimental work is an essential support to the learning process of theoretical topics. Practice is often constrained by the availability of proper resources. A virtual approach and computer networks can provide instrumentation access for a wider community. The effectiveness of virtual laboratories as experimental environment depends on the level of realism obtained by the operational conditions and on the simplicity and robustness of its software interfaces (Ferrero, A. 1999, G. Orange, G. 2000).

We are working on the project of an Internet shared instrumentation laboratory for measurement on electronic circuits. The project is addressed to drive real instrumentation and to control the real operational conditions, accessing the laboratory from any node on the network in a multiuser concurrent environment.

We realize a virtual presence into the laboratory since it is obtained through software interfaces that remotely allow instrumentation control. A big effort has been addressed to the implementation of these interfaces in order to lead to a high level of interactivity and reproduce, as far as possible, the laboratory environment. It is worth noting that the interaction with a real environment overcomes the typical constraints due to simulation-canned drills and leads to an effective learning by doing educational approach.

A major problem concerning real instrumentation control comes from the contemporary interaction of multiple users. In presence of instruments simulators, the software itself will provide coherency of the concurrent experiments execution reserving a separate task for each user, by forking or instantiating new processes; on the contrary, when real instrumentation is driven remotely, implementing coherency between actions and results for each user is more complex. We need to manage many contemporary experiments: each experiment has its actions queue, each user has to be sure to perform his/her own actions and observe the related results. The instruments must be reset to their previous state before any new action in order to avoid unpredictable results.
The experiment execution and management can be efficiently implemented through a laboratory server acting as a manager able to separate actions and data belonging to each specific experiment. Main tasks of this server are:

- identification of different workspaces for each experiment and reservation of resources for its execution;
- scheduling of the execution of different requests addressed to the same instrument;
- communication of action results.

The Project

The client-server paradigm is the basic architectural concept and the system functionality are distributed both on the server and the clients. On the client side, a web-based interface to the laboratory allows to select the experiments. The dialogue with instrumentation is developed by means of Java applets. On the server side the system is based on a web server that introduces users into the laboratory, implements access control, lets them select experiments and distribute instruments interfaces (e.g. applets). A specific application runs as a daemon and takes care of the communication with the clients and of the concurrency of many experiments. This is the core of the environment and can run on the same platform of the web server or on a dedicated one.

Our solution for the implementation of the system is based on the LabVIEW programming environment from National Instruments (see http://www.ni.com) and Java. The hardware requirements can be satisfied by standard PCs interfaced to the laboratory instrumentation. The laboratory core server has been developed using LabVIEW, since it is a standard "de facto" in measurement and virtual control of instrumentation. The client application is completely platform independent. It has been developed using the AppletVIEW Toolkit (see http://nacimiento.com/AppletVIEW/) that represents an effective solution for the integration of Java and LabVIEW. By this way no specific requirements exists for the client that can work through a Java enabled standard browser. The applets open a dedicated communication channel with the laboratory server using a specific TCP/IP port. All the data are passed through this dedicated channel until the end of the session, when the channel is closed and all the resources released. A measurement testbench has been implemented following the proposed model. In Figure 1 a sketch of the system architecture is shown. A waveform generator and an oscilloscope are the instruments available to conduct measurements on circuits under test. Registration and authentication tasks are carried on the basis of a user database and activity logs are available.

Abstract: The paper presents the architecture of student self-evaluation and on-line assessment system TestTool. The purpose of the system is to improve the web-based self-instructional mode of learning, grounded on the constructivist model of education. The TestTool assessment engine along with traditional types of questions includes a new question type, called as 'graphical construct', which is addressed to assess real problem understanding rather than recalling and looking for correct answer among a few predefined alternatives. TestTool is realized in JAVA and uses Oracle as a repository for various assessment data.

Introduction

With advancements in network-based learning Computer-Assisted Assessment (CAA) is being increasingly used in higher education institutions. CAA is seen as particularly appropriate for knowledge-based subjects with recall and recognition skills predominating. Typical subjects being taught at our technological university belong to category of science and technology where understanding of processes or constructions is needed. Engineering studies are based on knowledge building via real understanding how process or construction works as a whole. This real understanding must be achieved through accumulating subject knowledge base as well as through developing skills. CAA environments currently in use helps mainly to assess level of knowledge, but have limited skills testing possibilities. In this paper we focus on distinctive features of CCA using TestTool system developed at our University under the EU funded project MATEN. We will also discuss on results of extensive usability test from the tutor’s point of view.

Graphical construct question

The TestTool is comprised of three software modules – Tutor, Author, Student – to work together using data stored on database server. Technologically it is implemented in Java and due to many practical exploitation reasons is linked with Oracle database.

For authors and users as testing facility the system exposes a new significant feature. The TestTool assessment engine along with traditional types of questions such as various forms of Multiple Choice (MCQ) includes a new possibility addressed to assess real problem understanding rather than recalling and selecting a correct answer among a few predefined alternatives. That new type of question has been called as ‘graphical construct’ question (GCQ). The concept of the GCQ is in giving a student the task to create or assemble a correct construction from a set of objects displayed in constrained area on the screen, called a ‘graphical panel’. Non-movable objects are put in their fixed place, movable objects may be dragged into any place within the panel area. Behind the scene there is a correct construct created by the author, which is used by assessment engine when student submits his answer. Correctness is defined by checking whether movable objects were actually positioned in a proper place relatively to other objects.

To prove the strengths and weaknesses of the approach, self-evaluation exercises and summative assessment questions for the course module “Data Structures” were prepared. Three test sequences have been designed in accordance with content of the module (Tab. 1). Each sequence includes a given number of questions, which are selected randomly from a stock of variants during the testing session. The Test III includes mostly a GCQ type questions.

Table 1. Quantity of questions in the tests.

A rather simple example of GCQ is given on the Fig. 1. It is the view, which is seen by author when he sets up a single test question. The display is split into two graphical panels: left hand side is the area where question or task situation has to be created by selecting and drawing objects using graphical editor and menu. Equally on the right side panel author provides a desirable solution of the task, which must be stored as anticipated answer in the database. Definitely, a student taking a test receives only a left hand side view.

Let's have a look into left-hand side task panel. Bottom line is a task – to delete element 60 from the initial Bayer tree. A student has to make a several displacements and/or substitutions in order to obtain a correct data structure, i.e. Bayer tree. During the usability experiment it has been proved that performing such kind of constructive activities learners comprehend and gain data structures understanding rapidly.

The usability test has been done in real teaching setting when delivering “Data Structures” course module for CS undergraduates. The 266 students were registered. They took tests in training mode first, after that did examination test and were graded. The www discussion board and E-mail facilities were available for students to communicate among themselves or with tutor, also they were asked to express their opinions regarding content and procedure of assessment using TestTool. In general, students’ appreciations were positive.

Discussion

In current CAA systems dominate various forms of MCQs and Open Questions(OQ) are also in use. A standard web programming means can be used for MCQs implementation quite simply and cheaply. From didactic point of view, however, multiple choice significantly restricts students’ activity and does not support constructivistic mode of learning. On the other hand, OQs allows students to construct their answers and provide them in most suitable and clear for them form. But checking for correctness of such answers still is not computerized and must be performed by tutor. In the case of growing number of students it becomes increasingly less acceptable.

The GQC, we think, falls in between of these two extremities. This type of question allows to simulate constructivistic mode of learning. The mechanism to define correctness of answer using location of the objects within constrained area in some extent is a weakness of the concept. It is because a student may drag any movable object into approximately correct location, but it could be ‘not enough a bit’ to hit a target area for this object. The use of GCQs in practice clearly proved, that new didactic possibilities opened for tutors outweigh this kind of weakness. It should be anticipated, however, that it is quite difficult to create reasonable set of GCQs in a given subject area. Since TestTool technology allows to realize the given GQC scenario easily, it becomes worthy to do. The usability experiment, in which participated 266 students and three tutors, proved the correctness of the approach, also disclosed some drawbacks suggesting further improvements for developers.
Constructivist Instructional Design and Development of a Networked Learning Skills (NICLS) Module for Continuing Professional Education Distance Learning

Abstract: This paper proposes an ISD approach for the design and development of a basic Networked Information and Communication Literacy Skills (NICLS) module. The need for such courses as pre-modules for on-line distance education programmes for professional adults is presented and discussed. Furthermore, and as part of the design process the paper discusses and defines information and communication literacy and its main aspects. The curriculum is then designed using an experiential learning approach and the resulting web based educational approach presented and described.

Motivation

Online environments, and the use of the WWW in online courses, have been seen as the most recent educational panacea to try and provide students with such skills as online communication, online discussion and negotiation of meaning (Bowskill, 1998). The emergence of new educational approaches and epistemologies, such as constructivism and problem based learning, have also been identified as possible ways of fostering and promoting the mentioned skills (Nunes et al., 2000; Pincas, 2000).

As a consequence, students feel compelled to undertake new methods of instruction and provision without being properly equipped with the basic skills required explore a networked learning environment. In fact, students are expected to developed high cognitive skills such as negotiation of meaning, long-life learning, reflective analysis and meta-cognition without being properly trained in low-level skills such as the use of computer mediated technology, online etiquette, web navigation, and web searching. These skills were identified by Nunes et al. (2000) as basic networked information and communication literacy skills (NICLS) and are required to succeed in the online learning environment to which students are exposed, but also an essential part of all aspects of daily networked activity.

This paper concentrates on the design and development of a NICLS core skills pre-module for the MA Information Technology Management (MA ITM). The course is entirely a distance learning programme and course participants are professionals in the Information Technology (IT) sector. In previous years, it was assumed that, because of their professional and technical background, they would posses this type of skill, and therefore, that no particular training
was required. This resulted in under-usage of existing online resources and consequently under-performance and failure to match student and tutor expectations.

Educational Hypermedia Development Methodology

An educational web application can be seen as an instructional system, in the sense put forward by Nervig (1990): as sets of interacting, interrelated, structured experiences that are designed to achieve specific educational objectives, but organised into a unified dynamic whole. Hence, the design of such an hypermedia application should result from the design specifications emerging from the process of analysing curricular problems.

To design and implement these web-based applications, practitioners require instructional systems design (ISD) frameworks. The importance of this overall ISD rests in assuring that the whole environment is implemented using the same learning theory (Nunes, 1999). In fact, if not carefully planned, the web-based environment could result in a mix of eventually conflicting techniques from different theoretical perspectives.

Therefore this paper discusses the design and development of web-based applications for higher education (HE). Academic learning is here seen as an active process in which meaning is developed on the basis of experience, in accordance with the constructivist theoretical frame (Laurillard, 1993). So, to develop web applications in keeping with a constructivist approach, it is important to have an understanding of the kind of specifications that will result from constructivist instructional design (Tam, 2000).

Constructivist Instructional Design

In the design and development of our web based application the ISD model shown in Fig. 1 was used. Since according to the constructivist philosophy, knowledge domains are not readily separated in the world, information from many sources bears on the analysis of any particular subject matter and it is not possible to isolate units of information. A central core body of information must thus be defined in the curriculum design, but boundaries of what may be relevant should not be strongly imposed. Instead of dividing the subject matter into logical analysis of dependencies, the constructivist approach turns toward a consideration of what users of that knowledge domain do in real life contexts. The ultimate goal of this approach is to move the learner into thinking in the knowledge domain as if he/she were an expert user of that domain Bednar et al. (1992). The designer should then define simplified but still authentic tasks to be experienced by the learner. The goal is to portray authentic learning activities, not to define the structure of learning to achieve the tasks, since it is the process of constructing a perspective or understanding that is important and no meaningful construction is possible if all relevant information is pre-specified (Bednar et al., 1992).

Additionally, curriculum design must ensure that activities are situated in real world contexts, are authentic, and provide multiple perspectives on the subject matter. Some degree of coaching or guidance must be provided, by including meaningful examples and the different perspectives of experts and peers. A central strategy for achieving this consists in providing collaborative learning environments including computer mediated communication (CMC) facilities.

CMC allows both peer-to-peer and peer-to-tutor communication. Additionally, access to extra information sources must be enabled in order to allow different learner's needs to be satisfied.
It is in the design phase that all the components of the learning environment required by the curriculum design are defined and specified. During the development phase the learning environment is implemented according to the specifications coming from the design phase. Since different types of educational technologies may be needed, to implement all the planned activities, examples and communication channels, different development methodologies may then be applied. Finally the hypermedia application must be system tested and field-tested as an embedded component in the overall learning environment.

**Web Application Development Methodology**

The software development methodology that best supports the production of web-based educational applications is the rapid prototyping approach. A rapid prototype is a simplified and untested equivalent of the actual application, performing all the basic functions specified for the final product (Howell, 1992). As shown in Fig 2, by implementing a prototype first, the hypermedia designers are able to put forward a fully functioning application, presenting all the basic features of the final product such as: user-interface, link structure and coaching facilities. This is not a diagrammatic approximation or representation, which tends to be looked at as an abstract thing, but an actual implementation of the specifications for the application.

These prototypes can be realistically tested and assessed and rapidly changed in an iterative manner until consensus is reached. Evaluation and testing of these prototypes must be done by instructional designers and ideally include pilot tests using target learners. Furthermore, web-based applications are inherently different from other software applications. The volume of actual code produced in scripts is relatively low and emphasis is put in user-interface design, link structure design and definition of content entry as the different multimedia components. These characteristics, along with widespread availability of authoring tools, make it possible for rapid development and testing of prototypes.

**Curriculum Design for the NICLS Module for Online Distance Education**

NICLS can be defined, as the skills required to use networked communication and information technologies to support networked learning activities. Goodyear (2000) defines ‘networked learning’ as:

"learning in which information and communications technology (ICT) is used to promote connections: between one learner and other learners, between learners and tutors, between a learning community and its learning resources"

(Goodyear, 2000: 9).

Therefore, NICLS can clearly be divided into two main categories: CMC and information skills. CMC skills are related to the interaction of the student with the learning community and have very different features from both written and spoken language as proposed by Yates (1993,1995). Information skills are required due to problems of information anxiety and overload as well as access to the learning resources caused by the erosion of information boundaries (Pincas, 2000).
The curriculum being proposed was based on this theoretical framework as well as a preliminary survey of student requirements. This survey suggests that the latter of the two initial categories identified above, needs to be further subdivided. In fact, students have two main difficulties when using on-line resources: finding and evaluating them. Consequently the syllabus for the NICLS module was designed around the three main topics:

- Online Collaboration and Co-operation;
- Information Searching and Retrieval;
- Evaluation of Networked Information Resources.

The Pedagogical Approach

A constructivist pedagogical approach has been considered for the design of this module. The following assumptions are behind the selection of this approach:

- that learning involves an active process of construction on the part of the learners at individual and social levels, rather than the passive reception of data;
- that the role of the tutor is that of a facilitator to support independent engagement in the process of construction, “scaffolding” the learning environment by providing relevant resources;
- that collaboration and peer support relationships are as essential features as those of the educators in order to engage in dialogs and explore multiple perspectives, exchanging experience, ideas and feedback;
- that learning activities must be authentic and situated within a real context if learning and skills are to be transferred easily into another contexts;
- that course design should engages with learners’ individual experiences and encourage ownership of, and motivation to learning.

However, and as discussed by Wilson (1993) constructivism is a philosophy not a strategy, that is, constructivism is an epistemology of learning rather than a framework of teaching (Fosnot, 1996). Consequently as argued by Nunes (1999:53-57), educational practitioners require a clearer educational framework to design their courses. Experiential learning is a framework that can be used as a constructivist tool as described by Nunes and Fowell (1996). This course was designed using this approach. The aim is to encourage participants’ awareness of and skills in reflective practice, i.e. learning by doing. Thus, the course has been based in a selection of activities, which aim to encourage learner’s engagement with all the phases of the experiential learning cycle.

The course design comprises a blend of activities to set within the same platform in which learners are going to undertake their masters’ degree - WebCT. Therefore it promotes a hands-on and authentic learning environment conducive to collaborative learning. The NICLS course was structured according to the course outline presented in Appendix 1.

**NICLS Module Design and Development**

Since the NICLS module is supposed to be a preparation module for on-line learning and in a constructivist environment learning activities have to be situated, it was a natural choice to implement the module using WebCT. Design tasks involved choosing appropriate facilities and WebCT tools. Development consisted in preparing facilities and tools for student use. The resulting environment was prototyped with the participation of both lecturers and current students. An illustration of the current iteration of the course is shown in Fig. 3.

**Course Contents** provides links to resources such as: course overview, course structure, explicit materials for the five units, and a
Implementing hypermedia educational applications means much more than just designing a few screens and specifying their sequence (Nunes and Fowell, 1996b). Today, such an approach is not sufficient to support effectively support the learning processes envisaged in constructivist, collaborative or experiential learning philosophies. Understanding the web as an educational technology, and its role within educational practice, is the key to the development of successful learning environments. Moreover, the way to prevent a backlash against the use of this educational technology lies in recognising both the technical and pedagogic components of instructional design and integrating them in a methodologically coherent manner. Rapid prototyping is an ideal approach, which facilitates the integration of the different agents in educational software development: the subject matter experts, the instructional designers and the software developers.

However, designing good learning environments is clearly not enough to guarantee the success of the learning process. In fact, learners that are supposed to use these environments, have to be trained and allowed to acquire the skills needed to be successful on-line learners. The design and development process described in this paper is part of an ongoing research on Networked Learning Support. The module presented is currently being tested with new students enrolling the MA ITM course, prior to commencing their studies. The module and the instructional design process used to design and develop it, need to be carefully and thoroughly evaluated. If successful, this module will be used in all other programs in the Department, and eventually proposed as a University wide elective module. Furthermore, it is thought that, after the evaluation process, both the module and the curriculum will have to be remodelled regularly in order to accommodate the changing characteristics of both learners and networked environment.

Bibliographic References

Aims and Description:
This module aims to provide learners with a core competence of basic communication and information skills, prior to starting the MA in ITM programme. This will allow students to effectively carry out the course learning activities in the selected web-based learning environment with. Consequently, the purpose of this pre-module is mainly to deliver a hands-on experience with the tools and methods for networked learning that are to be used by learners in a web-based distance education master's degree course. The module also aims to encourage participants to work collaboratively with their peers, in order to become aware of the potentials and constrains of networked learning.

Objectives:
By the end of the course, students be able to:
- Demonstrate proficiency in the use of the technologies used for CMC;
- Show awareness of the social factors affecting CMC;
- Use and comply with the different conventions and etiquette for CMC;
- Effectively communicate and work collaboratively on-line with both peers and tutors;
- Formulate different searching strategies effectively;
- Demonstrate the knowledge of criteria for evaluating online resources;
- Evaluate the validity of search findings.

Methods/Course Delivery:
The module will be presented via a combination of online activities and tutorials. It runs for 5 weeks, prior to the start of the first module of the MA in ITM programme. Students are required to spend about 6 hours per week with different learning activities. Since participation is based to a large extent on on-line discussion and activities, students will need to set aside regular and reasonably frequent times for on-line participation. However, although the level of weekly participation is set at 6 hours, students' weekly timetable for the course can be flexible to fit in with changing needs and work patterns.

Assessment:
No formal assessment is proposed for this module. Students will be assessed on a Pass/Fail basis by means of a group project that involves the production of collaborative work.

Further details of the case study forming the basis of the coursework, along with a list of specific deliverables is presented during the week 3.
CREATING AND SUPPORTING ONLINE LEARNING COMMUNITIES

Philip Barker
School of Computing and Mathematics
University of Teesside,
Middlesbrough, United Kingdom
Email: Philip.Barker@tees.ac.uk

Abstract: Educational technology and the ways in which it is used have undergone considerable changes over the last three decades. Various technology-driven ‘change agents’ have been responsible for the ways in which this subject has evolved from ‘chalk and talk’ through ‘multimedia’ to sophisticated virtual reality training environments. Increasingly, educational technology has to be used to support online communities of learners. This paper discusses some of the issues involved and uses a case study to illustrate some of the important techniques that are currently in use.

Introduction

Many new ways are now becoming available for using computer-based communications technology to distribute and store online information. Such developments necessitate that we critically review the approaches that we employ for the realisation of the basic infrastructures that are used for the support of teaching, training and learning activities. This is especially so with respect to lifelong learning, work-based study, and continuing professional development. With this objective in mind, this paper introduces and discusses a model of teaching and learning that can be used as a basis for building new types of educational infrastructure based upon the use of web-based resources, peer group interaction and online tutoring.

Fundamental to this approach to educational delivery is the creation of an online community of learners involving students, academics, practitioners and subject experts. Members of such a community can interact with each other in both a synchronous and an asynchronous fashion by means of appropriately designed computer conferencing facilities, electronic mail and web-based resources. Naturally, the design and implementation strategies that are used to create and support online learning communities must cater for a variety of different study modes - such as individualised learning and situations that involve collaborative group work. Of course, it is also necessary to ensure that the skills students develop are accredited in appropriate ways using online assessment systems.

Some of the issues involved in designing and implementing online courses have been discussed in detail by Barker (1999a), Barker and Giller (2001), Duchastel (1997), Carr-Chelman and Duchastel (2000) and Ryan et al (2000). There is also a growing volume of literature available electronically through the Internet - both in the form of written publications and contributions to discussion groups. The following section of the paper briefly discusses some of the material that is relevant to the work that is described in this paper.

Some Basic Models

Three broad types of model are needed in order to understand, design and implement learning systems for online users. The first of these relates to the communities of online users for whom the systems are designed; the important issues here are concerned with the ways in which online communities are formed and the ways in which they behave (Preece, 2000). The second type of model relates to the role of technology in society and the ways in which its ongoing development influences the nature of what people do, how they react and the ways in which their goals and ambitions are influenced. The third type of model concerns the ways in which
technology can be used in order to fabricate new types of educational system and new approaches to teaching and learning. It is this latter type of model which is considered in the remainder of this paper.

The underlying model that we use to design electronic courses for online delivery has been described in detail previously (Barker, 1999b). Essentially, this model depicts the relationships that exist between an online learning community and the four major building blocks used to create an electronic course for such a group of learners. The four essential components that we believe are necessary to build an online course are: (1) the web-based resources that are needed to provide basic course content; (2) an online support infrastructure (tutors and technical help); (3) the communication strategies that underlie course-related online dialogue and student conversations; and (4) the various learning tasks undertaken by students during a given course. The latter may be designed to support skill development activities or assessment procedures. Of course, the tasks that students undertake during their studies will normally involve both individual study activities and group-based working.

In order to support the tasks involved in group-based working it is necessary to have an underlying model that describes the essential features of what is happening. In addition, appropriate tools will also be needed in order to support the basic processes that are involved. The tools that are most often used are described and discussed in the following section; this section therefore concentrates on the underlying model that we use for the support of collaborative learning at a distance.

Some of the important generic models upon which human communication processes depend have been described in detail elsewhere (Barker, 2000). Our model of collaborative online learning, through computer-mediated communication (CMC) techniques, evolves naturally from these. At its centre, the CMC model requires a problem space in which shared objects relating to an online learning activity can be created. The CMC environment must then be able to provide a communication framework that allows two basic functions to be realised. First, learners must be able to communicate with each other with respect to objects existing in the shared problem space; second, they must have available an appropriate repertoire of commands to enable objects in the shared workspace to be manipulated in various ways. Obviously, the power and utility of a CMC environment will depend upon both the nature of the shared workspaces that it supports and the communication/manipulation tools that it provides for its users. This latter issue is discussed in the following section.

**Communication Tools**

If students are to learn from each other through dialogue and conversation in an online environment then it is imperative that we put into place an appropriate infrastructure to facilitate their communication needs. A variety of different electronic communication tools exist to support the delivery of online courses. Typically, these include electronic mail packages, list servers, bulletin board systems and computer conferencing packages.

Undoubtedly, electronic mail has become one of the most common methods of exchanging messages using computer-based communication networks. Through the use of 'attachments' a wide variety of materials can be exchanged – such as essays, digital photographs, sound clips, video footage and executable programs. Each of these types of medium has a significant educational value in the context of online conversational activity. Although electronic mail is a powerful technique, it has many limitations for use within educational settings, particularly online learning environments. For example, there are no simple mechanisms to allow message threading to reflect the various dialogue strands that might emerge within an online discussion forum. Furthermore, it is not easy to look at message histories in order to identify who has (or has not) read a particular message. There is no control over who submits material and the nature of what is submitted, and so on. For simple online support, electronic mail has many attractions. However, for more sophisticated use it has severe limitations. More powerful CMC tools are therefore needed.
Some of the other important tools that are often used within online learning environments include: a web browser (of course); and programs that facilitate either the transfer of data files between users (such as ‘ftp’) or online ‘terminal’ sessions with remote computers (this is usually accomplished with ‘telnet’). Together, these three basic communication tools form an important ‘toolkit’ for users of online learning systems. However, as is the case with electronic mail, these tools do not really provide many sophisticated techniques for the support of dialogue processes between groups of students and/or tutors - of course, some browsers such as Internet Explorer (Version 5) do provide a group networking capability.

Computer-conferencing systems represent an example of the type of tool that is now often used to create and support online communities of learners (McConnell, 2000; Harris, 1999). Such tools often provide a wide range of built-in facilities that allow many of the limitations of conventional electronic mail to be overcome. Indeed, used in an appropriate way, alongside a suitably designed teaching web, a CMC system can provide a rich and powerful facility for both student and staff support within an online learning environment. In the case study that is described in the following section, a powerful computer-conferencing facility (SoftArc’s FirstClass system) is used as a basic building block within the online course that is described.

Both Persico and Manco (2000) and Blanchfield et al (2000) have described some of the ways in which the FirstClass system can be used in a teaching and learning environment. These latter authors provide a useful summary of the facilities offered by FirstClass. Namely, its ability to allow its users to: send email to and receive email from other users; browse, contribute and subscribe to special mail groups (called ‘conferences’); exchange files with other users; and use other features, such as the real-time chat feature. Of course, the system also provides many other ‘special’ facilities for tutors; these can be used to set up conferences, organise students into tutorial groups and monitor what students are doing.

Naturally, the transition from a conventional teaching and learning environment towards one that is based on online delivery of material (using the types of tool that were described above) has many implications for students, teaching staff and educational organisations. Changes in organisational infrastructure are needed and different types of working practice have to be developed. In addition, the expectations of students are likely to change significantly. Some of the important issues involved in making the transition from a ‘chalk and talk’ environment to a ‘web and email’ system have been described and discussed by Duggleby (2000) and Salmon (2000).

Case Study

In this section of the paper the underlying approach that we advocate for the design and creation of online courses will be illustrated by means of a case study involving the delivery of an electronic course that is taught entirely online and which involves no conventional face-to-face contact with students. A description of the basic objectives of the course is given along with a brief outline of how these are realised. The implications of this approach, for future educational systems development, will be briefly discussed. Particular emphasis will be given to the new roles that ‘online tutors’ have to play and the nature of the demands that are placed upon them.

The online course that is used in this case study is a UK Open University (OU) foundation level course (T171) entitled ‘You, Your Computer and the Net’. The aims of the course are to develop students’ understanding of their personal computers (PCs) and the ways in which these can be used as a tool to explore the Internet and facilitate study using the World Wide Web. These aims are realised through the utilisation of: an elegantly designed web structure (http://t171.open.ac.uk); a powerful computer-conferencing system (FirstClass); a network of online tutors; a collection of skill development tasks; and an automated electronic assessment handling system (ETMA). The T171 course was piloted in 1999 and then made available to students in 2000. The course attracted a record (for the OU) 12,000 students.
Essentially, the T171 course is organised into three main web-based modules. These deal with: [1] the development of both individual online learning skills and group learning in cyberspace (Module 1: Computing with Confidence); [2] the history and development of the personal computer (Module 2: The Story of the PC); and [3] the Internet and World Wide Web (Module 3: The Net, Where it Came from and How it Works). As well as the web-based multimedia materials, there are two set books which students are expected to read. In addition, the course is supported by a set of 15 online ‘Study Guides’ that tell students what they should be doing at any particular time. For tutorial support, students are grouped into cohorts of about 20 students; each cohort is then allocated to an online tutor.

During the course there are numerous practical exercises for students to undertake using their computers. Some of these involve individual effort while others require collaborative group working. If students run into difficulty while they are studying or while working on a practical exercise, they can contact their tutor either by electronic mail or by telephone. The skills that students develop as a consequence of studying the T171 course are assessed using a series of four ‘Tutor-Marked Assignments (TMAs) and an ‘End of Course Assessment’ (ECA). There are no formal examinations as such. Students are ‘graded’ according to their performance in the TMAs and the ECA.

Three of the most important support tools used in the T171 course (from both a student’s and a tutor’s perspective) are the online search engine, the FirstClass conferencing package and the OU’s own ‘Electronic Tutor-Marked Assignment’ (ETMA) system. The search engine allows the whole T171 web site to be searched (using words and phrases) to locate particular items of interest. The ETMA facility allows students to submit their TMA and ECA materials from their personal computers to a central server at the Open University’s main site in Milton Keynes. Subsequently, online tutors can download these materials (from the OU server) to their PCs, mark them and then complete electronic feedback forms. These forms and the marked assignments can then be uploaded from a tutor’s PC back to the OU central server for students to collect and inspect.

From a communications perspective, the FirstClass (FC) system is undoubtedly the ‘mainstay’ of the T171 course. This can be accessed in two basic ways: either using a web browser or by means of software that is installed on its user’s PC (this is called ‘FC Client’). Of the two approaches to using FirstClass, the latter is by far the most useful since FC Client provides far more capabilities - both for students and for tutors - and it can be used in off-line mode. In addition, FC Client also supports real-time chat facilities. These can be used to enable groups of students, with or without a tutor, to discuss issues arising from their studies. These discussions take place in ‘real-time’, that is, while the participants are actually online.

As was mentioned above, the FirstClass facility allows various types of conference to be set up - both by the ‘course team’ and by regional online tutors. The creator of a conference can specify what properties that conference has, who may access it and how it may be accessed (this could involve only reading, reading and writing, and so on). Within any given conference, sub-conferences can be set up so that particular items of importance can be discussed in greater depth. Usually, tutors act as moderators for the conferences that they create - although, sometimes the responsibility for this can be delegated to one or more students within a given ‘tutorial group’.

Once a given presentation of the T171 course is running, tutors involved in that presentation are emailed on a fortnightly basis with instructions about what students should be doing. These regular ‘Tutor Guides’ give tutors specific details of the various activities that they have to set up for the students in their tutor group. Throughout the course, each tutor runs a tutor group conference to which any student in his/her group can contribute. This main ongoing conference is supported by various other sub-conferences that are set up by tutors in order to provide a forum for discussing and debating issues relating to different parts of the course. As well as tutor group conferences, the T171 teaching team also sets up a variety of national and regional conferences to which students and staff can contribute.

The FirstClass system is also used to provide help and support for the network of online tutors involved in running the course. As an example of this, the ‘T171 Teaching Team’ conference contains four sub-conferences entitled ‘Tutors Notices’, ‘Technical Help’, ‘Course Help’ and ‘FirstClass Training’. The ‘Tutors
Conclusions

The creation of sophisticated electronic courses to support communities of online learners requires the provision and appropriate integration of four basic types of resource. In our opinion the important components that are needed to build a successful online course are as follows. First, an appropriate web structure containing the information that is to be assimilated and/or used as a basis for the course. Second, a range of online communication strategies that allows students to exchange information and converse with each other - and with their online tutors. Third, an appropriate set of problem-based tasks that will facilitate both the development of skills and their accreditation. Fourth, a network of online tutors that can provide help, assistance and motivation for members of the online learning community. Naturally, it is important that these resources are integrated and synchronised in ways that will lead to the derivation of high levels of learning synergy. This paper has introduced a model of web-based teaching and learning which will allow this goal to be achieved. The relevance of the model has been illustrated (using a case study describing a dynamic online course that involves no face-to-face contact with students) and some of the implications of such courses for online tutors have been briefly discussed. This latter issue is discussed and debated in greater depth elsewhere (Barker, 2001).

Networking Schools: What Services do we Need?

Patrick Barrett
Catholic Education Office - Parramatta
12 Victoria Road
Parramatta NSW 2150 Australia
pbarrett@ceo.parra.catholic.edu.au

Abstract: This paper outlines the planning and implementation processes that a Catholic education system has gone through to provide network and Internet services to some 80 schools across Western Sydney. It will outline the system planning process for the project including: the vision and objectives of the project, the personnel required to achieve the desired results, the types of educational services desired and required by schools (primary and secondary) and the skills training and professional development programs required to ensure the successful integration of technology across the school curriculum.

Background

The Catholic Education Office (CEO) of Parramatta, NSW provides systemic Catholic education across approximately 80 schools in the Western Sydney area and includes some 25 secondary schools and 55 primary and special education school facilities.

Decisions were made in 1996 to investigate the feasibility of providing network and Internet services to all school facilities. In effect, this meant providing cabled access to those services from every learning space in every school. A secure and private wide area network (WAN) was designed and progressively enabled over the period 1998-2001.

This paper discusses the importance of having clear project objectives and the right personnel in place to ensure that the proposed educational services are delivered.

Project Vision & Objectives

The CEO was attempting to address the issue of schools and teachers using the capacity of new technologies to enhance learning and teaching. As a system the response was to embark on a concurrent multifaceted strategic approach to assist in the process. The focus was not on the types of technologies to purchase, nor what software to run, but rather on researching good learning and teaching strategies and what tools and support can the system provide to enhance the teaching and learning in each school. As such, the focus was placed squarely on supporting the teachers and the students.

To support this vision, there were 4 major objectives from the planning period of the project (1995-1996):

1. Connect all schools and provide network and Internet services
2. Provide school support staff – this included:
   a. at an organisational level, the employment of a Learning Technologies Group (LTG) that included a Senior Education Officer (SEO) and 4 Education Officers (EO)
   b. at a school level, a time release position (called a Learning Technologies Support Teacher or LTST) in every school to train and professionally develop staff in the use of technology to enhance teaching and learning. The time release per school population was as follows:
      a. 0.1 FTE\(^1\) for school populations 1-359

---

\(^1\) FTE: Full Time Equivalent
b. 0.2 FTE for school populations 360-599  
c. 0.3 FTE for school populations 600+

3. **Establish an Information Technology Education Centre (ITEC)**
   - In March 1997 ITEC was opened as a purpose built centre to provide professional development and research opportunities for teachers and leaders in the system.

4. **Explore ways to give teachers access to hardware** for their personal use.  
The focus of each of these objectives was to enhance teaching and learning with technology.

### The Services Delivered

Investigations were undertaken to determine the types and range of services that schools might require in order to cater for the changing learning environment of the 21st century. These investigations informed the design and implementation of the services to be delivered including:

- **Network services** – each school has its own Novell server, router and switched fibre/CAT5 LAN which is connected via ISDN links to hub servers. Each school has the ability to drag and drop files across all school servers in the diocese (within their rights) as well as to create a private network within the school. The network services are essentially file, print and email with each school locally administering their LAN NDS² configuration.

- **Internet services** – all schools access the Internet via a single entry/exit point at the network firewall where there is a 2Mbps frame relay connection. The network is set up to provide caching at 3 levels prior to http:// requests exiting the firewall. This service is provided at no cost to the schools. There is no filtering of content by the organisation, however individual schools are strongly encouraged to implement acceptable use agreements with staff, students and the school community. There is the ability at the school level to use Novell BorderManager to filter sites as defined by local needs.

- **Personnel services** – the LTST role was created in every school and supported by the systemic role of the LTG. The role of the LTG was to:
  - Support schools – each EO supports approximately 22 schools in:
    - Strategic technology planning – how is my school reinventing itself to cater for technological change?
    - Professional development – how do I adapt my teaching to cater for the ‘new literacies’ wrought by technological change?
    - Training – skill development in the use of the technology? ITEC is used extensively for this purpose.
    - Setting up and configuring hardware/software/network infrastructure – the EO was the liaison interface and ‘interpreter’ between the school LTST, external value-add services providers and the technical consultants implementing the infrastructure
  - Provide school and system advice regarding the integration of technology into teaching and learning – this is showcased in the monthly publication of a newsletter by the LTG entitled *Bits 'n Bytes*
  - Develop draft system policy documents and tools for school support – the LTG has developed a number of documents and tools to support the work of schools including:
    - The *LTAC Statement* (Learning Technologies Across the Curriculum) – a statement concerning the development of learning tasks that promote critical literacy skills with the use of technology as an integrated component
    - The *SILT databases* – these databases are used by schools to provide snapshots of their planning for, and use of, technology with learning.

### Conclusion

This paper has shown how the development of a system-wide network infrastructure to deliver educational services requires clear project objectives and on-going training and professional development for teachers.
Reflections on the Use of an Integrated Computer-based Collaborative Learning Program in a Curriculum Design Course for Science Teachers

Abstract: This paper discusses the author's reflections on the use of an integrated computer-based collaborative program in a university-level curriculum design course for science teachers. The program, Daedalus, is composed of a series of modules that work together to help the learner during each phase of the writing process.

A relatively "traditional" curriculum writing and development course was re-designed to enhance the spirit of cooperative learning and curriculum development among teachers enrolled in a graduate level course in science education. The Daedalus module, "Interchange", was used in the course. "Interchange" is a real-time conferencing program in which the learner composes messages privately and then sends them to all members of the class. The newly developed collaborative writing course proved valuable in encouraging collaborative writing and development and in assisting each teacher to construct his/her "personalized" framework for a curriculum project. Perceptions of teachers and the instructor, examples of final curriculum projects, an overview and evolution of the writing process, and strengths and weaknesses of Daedalus will be presented.

This paper discusses the author's reflections on the use of an integrated computer-based collaborative program in a university-level curriculum design course for science teachers. The program, Daedalus, is composed of a series of modules that work together to help the learner during each phase of the writing process.

A relatively traditional curriculum writing and development course was re-designed to enhance the spirit of cooperative learning and curriculum development among teachers enrolled in a graduate level course in science education. The focus of the applied course was designed to enhance students' skill and knowledge base in curriculum writing and development in science education. Two drivers formed the philosophical underpinnings for the course: (1). The course must include activities that encourage the types of learning necessary for critical thinking, reading, and writing, and, (2). The course must focus on situations and opportunities for students to interact in a positive, supportive, collaborative learning environment.

The final product was a "curriculum", a meaningful set of research-based materials that illustrate good science teaching and learning. The course format included seminars, lectures, independent and group work, student presentations and cooperative writing via the Daedalus-Integrated Writing Environment. The Daedalus module, "Interchange", was used in the course. "Interchange" is a real-time conferencing program in which the learner composes messages privately and then sends them to all members of the class.

Based on the analyses of student discourse, seven reflective conclusions were generated: (1). The process of collaborative writing appears to be developmental. (2). It takes time for collaborative groups to construct
understanding. (3). The role of the instructor is the most important factor to ensure success throughout the collaborative writing process. (4). Students learn how to negotiate and manage conflict productively. (5). The process encourages students to see different components of the writing process— invention, pre-writing, composing, and revising. (6). It integrates students and instructors into a collaborative community of learners. and, (7). The process helps to "see" students " in a different way. The newly developed collaborative writing course proved valuable in encouraging collaborative writing and development and in assisting each teacher to construct his/her "personalized" framework for a curriculum project
Meeting Teacher Technology Competencies
In the Classroom with a Focus on Writing/Communication Skills

Dr. Martha J. Beasley
Division of Education
Lees-McRae College
Banner Elk, NC 28604 USA
beasleym@lmc.edu

Abstract: This paper is based on a series of workshops offered to kindergarten through eighth grade classroom teachers. The focus of the workshops was to increase student academic expectations and accountability through technology integration. Two built-in objectives of this staff development included the use of highly motivating student-centered technology activities to increase student academic involvement in writing and communication skills. Various teaching methodologies were encouraged throughout this process, including constructivist approaches and cooperative learning. A hands-on approach to the staff development and transfer to student learning was enhanced through innovative ideas and measures, group creativity, and exposure to web-based learning and exploration. Helpful teaching sites and activities are a part of the presentation, along with feedback regarding increased teacher awareness and knowledge on the use of technology in the classroom setting.

Overview of the Staff Development

This staff development included approximately fifty teachers and media-coordinators in two different public school systems. Both systems exist in rural areas in western North Carolina, USA. The participants trained in school computer labs, as they were later expected to duplicate their hands-on experiences with their students. This work was completed in the Fall, 2000 semester and End-of-Grade test results will be reviewed at the end of Spring, 2001. The goal of the staff development was to increase student writing and communication skills test scores, by increasing teacher technology awareness, involvement, and ability. These ideas were based on research that suggests “that the introduction of technology to classrooms does not radically change teaching; instead, technology can serve as a symbol of change, granting teachers a license for experimentation” (Sandholtz, Ringstaff, &Dwyer, 1997, p.171).

The overall approach used in the staff development and the approach to be transferred in the classroom environment were “Piaget’s basic concept of constructivism, which is that children construct their understanding of any given object, concept, or idea based on their own explorations; and Vygotsky’s idea that social interaction is a critical ingredient in furthering the child’s understanding” (Brown, Metz, & Campione, 1996). In order to implement this approach and cognitive theory, extensive student/teacher exploration and hands-on activities were encouraged.

North Carolina Computer/Technology Skills Curriculum

Specific goals exist for all students in the North Carolina Competency-Based Curriculum (1992) and the staff development plans revolved around these goals. Goal 1 states that the learner will understand important issues of a technology-based society and will exhibit ethical behavior in the use of computer and other technologies. Goal 2 states that the learner will demonstrate knowledge and skills in the use of computer and other technologies. Goal 3 states that the learner will use a variety of technologies to access, analyze, interpret, synthesize, apply, and communicate information.
Workshop Outline

Introductory processes involving various servers, common domains, and interest searches set the stage for basic information and Internet research. This section was stressed as a vital part to introducing sites to students, along with the importance of student input and inclusion in class activities.

Teachers were then introduced to the idea of on-line journals and student publishing sites as a means for developing writing skills. Sites were reviewed that allow student input and on-line publishing opportunities. Branching away from simple journal and/or story writing experiences, poetry was also introduced as a method for writing and publishing. For example, "a structured option is to have students read a specific poem on-line, then have an activity that relates to that poem. It can be as simple as creating some type of collage of art to represent the poem, or writing a short story that ties into the poem. You can also study the poem’s structure—dissecting the parts of speech used, rhyme scheme, etc." (Goodson, 2001, p.13). Other publishing ideas included the creation of books, school newsletters, the creation of posters, pen pals, and graphic organizers.

The next topic centered around student organization and structure required of writing. Different web or outline activities were introduced. Many students require a more visual organization effect when organizing their thoughts on paper. Again, various forms and software packages were introduced to the teachers.

Teachers were introduced to the many uses of on-line newspapers and current event topics to be used for writing prompts. Time was also allotted for exploration on various news sites and methods of integrating these into all subject areas. The ability to critique current events in classroom debates and discussions through the use of reading on-line editorials and writings was discussed as a vital method to enhance cognitive learning and individual critical thinking skills.

Power Point presentations and displays were introduced as a means for student involvement and assessment variation in the classroom grading system. In addition to student power point presentations, on-line presentations were reviewed for more interesting and motivating teaching lessons.

Last, time was allotted for exploration on the many available teaching sites with ready-made lesson plans and ideas. These sites ranged from simple phonics, yearbook publications, grammar lessons, word processing, to writing with the Thesaurus.

Conclusions

Based on the general observations, surveys, and group discussion, the workshop proved to be helpful and easy to adapt to various classrooms. Writing and communication skills test results will be viewed and assessed when available.

The New Digital Civilization:
The Best of Times, the Worst of Times

Melissa Roberts Becker, Ed. D., Teacher Education Department, Northeastern State University, United States of America, beckermr@nsuok.edu

Donna G. Wood, Teacher Education Department, Northeastern State University, United States of America, wooddg@nsuok.edu

Abstract The purpose of the new digital civilization research was twofold. First, the study compared the learning style preferences of undergraduate students enrolled in an on-line version of an education course (Technology in Education) to students enrolled in the traditional, face-to-face version of the same course. Second, the primary investigators restructured both versions of the course to effectively address identified learning styles by providing new strategies and developing multimedia products, which appeal to visual, auditory, and/or kinesthetic learners.

Narrative

The year 2001 offers educators the best of times for making use of technology in the teaching and learning environment. Access and availability of digital tools increases as the global society evolves into an inner-connected digital civilization (Dockerman 99). Technology of the new digital civilization presents innovative opportunities for increased student learning, assessment and communication. Through the use of technology, individual learning styles of students is readily addressed with the use of contemporary digital tools (Becker 99). The tools include presentation graphic software, Internet resources and interactive multimedia applications in a variety of content areas. Authentic assessment of students takes place as students use digital technology to create products reflective of their understanding of educational content. Communication with educators and peers takes place at the point of instruction, in either a synchronous or asynchronous learning environment (Gates 96). 2001 truly presents the best of times for learning.

However, these same pioneering digital tools present instructors at all levels of education with a worst of times challenge. Technology has changed expectations of students in their educational experiences. Digital tools change and expand at a rapid pace. Comprehensive training is required to keep pace with these changes if students are to be taught in an effective and contemporary manner. Members of the new digital civilization disengage with instructors who are not able to participate in the civilization’s digital velocity (James 96).

The purpose of this study is to examine emerging roles of the primary investigators and undergraduate students in the on-line environment as compared to the face-to-face traditional classroom. Learning styles of the students will be compared and contrasted in both environments. The Environmental Preference Survey (created by Dunn, Dunn, and Price) was used for the evaluation.

Procedure

Students in each group (on-line and face-to-face) were randomly selected for voluntary participation in the study. The total number of participating students was 37. The students completed the Environmental Preference Survey (EPS) during the fall 2001 semester. Comparison of the two groups’ scores on the EPS was determined significant at the .05 level.

Undergraduate students enrolled in EDUC4823, Technology in Education, were asked to voluntarily participate in a comparative study to evaluate learning style preferences and computer anxiety reduction in an online learning environment and a face-to-face (FTF) learning environment. Students were randomly selected for participation from each version of EDUC4823 class. (12 on-line participating students and 25 FTF participating students). The data for this study was gathered as a pilot study during the fall 2000 semester. During the semester, the students completed an Environmental Preference Survey (EPS) to determine individual learning styles preferences. The EPS instrument was developed by Dunn, Dunn, and Price (1985) and is used
currently by the campus-supported institution OIL, Oklahoma Institute for Learning Styles, to analyze and summarize results of an individual's environmental preference while performing learning tasks.

Random number codes were assigned and individual student scores entered and compared. All individual identifying information was eliminated within each type of Technology in Education course, insuring complete anonymity. The individual learning style preferences were investigated using a t test by preferences within each group. Statistical significance was determined at the .05 level.

Results

Using a two-tailed t test, there was no significant difference in the learning styles preference between the two groups of students. These results will make the second purpose of the study straightforward: restructuring of the course and production of multimedia products for both courses. Using a one-sample t test, the learning style preference of structure was a significant factor for both groups of students. The instructors will field test the restructured course format and multimedia products in the fall 2001 semester. For example, specific guidelines for all course projects will be provided to both classes. In addition, a timeline for course content will also be provided in an interactive, on-line format for both classes. This will be the first of the multimedia products created as a result of the research.

Implications and Further Study

There exists a myriad of implications for this study. The Technology in Education course will continue to be restructured and modified as a result of the study. Additional multimedia products will be created by the principle investigators and shared with campus faculty through the university website. As instructors from all levels of education seek effective methods to improve student learning, appropriate use and application of technology in the learning environment will prove invaluable.

The research could be further strengthened through follow-up studies that will involve the retention of online students and FTF students based on the development of learning style strategies utilizing technology. Another aspect of the additional study could address learning style preferences based on each group's birth year, gender and area of education content concentration (elementary education, early childhood and secondary education). Finally, other determining factors in selecting a course on-line rather than the traditional face-to-face version of the same class could be investigated. Assessing student learning styles and the role of these various styles can be explored by comparing changes in computer anxiety levels of participating students. Reflective journal entries of participating students could provide a qualitative element to an additional study.

Conclusion

As contemporary educators seek unique methods to meet the technological challenges of the emerging digital civilization, focused attention must be given to the learner (Becker 99). This study addresses essential elements brought to the learning environment by both the student and the digital tools. Results of the study can assist undergraduate instructors and students in narrowing the digital divide, celebrating the best of times.

Abstract: This paper discusses the use of tools that allow the development and presentation of time and place-independent courseware. Such tools make the Internet another valuable delivery method for distance education courses. The use of the tools is discussed in relationship to a course currently being offered at the Community College of Southern Nevada that prepares students to take and pass an industry recognised certification test.

Introduction

The Community College of Southern Nevada (CCSN) is responsible for delivering educational opportunities to a 45,000 square mile area in Southern Nevada. Enrolment at CCSN was approximately 36,000 students for the fall semester 2000 (September through December 2000). To meet the need of so many students, CCSN has built five major and over a dozen outreach campuses. Many students however, are still not able to take classes due to working schedules or distance from one of the campuses.

A continuing option for students who are unable to attend normal classroom instruction has always been distance education (DE). The increased availability and power of computers has created distance education possibilities not available just four years ago. But the use of these components is often sporadic, if they are used at all due to many factors including the cost of entry for the school (Matthews, 1999; Chambers, 1999, Barley, 1999) and possible higher costs for the student (Matthews, 1999; Barley, 1999; Blumenstyk and McCollum, 1999). Many of the distance education modules at CCSN are still delivered in a manner that requires students and instructors to meet at specific times for discussion, interaction and presentation. These modules offer students limited by distance the ability to take modules. However, for students with unusual or irregular work schedules or other time conflicts, such meetings are still constraining and the students may still be unable to take modules. For modules to offer students the two greatest advantages of distance education, modules must offer both time and place flexibility (Shave, 1998; Fender, 1999; Alexander, 1999).

An additional constraint is the lack of technology experience and knowledge that instructors have (Shave, 1998; Mudge, 1999). Technology improvements alone do not offer most instructors the ability to offer distance...
education modules unless they are familiar and comfortable with the technology (Shave, 1999; Alexander, 1999; Matthews, 1999; Carnevale, 1999; Trinkle, 1999; Grill, 1999; Mudge, 1999). In addition, instructors must have the time and patience to learn how to use the technology. This can include expanding the frame of reference an instructor has from classroom-based instruction to instruction that is independent of place and time. Many instructors find this difficult. The learning curve experienced by instructors can be partially alleviated by a good computer support department at the college or university. However, the use of outside providers can affect a faculty member’s control over his or her intellectual property.

Delivery that is independent of time requires the creation of online courses that can be accessed at any time and place, as long as Internet access is available. In order to explore some of the issues involved in distance delivery a particular module was used as a test case. The module selected for use in the work described in this paper was Computer and Information Technology 106B. This module is a preparation course for students who are preparing to take the Computing Technology Industry Association’s A+ Core certification test. This test is one of two tests required to become an A+ Certified PC Technician. In order for the module to be as close as possible to the actual on-campus presentation, streaming audio and video were selected so that the classroom lectures could be transmitted over the Internet. This type of technology does not require that files be downloaded before use. In addition, the use of streaming technology does not require specific class meeting times. This module required a means for grading and evaluating a student’s knowledge acquisition as well as support options that are also independent of time and place. This does not mean the instructor must be available at all times, but that students have the ability to ask questions whenever the module is being accessed. Such support can be offered using email, voice mail, snail mail, and office visits.

Creating such modules is beyond the ability of many instructors, not necessarily because of ability, but due to time and knowledge constraints. Effective tools can make such development not only easier, but more realistic for non-technical instructors.

Development Process and Tools

Any module requires three components. First, the learning material that is covered needs to be disseminated. Second, communication between the instructor and student for questions and other feedback needs to be set up. Finally, learning must be evaluated and assessed. CCSN adopted a Web development tool set called WebCT. WebCT provides Internet-based tools for testing. While there is a learning curve with WebCT, the curve is similar to the learning curve of a new word processing program instead of a programming language. Once the tests are in place, students can receive immediate feedback after a test is submitted for grading.

A web site was developed to provide communication between the instructor and students. The web site could be used to post messages of concern for all students as well as contain an email link so that students could send the instructor an email during the module’s delivery. Additional information could be added to the web site if needed. Students’ learning is evaluated and assessed through four tests administered on demand through WebCT. The first three tests are not comprehensive. The fourth test is comprehensive with questions covering all of the learning material presented. The current web site (http://131.216.93.7) contains module syllabi, course information, textbook listings, and certification testing information.

The second and third components used one or two software packages to help facilitate their development. But that was not true with the first component. A number of different tools are needed to develop courseware for streaming. Each tool is required in order to finish with a file that the streaming server can transmit to students on demand. Each tool fits into the development process. The development process is a seven-step sequence. Each step in the sequence uses different tools to provide the needed result. The CIT 106B course was developed using the tools and process that are described below.

Step 1: Recording of lectures and video aspects
Microsoft PowerPoint was selected as the first tool due to its ability to record narration along with the PowerPoint slides. Other presentation software also has this ability, but the author was already familiar with PowerPoint. When narration is recorded, using a standard headset and microphone through the computer’s sound card, PowerPoint stores the recorded sound in separate .wav files. One .wav file for
each slide. The.wav files are stored using sequential naming so that the order and slide to file relation is simple to follow. These files could be used for transmission over the Internet, but they are quite large and would require a complete download before being playable. In addition, there is no copyright protection for the files. For these reasons the second tool and step are necessary.

**Step 2: Conversion of slides to jpg format**
A tool is required to take the PowerPoint slides and convert them to a different graphic format (jpg). The new format requires less storage space and is optimised for Internet use. The tool selected was Paint Shop Pro 4. There are other tools available for use at sites like tucows.com and shareware.com. The only requirement is that the program has the ability to accept pasted objects and then save the object in jpg format.

**Step 3: Combining of audio and video into a single file format**
PowerPoint stores the slides and audio files as separate entities. A tool is required that can take the video slide, combine it with an audio file and create a single audio-visual file, using the avi format. The tool selected is Dublt. The first reason this program was selected was due to its free 30-day evaluation period. The first author was able to complete the conversion of the CIT 106B lectures in the trial period. The first author found the tool so helpful and useful that he purchased it. Dublt combines the slide and associated .wav file and then allows it to be saved as an avi file.

**Step 4: Conversion of digitised data to stream data**
The tool selected for this step was chosen due to the fact that Real Server was selected to stream the files. Real Systems has other tools available for download that help in the preparation of streaming files. RealProducer is a program that accepts avi files and then converts them to streaming files. The interface is quite understandable and easy to use. The program is free to download with most of the features enabled.

**Step 5: Installation of Server software and storage of stream files**
A Windows NT Server 4 machine was selected as the Real Server. The Real Server software was purchased and installed. The installation is straightforward and Real Systems provides good technical support if there are any questions during and after installation. Once the server is installed, the files generated in step 4 need to be copied to the selected directory. One important concept is file security. Only the desired amount of access should be granted to the individuals accessing the files. In most cases this would be the permission to read.

**Step 6: Creation of front-end delivery site**
This step required a great deal of work. The majority of the work was learning HTML for web creation purposes. The HTML editor used was HomeSite 4. The front-end delivery tool selected is Internet Information Server 4, a free add-on from Microsoft to the Windows NT Server 4 platform. Installation of the IIS 4 software is simple and not time consuming. IIS includes a sample Internet site that can be used as a guide for adding connections in step 7. Pages need to be designed that provide access to students.

**Step 7: Connecting the front-end delivery site to the stream server and files**
The software package used to connect the streaming files and the web site is WebCT, or Web Course Tools. WebCT simplifies the process by providing student management, test generation and offering tools, and grading. Links can be added from the website that provides logon access to the WebCT server. Links in the WebCT server pages connect the user to the Real server. A valuable aspect of WebCT is that the program is free to download and use for development. Licensing is only required when a module is available for student access. This allows an instructor the ability to create and view the module as well as test the various aspects of the presentation. It also provides a good evaluation opportunity for those who are still uncertain about the use of WebCT. If WebCT is used, the license fees are quite reasonable.

The CIT 106B module, developed using the above methodology can be viewed at http://webcampus.ccsn.nevada.edu. Select the "Logon to MyWebCT". The sample ID is tstudent and the
password is temp. All lectures will be available, but due to academic constraints, the module tests will not be available. The account above will be active during the EDMEDIA conference.

Lessons Learned and Emerging Guidelines

The development of the module required a large number of new software packages and hardware. The first author was already experienced with computer software and hardware as a senior systems analyst as well as holding certifications from Novell, Microsoft, and CompTIA. However, the amount of knowledge that had to be acquired was daunting. Developing a web-based or multimedia course requires a large amount of development time. The amount of time required can be discouraging for many instructors. If a large amount of time and effort is required, the resultant module needs to be usable for a good period of time. For instance, the British Open University plans courses to last for 8 years (Blumenstyk, 1999). Such a long time frame can be difficult when dealing with topics that change frequently. CompTIA has announced a major revision of the certification program of which the CIT 106B module is part. This will require a complete rewrite of the current module for use in the spring of 2001. The last revision of the certification content was made in 1998.

The development of this project confirmed that there are disadvantages associated with distance education modules, especially those mentioned in section one. A large amount of hardware is required for the creation and maintenance of a distance education module. In many cases it was difficult to procure the required equipment and the first author was required to purchase items so that the module could be created. In addition, the time spent learning the software and hardware was not reimbursed, in any manner, by the college. Many instructors are not willing to invest their own money and other resources to develop modules without reimbursement. Though some instructors might be willing to fund the development of the module so that they can retain ownership. However, if this investment includes items required to deliver the modules the institution benefits at the expense of the instructor.

There was not one specific software package available to create the required media offerings. Instead, one package was used for one part, another package for a second part, and then a requirement for additional software was identified when the shortcomings of the first packages were discovered. This created a steep learning curve for an experienced software engineer, not to mention instructors unfamiliar with the hardware and software required. But once an instructor learns the various hardware items and software packages, subsequent use for module development should not be as time and effort consuming. Some of the disadvantages of distance education are not controllable by the instructor, but rather must be addressed by the institution. This includes the cost of hardware and the support infrastructure required to offer distance education modules. However, institutions can start by offering a limited number of modules and then expand the offerings as demand increases. This will allow the budgeting of support items over a longer period of time.

The learning curve of instructors can be alleviated using mentoring. Instructors who have developed modules can help those who are inexperienced to understand and use the hardware and software tools available for distance education development. CCSN has addressed this issue by offering a number of workshops at the beginning of each semester, as well as others offered during the semester, as needs are identified, that help educate instructors in the use of the tools mentioned above.

Conclusions

The use of technology, along with various tools can make truly independent learning a reality. The offering of a module with time and place flexibility offers opportunity to students who otherwise would not be able to take advantage of higher education. Since the module is delivered via the Internet, learning can take place at home, while traveling, or at an institution's computer lab. The module can also be offered to students not normally included in an institution's audience; a global audience. This type of module offers self-paced study to the learner. Lectures can be repeated multiple times if a student is having difficulty grasping the subject. Something that is not possible in the normal class-room environment. We feel that the advantages associated with this type of distance education module are sufficient motivation to continue the development of more similar modules, with the second module available in Spring 2001.
However, although there are advantages to distance education, there are problems and concerns. The identified concerns must be addressed. Creation of the modules and the supporting web links is a time consuming process even for experienced designers. For normal staff, the time and effort required could seriously affect their other teaching and non-teaching assignments. Institutional support, or at the least, cross department co-operation, is required if such development and presentation options are used in more than isolated instances. Institution-wide tools need to be selected and faculty training provided. If an institution-wide standard is not created, training and support become very difficult, if not impossible. The institution-wide adoption of specific software and hardware platforms also ensures that modules developed and offered to students by different academic departments will be transparent to the students.

While this type of distance education module might not fit all disciplines, the ability to generate and offer such modules is in the reach of all instructors. Despite the technical concerns and instructor learning curve, we believe that the benefits associated with this type of distance education module for the college and the students far outweigh the negative aspects encountered to date. We are optimistic that our development plans for additional modules will provide educational opportunities to students that otherwise would not be able to improve their education.

Tools to Create Time and Place-Independent Modules

Brief Paper Demonstration

EDMEDIA 2001

Professor Scott Beckstrand
Community College of Southern Nevada
North Las Vegas, NV
United States of America
Email: scott_beckstrand@ccsn.nevada.edu

Abstract: One constraint in the development of time and place-independent distance education modules is the lack of technology experience and knowledge instructors have. Many instructors are not familiar and comfortable with technology. Their learning curve can be partially alleviated by a good computer support department. However, the use of outside providers can affect a faculty member's control over intellectual property.

Delivery, independent of time and place, requires the creation of online modules that can be accessed at any time and place through the Internet. Streaming audio and video were selected so that the lectures could be transmitted over the Internet. Understanding the various tools available to create such modules can help instructors expand their instructional offerings, and reach students who otherwise would be unable to attend classroom instruction. This tutorial will take a sample lecture through all steps of development cumulating with the lecture being streamed over the Internet.

Objectives
This demonstration will show attendees how to use tools that create distance education modules that are time and place-independent. Each of the seven development steps will be discussed and illustrated, as time permits. A finished module will be available for review during the conference. The steps discussed and demonstrated include:

1. Create graphics for use in a lecture presentation
2. Record lectures onto a computer system
3. Convert graphics into compressed formats for Internet dispersal
4. Combine audio and graphics into a format for Internet dispersal
5. Convert digitised data to stream format
6. Use of Streaming Server software and where streaming files are stored
7. Basic HTML pages for front-end presentation
8. Connecting the HTML pages to the streaming files

Intended Audience
Anyone interested in developing time and place-independent distance education modules would find this tutorial of value. No experience is required.

Length
The demonstration normally lasts 30 minutes. Internet access via modem or ethernet network is needed.

Outline
Recording of lectures and video aspects
Use Microsoft PowerPoint to create one or two presentations slides with recorded narration for each slide.
**Conversion of slides to gif format**
Use Paint to convert the PowerPoint slides into a different format.

**Combining of audio and video into a single file format**
Use DubIt to combine each slide and .wav file into the .avi format.

**Conversion of digitised data to stream data**
Use Real Systems RealProducer to convert the .avi files into streaming files.

**Installation of Server software and storage of stream files**
Using a pre-configured server, place the streaming files in the correct directory location on the server.

**Creation of front-end delivery site**
Create a simple HTML page as a front end connection for the streaming files.

**Connecting the front-end delivery site to the stream server and files**
Make the links in WebCT for lesson access and create a student account.

**Questions and access**
Access the file and demonstrate the created lesson. Answer any questions from tutorial attendees.

Access to an actual developed course offered at CCSN will be available to conference attendees during the ED-MEDIA conference.

**Instructor Qualifications**
Scott Beckstrand is a Professor of Computing and Information Technology (CIT) at the Community College of Southern Nevada (CCSN) in Las Vegas, Nevada, USA. CCSN is a two-year degree granting institution with approximately 36,000 students. The college has five large campuses, and over a dozen outreach-centres in its 45,000 square mile area of responsibility. Professor Beckstrand has been instrumental in developing certification education programs, preparing students for Novell, Microsoft and CompTIA certifications. He currently oversees the Microsoft and CompTIA programs. Professor Beckstrand holds certifications as a Certified Novell Administrator, Certified Novell Engineer, Certified Technical Trainer, Microsoft Certified Trainer, Microsoft Certified Professional plus Internet, Microsoft Certified Systems Engineer, A+ certified PC technician, and Network+ certified technician. Professor Beckstrand also pioneered distance education offerings in the CIT department, as part of a doctoral program he will be concluding in the near future at the University of Teesside, with the creation and successful offering of CIT 106B. This course is wholly presented over the Internet. Additional courses are planned for introduction in 2001.
De Bono’s Six Thinking Hats Technique: A Metaphorical Model of Communication in Computer Mediated Classrooms.

Karen Belfer, M. Ed.
Program Evaluation and Assessment Coordinator
Technical University of British Columbia
Canada
belfer@techbc.ca

Abstract: In a computer mediated classroom the technology is used both as a medium for transmitting content and a human arena for interaction. The quality of the learning climate of online environments depends on effective communication. The way people think, hence their guiding metaphors, can become either bridges that support or obstacles that impair the human exchange of ideas. Instructors have to manage personal images and can use different techniques to outline group metaphors to facilitate the information exchange and develop the communication framework. De Bono’s Six Thinking Hats technique was a successful method to achieve this in the course, Business Information Systems.

Introduction

A Computer Mediated Classroom is a fairly successful model of learning that has been actively practiced for over 20 years (Hiltz, 1997). This model has allowed the technology used to become both a medium for transmitting content and a human arena for interaction. Both learners and instructors report high levels of engagement with the content in courses based on asynchronous conferencing. In this model the integrated use of technology offers many educational opportunities and possibilities. Instructors can use varied instructional delivery formats to provide a richer environment while learners are allowed the freedom to explore alternative pathways to find and construct knowledge and their own style of learning.

Current learning theories state that meaningful learning requires the students to interact with the new information.

Electronic discussion has been a common collaborative learning approach used in this model. Research shows (Savery & Duffy, 1999) that participating in a debate or argument develops the learner’s ability to think critically and to view a problem from multiple perspectives. “Other people are the greatest source of alternative views to challenge our current views and hence to serve as a source of puzzlement that stimulates new learning.” (vonGlasersfeld, 1989)

That is why it is so important to maintain the quality, quantity, and patterns of communication in the skill set students practice during learning- a change that requires, in many cases, both teachers and students to learn different roles.

The online nature of the model promotes long-distance collaboration between student and content specialists from diverse backgrounds and geographical areas. Therefore embracing communication in a state of resonance where there is respect, tolerance and opportunities for the individuals to pursue their personal interests will be the constant challenge. Evans-Harvey (1995) outlines the importance of promoting and developing a positive learning environment, where instructors meet the specific interests and aspirations of such diverse group of students, as a prerequisite to having them engage in the course content.

Members of a group perceive and describe the learning environment in terms of values of a particular set of characteristics or attributes. Some researchers (Halpin & Croft, 1963, Tagiuri, 1968, Fraser & Wilkinson, 1993) have referred to this process as climate.

Climate has an influence on behavior and has been found to determine the successful achievement of a variety of educational products such as cognitive achievement, satisfaction, motivation, and personal development (Fernández, Asensio, 1981). This influence encourages climate to be a fundamental element on its own.

Instructors can use metaphorical models to facilitate the information exchange and develop the communication framework that promotes a good learning climate.
Communication Metaphors

Metaphors are related to the interaction that takes place between people's communications and to the images they hold around their hearts and minds. People are not always conscious of the way they see things and the guiding metaphors they are using. These can become either bridges that support or obstacles that impair the human exchange of ideas. A metaphor can be deeply flawed if it represents a narrow or shallow view. The inability to articulate it can alienate people (White, 2000).

Every metaphor is best suited to a particular purpose. Each metaphor provides us with a different perspective on information and communication. No perspective provides a complete picture of reality, but different perspectives can complement each other and bring out the excess of other metaphors (Gandenfors, 1995).

Personal Perspectives That Can Affect the Learning Climate

Argumentative: Arguments are means to move forward, but sometimes protagonists get locked into their positions and become more interested in winning or losing than in exploring the subject of discussion.

Ego and performance: Usually ego and performance are so closely tied together that when someone does not like an idea, they will not make any effort to find a point in favor of it.

Persistent negativity: Some people are negative by nature and feel the need to always put forward the possible dangers.

Individuals’ perceptions can change if they are encouraged to try. That is why instructors facilitating an online course have to manage the metaphors of communication to maintain the quality of the learning environment.

Role playing, lateral thinking techniques and clear expectations of etiquette are some of the available methods an instructor can use to manage personal perspectives and group metaphors in online interactions.

One technique that has been heavily used, at a metaphorical level, and as a teaching method framework for lateral and creative thinking, is Edward De Bono’s Six Thinking Hats.

De Bono’s Six Thinking Hats

This technique is used both in schooling and in business management. As a management tool it has been used by many major corporations around the world (e.g. Du Pont, Prudential Insurance, IBM, NTT). As a teaching tool it is used as a teaching method for lateral thinking.

The Six Thinking Hats technique is extremely simple but it is powerful in its simplicity. Each of the thinking hats has a color: white, red, black, yellow, green and blue. The color of each hat is related to its function.

White Hat: Looks objectively at data and information. Is neutral and concerned with facts and figures.

Red Hat: Legitimizes feelings and gives an emotional view, hunches, and intuition. Red suggests anger (seeing red), rage and emotions.

Yellow Hat: Is positive and constructive. The yellow color symbolizes sunshine, brightness and optimism.

Black Hat: Is logical, negative, judgmental, and cautious. Is gloomy, suggests why it cannot be done.

Green Hat: Is about new ideas and creative thinking. Green suggests vegetation and abundant fertile growth.

Blue Hat: Controls the thinking process. Blue is the color of the sky, which is above everything else. The blue hat is concerned with control and the organization of the thinking process (De Bono, 1985).
The six thinking hats theory works as a teaching method in a metaphorical level because it:

- Allows the legitimate expression of feelings and intuition in-group discussions - without apology or justification. "This is my feeling" or "This is what I feel"
- Allows an 'unbinding' of thinking so that each mode gets full attention. It avoids the confusion of trying to do everything at once.
- Provides a simple and direct way of switching thinking without causing offence: "What about some yellow hat thinking here?"
- Requires all thinkers to use each of the hats instead of sticking to only one type of thinking.
- Separates ego from performance in thinking. Frees able minds to examine a subject more fully.
- Provides a practical method of thinking for using different aspects of thinking in the best possible sequence.
- Gets away from arguments and allows parties to collaborate on constructive exploration.
- Makes for much more productive discussions and group work.

Application

The Course was Business Information Systems of the E-Commerce Program of the University of New Brunswick, offered at the Technical University of British Columbia.

Logistics

Students met with learning staff in a classroom once per week to participate in team-based learning activities. Prior to the class meeting, information was presented to the students through a weekly web presentation, textbook and supplementary readings, processed by students through an electronic discussion in an asynchronous online conference.

To guide the conference discussion the learning staff posted two or three discussion questions based on the information available on the web presentation.

The total duration of the course was 14 weeks. After 4 weeks the learning staff could perceive a communication pattern on the online conference. Before reading the thread they could guess what the answers could be and which metaphors of communication were used by each student. The interactions between students were becoming blunt.

The learning staff decided to use the Six Hats technique to better manage the communication. Each student was assigned a particular colored hat.

Results

In the Online discussion

- Posting reflected that the students were in fact using the hats they had been assigned.
- Because of the hats, postings tended to be broader, going beyond the case study. The initial posting reflected that the students' perspectives had changed.
- Some students responded to "other hats" postings using their own hats. In the face-to-face session:
- Students would start changing or borrowing hats.
- Hats were used as a basis for organizing discussion.
- Students' motivation for participation was increased.
- Hats lead to more balanced participation, especially from those students with a less articulated orientation.

Flexible Delivery Damaging to Learning?
Lessons from the Canterbury Digital Lectures Project

Tim Bell¹, Andy Cockburn¹, Bruce McKenzie¹, John Vargo²
¹Department of Computer Science
²Department of Accountancy, Finance and Information Systems
University of Canterbury, Christchurch
{tim, andy, bruce}@cosc.canterbury.ac.nz
j.vargo@afi s.canterbury.ac.nz

Abstract: Preparing courses for flexible delivery and distance education is normally a time-consuming and expensive process. This paper describes the design and evaluation of a system that automatically captures and indexes audio and video streams of traditional university lectures without demanding any changes in the style or tools used by teachers. Using a 'wizard-of-oz' technique to simulate the automatic indexing, we ran a four-month trial of the system in a large (746 students) first year Computer Studies course. The results reveal some surprising social implications of making flexible delivery available to students at a residential university. Early in the trial, many students expressed an intention to use the system, but few did. Late in the course, many students stated that they urgently needed the system for revision, but even fewer used it. At the same time, lecture attendance appeared to be lower than normal. We hypothesise that the availability of a flexible alternative to lectures removed the necessity of attending lectures, and that students deceived themselves about their intentions to catch up using the digital medium.

Introduction

Flexible delivery', 'distance education' and 'virtual learning' have become popular buzzwords within academia. There are, however, many technological, financial and social constraints that limit the practicality of the 'glamorous' visions of virtual learning involving real-time distributed classrooms supported by high-bandwidth multi-party video interaction. High-bandwidth networks will eventually be sufficiently ubiquitous to enable rich virtual learning environments with equitable participation possibilities for proximate and remote students, but current implementations are severely constrained by bandwidth and other considerations.

In 1999 the leaders of our university—the University of Canterbury, New Zealand—announced their intention to equip all lecture theatres on campus (approximately 20) with the necessary equipment to support virtual learning. Unsure what this would entail and at what cost, the authors of this paper proposed a trial research project to investigate practical methods for flexible delivery of lectures.

Without massive institutional change, it was clear that Canterbury academics would not have time to develop extensive course materials for virtual learning. With this constraint in mind, we focused on designing, implementing and evaluating a system that would maximise the pedagogical benefits to students while minimising (to zero if possible) the additional work for the academics who deliver and administer the courses. Having designed and implemented the system we trailed it as a resource available to the 746 students taking a year-long first year 'Computer Studies' course.

This paper describes the results of the four-month trial of the Canterbury 'Digital Lectures' system. The system was designed to automatically capture and index traditional lecture content without requiring course teachers to change their presentation styles in any way. Students who were unable to attend lectures at their normal time and place would be able to view them by accessing CD-ROMs held at the university library and in computer labs.

The following section provides the background design rationale for our system by reviewing various possible implementations of 'virtual learning'. We then describe our system and its objectives, followed by a discussion of the unexpected findings from the evaluation. The final section concludes the paper.
Dimensions of Virtual Learning
This section presents four dimensions of ‘virtual learning’ that critically influence the capabilities of technology for enhancing learning.

Learning media
The traditional lecture remains a defining element of most university courses. Although there are many ways to stimulate interaction and small-group work within the lecture environment (for example, see Fischer (1998)) lectures remain, at least on the surface, a largely one-way interaction from the professor to the students. The course notes, readings, and text-book support students in clarifying and elaborating on the ‘seeds’ of knowledge that are (hopefully) planted during the lecture. Arguably the most valuable part of traditional courses occurs when students actively test, articulate, and manipulate their understanding. This normally occurs in seminars, tutorials, labs, and assignments.

A wide variety of computer-supported media can be used in an attempt to enhance, offer a surrogate for, or replace these traditional ‘media’. For example, it is becoming common for students to bring tape-recorders to lectures, but the lack of any indexing into the audio-stream severely inhibits the potential utility of the recordings for a student who “understood all of a lecture except for the bit on topic X”. Systems such as the Classroom 2000 project (Abowd 2000), the Cornell Lecture Browser (Mukhopadhyay and Smith 1999), and our Digital Lectures project aim to overcome these limitations by automatically capturing and indexing lecture content.

A key distinguishing characteristic of new computational learning media is the level of activity required from students. Passive media simply provide a static resource for the students. Recording and indexing lectures and the now standard practice of putting course materials on the web are both examples of relatively passive media. Passive approaches to learning media have been criticised as ‘gift-wrapping’ (Fischer 1998), but it seems reasonable to expect that they can provide improvements to courses at relatively low costs. For example, web-based course handouts can be updated and improved on-demand, and indexed lecture recordings can aid students who were unable to attend the original lecture.

In contrast to passive media, active media provide an interactive resource that students can use to test and build their understanding. There are three types of active educational systems. Firstly, interactive simulation and exploration environments let students explore the effects of changing properties within an interactive space. For example, animations of algorithm execution (see Brown and Sedgewick (1985) for an early example) allow students to explore the algorithm’s behaviour by changing data and parameter values and observing the resultant behaviour. Secondly, intelligent tutoring systems (Sleeman and Brown 1982) attempt to model the student’s understanding of a problem domain, and then tailor the information they present appropriately. Thirdly, reflection and discussion spaces, such as bulletin board and Net News systems, allow students to build a repository of information that interlinks contributions by a potentially wide range of participants and sources. Examples include the Dynasites system (Fischer 2000) which was explicitly constructed as an environment to support lifelong learning, and a wide range of design-rationale and FAQ type systems such as the Answer Garden (Ackerman and Malone 1990) and gIBIS (Conklin and Begeman 1998).

We do not advocate either an exclusively passive or active approach to computational media in support of learning. Rather we see that the optimal solution will combine and integrate a variety of media to allow users to choose tools that best suit their needs at a particular time.

Time and place of learning
A key feature of ‘flexible delivery’ through computer supported learning tools is that it frees students from the need to be in a particular place at a particular time.

There are several important implications of this capability. Firstly, the flexibility gained broadens the potential student base, opening a wide range of educational possibilities for ‘lifelong learning’ for the full-time employed and those with family commitments. Secondly, the perennial problems of time-tabling clashes need not exclude students from particular courses. Thirdly, lecture theatre capacity no longer needs to constrain course sizes. Fourthly, on-line media can be reviewed as many times as the student feels is necessary. Traditional lectures, in contrast, are a once-only medium, and students who missed the lecture or temporarily lost attention have no way to review the real-time explanation. Finally, the freedom from time and place constraints opens the possibility of globally competitive education markets. Commercial Internet-based education resources such as stanford-online.stanford.edu and unext.com are early entrants into this market.
Support for collaboration

Traditional courses, taught at residential universities, provide a natural infrastructure for supporting and promoting peer learning. One of the risks of ‘distance education’ is that the lack of physical proximity will act as a barrier to this valuable resource.

On-line systems can support collaboration through simple text-based bulletin boards, through collaborative simulation and exploration environments that explicitly account for multiple users (for example TurboTurtle’s synchronous collaboration (Cockburn and Greenberg 1998) and AgentSheet’s asynchronous collaboration (Repennig, Ioannidou, and Phillips 1999)), or by supporting collaboration around a passive medium such as recorded lectures. Of particular interest to us is the notion of supporting collaboration around video recordings of lectures. In an early study on video-based instruction, Gibbons, Kincheloe and Down (1977) showed that learning can suffer when students watch lectures individually. However, by supporting discussion and collaboration around the video using the “Tutored Video Instruction” (TVI) model, learning improved over traditional lectures. Subsequent research, such as that reported in Cadiz, Balachandran, Sanocki, Gupta, Grudin, and Jancke, (In Press) has begun to investigate distributed versions of the TVI model, where physically remote students are connected to each other by multiple audio/video feeds.

A final issue is that of equity between students participating remotely and locally. Anecdotal evidence indicates that remote students in ‘live’ video lectures (one-way video, but two way audio) felt like ‘second-rate participants’. Some of the students, however, may value the more relaxed atmosphere of a video-linked lecture—for example, walking out of the theatre mid-lecture without disturbing, or being seen by, the lecturer.

Capital Investment, Effort and Social Factors

The final dimension that critically affects the nature of on-line learning support is the degree of capital investment and effort put into developing the resources.

Institutions with a long history of supporting distance education—for example Stanford University in the U.S. and the Open University in the U.K.—make large capital investments in producing high quality media such as broadcast quality TV lectures/documentaries to support their courses. These financial outlays are then amortised over thousands of students across the entire nation, and over several years.

Clearly, not all teaching institutions can compete for distance learning students against highly commercialised alternatives. The question then becomes the following: how can traditional residential universities best use their available resources to enhance their support for learning?

Beyond the resources dedicated to on-line courses, there are also many social factors that must be addressed in preparing courses for flexible delivery. Systems that depend on lecturers and course administrators changing their teaching habits may promise a wide range of learning benefits to students, but if the lecturers fail to make the necessary changes then no benefits can be realised. Furthermore, many lecturers have concerns about issues such as copyright, liability and job-protection when every action and utterance in the lecture theatre is captured on multiple media.

Canterbury’s Digital Lectures Project

The goal of Canterbury’s Digital Lectures project is to develop mechanisms for flexible delivery of conventional lectures that enhance learning while requiring no modifications to the lecturer’s teaching methods. Like related work on the Cornell Lecture Browser our goal is “to allow a speaker to walk into a lecture hall, press a button, and give a presentation using blackboard, whiteboards, 35mm slides, overheads, or computer projection. An hour later, a structured document based on the presentation will be available [...] for replay on demand” (Mukhopadhyay and Smith 1999).

The main difference between our work and that of the Cornell Lecture Browser is that we focus on the ways in which students used the end-products, while Mukhopadhyay and Smith focus on the technology used to generate the end-product.

The Student’s Interface

Figure 1 shows the prototype interface to a digital lecture. In this prototype there are two video streams, represented by the thumbnail images at the top-middle of each window. In Figure 1 the user has chosen to watch a broad video stream showing the front of the lecture theatre, including the lecturer and the overhead projection screen. In Figure 2, the user has clicked on the other thumbnail image to zoom into the text on the overhead material.
-of-oz' technique (Gould, Conti, Hovanyecz, 1983) that used human input to simulate the automatic capture of the digital lecture. The student's interface, however, was unaffected by the 'wizard-of-oz' data capture. During the lecture, a camera-person operated the camera. The feasibility of automated camera management is demonstrated by Liu, Rui, Gupta and Cadiz (2000) who show that most people could not tell whether lecture room video was captured by a person or by an automatic system. After our lectures, an operator ran a series of programs that captured and burnt the lecture contents onto a CD-ROM. The programs translated the digital video (DV) tape into a motion-JPEG stream with a synchronised MP3 audio stream. Finally, the operator watched the video and created hypertext links—identifying topics in the lecture—synchronised with the video stream. Again, the feasibility of automatic techniques is demonstrated by Mukhopadhyay, and Smith (1999) who describe techniques for automatically identifying slide changes and by Wellner (1993a, 1993b) who discusses techniques for retrieving text from video-images.

The CD-ROMs (one for each lecture throughout the course) were available for students to use in the university library. Using CD-ROMs as a distribution medium allowed us to closely monitor use of the medium, and we required students to complete a questionnaire each time they used a CD-ROM.

**Evaluation and Results**

In the second semester of the year 2000 academic year (July to October), digital versions of each lecture in the large (746 students) first year Computer Studies course were made available to students. At the start of the study, students who wanted to use the digital lectures were required to sign an ethical consent form. Ninety-four students requested to do so.

Initial use of the system was extremely light, with only four students attempting to use the system throughout July and August. At the same time lecture attendance appeared to be lower than during the previous term.

In September only two people accessed the digital lectures. As a result, the course lecturer sent an email message to the class asking whether it was worthwhile continuing to make digital lectures available. Much to our surprise (given the extremely low use of the system until then), fifty-three students replied, strongly urging us to continue producing the lectures. Comments from the students in their email replies indicate that many had been *intending* to use the digital medium for some time, but had not got around to doing so:

> Do you intend to view the Digital Lectures before the COSC110 exam?

Yes I do intend to use the lecture disks but mainly for the lectures I've missed or need to brush up on (that's probably all of them if I was completely honest)
> When are you likely to want to view them?
I intend doing this over the next few weeks when time permits (I work full time)
> Have you tried to use the Digital Lectures already?
No I haven't used them at all yet, so I'm one of the guilty that signed up and
not used them.

Despite the appeals for us to continue, only seven students subsequently accessed the CD-ROMS.

Discussion
It appears that students deceived themselves about their intentions to catch up on lectures using the digital alternative. We hypothesise that by making lectures available at any time, we removed the need for students to attend the 'live' lecture. Normally, the 'live' lecture is a one-off event, and if students miss it their chance to benefit from it is gone. The damaging part of the digital media (in our experiment), however, is that the students never fulfilled their intention to access it. Gerhard Fischer (private communication) suggested a 'local traveller' analogy to explain this effect. It is not uncommon for residents in an area to have never visited some of the local attractions: they intend to, but the attractions are constantly available, and there is no pressing need to visit them immediately. Tourists visiting the area, however, typically have only one opportunity to see the sights, and consequently make concerted efforts to ensure that they exploit it. By making lectures freely available to the students they were able to postpone viewing the lectures because "they'll still be available tomorrow". Like local residents, these intentions are sometimes postponed indefinitely, or until too late.

Conclusions
Advances in desktop multimedia and the World Wide Web have brought about a wide range of new possibilities for education. Many research projects are exploring the possibilities of the technology while others are deploying first generation systems. This paper investigated some of the possibilities and problems of virtual learning systems. In particular, we reported the somewhat surprising results of a four-month trial of the Canterbury Digital Lectures Project. In essence, the results of our trial suggest that providing too much flexibility to students at a residential university can have negative learning results. By providing a digital surrogate for 'live' lectures, it appears that students made less effort to attend the lectures, and that they never fulfilled their intention to catch up using the digital media.

In retrospect, it is unsurprising that misplaced technological support can have negative effects on learning (or at least on class participation). In our further work we intend to address the questions that identify the conditions under which learning technology is well placed. For instance, we would like to know whether our technology would have had a positive effect if we had used the web to bring the lectures to students who could not otherwise have participated in classes.

Abstract: Urania (www.cieloblu.it) is a weekly Web Astronomy and Astronautics news-bulletin, in the Italian language, created by professional astronomers. It is addressed to both young people and adults who are interested in or curious about Science. The users can see Urania and listen to it by connecting with its Real Video version or they can read the news as in a normal Web Site. Urania makes the most of all the Real Video technology to give information in a fast, funny and stimulating way. Its intent is to bring people, in particular young people, closer to this Science, taking in consideration the fact that Astronomy is a challenge and an adventure, still full of unknown and undiscovered aspects.

Introduction

Urania (www.cieloblu.it) is a weekly Web Astronomy and Astronautics news-bulletin, in the Italian language, created by professional astronomers. It is addressed to both young people and adults who are interested in or curious about Science. The users can see Urania and listen to it by connecting with its Real Video version or they can read the news as in a normal Web Site. Urania is the latest initiative of "Prendi le Stelle nella Rete!" ("catch the stars in the Net! www.lestelle.net for the Italian version also available in English language at www.astro2000.org). It is a Web-based project for education and outreach in Astronomy, managed by the Astronomical Observatory of Padua (Italy). Since 1997 this research Institute has been engaged in astronomical Education via the so called new technologies. This is also one of Urania’s most important features: for the first time, information for the public is directly produced by experts (astronomers) and not only by professional journalists.

Urania is an innovative way of satisfying the ever increasing interest in Science especially among young people - particularly in Sky and Space - using rapidly evolving technology. The Net and the new technologies are the most used form of media among teen-agers and so, in our opinion, the best for involving them. For this reason Urania can be very useful at School, both as an educational support, and as an informative tool to stimulate curiosity, questions and research.

Furthermore Urania can be considered a “format”, that is its design can be used for the outreach in other Sciences and contents, for example video-lessons, distance-learning, and so on.

In addition, Real technology adapts itself to the band-width available: on one hand, it implies that users with low band connection can make use of it. On the other, it is ready to take advantage of the high band connections that will be available in the very near future.

Why Urania?

The interest in Science is growing every day, and more and more space is given to it by the press and TV. Moreover, Science and technology are becoming more important in the culture and daily life of the new millennium. Italy is very involved in astronomical and Space research, even if the Nation doesn’t seem to be so informed about it.

Teen-agers are very interested in novelties and are fascinated by Space, which they see as mystery, charm, adventure and discovery. Italian boys and girls read more than the national average (almost 70% of children aged 5-13 have read at least one book during the last year, compared to 41% of adults, Doxa, 2000) and 48% of Italian children use the PC (Istat, 2000). Finally we must point out a fact that is usually forgotten: over 80% of Italian schools, have
multimedia classrooms and over 75% are connected to the Net (MPI, 2000). They don't use often this machinery because of a great lack of contents suitable for the utilisation in the classrooms.

In this situation, Urania was not born with the purpose to teach, but to inform in an exciting way. It uses a different technology from newscasts, radio-news, and also from the Web. For this reason its way of communicating and its language are new and still in evolution. Sentences are short and the style is dynamic. The language is simple, it does not use technical words, but it always keeps its scientific correctness.

**What is Urania?**

Urania is a weekly Web news-bulletin of Astronomy, space missions, sky events, curiosities. You can read the news-bulletin with a common browser (for example Internet Explorer or Netscape Navigator). To listen to it you need a Multimedia PC and Real Player. If you don't have Real Player, you can download it free from the Net. You can do it very easily, and you can find the instructions on the Urania site itself.

We choose Real Player for different reasons. First, it is one of the most common tool for visualise video and audio information on the Net. Then, it adapts itself to the band-width available so that users with low band connection can make use of it too (actually Urania is optimised for 28.8 Kbps connections, the most widespread in Italy). Finally it is ready to take advantage of the high band connections available in the near future.

Every issue of Urania is the result of a series of intermediate steps. First, every week the staff discusses all the news from reliable and checked sources (Space Agencies like Nasa or Esa, Research Institutes, Scientific Magazines, Press Agencies). Then, the staff chooses the most relevant news in the scientific field and the most curious or fascinating ones.

We give special emphasis to the consequences of astronomical and aerospace research on everyday life, with particular attention to European missions. In addition we try to expose correctly all the information heard on Television and Radio stations by our users, without excessive sensationalism or wrong knowledge.

So, we can satisfy our audience expectations and meanwhile we can give information with a scientific correctness. If possible, we interview astronomers and scientists engaged in such researches.

The news bulletin is made up of four articles, that each last for one minute length. In the Real version there is also some short news. Reading or listening to Urania requires a few minutes, and always less than ten minutes.

The first article is a scientific one: its aim is to deal with a particular concept or astronomical problem. The other ones are more informative.

Every article is illustrated by three images. These images are professional pictures or drawings taken by the most important terrestrial and orbital observatories. The pictures are carefully chosen for their suggestive charm.

The Web version of Urania contains the same four articles. Here, the users find special thematic cards where they can deepen specific arguments (planets, black holes, Big Bang...). All the articles are recorded every week and the users can find them using a temporal index or a special search engine.

**Conclusions and future views**

Urania makes the most of all the Real Video technology to give information about the astronomical and astronautical news in a fast, funny and stimulating way. Its intent is to bring people, in particular young people, closer to this Science, taking into consideration the fact that Astronomy is a challenge and an adventure, still full of unknown and undiscovered aspects. Therefore we are trying to make Science a natural part of common life, stimulating discussions and investigations at home or at school.

There are many possible developments of Urania. In particular we think that:

- it could become a daily news bulletin, with more integration between Web and Real Audio technologies;
- its format can be used for the outreach of other sciences and contents, for example videolessons, distance-learning, radio, etc...;
- it can be used to provide teachers, who use Urania in their schools, with monothematic lessons, according to their needs;
- it is ready to take advantage of the high band-width connections, which will be available in the near future.
The Virtual Planetarium: The use and improvement of a Website as a case study of collaboration between Scientists, School Teachers and Students

Leopoldo Benacchi1, Melania Brolis2, Giovanna Mistrello3
Astronomical Observatory of Padua
Vico lo dell'Osservatorio, 5

1benacchio@pd.astro.it, 2brolis@pd.astro.it, 3giomistr@tin.it

Abstract: The "Virtual Planetarium" is an astronomy course on the Web developed in the '98 and refined in the last 3 years with the integration of the experiences gathered in several classrooms over the Country. The course is part of a more complex Project of didactics and outreach of Science (catch the Stars in the Net! www.astro2000.net) via the new technologies. The practice in the use of the network in these years allowed us to develop a new method and approach both to didactics and outreach. The main point is not a technological one, but is represented by the use of a strict and direct collaboration between scientists, teachers and children. All these "actors" are needed to develop a successful piece of multimedia for kids and students.

The "Virtual Planetarium" is part of a more complete and complex project, carried out at the Padua Astronomical Observatory, in Italy.

The "Catch the Stars in the Net!" Project

Catch the Stars in the Net! is an Education and Public Outreach program carried out by the Padua Astronomical Observatory, with the support of the main Italian telephone and Internet Company: Telecom Italia. The Project is in fact based on the Web and the so-called "new technologies" of communication (www.astro2000.net for the international edition or www.lestelle.net for the Italian one). The Project started in 1997, after an Exhibit of Astronomy organised by the Observatory in collaboration with several technological sponsors. The success of the event forced the authors to decide a radical change of approach to the public outreach: to use the Network and other emerging technologies to approach the public, especially young people.

A new working method, more complex and time consuming of the traditional one, but also more interesting and rich of results was adopted. The project produces the Web site, but every initiative, studied and realised by the astronomers, is first of all proposed to a focus group, Schools if didactics is concerned, a group of "typical" users for public outreach. The initial version is given to these users, from which suggestions, criticism and remarks are collected and used for the production of the final release. Only after this procedure a module or an initiative becomes public in the Web site. In other words the Web site only represents the "visible" part of a more complex project of education and popularisation of our Science. The goal is to satisfy the interests of the Internet surfer who wants to learn some Astronomy concepts, or who is simply curious about these themes. At the present, several levels are satisfied: from the Primary School children to the Secondary School students, to adults that want to "know more" about the sky.

The Project received a lot of awards from the public and the critics (i.e. 1998 New Media Prize, 1999 Kidscreen Digital Kids).

Astronomers, Students, Teachers and the Network

In this framework the collaboration between the Public School and the Padua Astronomical Observatory has been of crucial importance for the success of the Project itself. Teachers and children collaborate with the Astronomical Observatory of Padua, experiencing, as a "focus group", all the modules of education and public outreach of the project before the public release. They tested especially the "Virtual Planetarium", a multimedia course on Astronomy and Astrophysics for the young students (10-13 and 14-18) before the publication in the public Web. They used, analysed and criticised all the more than 200 pages of the whole course, in terms of contents, realisation, comprehension, language used etc. In a couple of months the
testing phase became an actual collaboration between "the scientists", the students and the teachers. They became, day by day, co-authors of several initiatives.

The main aim was, at the first attempt, to have a "beta testing" phase of the different modules of our sites for school and public. This goal has been of course reached, but both, students and teacher, started in discussing with us on the contents, method etceteras, as from their point of view. This criticism and suggestions give us the means to integrate new chunks in the main module, the astronomy course Virtual Planetarium, and then to add new modules to the Website, to ameliorate the language used, to clarify several important points on the target audience. In a few words the teacher and the students collaborated with us for all the year, giving a not trivial example of use of multimedia and learning by network capabilities.

We can without any doubt that the Website, that received two Awards in the 98 and 99, is certainly so useful and used by students in Italy also thank to this new method of collaboration between the researcher and the students, via the intelligent action of the teacher. The collaboration is still working and the aim is to ameliorate and develop the site also thanks to the suggestions and criticism from these young "consultants".

From 1998 some 20 classes and 500 students studied Astronomy with the Virtual Planetarium and gave their precious criticism, suggestions, results.

In the last year, they collaborated also, via the Net, with a School in Argentina (Liceo Informatico, Santa Rosa, Argentina) that also use the Website, exchanging data, information on different seasons, etc. This collaboration is now widening also to other areas different from astronomy, and a student exchange activity is forecasted next year. Of course, the use of the Website (www.lestelle.net or www.astro2000.org) is embedded in a didactical layout designed by and with the teacher month by month.

We can conclude that students not only learned astronomy, they learned also how to use the Web and to integrate several media (computer and networks, books, lessons of the teacher, hands on of astronomy) in the learning process. They learn also to positively criticise the course, to discuss with the producers and to explain to the producers themselves how to ameliorate the product, from their point of view.

The Website and the "Virtual Planetarium"

The site is composed of didactic or popular "modules", organised in different levels of complexity and depth, in order to meet the specific interests of the user. Each module presents careful links to the other sections of the Project, thus offering the possibility of going in depth in other Astronomy themes, but without the risk for the user to "lose his bearings" and be overloaded with information.

The site is accessible to everyone, but each modulus is designed with a privileged user in mind (i.e. teachers, students, less than 10 years old children, teens, curious and simply interested). A careful modality of exposition of contents and themes (i.e. didactics, outreach, history, curiosity/news and communication) is used in the design of the site.

For what concerns didactics, we have to spend a word apart for the Virtual Planetarium, a module of the Project that is nowadays an example and reference in the teaching of Sciences via the Internet in our Country. The Virtual Planetarium is in fact used by a lot of schools in their scientific curricula and by individuals. Using this site as a real interactive course of Astronomy, students can experiment with a new way to learn. It is a lively way that surpasses the traditional limitations of texts. This gives the opportunity to learn the arguments following a favourite way and with an adequate rhythm to individual capabilities. You learn by yourself, that is a very good way to learn.

The Virtual Planetarium is an interactive Astronomy course via Internet for 10-18 years old students. It contains 27 didactic chapters, in which there are the main themes of Astronomy, from the Earth and the theory of gravity to the stellar evolution and cosmology.

The course contains more than 800 text pages, hundreds of pictures, movies and animations, and also virtual experiments, all specifically build for the project.

The Virtual Planetarium can be used as a self-learning tool and as an aid to teachers who can adapt it to the scholastic curriculum and to the peculiarity of each class of students.

The chapters are independent, so that they can be explored one by one and then appropriately inserted in the annual curriculum. A peculiar didactic method is used in the teaching of Science (Karplus Cycle), by cutting a priori misconceptions. Wide space is given to the "teacher page", containing the experiences of teachers that have adopted the Virtual Planetarium in the scholastic curriculum.
Abstract: Energy-efficient solar architecture is of great importance for sustainable development of future societies in both meeting tougher energy standards and reducing greenhouse gas emissions. Experiences on passive solar and energy conscious building meanwhile exist due to recent research and technical development programs. The results however are not at all widespread. The software "Interactive Study & Seminar of Innovative Solar Architecture - ISIS Architecture" intends to assist education and training of architects with respect to energy-efficient building. ISIS Architecture combines lectures on energy-efficient architecture with calculation tools and an encyclopedia to give a feeling for the importance of low energy and solar architecture, to provide basic knowledge of design concepts for innovative building and to allow for direct application of the acquired knowledge to solve practical design tasks.

Introduction

For modern architectural education it is of great importance to integrate new social and technical developments to cope with new ways of designing buildings - naming e.g. revised building energy standards and regulations. Electronic media offer an opportunity to visualize innovative results from R&D-projects, present them in an informative and appealing learning environment and thus give students and professionals the possibility to keep up to date with knowledge needed to solve design tasks.

Content of ISIS Architecture

In a multimedia way ISIS Architecture shall firstly introduce learners into the basic principles of energy-efficient building. ISIS Architecture explains why there is a necessity to reduce energy consumption and greenhouse gas emissions for buildings during the whole life-cycle of architectural projects. Overviews about global and national energy consumption and greenhouse gas production are linked to topics like building comfort, green building, energy demand and energetic analysis of buildings. Building examples illustrate practical aspects of innovative architecture. Following the design path of architectural projects ISIS Architecture goes from general into detail, e.g. from the first draft concerning orientation of zones and façades to lessons on passive solar design of

![Figure 1: Content of ISIS Architecture goes from general into detail – e.g. from greenhouse effects to window design.](image-url)
buildings, energetic optimization of components and how to implement low energy technical equipment [Figure 1]. Links between chapters, from chapters to glossaries and also to external resources allow students to choose their own degree of going into detail for their individual learning process.

Interactivity

Calculation tools [Figure 2] are of major importance for the concept of ISIS Architecture. Learners shall work on exercises to model buildings or building parts in adaption to real design situations. By the interactive combination of lectural content with practically relevant design tasks the knowledge transferred with the help of ISIS Architecture is immediately applied and thus anchored in the learning mind, remembering what Confucius said: "What I hear, I forget. What I see, I remember. What I do, I understand." This is a major advantage of interactive new media over traditional books or lectures. Moreover all calculation tools stay with the learner after completion of classes and prove to be valuable helpers for everyday work. A quiz lets learners check their achieved degree of understanding by recalling relevant facts and definitions and solving illustrative problems.

Distribution to users

ISIS Architecture is available in German language. A free demo version is provided at the website of the Group for Building Physics & Solar Energy, University of Siegen at: http://nesal.uni-siegen.de/. Distribution to other universities takes place within the Universitätsverbund MultiMedia of North Rhine-Westphalia, Germany. The BauNetz – a major Internet content and service provider for the building sector in Germany – intends to integrate ISIS Architecture into its web space for architects and other building related professionals.

Conclusion

The authors feel that educational multimedia software like ISIS Architecture can efficiently improve architectural education and information regarding low energy and solar architecture aspects, for students as well as for professionals. The concept of ISIS Architecture makes it well-suited to play a helpful role in this regard.

Acknowledgements

The authors thank the Universitätsverbund MultiMedia and the AG Solar of North Rhine-Westphalia, Germany, for financially supporting the project. The BauNetz Online-Dienst GmbH & Co. KG, Berlin, makes a large own contribution to the project's costs. We thank Prof. Müller and his team, Lehrstuhl Klimagerechte Architektur, University of Dortmund, Prof. Bohne and Prof. Zumbroich, Dept. of Architecture, University of Siegen.

Developing Web-based Courses on Computing Using a Hypermedia Model

J.V. Benlloch, F. Buendia, M. Agustí, J. A. Gil, A. Rodas
DISCA
Escuela Universitaria de Informática
Universidad Politécnica de Valencia
46022-Valencia, SPAIN
{jbenlloc, fbuendia, magusti, jagil, arodas}@disca.upv.es

Abstract: A large number of courses, teaching several computing and engineering subjects, has been developed using the Web as a delivery medium. New generation material includes features such as a high interactivity and the integration of multimedia educational resources. Moreover, the complexity of teaching new technologies attached to disciplines like Computing, requires the application of modern methodologies to organize the multiple relationships between the information items. This paper proposes the use of the Labyrinth hypermedia model to represent the structure of multimedia components involved in a web course and the ways to interact with them. It also introduces the mechanisms to translate this abstract model to an implementation based on open and standard web technologies such as DOM, XML, HTML and Java.

Since its creation, the World Wide Web opened up the possibilities of global training, which can be accessed by any user, at any time, and from any location. This circumstance has determined the development of a lot of courses teaching multiple subjects and using the web as a delivery medium. Web-based courses have been classified (Steed 1999) into three general categories: text and graphics courses, interactive courses and interactive multimedia courses. Most of the current courses fall into the first category and they are close to the traditional book-based courses. Second category shows the importance of interactivity as a way for engaging the user's mind and stimulating the learning. The introduction of multimedia elements in the third category adds richer resources for enhancing the effectiveness of the user learning.

The development of web-based courses in areas such as Computing and other technical subjects shares previous features. Most of them have been developed as a support or a complement for the traditional book-based courses. They are oriented towards university degree students and in this context, it is not frequent the use of specification and design methodologies so the resultant application is hard to keep updated or being reused. However, the topics taught in these courses are associated to complex technologies that combine a lot of concepts that can be viewed from different points and accessed through multiple paths. Hypertext models are good candidates to represent these units of information and their links, but they are unable to describe contents of multimedia information and their temporal and synchronisation relationships. Furthermore, computing courses have experimental and technical features that make interesting the deployment of interactive and multimedia resources as components of the course. More advanced courses introduce this type of resources such as simulations, access to remote laboratories, graphic animations, virtual reality scenarios, ... Such resources enhance the description of a topic but introduce more complex relationships as well. In this context, hypermedia models provide a powerful way to represent this kind of resources and also to model sophisticated navigational capabilities.

There are several hypermedia models but most of them are limited to specific authoring or programming tools. Other models cannot be used to define some features of hypermedia applications such as the heritage of common characteristics between elements of the model or the creation of dynamic links. The current paper proposes the use of Labyrinth hypermedia model (Diaz et al. 1997) for specifying web-based courses on Computing.

An abstract model like Labyrinth is a powerful tool for designing hypermedia applications such as a web course. It provides an unambiguous description of the static components of a multimedia course as well as the definition of the dynamic interactions between these components. The Labyrinth model represents a hypermedia application by means of a basic hyperdocument. In addition, each user or group of users can have a personalized hyperdocument in which users can adapt or modify the components of the basic hyperdocument to their own requirements (e.g. student's knowledge in order to get an individualized learning). The basic hyperdocument is composed by the following elements: Users, Nodes, Contents, Anchors, Links, Attributes and Events. A contribution of the paper is the management of active contents such as simulators and other program based
resources, within the Labyrinth model. This includes the management of events to obtain relevant information related to the use of these resources.

In the context of Computing, an example of hyperdocument has been generated to show the application of the former model. It is part of a distance learning project at the School of Computing in the Universidad Politécnica de Valencia. Fig. 1 shows the distribution of elements in the hyperdocument example having a root node ("Introduction Node") which presents the basic concepts of the Memory Management. The first part of the node includes a special type of content (contextual), called "Introduction guide" that acts as the plot of the remainder of contents. The next content is a definition of the memory concept from an operating system point of view. It has attached a graphic animation content that shows a graphic and interactive view of an example of memory area.

![Fig. 1: Example of hyperdocument.](image)

The paper also presents a design strategy to create web-based courses from a hypermedia specification. To date web application development has been focused on the tools and little attention has been paid to the development process itself. In (Fraternali 1999) there is an overview of tools for web development, mainly oriented to data-intensive applications. Other approaches such as the presented in (Conallen 1999) intend to model a web application using a formal notation (e.g. UML). For web applications, there is an object oriented model called DOM (Document Object Model), which is becoming a web standard [http://www.w3.org/DOM/].

The option chosen here is the use of the DOM as the basis to implement Web-courses. Its main purpose is to define "a platform - and language neutral interface - that allows programs and scripts to dynamically access and update the content, structure and style of documents". DOM can use HTML to represent most objects of a Labyrinth course specification. However, the HTML format imposes the presentation aspects when the course document is browsed. In order to separate the course contents from the visual presentation of these contents, a language such as XML (Extensive Markup Language) can be used. XML allows the author to define his own tags and his own document structure. This aspect is fundamental in the course design because in this context, there are multiple sources of information each one with its own structure and characteristics. Some of these sources can have a predefined syntax.

In this work, one of the main contributions is to show how to translate the Labyrinth entities to a model like DOM based on entities such as Document, Nodes, Elements or Attributes. The main problem to apply these design and implementation strategies is the lack of tools to support them. Future works plan to develop this kind of tools.

Learning About Multimedia Design Through Real-Life Cases

Sue Bennett, Barry Harper & John Hedberg
Centre for Research in Interactive Learning Environments
Faculty of Education, University of Wollongong
Wollongong NSW Australia
Email to: sue_bennett@uow.edu.au

Abstract: Constructivist and situated approaches to the design of multimedia and Web-based learning environments have sought to engage learners in authentic activities set within meaningful contexts. Real-life cases can be used to support authentic activity by presenting learners with complex, realistic situations. In this study two such cases were developed for analysis by students in a graduate level instructional design subject. A range of data was collected and analysed to gain a fuller understanding of the ways learners engage with the case-based materials and how they use their interpretations to support the design of their own multimedia projects.

Introduction

Providing a meaningful context in which learners can engage in authentic activities has been the aim of many recent applications of constructivist and situated approaches to the design of interactive learning environments. Multimedia and Internet technologies have been used to support such learning experiences by facilitating access to dynamic information and resources (Natesan & Smith, 1998); representing realistic environments and situations (Harper & Hedberg, 1997; Herrington & Oliver, 1997; CGTV, 1997; McLellan, 1991) and; providing access to computer-based cognitive support tools (Jonassen, 1996; Jonassen et. al, 1999).

Within these contextually-rich technology-supported environments, a case-based approach is one way to engage learners with complex, realistic situations (Jonassen, 1999). However despite the historical and continuing popularity of case-based methods there is a significant gap between theory and practice and little is known about how learners build their understanding through cases (Sykes & Bird, 1992).

For instructional designers the task of working in an unfamiliar discipline to help content experts create a learning experience requires them to draw upon both conceptual knowledge of learning theory and its practical application. Design problems are not always well-defined or amenable to rule-based solutions. Instead a range of contextual factors must be taken into account to reach the most appropriate solution (Tessmer & Richey, 1997).

Realistic cases which present design problems and solutions with all their attendant complexity may provide learners with an opportunity to gain an understanding of the context within which a product was developed, thereby providing insights into the process (Ertmer et. al. 1996).

This study aims to explore the ways in which students in a graduate level instructional design subject engage with a case-based learning environment and to discover how they make use of their interpretations in the construction and application of their knowledge. A better understanding of the learner's perspective may suggest improvements to the instructional strategies and support tools used within these kinds of environments.

Case design and implementation

Preparation for this study required the design, development and formative evaluation of suitable case materials. Two cases were chosen for full development, each focusing on a multimedia CD-ROM product developed by the Interactive Multimedia Learning Laboratory at the University of Wollongong. The case materials include an overview of the project, a timeline of major events, interviews with key informants and access to original documents and prototypes. These resources were developed from interviews with project staff and examination of archival materials including project diaries, meeting notes and communication records.

The cases were implemented in a Master of Education subject which focuses on the development of a multimedia product or prototype for a 'real' client. Students worked in teams to develop a concept into a formal design statement and
then into an instructional multimedia package. Case analysis and discussion questions were included to assist students develop their understanding of the cases through individual and group activities. Students worked through open-ended questions individually, then took part in small-group and whole-class discussions. These activities ran in parallel with the team development of a multimedia project which addresses a complex, realistic design problem. Finally, project teams prepared a written case documenting and reflecting on their own experience.

Analysis and findings

The subject has been run with two class groups – one based in Wollongong and one based in Hong Kong – comprising 27 students in total. Although the materials and requirements were the same for each group, differences in the schedule of group meetings and access to resources and instructors require that each class be considered and analysed as a separate case.

Assessment tasks, class activities and interviews comprise the primary sources for the rich set of data collected for this case study. Student work has been sourced from writing activities and multimedia design tasks. Semi-structured interviews with half of the participating students provide further insights into the ways learners have interpreted and made use of case materials. Observations made during class meetings, records of electronic discussions and interviews with the main instructor provide additional sources of data which may raise further issues for consideration and provide support for interpreting other data. The researcher's own reflections have also be recorded throughout the investigation.

Upon completion of data collection, student work and interview transcriptions have been coded and analysed to identify categories and themes. Coding schemes for students' written and interview responses were derived from the research questions and other themes which have emerged from the data. Coding for assessment work was also based on the assessment criteria and evaluation protocols from the literature as appropriate.

A comparison of responses given by each student highlights the similarities and differences in their interpretations and experiences, whereas an examination of a student's responses across the data collection phase indicates the changes in their understanding over time. Differences between the two class groups may provide insights into factors such as distance, culture and the role of technology.

Preliminary analysis of students' case analysis responses suggests that these cases encourage learners to focus on the design process rather than on the end-product, and that they use their past experience and interpretation of the literature to frame their analysis of the case events. Further findings will be included in the presentation of this paper.

Creating An Active Learning Environment Using Digital Video
What I Did And How I Did It

Alfred Benney
Fairfield University
Fairfield, CT 06430-5195
benney@fairl.fairfield.edu

Abstract: This is a case study presentation of an undergraduate experimental course in Religion which uses digital video clips to engage students in conversation and debate on the subject matter. We will consider how the digital video resources were developed, rationale for the course structure and expectations, outcomes and student responses, and finally we will give a short simulation of the class itself. The audience will be invited to join in a conversation regarding the application of these pedagogical resources and strategies to other disciplines.

I The Rationale

In humanities education, student engagement in content questions and issues is often difficult to stimulate because of their perception that theoretical questions are disconnected from everyday life. In particular the study of religion is often assumed to be an exercise in propaganda or a recitation of "unprovable propositions" unrelated to practical life skills. How student perception and expectation influence their ability to learn in any given course is an interesting component of teaching strategy development. Robbins (1991) suggests that the culture of the classroom which is perceived as biased towards theory is at odds with the culture of a working discipline which is oriented towards problem solving (see also Resnick, 1987).

It is clear when one explores the work of dedicated scholars in religious studies that there is a value to their efforts to understand this complex human phenomenon. If a person hopes to be successful in working with Mormons, or Conservative Christians, Moslems, Buddhists or Hindi, it would be useful to understand their "world philosophy." Personal issues of mortality and death often motivate people to explore solutions proposed by religion. Consequently, it is not hard to imagine that contact with these systems in an educational environment would be a worthwhile thing with real and practical consequences.

Most certainly video is a successful medium for taking students into the field to observe facts, processes and emotional events which would otherwise be impossible to see and experience. That is the nature of a good documentary. The dated but very interesting work by Jerry Mander raises several pertinent questions on how television (video didn’t really exist then) changes the way people perceive reality (Mander, 1978). It is also a passive medium that implies that students are like sponges absorbing the (often unusual) information served to them by the "film." In the end, this is a rather boring educational strategy. It also implies that getting information is the same as learning. The notion that “Video is now conceived as an information destination . . . where students can go to experience multi-sensory learning synchronously or asynchronously” and using further catch phrases as “information rich environments” seems to suggest no further pedagogical strategies are needed beyond exposure to video (Lynch, 1998).

Dr. Thomas Reeves points out that “Technology [including video or even a telephone] is best used as a cognitive tool to learn with rather than a surrogate teacher. Pedagogy and content matter most; technology and media are only vehicles. . . .”(Reeves, 1998). And so the thrust of this experimental application focuses on the question, how can the teacher use digital video as an effective learning tool?

It is possible to use video to bring "experts" into the classroom and to use them to change the dynamics of the classroom learning environment (Benney, 1999). Using video to create a dialogue between students
and the author of their text, for example, would involve some of the students\textsuperscript{1} in an active learning situation and would be a very desirable classroom strategy. Undergraduate students seem not to respond well to courses that are conceptually based in theory or a global setting. But if the beginning point for learning is in some way brought into their classroom and if the data presents a challenge to their commonly accepted "answer," they more readily engage in a learning conversation (Benney, 1996). Milton Glick and others points out "... that it is not what the teacher does but what he or she gets the students to do that results in learning" (Glick, 1990).

Finally, videotape programming is unwieldy to use because of the time delay in queuing the tape to the appropriate cut and risking the possibility that it is really the wrong cut! But technology can provide us with an easily developed system for access to video data -- one that anyone can use.

II An Experiment

So why not digitize cuts of scholars commenting on essential questions in their discipline, burn the digitized video onto CD-ROMs, create an index using a common Windows program so that it is easy to que up the response of each expert to a particular question and take the whole package into your classroom. Now create a course in which you ask students to read a text and then introduce them to the author "in person" and allow them to dialogue with the expert with you as the mediator.

At Fairfield University I am teaching an undergraduate course on an experimental basis that focuses on this pedagogical strategy. Using video clips from a database of more than 350 video clip commentaries by notable scholars of religion in America, I have structured the course to alternate between discussion of text and conversation with the scholar who presents his/her ideas via the video clip. Student response has been good.

III Overview

There are two issues central to the experiment. First, the technological "product" must meet a certain standard. Is it possible to produce and process video that is "adequate"? Is it possible without great expense to produce digital video programming, edit and process the programming and burn it onto CD-ROMs and get at least 1/3 screen viewable programming?\textsuperscript{2}

The second issue is the question of pedagogical strategies. What can the teacher do with the programming that he/she could not otherwise do? Why video rather than text? Why not web-based exploration? Just looking at "moving pictures" does not in itself do anything more than provide the experience of watching moving pictures perhaps entertaining, but not by itself educational. It is clear

\textsuperscript{1} Based on input from students themselves, I do not think it is reasonable even in an elective course to expect that all who are there are either willing to learn or to participate. Since class participation is evaluated in my classes, students will on a regular basis (about 10%) explain to me that they are "shy" and never participate in class. The actual number who never participate varies, but seems to average around 20%. This certainly needs further study, but it is not reasonable to expect that participation will ever be 100% in most undergraduate classes.

\textsuperscript{2} Many video pundits suggest quite strongly that "talking head videos" are of little production value. But with the exception of sports programming and the likes of "action" movies, much of what is available on commercial TV is exactly that. What really seems to matter is whether the "talking heads" are interesting personalities and/or whether the subject of discussion is engaging and perhaps emotional. I would suggest that "Oprah" often satisfies both qualifying factors as do some of the "soaps". The evening news and C-Span occasionally raise interesting topics (the weather) and viewers tune to Jerry Springer for emotional stimulus. Sesame Street showed us that if the cut is short, even not very interesting topics can hold our interest. The seductive nature of TV keeps our attention in the hope that something will eventually happen. So keep the clip short, illustrate the personality of the scholar, and demonstrate the importance of the idea.
that the video programming (almost like the separate segments of Sesame Street) will not stand alone, but
must in some way be part of a larger teaching plan/objective. There are two teaching objectives that guide
the use of video in this project: to create an environment of contradiction and disagreement that
practically forces conversation to understand and explain the controversy; second, to demonstrate that
scholarship is not getting neat answers to questions, but is the messy business of trying to figure out and
understand the question. The first can be accomplished within a collaborative framework that sees the
teacher as part of the community of learners and one of the “experts” in the discussion. Other “experts”
are added to the conversation as the course develops because with digital video it is easy to go back to
what one of the scholars has said before. The second is more subtle and challenging to the professor.
Students tend to take a relativistic view of scholarship. They have often not been taught logic nor analysis
and so believe that meanings depend entirely on their interpretation – that what someone intends to say is
less important than what the hearer heard them say. This is, of course a relativistic position that is self-
defeating: “there are no rules of discourse” which is itself a “rule” or else meaningless. It is essential to
hear what the “expert” is saying and to analyze his/her meaning, and then argue in support of or against
the conclusion. This “critical thinking” component is in some ways the most important scholarly
objective.

Finally, it seems to me that any attempt to evaluate outcomes that stem directly from the use of these video
clips would be difficult to impossible. I can demonstrate that student satisfaction is changed by the use of
technology, but I do not know if they respond in this fashion because they think they are supposed to or
because it is novel (see Najjar, 1996, p.132). It also seems to me that some students resist change in the
structure of a class even more so than teachers. They seem to understand education as getting answers to
questions that will be on the test rather than engaging in critically thinking through some problem or classic theory. Lenore Langsdorf puts it this way:

In teaching . . . [students in a required humanities course] I have found a widespread . . .
inability to understand and evaluate the ideas presented in the traditional texts of our
cultural and philosophical heritage. Perhaps the clearest evidence of this inability is that when asked to identify, paraphrase,
and evaluate an argument developed over an extended text (for example . . . Descartes’
argument for systematic doubt in Discourse on Method), students will usually merely
rehearse the conclusion. When pushed on the question of why the author states that
conclusion, the almost universal response it that it arises out of the author’s “opinion” or
“feeling.” In other words, students typically do not distinguish between the text’s

It might simply be easier to evaluate teacher satisfaction with goals such as student involvement in
discussion, willingness to argue a point of view, and curiosity evidenced by questions during or after class.
In the case of this project, these elements were numerically more frequent than in a class that did not use
technology in this way. But again, the ability of students to explain what the author is saying rather than
to impose meaning by personal interpretation (mostly based on their lack of experience in the domain) can
be tested. What remains uncertain is whether in the case of video, students defer to what I call “tube
hat we see on television must be true because we are seeing it; the data we
receive through the monitor from the web must be true as well because we are seeing it. This is also an
interesting item for further research.

---

3 Course evaluations for the two sections in which this approach was used showed:

<table>
<thead>
<tr>
<th></th>
<th>disliked the video</th>
<th>liked the video</th>
<th>no opinion</th>
<th>total</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spring 00</td>
<td>1</td>
<td>11</td>
<td>11</td>
<td>23</td>
</tr>
<tr>
<td>Fall 00</td>
<td>1</td>
<td>17</td>
<td>8</td>
<td>26</td>
</tr>
</tbody>
</table>

Because of other positive remarks, the students who had “no opinion” regarding the video component could
not be interpreted as negative.
IV The Process

The process is easier than you might expect; I will explain what I do and how I do it: the hardware and software used and a short illustration of the steps involved. Believe it or not, the key is adequate lighting, clear audio and an uncluttered picture.

+ The Interview/Commentary -- Content: The programming is not really “interview” style, but commentary. Since the producer/director is also the camera operator, any sort of dialogue would be between the subject and a voice “off camera” -- ineffective and really distracting to the future audience. In fact, there often is this sort of dialogue, but the “mystery voice” is eliminated in the editing process sometimes replaced by text.4 The scholar is asked to respond to a series of seminal questions which he/she sees weeks before the taping. The subject is also told to limit the response to a nominal five minutes (range of 3 to 7). This is done both for the sake of pedagogy as well as technical limitations of the software to handle larger raw video files. Perhaps the most important directive is that the objective of the programming is not actually to answer these (unanswerable) questions, but to highlight the unique approach each scholar takes to the subject. What video can do that text and still image cannot is illustrate the unique individuality of the person and how it is reflected in his/her work.

+ The Interview/Commentary -- Setup

* Lighting: Natural and Tota lights + umbrella - an easy solution; if it is possible to use natural lighting (a north-facing room with large windows on a bright day) this often gives the best results, but the light can change rather quickly because of clouds or time of day. A 250-watt Tota light either reflecting off of the ceiling or an umbrella gives more than adequate light which will remain constant. Very bright lights can create high contrast and dark shadows that are very distracting. Keep the subject far enough from the background so that their shadow does not appear in the picture. Set the camera angle to get the most evenly lit image.

* Audio: Radio Shack to the rescue -- sound is often the problem; the longer the cable on the microphone, the more likely it is to pick up hum or noise. There are a variety of ways to get good sound and most of them are expensive. The microphone on the camera is quite sensitive and often will pick up too much. It is possible to attach a directional (shotgun) mic to the camera (Sony makes one for the TRV900, an ECM-HS1), but often the acoustics of the room create a distracting hollow sound with this device. I have had the greatest success with an “Ultra-miniature Tie Clip Microphone” from Radio Shack (# 33-3003). It has a 20-foot cable, great sensitivity at close range and is very quiet.

* Camera: Sony DCR - TRV900 Digital Video Camera - the advantages; this is a three chip camera with the reliable Sony mechanics. The image is superior to an S-VHS camera and each tape will hold an hour’s worth of video. Using the camera with the AC power supply occasionally introduces hum on the audio and so I record using battery power (the infolithium 750 gives a recording time of more than two hours). The camera has too many features to report here, but I would mention white balance controls, zebra pattern, large color LCD screen, tape and time counters as well as smooth zoom and focus controls and gain shift adjustment as elements found only on expensive professional video cameras. It is not hard to learn to use these.

+ The Digital Product

* Hardware: Gateway E-5250 - 550 MHz single processor, 256 MB, Viper V770 graphics accelerator, Ultra SCSI internal 9 gig HD, external 18 gig and 1 gig hard drives; the computer is adequate for the capture, editing and processing tasks, but might not be without the SCSI hard drives.

* Software: Windows NT 4.0, ToolBook II, 6.1a, PowerPoint 97;

+ Production

* Capture/edit: Intel Smart Video Recorder III (old, but workable) – this seems to be the weakest link in the hardware. The board is no longer supported and the drivers are old. Occasionally attempts to set up for capture are rewarded with the dreaded “blue screen of death.”

---

4 The clear advantage of having the content person also direct the filming is that he has control over any accidental or planned diversion. Knowing the work of the scholar allows the director to insert additional questions that can focus the subject’s commentary on issues that are peculiar to this individual.
MiroVideo DV300 capture board (could not get it working—VERY poor technical support from Pinnacle Systems) and so do not capture the digital video using “Fire Wire” but use the S-VHS output of the camera. The results are more then adequate.

Adobe Premiere 5.1c (soon to try 6.0); an outstanding capture and editing program.

* Audio/video processing: Media Cleaner Pro 4.0.2
* Compression: Ligos LSX-MPEG Encoder 3.0
* Programming: Adaptec Easy CD Creator plus an Imation CD-R 8x20 Super Recorder

Using the S-VHS cable to the “Smart Video Recorder” and the audio connected through a 15 band equalizer to the “Sound Blaster AWE 64” soundboard, the video clip is captured using the “capture” utility of Premiere. The digitized clip is trimmed and if necessary edited using Premiere. Then the final version is exported to the storage drive (as uncompressed AVI). Next, the clip is processed with Media Cleaner: the audio is normalized and sweetened and if the video needs color or brightness/contrast adjustment it can be done (to a point). It is not really possible to “fix” bad video and this is a common misconception. It is never acceptable to “settle” on poor quality videotape with the expectation that it can be “fixed” by the computer. Finally the processed video is compressed using the Ligos LSX-MPEG encoder. After all the clips have been processed and stored on a dedicated drive, the PowerPoint program is created to manage the video and the CD Master is created.

+ In the Classroom – PowerPoint 97 is used as the presentation/program-management software for classroom applications. It would be desirable to manage the video with an html program, but there are difficulties in playing MPEG video within a browser.

+ Enhancement – It would be very useful to have either a very large (72GB) hard drive or multiple (5/6) CD players so that a greater number and variety of scholars could be instantly accessed. If the professor was very familiar with the archived videos, he/she could easily play a clip on demand that fits a students question or that refutes a students argument/conclusion thereby continuing to create the conflict situation that could encourage debate and discussion.

V Course Structure

The structure of the course is fairly rigorous for an undergraduate program. The class met twice a week for 75 minutes. After seven classes that were introductory and designed to give every student a common vocabulary and historical background, a set routine was followed: the first class on a particular scholar, students would discuss an article they had read and summarized in two pages. The professor would comment on problematic points of the reading and mediate the discussion. Students would annotate their summary papers and turn them in for evaluation. Late papers were rejected as the exercise was considered essential preparation for class participation. The second class on the scholar was spent watching and discussing the short video commentaries by that particular subject. Students handed in a short biography they had done on the scholar. The professor would ask questions regarding the video such as “Why did the scholar not finish this idea? How would you finish it? What is peculiar about this person’s work? What problems does he/she raise/cause/solve?”

The opportunity for collaborative learning is clear. But it is important to understand that collaboration here includes the professor whose role as an “expert” is shared with the video subject and, in fact, as the class progresses with all the other “video scholars.”

Clearly the pedagogical issue is not whether the video commentaries are designed to deliver content to the student. Reading assignments have already provided students with information and key ideas. The application has more to do with process and such questions as, “What do scholars do?” and “How do the experts arrive at solutions to problems in their field?” If students are expected to develop learning strategies suitable for their own learning goals and if there is more than one way to do this, then illustrating for them some of the possibilities would provide additional support for this objective by:

- Providing differing models of scholarship in their field of study;
- Illustrating the feeling, hesitation, groping for words, logic, asides and distractions that are part of the way scholars work out their understandings in real life;
• Suggesting that there are disagreements about the “solutions”.

Again, the issue is to reject the notion that scholarship is getting answers to questions and to foster the understanding that knowledge is the result of critical analysis of data and trial by debate. The most effective use of these video clips is to foster debate among the students by giving them reasons to adopt differing viewpoints as their own and to construct arguments supporting their perspective as well as to create the opportunity for students to develop their analytic skills.

VI Demonstration

As time permits, a short demonstration of the video programming will be given with a view to showing both the quality as well as the versatility of the PowerPoint module. Commentary and discussion will be encouraged first with a view to clarifying this particular course event, but especially with a view to showing how applications in other fields could easily be made using the same digital video techniques.

Satellite Home Tutorials vs. Satellite Classroom Tutorials

Ruth Beyth-Marom, Edna Yafe, Meira Privman, Hamutal Razy Harpaz
The Open University of Israel
Ruthbm@oumail.openu.ac.il

Abstract: In the present study students who registered for a course at the Open University of Israel could choose the tutorial method they preferred: group face-to-face tutorials with a local tutor in their residential vicinity, tutorials via satellite broadcasting to groups of students around the country, or getting the same satellite tutorial at home on the computer screen. The three groups of students differed in percent of males, age, computer experience, English knowledge, and number of university credits. Satellite classroom tutorials were the least preferred method regarding most dimensions students were questioned about. Satellite home tutorials were preferable because they allow higher concentration, ease of summarizing, more enjoyment and a higher degree of comprehension of the material. The paper concludes with a number of pedagogical and methodological implications regarding research on educational technologies.

Background

Teaching and learning at the Open University of Israel (OUI) are based mainly on textbooks written especially for distance learning. In addition to this written element the component of interaction between students and the teaching staff is essential. In order to remain faithful to the distance teaching emblem and avoid obligating the student to travel to the University campus, this interaction takes place at learning centers distributed throughout the country. Most of the OUI courses offer the students meetings once a week (IT-Intensive Tutoring) or once every three weeks (RT-Regular tutoring), at learning centers in their residential vicinities, conducted by a local tutor.

Indeed, meetings with tutors at learning centers bring the University closer to the students (who can participate in tutorials near their homes). However, these tutorials are not an ideal solution. It is not always possible to find enough expert tutors for all groups of students, there are not always enough registered students in each region to justify opening a group and recruiting a tutor, and this is surely not a solution for those students who cannot leave their homes for one reason or another (temporarily due to childbirth for example, or permanently because of disability).

One of the solutions for these difficulties is making the meeting an asynchronous virtual one through discussion groups on the Internet. Today, the students of the OUI can carry out asynchronous interaction with the University staff by means of an Internet Hebrew study environment, which was developed by the University. Nonetheless, this solution does not respond to the need of most students for synchronic instruction in which there is direct and synchronic contact between the tutor and the students and among the students themselves.

Another solution has been implemented at the OUI, over the last five years in cooperation with Gilat Company. There are two studios operating at the University's central building from which lessons are broadcast, through satellite media, to classrooms throughout the county. This system, designated for synchronous teaching, enables tutors to conduct tutorials and review lessons, experts to give lectures and so forth. The communication between the lecturer and the students is visual, audio and data based. The visual communication is uni-directional, only from the studio to the classrooms. Though the lecturer is seen and heard in all of the classrooms on a TV screen, he can not see the students. The satellite communication is based on a wide broadband. Thus, the lecturer is able to integrate films, presentations, Internet pictures, etc. in the lectures. Audio information is bi-directional (from the studio to the classrooms and from the classrooms to other classrooms and to the studio). The lecturer and the other students can hear the voice of each student that has been given the floor by the lecturer. With respect to data communication, the lecturer can present multiple choice questions to the students, ask them to answer the questions by pressing an appropriate button on the satellite phone, and immediately present the distribution of answers to the students. This teaching system solves the first problem stated above regarding the tutorials at the study centers throughout the country – all students study with the best tutor and are exposed to professional and quality teaching.
This system does not provide a solution for the students who do not reside near centers with classrooms receiving satellite transmission nor for those who are unable to leave their homes. Furthermore, in accordance with the OUI's goal to enable flexibility in study methods and adapt the methods to the learning style of the student, and its belief in student autonomy, students should be allowed to choose the most suitable learning method: to study from home, to study at a study center, to receive abundant tutoring (intensive), a little tutoring (regular) or none at all, to receive face-to-face tutorials (synchronized, at the time and place determined for the student), virtual instruction (synchronized, from afar, at home or in a classroom that receives satellite transmission) or computer-mediated asynchronous tutoring (through the computer and the Internet at a place and time convenient for the student).

The present study was designated to examine the possibility of providing solutions to those students who wish to receive synchronized tutorials but are unable to leave their homes, or prefer to be instructed at home rather than in the classroom. The solution examined was transmission of tutorials from the studio through satellite broadcasting concurrently to classrooms distributed throughout the country and to the homes of students who requested this study method. The aims of the study were:

1. To examine the technical feasibility of transmitting satellite tutorials concurrently to homes and to classrooms.
2. To examine whether students interested in RT at home differ from those interested in RT in classrooms. Consistent with past research, we hypothesized demographic and achievement differences in preferences of learning environments (e.g. Beyth-Marom et al., 2000; Rosen, Sears, & Weil, 1987; Yaghi & Abu-Saba, 1998).
3. To study the opinions of the classroom students and home students regarding the technical, pedagogical and social aspects of the satellite learning environment.
4. To examine whether tutor-students interaction patterns of students at home differ from those in classrooms.

The present paper will present some of the data concerning aims 2 & 3 and discuss their implications.

Method

The course “Mass Communication” was chosen as a platform for the experiment (delivering satellite tutorials concurrently to classes and to students’ homes) since it already had an Internet home site, regular satellite tutorials transmitted to classrooms and its tutor had previously gained technological experience. Cost considerations (loaning the equipment by the students and its installation at their homes) determined the number of home students between 15 and 20.

Six hundred and twenty four students registered for the course. 555 of them registered for classroom, face-to-face, IT (Intensive Tutoring) and 69 registered for RT (Regular Tutoring). IT is given once a week to groups of students, in study centers, by several tutors. RT is delivered once in two to three weeks to classrooms through satellite communication, by one tutor. The students who registered for RT were sent a letter inviting them to take part in an experiment in which they would participate in tutorials transmitted by the satellite system to their home computers.

Eventually, 16 students volunteered for the experiment, of which only 10 were connected during the second month of the semester. All other RT students (59) got the satellite RT in special classes located at study centers around the country. 555 students received face-to-face IT in conventional classes in the same study centers. Thus, the study involved three groups of students though the first two were the main focus of the study.

Various sources provided information for the diverse goals of the experiment. We will mention here only those relevant to the present report. Information on the participants' characteristics (for the three groups of students) was received from the University’s central database. The variables examined for each participant are listed in Table 1. Feedback from students on technical, pedagogical and social aspects of the learning environment they experienced was collected by questionnaires which were sent to the students studying through the satellite system (at home or in the classroom) immediately upon completion of the experiment. The 53 students who registered for RT and didn’t volunteer to study at home received a questionnaire regarding their experience with the satellite system. The ten home-students received a similar questionnaire (as they had an experience with the satellite class system.
before the home-system was installed) and additional questions regarding their experience with the system at home.

Results

Characteristics of Students in Various Types of Tutorial Groups

Table 1 summarizes the data collected about students' characteristics. Columns 2 and 3 compare the satellite home students to the satellite classroom students and columns 4 and 5 compare the satellite students who participated in regular tutorials (at home and in the classroom) to those who participated in face-to-face IT. The numbers in bold signify the differences.

* Significant difference according to the t-test.
** Significant difference according to the Fischer test.

As the group that studied at home was a very small group, any conclusion derived from its findings can only constitute an assumption for future research. We will therefore only compare the entire group of students who participated in the RT through the satellite system (at home and in classrooms) with the face-to-face IT group (comparison of columns 4 and 5).

The results were similar to those revealed by a previous study (Beyth-Marom et al., 2000) on students choosing computer-mediated technology: the students studying in the regular tutorials (and in the present case those studying through satellite technology) are more veteran students, a greater number of them completed their English requirements, completed a course in Math or Statistics and completed the computers application course. There are also more male students in this group. However, unlike the findings of the previous study (on computer-mediated learning) those who chose RT by satellite are not
necessarily better students (as evident in their average grades towards their degree and in the grade of the present course).

Since in the present experiment all the students who chose the regular tutorials studied through satellite (at home or in the classroom), and all those who chose intensive tutorials studied through the face-to-face method, it is impossible to know which variable is responsible for the differences in the characteristics of the two groups. More pedagogical and methodological implications regarding these group differences will be discussed in the last part of the paper.

Students' Opinions regarding Satellite Tutorials

Nineteen of the students in the classroom satellite RT filled in the questionnaires that were sent to them. 15 of those attended at least one tutorial. Four of the students that studied at home also answered questions regarding satellite classroom tutorials in which they took part before they were connected from home. Their data was not included because of their small number. Nine of the ten participants in satellite home tutorials filled in their questionnaire. In the questionnaires students were asked many questions to meet all research aims. We will report only about their opinions regarding the different types of tutorials.

The classroom students were asked to respond to the following statement: "Below are two types of tutorials with which you are acquainted: face-to-face tutorials and satellite classroom tutorials. On the assumption that the same tutor teaches the tutorials, mark with an X under the method that you believe is the best way of learning with respect to the dimensions below." The home students were asked to respond to the same statement but with regard to three types of tutorials: face-to-face classroom tutorials, satellite classroom tutorials and satellite home tutorials. Table 2 presents the distribution of responses in both groups.

</table>

The comparison between the face-to-face classroom tutorials and satellite classroom virtual tutorials done by the classroom students revealed that face-to-face tutorials were considered to be advantageous...
with respect to all the cognitive and affective dimensions that the satellite classroom students were asked about.

For the home students who compared the three methods, the satellite classroom remained the least preferred method with respect to all the dimensions (except - "questions I ask get more responses"). However, the results of the comparison between face-to-face classroom tutorials and satellite home tutorials were very interesting: Home students believe that satellite home tutorials are preferable because it is easier to concentrate, to summarize and understand the material, as well as being more enjoyable. However, they have the feeling that they ask more questions in face-to-face classroom tutorials in comparison to home tutorials. In contrast to the satellite classroom group, half of the home students felt that they have good control of the situation, more than in face-to-face or satellite classroom tutorials.

A comparison between the choices of the two groups raises doubts concerning a number of traditional claims regarding satellite tutorials (e.g., it creates a feeling of anonymity and of no control) and shows again that students differ in their preferred learning methods.

**Discussion and Conclusions**

In the present study an attempt was made to examine a number of pedagogical, methodological and technological issues in the process of launching a new learning technology. In this section we will summarize the main findings and conclusions concerning the pedagogical and methodological issues.

**Pedagogical Issues**

An examination of the characteristics of the three groups of students: those who volunteered for the satellite home experiment, those who chose regular satellite classroom tutorials and all the other students who chose intensive face-to-face tutorials, revealed that each group had unique characteristics.

The group of students studying at home was older and included more veteran students, had more experience with computers and had more experience studying in satellite classrooms in comparison with the satellite classroom students and in comparison with the face-to-face tutorial students. A larger percentage of the students studying at home had an exemption in English. These distinctions are maintained when combining the satellite home students and the satellite classroom students into one group for comparison with the group of students studying intensive face-to-face tutorials.

Since the groups differ not only in the technology but also in the frequency of tutorials - the question arose as to whether the factor distinguishing between the groups was the preference of the technology or the preference of a certain number of tutorial meetings. Only a future examination of the unique differences between students who choose face-to-face regular tutorials and those who choose face-to-face intensive tutorials will provide an answer to this question.

When comparing only face-to-face tutorials to satellite classroom virtual tutorials the later are considered inferior with respect to all the cognitive and affective dimensions about which the satellite classroom students were asked. Satellite classroom tutorials remained the least preferred method regarding most measures also when face-to-face tutorials, satellite classroom tutorials and satellite home tutorials were compared. However, when satellite home tutorials and face-to-face tutorials were compared an interesting finding was revealed: the satellite home tutorial students believe that satellite home tutorials are preferable because they allow higher concentration, ease of summarizing, more enjoyment and a higher degree of comprehension of the material. They also had the feeling that they asked more and received more responses in face-to-face tutorials than in satellite home tutorials. In contrast to the satellite classroom students, half of the satellite home tutorial respondents believe that from home they have good control of the situation, more than in face-to-face classroom tutorials or satellite classroom tutorials.

The responses of the students to the comparison of the various types of tutorials may indicate that in the perception of most students, face-to-face classroom tutorials are the preferred type. If one must compromise on a technology (for various reasons), it is preferable that it reaches the student's home. In a comparison between satellite home tutorials and satellite classroom tutorials, it seems there is no advantage to satellite classroom tutorials. A student who seeks for a peer group of learners prefers the social interaction of a face-to-face tutorial over that in a satellite classroom tutorial.
Students' preferences and their responses, as well as their different characterizations highlight, more than anything else, the individual differences between them. Different students prefer different styles of learning and have different needs, which determine their preferences. If we wish to respond to needs and preferences, it is impossible to search for the best method, but rather to offer the student a variety of methods to choose from.

**Methodological Issues**

The present experiment raised interesting methodological issues common to many studies on educational technologies. Below are a number of them:

1. The main limitation of many of these studies is their poor design (The Institute for Higher Education Policy, 1999). Very often a comparison is made between two groups which differ in a number of variables, in addition to the one independent variable studied. Such poor design doesn't allow for valid conclusions.

In comparisons between different technologies usually there is no meticulousness regarding intervening variables such as different lecturers, different learning materials, different examinations and different students. As long as the study does not control for such variables, it is impossible to interpret the results. In comparing the two satellite groups (classroom vs. home) in the present experiment, attention was paid to controlling for a number of variables: a. for the kind of material (by ensuring similar tutorials to the two satellite groups at home and in the classrooms); b. for tutor (by ensuring the same tutor to the two groups) and c. for time (by having the tutorials at the same time in both groups). The groups differed only in the technology (the independent variable that was the focus of the study), as well as students' characteristics.

In a comparison between the satellite tutorial groups (at home and in the classroom) and the face-to-face tutorial group, an additional intervening variable could not be excluded, namely, the frequency of the tutorials. This variable should be controlled for in future studies.

2. A field-study on learning technologies that involves technical, pedagogical, affective and cognitive behavioral aspects requires a multi-operational approach examining each theoretical variable with various measurement tools in order to guarantee independence between the method of measurement and the findings. This approach was taken in the present study with regard to variables not mentioned in the present report (e.g. Self report on the frequency of the interaction and its efficacy together with the observation and listing of the same interactions).

3. The inclusion of volunteers in an experiment may cause problems which become even more serious when one compares two groups of which only one involves volunteers (Rosenthal & Rosnow, 1969). In this type of experiment three difficulties exist:
   a. Volunteers for experiments are substantially different from those who do not volunteer, and thus the two groups are different in regard to variables other than the independent variable under study. The examination of these variables, done in this experiment, is a partial solution. Such examination might reveal differences that may shed more light on the findings.
   b. The volunteers in an experiment have a great commitment to it. The relatively high satisfaction with the satellite home communication system may stem from pertinent reasons ("the tool is wonderful and has many possibilities that only technical reasons prevent their full realization at present"). But this satisfaction may also express a type of justification for volunteering, post factum.
   c. Volunteers for technological experiments usually receive special treatment. They are in frequent contact with the technical support team (because of technical failures), and with the course team (because of their small number and special problems). Satisfaction with these special treatments may cause some halo-effect and influence the general satisfaction with the experiment and with other aspects of the learning environment.

The Essen Learning Model -
A Step Towards a Representation of Learning Objectives

Markus Bick, Jan M. Pawlowski, Patrick Veith

Information Systems for Production and Operations Management
University of Essen, Germany
{Bick|Jan.Pawlowski|Veith}@wi-inf.uni-essen.de

Abstract: The importance of the Extensible Markup Language (XML) technology family in the field of Computer Assisted Learning (CAL) can not be denied. The Instructional Management Systems Project (IMS) for example provides a learning resource XML binding specification. Considering this specification and other implementations using XML to represent learning contents in different ways, we developed a new approach to use an XML based representation of learning objectives during the development process of a Computer Supported Learning Environment (CSLE). Identifying and representing learning objectives is an integral part of the Essen Learning Model (ELM), a generic development model supporting developers, educators, and users on different levels of educational activities. We illustrate how to use XML data in the context of learning objectives to support the implementation of learning environments.

Introduction
Due to the enormous interest in the Extensible Markup Language (XML) a variety of approaches in the field of Computer Assisted Learning (CAL) have emerged recently. Current approaches more or less focus on the representation and structuring of learning contents, e.g. the Learning Material Markup Language (LMML) (Suess, 00). Another good example for the increased significance of XML in CAL is the XML binding for the Instructional Management Systems Project (IMS) Learning Resource Meta-data Information Model, which is based on the IEEE Learning Technology Standards Commitee (LTSC) Learning Object Meta-data (LOM) base document (Anderson, Wason, 00).

Textual formulation of learning objectives can only be used to outline a course (Adelsberger, Bick, Pawlowski, 00a). In this paper we will focus on the gathering and classification of learning objectives using XML. A more detailed analysis of those learning objectives, which helps the teacher to find and to design an adequate didactical method is needed to prioritize the contents. Accordingly, we developed the Essen Learning Model (ELM), a generic development model, supporting developers, educators, and users of different levels of educational activities (Pawlowski, 2000).

The ELM application, an advancement of the Essen Learning Model, supports a well-structured classification of learning objectives. Current classifications often show a lack of consistency.

We will present a new approach to classify learning objectives using the Essen Learning Model by explaining our classification and providing our representation using XML. Finally we will review consequential alternatives for the creation of a Computer Supported Learning Environment (CSLE).

Essen Learning Model (ELM)

ELM Development Model
The Essen Learning Model is a modular system (Fig. 1), supporting development processes as well as the system's use on different levels: the support of curriculum design (C-level), the development of learning sequences (D-level), and the development of learning units (E-level) (Pawlowski, 00). We distinguish between three abstraction levels: The generic development model provides knowledge for a variety of contexts. This generic model is customized depending on the users' needs and preferences, and transformed into a specific process model for each development project. The process model is implemented using the Architecture of Integrated Information Systems (ARIS) and provides a framework for educational technology projects. ARIS is a frame concept for a global description (modeling) of computer supported information systems, covering the whole life-cycle range - from business process design to information technology deployment (Scheer, 98). The third level is the result of the development process in the form of certain implementations for each module.
Figure 2 represents the main processes of the Essen Learning Model. The result of ELM-C is a detailed network of learning objectives and goals, determining structure and relations of learning sequences (courses). Based on these results, learning sequences are being developed in ELM-D. The focus of this phase is to find an adequate didactical method together with the right technology depending on learning objectives and user groups. Finally, single learning units are designed and implemented in ELM-E, using the Extensible Markup Language (XML).

### ELM Application

To simplify the complex ELM development process, we developed an application which supports the author, who implements a course or a learning unit (Fig. 3). This application is programmed in JAVA, a language supporting an object-oriented, portable, and architecture-independent approach.

Compliant to the ELM development model the application uses the XML technology family on all of its implementation levels. XML provides the distinction between contents and its representation. Thus it is possible to represent a single contents in different ways (W3C, 98).

During the CSLE development process, special information about the learning contents and learning objectives is collected. The ELM application supports the author in classifying this information, as part of the Knowledge Base and converts it into XML documents. He can select an adequate teaching method according to the learning contents and user preferences (Methods Base). For this reason, the User Model contains attributes, characteristics, and the knowledge of a user. Ideally, the knowledge is represented adequately in accordance with the User Model, e.g., individual learning pace, preferred learning method, or preferred presentation format.
Considering that information and regarding the XML documents already mentioned, the ELM application generates a template, which could be tailored by the author according to his preferences and experiences. This adapted XML template results in an XML learning environment, which can be used by the learner.

Classification and Representation of Learning Objectives
Learning objectives allow to organize courses, plan teaching strategies, and evaluate testing techniques. Unless a course is defined in terms of learning objectives, a course author has no concrete means to measure the student’s success. Without any objectives at all, there is the danger of "teaching A and testing B". Using clear learning objectives, both the students and the instructor know where they are and what needs to be done (CIT, 97).

The textual formulation of learning objectives can only be used for an outline of a course. A more detailed analysis of those learning objectives is needed in order to prioritize the contents. Furthermore, this analysis helps the teacher to find an adequate teaching method.

Unfortunately, a variety of classifications of learning objectives are currently in use, often resulting in inconsistent classifications and terminologies. We suggest to use a classification of learning objectives, containing the criteria abstraction level, dimension, and kind of content in the ELM-Application. Our suggestion is based on the work of (Moeller, 73), (Bloom, 73), and (Baumgartner, Payr, 94).

Classification
(Moeller, 73) distinguishes learning objectives between three different abstraction levels according to (UNESCO, 00):

1. **strategic**,  
2. **general**, and  
3. **specific**.

By means of this abstraction levels, a certain hierarchy concerning the learning objectives can be realized. For example, in the field of simulation, a strategic objective is the optimization of a production planning process. For this purpose, using simulation is a general objective. Finally, performing a simulation study using a specific simulator describes a specific learning objective.

Secondly, we use a classification of dimensions. Extending Bloom’s classification of intellectual behavior (Bloom, 73), we distinguish between four dimensions:

<table>
<thead>
<tr>
<th>Dimension</th>
<th>Complexity</th>
</tr>
</thead>
<tbody>
<tr>
<td>cognitive,</td>
<td>knowledge,</td>
</tr>
<tr>
<td>affective,</td>
<td>comprehension,</td>
</tr>
<tr>
<td>psychomotor,</td>
<td>application,</td>
</tr>
<tr>
<td>social.</td>
<td>analysis,</td>
</tr>
<tr>
<td></td>
<td>synthesis, and</td>
</tr>
<tr>
<td></td>
<td>evaluation.</td>
</tr>
</tbody>
</table>

The social dimension describes skills like the capacity for teamwork, solving conflict situations, the ability to assert oneself, etc.

In order to identify an adequate didactical method, it is necessary to identify the complexity of learning objectives. In our example we focus on the cognitive domain. Bloom identified six levels within this domain, from the simple recall or recognition of facts as the lowest level, through increasingly more complex and abstract mental levels, to the highest level which is classified as evaluation.

The third approach is according to (Baumgartner, Payr, 94) the classification concerning the kind of learning content:

1. **learning facts and rules** (remember, receive)  
2. **rules, procedures** (apply, imitate)  
3. **problem solving** (decide, select)  
4. **gestalt perception, pattern recognition** (explore, understand)  
5. **complex situation** (invent, master, cooperate)
The first level describes learning environments whose main purpose is to present and transfer contents (verbal, multimedia). The main activity of the user (interaction) is to navigate among pieces of information. The second level typically consists of exercises and tests. The learner acquires and tests procedural knowledge. On the next level, the learner is asked to deal with more complex situations by planning his own procedures. The goal of the fourth level is to perceive and holistically understand processes with their causes and effects, and to discover common characteristics and patterns in various "cases" (Baumgartner, Payr, 98). The experience of complex situations, e.g., in simulation games, offers the student the opportunity to increase his thinking flexibility (Geuting, 89).

Taking into account the criteria of classifying learning objectives (e.g., abstraction level, dimension, complexity, and learning content), we specified learning objectives for a computer based simulation course for graduate students of business information systems (Tab. 1). In this course we focus on the basic methods and concepts of simulation. The students learn how to model, implement, and evaluate simulation systems for specific manufacturing problems in selected simulation languages.

Table 1: Extract of the Learning Objectives Network

Representation
After presenting our approach to classify learning objectives, we will now lead over to the implementation of them in XML. Besides a multitude of dynamic representation alternatives, XML could be described as a simple dialect of the Standard Generalized Markup Language (SGML). Whilst designed initially for the display of documentation distributed via the World Wide Web (WWW), XML has been widely adopted as
a means of interchanging information between computer applications. XML in particular is widely seen as the best solution for the interchange of meta-data about stored objects and programs (ETHOS, 00).

Obviously, XML is not only a markup language similar to HTML (Hypertext Markup Language), but rather a meta-language, which supports the definition of own "tags" to structure a document. The existing XML recommendation will be complemented by two extensions. The Extensible Stylesheet Language (XSL) will provide a method to specify the presentation style and control the behavior of XML elements. The Extensible Linking Language (XLink) will enable XML documents to be linked together (ETHOS, 00).

The rather complex process of creating a CSLE and especially the process of creating a learning objectives network is simplified significantly with the use of the ELM application. The conceptual model of the learning objectives network, as shown in Table 1, could be seen as a hierarchical model, which represents data consisting of elements and subelements. XML is most suitable to represent this hierarchy.

In our approach, the process of classifying learning objectives is managed using the ELM application form (Fig. 4). Here, the ELM application stores this data, as shown in Table 1, in an XML document (Fig. 5).

Generating a special report, the ELM application offers all people involved, a way to comprehend the learning objectives network implementation process. The generated XML document contains the essential information, it acts as the learning objectives database. This XML document supports the author during the CSLE development process, using the features offered by the XML technology family; on the other hand a report can be generated using the same base document.

Conclusion
We described the importance of identifying and classifying learning objectives. The Essen Learning Model supports a classification approach regarding abstraction level, dimension, complexity, and learning content. Using a multilevel-development model we support the development process for CSLE during the important Curriculum Analysis (Fig. 2). In this paper we focused on classifying learning objectives as well as representing and storing them using the advantages of the XML technology family.

We illustrate how the XML technology family could be utilized during the development process of a CSLE besides the sole structuring and representing of the learning contents. Combining this approach and our related work of a standard model of learning processes (Adelsberger, Bick, Pawlowski, 00b) the development process of a learning environment can certainly be improved. In the next step of development the ELM application will also support the representation of teaching methods using the XML technology family.

A Scripting Language for Multi-Character Presentation Agent based on Multimodal Presentation Markup Language

He Binda, Santi Saeyor and Mitsuru Ishizuka
Dept. of Information and Communication Eng., School of Engineering,
The University of Tokyo
7-3-1 Hongo, Bunkyo-ku, Tokyo 113-8656 JAPAN
{tsutsui,santi,ishizuka}@miv.t.u-tokyo.ac.jp

Abstract: This paper proposes an alternative scripting language to control multi-character agent for presentation system. In presentation systems, it is more fascinating when we conduct the presentation stream by the explanation or conversation of presenters. And in order to provide the presentation on demand on the Web, we need character based presentation Agent. There are several ways to control such agents but some are too complex to be used by general users. We try to propose an easy way for the uses. For this purpose, we have developed Multimodal Presentation Markup Language (MPML), which allows many users to write attractive multimodal presentations easily. MPML is a markup language conformed to Extensible Markup Language (XML). It supports functions for controlling verbal presentation and agent behavior. In this paper, we present the specification, related tools, and application of MPML when used as a tool for composing multimodal presentations on the WWW.
Electronic Portfolios in Tenure and Promotion Decisions: Making a Virtual Case

Dr. Kristine Blair
Associate Professor of English
Associate Director
Center for Teaching, Learning & Technology
Bowling Green State University, Ohio
United States
kblair@bgnet.bgsu.edu

Abstract: A current problem at many American universities is that tenure and promotion procedures continue to privilege print-based evidence of teaching and research productivity, or do not acknowledge the impact of technology on teaching, scholarship, and service. Despite these problems, this paper makes the case for electronic teaching portfolios as professional development tools for both faculty and graduate students and outlines a range of training and professional development initiatives. As part of the discussion, both advantages and disadvantages of electronic portfolios are discussed. In spite of the possible benefits, institutional education about the potential of electronic portfolios is necessary. Ultimately, such efforts are a way of providing incentive and reward for faculty to utilize technology in ways that genuinely enhance their teaching and overall professional development.

Introduction: The Case for Electronic Portfolios

In their article “Implementing the Seven Principles: Technology as Lever,” Arthur Chickering and Stephen Ehrmann (1997) apply Chickering and Gamson’s (1987) original principles for good practice in undergraduate education to the use of technology in the classroom. Among those principles are the following: Good practice encourages contacts between students and faculty; develops reciprocity and cooperation among students; uses active learning techniques; gives prompt feedback; and several others related to learning styles and maintaining curricular standards. In their overview of the advances in educational technologies that help to foster some of these goals—including synchronous and asynchronous discussion networks—Chickering and Ehrmann question “How are we to know whether given technologies are as useful in promoting the Seven Principles and learning.” Although such a question focuses on the role of technology, faculty are often encouraged to analyze and evaluate the relative effectiveness of any instructional strategy on student learning outcomes, whether it be cooperative learning, service learning, problem-based learning, or more lecture and presentation based modes of content delivery. Thus, in order to document indicators of teaching effectiveness, many universities across the United States have opted for the teaching portfolio, a collection of multi-genred documents that reflect teacher professional development and quality of teaching and learning.

Yet because technological literacy is so much a part of teacher and student professional development, and because of the changing student populations and student needs that call for distance or distributed teaching and learning forums, it is clear that technology plays a large role in the assessment of student learning outcomes and the demonstration of teaching effectiveness, common topics in the general assessment of candidates for tenure and promotion. Despite the significant impact of technology on the professoriate at forums such as the American Association of Higher Education’s 2001 Conference on Faculty Roles and Rewards, the manner in which candidates continue to be assessed focuses on activities and genres that are more traditionally researched based, and print-researched based at that. Ironically, as we recognize that student work can be created, delivered, and assessed electronically, and often through an electronic portfolio approach, faculty work—even when technological in nature—is all too frequently
reviewed in a print forum and not an electronic one. Consider, for instance, the lessened impact of reviewing a faculty member's online syllabi as "hardcopy" in a portfolio, with departmental and college level review committees unable or unwilling to review materials online and admittedly ill-equipped to do so because of a lack of "local" criteria for evaluating the effectiveness of technological learning spaces.

While Chickering and Ehrmann as well as scholars such as Lawrence Ragan (1999) acknowledge that "good teaching is good teaching," whether it be face to face or technologically mediated, there are some distinctions between how such effectiveness may manifest itself between one environment and another. For instance, Dave Madden's online discussion of the "17 Elements of Good Online Courses" notes a range of indicators for effectiveness, including navigability, usability, and instructional considerations ("material should be presented in such a way that it is compatible with a number of learning styles, "students should be able to readily and easily communicate with the instructor online, and "special attention should be given to testing design and procedures" online). Indeed, in their article "The Electronically Augmented Teaching Portfolio," Lieberman and Rueter (1997) contend that technology offers several options for enhancing the traditional print-based portfolio, including the ability to "capture information about our teaching that previously was not part of our teaching frame of reference" and allowing "efficient means for storing and critiquing the portfolio" itself (p.47).

Regardless of these advantages, tenure and promotion candidates still face difficulties in educating peers and administrators about the impact of technology on teaching, particularly in relation to academic workload. Often those who are designated as "early adopters" of both face-to-face and online educational technologies are tapped as administrative resources as well. Such individuals are frequently called on to serve on committees and to assist in departmental and university-wide faculty development initiatives that are certainly rewarding, although not always "rewarded" at tenure and promotion time, given traditional weightings at many universities that privilege research over teaching and especially over service. Although faculty should be informed about whether and how work with technology and online teaching/scholarship will be considered in the tenure and promotion process, members of tenure and promotion committees, chairs, and deans must educate themselves about candidates' technological work. Thus the importance of such work rests jointly on the committee and the candidate.

Moreover, because it is important that the candidate's work be evaluated in the medium in which it was produced, it is equally important to solicit internal and external reviewers qualified and prepared to review non-traditional sources of evidence, including websites, discussion boards, CD-ROMS, and instructional software. Yet the current problem at many institutions is that tenure, promotion, and merit documents continue to privilege print-based scholarship or do not acknowledge the impact of technology on teaching, scholarship, and service. Despite this continuing problem, this paper outlines a range university-wide training and other faculty development programs implemented at Bowling Green State that support an initiative for electronic teaching portfolios as professional development tools. For Lieberman and Rueter (1997) the advantages of electronic portfolios include more technological work being viewed in its original medium, more types of information being displayed, more immediate access and distribution (via the web and CD-ROM), and more visual and audio documentation appealing to diverse reading and learning styles, as opposed to strictly textual evidence. But despite these possible benefits, it is clear that institutional education about the potential of electronic portfolios is necessary. While technological problems may include the need to provide portfolio readers with appropriate hardware or software to access information on disk, CD or the web, there is also need to de-emphasize the "bells and whistles" of the portfolio to instead using the opportunity for a electronic-based format to support the same educational objectives and curricular contexts as its print-based counterpart. Thus, in addition to training and professional development initiatives, this paper also outlines both candidate and administrative responsibilities in educating peers and reviewers about the role of technology in tenure and promotion. Ultimately, such efforts are a way of providing incentive, support, and reward systems that encourage faculty to utilize technology in ways that genuinely enhance their teaching and overall professional development.

Training and Professional Development Programs

Whether a tenure and promotion portfolio is print-based or electronic, it is clear that a candidate is indeed making a persuasive case about the quality of his or her teaching, scholarship, and service.
contribution. In the case of teaching with technology, candidates, while they may indeed possess some technological savvy, may not possess the institutional savvy about ways to discuss, organize, document, and distribute electronic materials in tenure and promotion. As a result, faculty development units such as BGSU's Center for Teaching, Learning, & Technology (http://www.bgsu.edu/offices/ctl), often provide a range of theoretical and hands-on training for faculty and graduate student instructors wanting to utilize technology as a teaching and professional development tool. The following are a range of existing programs that can help to contribute to such development.

Technology and Teaching Institutes

In spring 2000 and winter 2001, The Center for Teaching, Learning, & Technology developed a three-day institute “Developing Online Pedagogies: Integrating the How and the Why” for faculty. As a pilot program, the institute was designed to promote technology infusion in an integrated way and serve as a significant professional development and incentive opportunity for faculty. The institute was designed to help participants define and determine the extent to which technology can enhance teaching and learning within their specific curricular contexts and teaching formats. Hands-on sessions helped participants develop a range of technological skills to integrate and manage an online presence and assess its impact on pedagogical goals. Among the hands-on sessions were the following:

- Developing and Managing an Online Presence with Course Management Tools
- Creating and Converting Syllabi with .html and authoring tools
- Delivering Classroom and Web Presentations through Microsoft PowerPoint
- Scanning and Digital Imaging with Adobe Photoshop
- Storing and Distributing Course Materials with CD-ROM Technology

Participants had the opportunity to bring relevant pedagogical materials for use in sessions and to work on independently during several “open-lab” times. Staff consultants were available during sessions to provide both pedagogical and technological support. In addition, luncheon sessions featured faculty from across the university utilizing online pedagogies and addressed issues such as managing and assessing online courses as well as institutional support and reward for technology-based course development. A final session allowed participants to save to CD-ROM all materials produced during the institute and discussed this technology as one mode of delivery of course content for students as well as the tenure and promotion portfolio. In addition to a notebook of useful documentation and articles related to online teaching and learning, including important issues such as copyright and fair use, participants received a follow-up individual consultation session with suggestions for continuing their online work and to work with technological consultants and faculty experts in the area of technology-infused pedagogies.

Portfolios as Professional Development Tools

The Center for Teaching, Learning & Technology also developed a series of workshops on the subject of teaching portfolios for faculty and graduate student instructors, one focusing on print-based portfolios and one focusing on electronic portfolios.

In the case of the print-based workshop, “Teaching Portfolios as Professional Development Tools,” general questions addressed were: What is a teaching portfolio? Why should you have one? What documents can/should be included? For whom is such a document produced? A special focus of this session was the “teaching narrative,” a vital document that determines what other documents to include as evidence of teaching effectiveness. Participants brainstormed possibilities for their own portfolios based on their particular curricular context.

A second session was titled “Developing your Electronic Portfolio.” General questions included: When should a teaching or professional development portfolio be an “electronic portfolio”? Who is the audience for an e-portfolio? How are documents similar to and different from a print-based portfolio? Facilitators overviewed the goals, formats, and delivery options for e-portfolios, including web and CD-ROM and also profiled a range of electronic document formats, including a curriculum vitae in both hypertext markup language (.html) and portable document format (.pdf), and a teaching philosophy in digital video format as a model of the ways an e-portfolio can enhance traditional print-based genres required for tenure and promotion. Participants were asked to bring a copy of their resume or some other document in Microsoft Word to get a sense of how such a document could be easily converted to a format appropriate for web or CD-delivery.
In addition, because our own institution does not currently accept electronic portfolios only, both sessions demonstrated the integration of print and electronic formats, focusing on specific references to URLs in print-based portfolios as well as inclusion of CDs in the overall hardcopy portfolio. Electronic portfolios in CD-format were profiled in both sessions as a way of storing and delivering a range of documents, whether they be print-based or more genuinely electronic document formats. Given the sheer bulk of print-based portfolios and the space and bandwidth restrictions of campus and commercial provider web servers, CD-ROM versions of portfolios were stressed as viable for both internal and external levels of review, particularly because external reviews tend to privilege of traditional model of scholarship that often exclude a range of teaching materials.

Internal and External Grant Initiatives

The importance of grant initiatives cannot be stressed strongly enough, for in addition to providing vital resources in the development of technology-infused curricula, grants are seen as a form of scholarship in many tenure and promotion contexts. At Bowling Green State University, a number of internal and external grant initiatives have helped in this area:

Tech Grants 2000

Promoted as an opportunity to take advantage of new technology infrastructure project at the University, the internal "Tech Grant 2000" program offered a series of three internal grant initiatives designed to help faculty and staff promote creativity in technology to enhance teaching, learning and business operations: Development grants ranging from $1,000 to $10,000 for teaching and learning projects that would be applicable to hardware, software, faculty course reductions, and student/staff technical support; travel grants awarded to faculty and staff for travel to universities and conferences for "best practices" observation of the ways in which technology is used and supported; and laptop grants that allowed faculty and staff to enhance and augment the quality and quantity of technology available to them through their own academic units for both teaching and research. Recipients of these grants totaled over 150 faculty and staff members, including the Center for Teaching, Learning & Technology for developing online training tutorials and best practice travel for two of its staff members.

Ohio Learning Network Faculty Professional Development Grant Program

The Center for Teaching, Learning & Technology applied for and received a $50,000 external grant to help faculty in the University's two-year branch campus receive training and support for distributed learning initiatives. Because the branch campus is 90 miles away from the main campus where the Center is housed, the incentive for this program was the ability to provide onsite and online training for faculty in a way that alleviated the workload for the cadre of primarily pre-tenure faculty awarded mini-grant (similar to the Tech Grant 2000 program) funding through this initiative to develop web-enhanced or fully online courses.

Other grant programs included several in the College of Education that focused on technology-infusion in the all courses required by pre-service teachers as a type of modeling process for this group. Both internal and external grants awarded for technology-based teaching ultimately bridge the gap between traditional research and teaching functions, thus helping to create a culture that fosters the "scholarship of teaching," a concept beneficial to both current and future faculty. Equally important, as more and more faculty adopt technology-based pedagogies, it will become increasingly important to develop policies and templates for helping them to analyze and assess the effectiveness of these pedagogies for the purposes of tenure and promotion.
Tenure, Promotion, and Technology-Infused Course Development

The following points address a range of guiding questions and responsibilities departmental and college review committees should acknowledge in evaluating the role technology plays in teaching, scholarship, and service, as well as in using technology as a medium for such evaluation.

Guiding Questions

- How can/must existing tenure and promotion guidelines regarding teaching effectiveness account for the changing delivery models of technology-based learning?
- How can the concept of “the scholarship of teaching” contribute to better understanding of the ways in which online teaching contributes to teaching, research, and potentially service?
- What constitutes “evidence” of teaching and learning effectiveness in a technology-infused education model?
- How does relying on a primarily print-based review of candidate files hinder understanding of the impact of technology on teaching and learning?
- How does the level of faculty support for course development (course reductions, reduced class size, technical support and team-development models) impact teaching effectiveness?
- What constituencies on campus must be involved in discussions of technology’s role in tenure and promotion decisions? (Faculty Development units, Faculty Senate, college technology committees, departmental and college tenure and promotion committees)

Candidate Responsibilities

- To offer commentary within teaching narratives that “guide” internal and external reviewers to weigh and evaluate online course materials and to clearly connect technological initiatives with indicators of student success within that discipline.
- To arrange for “peer observation” and evaluation within an online/distance or any technological setting (Note that options may include virtual observation/participation of online discussions or chats, quantity and quality of course customization, ease of access and navigation to course materials, the extent to which courses account for multiple learning styles, and so forth).
- To provide specific evidence, preferably in its original medium, including transcripts of online discussions, web-syllabi and electronic course content in various media, and student technology projects
- To educate departmental and college review committees about existing guidelines within the discipline and through national distance learning organizations that would support the candidate.

Departmental/College Tenure and Promotion Committee Responsibilities

- To review and revise existing student evaluation forms to account for distributed learning models/technology based teaching
- To commit to review candidate’s distance/technology-based teaching in its original medium (Video, Audio, WWW, CD-ROM)
- To collaborate with faculty development and instructional technology specialists and department/college technology committees for training of internal reviewers to review online course materials
- To secure external reviewers knowledgeable about the role of technology in teaching and learning and to provide reviewers with guidelines about departmental/university standards in this area for tenure and promotion
- To explore options for implementing an electronic teaching portfolio program for technology-based teaching and learning

Conclusion: Seeking Institutional Change

As some of the above guidelines indicate, some disciplines have relied on their major professional organizations (e.g., the Modern Language Association and the Conference on College Composition and
Communication) to help define and assess the role of technology in the curriculum. Yet to ensure institutional recognition of the importance of technology in tenure and promotion decisions, these national standards and guidelines must be contextualized around the role technology places in the localized teaching and learning community. For instance, rather than rely solely on national and disciplinary guidelines, college and academic units can also rely on case studies of actual faculty examples of how technology is employed in the teaching, research, and service roles. This is particularly important at both the College and Provost review levels in which reviewers are outside the discipline and less able to assess how such work is valued within the tenuring unit.

Nevertheless, tenuring units must themselves be prepared to revise traditional teaching review processes, particularly student ratings and peer and supervisor evaluation. Indeed, in their discussion of evaluating online courses, Palloff and Pratt (1999) stress the importance of considering all aspects of the course, including student performance, course design, online conversation, and other elements that usually don’t make their way to the standardized rating form. Because the ultimate goal is to help students meet the learning outcomes expected in a multimedia lab-based, significantly web-enhanced, or fully online course formats, tenure and promotion cases that demonstrate as specifically as possible the extent to which these outcomes were met are most likely to be successful ones. Electronic portfolio assessment has incredible potential in this regard. While teaching portfolios, including electronic teaching portfolios, are recommended for all teacher education students by the National Council for the Accreditation of Teacher Education, such professional development tools must be extended to university-level educators. Yet in advocating such an initiative, the material conditions of the institution must be addressed, including issues of access, technical support, learning curve, workload, educational philosophy, and institutional rewards. More than any other group, the college professoriate is charged with educating future teachers and working professionals in the newest technologies of literacy and communication and with meeting the diverse needs of learners both inside and outside the traditional boundaries of academe. Electronic portfolios provide an opportunity to both demonstrate our curricular efforts in this arena and to be rewarded for those efforts. As this paper has stressed, working toward these goals is the collaborative institutional responsibility of faculty, administrators, departmental and college tenure/promotion committees, and faculty development units.

Porto Alegre, RS, Brasil
elisa@inf.pucrs.br
giraffa@inf.pucrs.br

Abstract: This paper presents a software named Tirinha. It is an educational environment to build comic strips in a cooperative way. It was built to assist the teaching-learning process in elementary schools. The environment has a methodological approach that should be followed in order to create the stories. The environment enclosed a tool to match drawings or pictures with texts, a chat tool to support the co-operation process among children, and an edition area to construct the comics.

Introduction

The new medias integrated with new information technologies offer us an opportunity to create new methodologies in order to improve the learning process, and overcome the limitations of traditional methodologies in schools.

Teachers and psychologists have different interpretations about the contribution of comic strips for educational process. They can be used as a teaching-learning resource; their application has been analyzed and evaluated by specialists. Comic strips entail the idea of movement, and are composed by images and texts (Rade, 1997). In fact, comic strips can be defined like a graphic/literary set formed by image and texts (Luyten, 1985).

The use of images helps the student to understand the process of reading or writing in any language. Thus, the image can be seen as a new resource to support Portuguese learning (or others fields) and as a source to develop interdisciplinary activities. In our methodology, the teacher proposes a specific subject that will work as a common theme to be discussed by students. They will interact in order to create and organize the script, characters, and other details that will compose the story, generating a comic strip as a final result.

We believe that teachers need to create and apply new methodologies in order to promote a more efficient learning process. So, an educational environment must provide the teachers tools to explore different tasks using methodologies that allow the students to explore the domain, and understand the way they acquire knowledge about something, in other words, a “learn-to-learn” approach. To achieve this we need to offer open environments that allow teacher and students to test hypotheses, and create alternatives to better understand the different possibilities that arise from a specific domain exploration.

This paper is organized as follows: section 2 presents some issues to be considered when building comic strips in a cooperative way, and methodological aspects of comic strips building; section 3 describes the Tirinha environment; section 4 presents the preliminary results, and future work.

Methodological Aspects of Comic Strips Building

Piaget and Vygotsky have emphasized that social abilities (e.g. communication, cultural inheritance) promote the development of comprehension and help the learning process. Collective activities are usually separated in two different categories: collaborative and cooperative learning. In this paper, we use Barros’ (Barros, 1994) definition, because the cooperative concept presented has a wider scope. Moreover, it considers collaboration as being an assumption for co-operation. The result of a cooperative work consists of the individual contributions discussed among the group members in order to create a final work where it is not
possible to identify the contributions of each group member. Co-operation implies the existence of collaboration.

We have developed a survey with Portuguese language teachers in elementary schools. The goal of this survey was to elicit the teachers' profile concerning: software selection, methodologies adopted when using comics strips as a complementary activity for their classes, and their opinion about resources that could be included in an environment that intends to support cooperative comics strips production. Out of a universe of twenty schools, we have selected just four. This is due to the fact that we needed schools where teachers were using new teaching methodologies, as well as performing interdisciplinary activities. Nine teachers answered our questionnaire. When we proposed the research, we thought we would have around fifteen teachers collaborating with us. However, in fact, our expectations were not fulfilled. Most of them did not answer the questionnaire and said that they are not available for interviews.

This small number of participants needs further reflections from Education/Psychologist specialists. The reasons of this behavior need much more reflection, because it seems to us typical of teachers from the elementary level. We developed in our group other survey with the same target public, and we found the same problems.

In this survey we have observed that private schools normally use educational software in classrooms and comic strips to support Portuguese language teaching. This methodology (the use of educational software and comic strips) can be enriched via a computational cooperative environment where students are not space limited and can use the Internet, educational software and where there are software resources to be used together.

**The Tirinha Environment**

The Tirinha environment was designed under the computational and pedagogical viewpoints that we identify on a previous survey with correlated environments. We evaluate two commercial products developed to support the children comic strips building, Microsoft Fine Artist (http://www.microsoft.com/brasil/produtos) and Quadrinhos Turma da Mônica (http://www.monica.com.br), from Mauricio de Souza Produções. These products were selected because they were mentioned during our survey in schools.

Tirinha has a set of tools that makes it possible to create comic strips in a cooperative way. This set consists of a chat tool, a whiteboard to visualize the chosen images (pictures or drawings made by the student) and the current version of each picture that compose the comic strip. The images are stored in a shared database and are accessed through an editing window.

Tirinha has several activities that can be accomplished individually (activities like creating student’s database of pictures) and others that can be performed co-operatively (like making decisions about the comic strip’s pictures, texts, and so on). The interface has the following resources:

- Chat Tool;
- Access to shared and distributed databases;
- In the database management each student has his/her own database that can be shared among the workgroup and with images ready to use.
- Window for comic strips’ picture edition;
- Group members’ visualization;
- Visualization of the available comics in the shared databases;
- A whiteboard for cooperative pictures edition.

The work resulting from student’s activities is a set of HTML pages. Students can also create presentations, for example, in the Microsoft Power Point tool pattern.

The Tirinha environment was design to get objects (images, pictures) that are distributed at students computers and include them in the whiteboard tool. The students can get the images to put in the comic built in a cooperative way. The whiteboard tool was developed by Delphi language and it has the features of insertion of rectangles, circles, text and images. Also it is possible to print the comic, to open an old comic, save and edit a new comic. The comic construction is made in a cooperative way, and all participants connected in the same server can receive the alterations occurred in the screen. When a student make an interaction in the whiteboard tool, for example, writing a text or drawing, happens an image lock and this image is free when the student when the student release the mouse button. After the edition, the image co-ordinations are transfer through the server to the clients.
The clients applications are developed by Delphi language and have both applications in it: whiteboard and chat. The server application was developed in Java language and uses the sockets feature to communicate with clients.

The chat tool has features like: communication with all session participants, send messages just for a person or a selected group of people connected in the same server and save a log file to retrieve the interactions.

The Tirinha environment integrates, in the same interface, the whiteboard and chat tool to allow the cooperative comics construction. The Fig. 2 shows the Tirinha interface with four main regions:

1. comic construction area;
2. area that shows the students interaction through the chat tool (example in Portuguese);
3. area when the students type the interaction to send to other students and
4. open picture button to select and add images in the whiteboard screen.

![Tirinha's interface](image)

**Figure 1: Tirinha's interface**

Besides the computational environment support, Tirinha has a methodological support to help the teaching activity. A homepage was built to assist teachers in their classes. In this homepage is available some suggested methodologies to use the Tirinha computational tool. Also, you can find system documentation, correlated works and the prototype of Tirinha’s download.

After the survey conducted at schools and interviews with specialists, we can select some methodologies used by teachers in their classes (Boff & Giraffa, 2000) and suggest any other. Other methodologies can and must be suggested by teachers, because the Tirinha environment was conceived to be used in different ways.

**Preliminary Results and Future Works**

The internet and the associated technologies (e.g., local area networks) brought something really good for educational environments: they enabled us to do much more than just transport traditional methodologies to virtual classes. The need to create new environments and methodologies that allow teachers to explore different possibilities to improve the educational process is something very exciting, and the big challenge for educational researches. Only teachers can create new methodologies, computers just enlarges the set of tools available for the teachers. To better explore the environment possibilities it is necessary to have a creative and a participative teacher.

The results of this project allow us to demonstrate the enrichment that comes from the cooperative work when we combine different research lines with a multidisciplinary approach. Besides, we believe that the main contribution of this work is also the environment that allows students to build cooperative comic strips supported by a proper methodology with an integrated interface.

We have tested the different tools that were developed (chat, whiteboard, and database). These results show us the potential of the environment. To better achieve a good design for it, a specialist in comic strips supervised our prototypes, and helped us to test the available possibilities with the children. Also, teachers were interviewed to provide information about methodologies and comic strips usage in the teachers classes. The
design, the implicit methodology, and all the aspects that are found in our environment were possible because we work in an interdisciplinary team. The system validation was made with the teachers that supporting us during the environment design and it shows the system potential. In the future, we intend to make the system validation with children at schools and provide the tool feature of comic (scenarios, character) edition.

E-LEARNING: CHALLENGES AND INHIBITORS

Prof Dr J A Boon
Director: Telematic Learning and Education Innovation
University of Pretoria
South Africa
jaboon@up.ac.za

Abstract: E-Learning has become a major drive in some institutions of higher education. E-Learning programmes need management and faculty participation to succeed. In this paper some of the methodologies in the implementation of E-learning is explained. The use of ICT in teaching is too an important issue to be left to individuals and should be managed university wide.

INTRODUCTION

E-Learning is fast becoming a mainstream activity of many universities. To promote educational excellence the strive is for education innovation involving all faculty staff members. It is not just creating course material on the Web and making it available in the case of MIT free charge to everyone. E-Learning involves more than transferring information in electronic form. It involves teaching strategies like communication [discussion, chat, questions and answers]; formative assessment, participation, case studies and problem solving, assignments, demonstrations, simulations and record keeping. E-Learning as mainstream activity should be an integrated solution to some of the problems of contact tuition, but cannot in anyway exclude or supersede contact teaching.

METHODOLOGIES

Some of the methodologies in the implementation of E-Learning at the University of Pretoria are:

Combining top-down and bottom-up approaches

In June 1997 the Council of the University adopted a resolution to make telematic education part of the main-stream teaching activity. Simultaneously every academic school was asked to draw up education innovation plans following a general guideline document that was drawn up by the senior management of the University “University-wide Education Innovation: points of departure and guidelines”. Deans were asked to identify champions who could start E-Learning by putting their material on the Web and experimenting with new ways of teaching and learning.

Change management plans

Schools were asked to send faculty members to change management workshops. Every school appointed education innovation managers/coordinators. These people report directly to deans who take the overall responsibility for education innovation in their schools.

Seed funding

Champions draw up project proposals and business plans. Seed money was made available for every project according to specific needs in schools. The big advantage of this money lies in the fact that project managers were able to attract people and other resources like graphic artists and instructional designers over and above their normal resources.
Project management

This proved to be a very important part of the success the University had so far. Every programme that is put on the Web is managed according to project management principles. The Department of Telematic Learning and Education Innovation appointed project managers in collaboration with faculty members.

Involvement of management and academic staff members

It is sometimes difficult to involve busy academic managers. Seed money was only made available after a decision of the relevant pro-vice-chancellor. He/she is kept up to date in terms of the progress of every project.

VIRTUAL CAMPUS

A Virtual campus was created using the WebCT platform and integrating academic support services: the library, admissions, e-pay, student administration, etc. 7 500 students are now following more than 100 programs on the Web through the virtual campus. The virtual campus has been running since October 1988. Band width and communication problems were and still is our biggest headache. Integrating the academic information service/library has been the biggest success. Students are now able to retrieve full text materials without coming to the library. Online communication between students and lecturers [discussion groups, chat rooms, etc.] is working although lecturers have to adopt to their new role of learning facilitator/coach.

INHIBITIVE FACTORS

Inhibiting factors that hamper us in rolling out e-learning with adopters and late adopters are:

- general perception that quality of teaching is not so important;
- established formula for resource allocation;
- time to develop content in appropriate form for E-learning;
- workload;
- new role of the lecturer; and
- need for instruction in E-learning [just in time]

A number of strategies are being developed to overcome some of these factors.
Supporting Developers by Building-Block Methods: The Case of the Templates

Eddy Boot
TNO-Human Factors, Soesterberg, The Netherlands
Kampweg 5, P.O. box 23, 3769 ZG Soesterberg
E-mail: boot@tm.tno.nl

Abstract: The development of advanced learning environments requires a considerable level of technical and didactical expertise. Also, the time and costs of the development process is often substantial. In order to promote development by Subject Matter Experts (SME’s) and instructors, we have suggested using building-block methods that provide pre-structured software templates (Boot & Barnard, 2000). We have started a number of projects to investigate this issue. The first project, the Templates-project, has shown that it is possible to support developers in creating courseware for relatively simple learning objectives but with a high level of technical complexity and interactivity. The second project, the BAOZ-project has shown that it is also possible to embed more advanced didactical functionality such as case-based learning into templates. In the current project, the TOP-project, we investigate these issues in the context of telelearning. Amongst others, we focus on integrating work and learning by using real work-related material into case-based learning templates, and the reuse of learning material by means of standardized meta-data structures.

Introduction
The development of advanced learning environments requires a considerable level of technical and didactical expertise. Also, the time and costs of the development process is often substantial. In order to promote development by Subject Matter Experts (SME’s) and instructors, we have suggested using building-block methods that provide pre-structured software templates. These should be able to scaffold the development process by offering pieces of program flow and user interface components, that can be filled with learning content and multimedia components. Connected to each other, they constitute a complete courseware program. This development process can be guided by means of wizards (see Boot & Barnard, 2000). We have started a number of projects to investigate these issues. In this paper, these projects will be presented and discussed.

The Template project
The first project is aimed at supporting courseware developers within the Royal Netherlands Army (RNL). In general, these developers are instructors and SME’s, and don’t have much experience in programming, multimedia development and instructional technology. Most often, they develop courseware for relatively simple learning objectives such as operating procedures, the organizational structure of the army, and recognition of material such as tanks and airplanes. It is their desire to make the courseware appealing (by means of multimedia), interactive (by means of many learning activities) and manageable (by means of Computer Managed Instruction (CMI)). These requirements cause a high level of technical complexity of the courseware and courseware production. To lower this level of complexity, we developed courseware templates that a) guides them through the development process by means of wizards and b) offers automated construction of the course structure, interactivity and embedded multimedia elements. The templates are created with Authorware®’s Knowledge Objects.
The BAOZ project
In the second project, we focus also on the application of more advanced didactical functionality such as case-based learning into templates. The Royal Netherlands Navy (RNL N) experienced problems in educating cadets the Rules of Engagement at Sea (in Dutch: Bepalingen ter voorkoming van Aanvaringen op Zee (BAOZ)). These Rules are very judicial and cadets have trouble in applying these formal rules correctly and optimally in real life situations. In bridging the gap between classroom lessons and simulated-and real navigation lessons, we suggested using courseware based upon case-based learning. Case-based learning is especially beneficial for acquiring complex, cognitive skills in domains that have no equivocal, straightforward solutions (Schank, 1997; Spiro & Feltovich, 1991; Spiro, Feltovich, Jacobson, & Coulson, 1992). Cases present realistic problem situations that evoke authentic learning activities, that guide the transfer of learning formal knowledge (the Rules) into application of that knowledge in fuzzy, uncertain and unpredictable real-life situations.

Unfortunately, implementing case-based learning into courseware is difficult and often very expensive. Furthermore, the RNL A does not have professional expertise in courseware- and multimedia development available. However, considering their desire that officers and instructors should be able to adapt the courseware and cases to their specific requirements, complete development of a course by a third party is not a good option. Therefore, we developed case-based templates, which allow RNL A officers and instructors to create problem situations within cases, and build courses based upon series of cases.

The case-based templates provide cases that contain a generic navigational problem that unfolds itself within a simulated situation. Within each case, the cadets are confronted with questions about the problem situation, and can adjust their point of view (egocentric vs. different helicopter views) and the speed of the ships. The RNL A officers and instructors can adjust different parameters that configure each case within a Scenario Editor. Context parameters define the kind of surrounding (harbors, open sea), kind of ships, waypoints for the routes of each ship etc. Case parameters define the kind of questions that are asked, the Rules that are presented, the answers that are suggested and the feedback on those answers. Course parameters define how the series of cases constitute a course. This enables the officers and instructors to courses and cases based upon the rules as well as their own experiences in difficult navigational problems.

**Future developments**

To conclude, both projects have shown that it is possible to a) build templates that lower the technical complexity of the development process and b) incorporate advanced didactical models into templates. In a current project, the TOP-project, we investigate the issues presented in this paper in the context of telelearning. Telelearning offers possibilities to extend case-based learning by interacting time- and place independent with information sources, experts, coaches and other learners. Amongst others, we focus on integrating work and learning by using real work-related material into case-based learning templates, and the reuse of learning material by means of databases and standardized meta-data structures.

Abstract: This paper is a follow up of the papers that discussed how information technologies could be used in teaching Advanced Mathematics (Bouniaev, 1995) and in developing general logic actions (Bouniaev, 1999). Here we discuss the possibility of using databases in teaching Advanced Calculus. The psychological foundations of our considerations are Stage-by-Stage Development of Mental Actions Theory.

Introduction

This paper is a follow-up of research contained in the paper “Some Psychological Aspects of Developing Computer Based Instruction in Undergraduate Advanced Mathematics” (Bouniaev, 1995) as well as in “Computer Based Instruction and General Logic Action Development In Teaching Mathematics” (Bouniaev, 1999) In these papers, we mainly discussed the methodology of using Information Technology (IT) in studying such disciplines as Calculus and Foundations of Algebra and Analysis. They focused on the development of elementary general logic actions such as classification and attributing to a concept. The psychological foundation of the above-mentioned papers was Stage by Stage Development of Mental Actions Theory (SSDMA theory).

Since the first paper in the series was published, long discussions and collaborations with M. Connell led us to the conclusion that SSDMA prescripts for organizing a learning process practically coincide with those of the constructivism (Connell & Bouniaev, 1996). Thus we would like to emphasize that although we still explicitly proceed from the concepts and recommendations of the SSDMA theory, implicitly there are no contradictions with the theory and practice of constructivism. Proceeding from the above-mentioned psychological theories as a fundamental basis for using information technologies (IT) in this paper we discuss the possibilities of using databases in organizing instruction process of such an abstract discipline as Advanced Calculus. This discipline is a part of most math teacher training curricula and can substantially impact the efficiency of teaching Calculus in high schools.

As theoretical and experimental research shows (Bouniaev, 1994) databases and bases of knowledge (complete with a designed interface) can serve as construct frameworks for implementation of basic theses and prescriptions of the SSDMA theory of developing mental actions in organizing interactive computer oriented instruction. Therefore, theories of artificial intelligence and data and knowledge representation were used (see Durkin, 1994; Haes-Roth et al, 1983) in this research.

Newman et al (1989) emphasized that Intelligent Tutoring systems cannot substitute teacher’s performance which is certainly indisputable. However, a current tendency to present knowledge in Artificial Intelligence format makes a substantial impact on instructional software design which does not formally belong to Artificial Intelligence Systems. We consider the frame structure of knowledge presentation very useful for our purposes.

Basic concepts of the SSDMA theory

This paragraph is based on the monograph of Talysyna (Talysyna, 1975). According to this theory the major goal of instruction is developing mental actions with objects of the studied field. Instruction is
viewed as controlling students' activities and hence controlling the process of development. Thus, instruction efficiency is determined to a great extent by a well-developed system of control.

All actions can be referred to two categories: general logic actions and specific actions. General logic actions are inherent in every subject field and are different only in objects at which they are directed. Examples of such type of actions are qualification; break up into classes, comparison, contributing to a concept, action of proof. For example, qualification as a type of action exists in mathematics (qualification of the conics and differential equations) as well as in other disciplines. Specific actions are basically inherent to a given subject field. For example, in mathematics they are arithmetic operations, differentiation, etc.

The SSDMA theory specifies four independent characteristics of any action used to judge the level of development of an action:

- Each of the described forms of actions has another three independent characteristics: (a) degree of generalization; (b) degree of completeness; (c) degree of assimilation.

(a) Generalization of an action means ability to apply it to objects of a different nature. If the degree of generalization is high enough a person can easily apply this action to different objects, or example, if the action of qualification of conics is developed with a high degree of generalization then it can be applied to a similar problem in three-dimensional space. In this case a person has developed some general ideas how to perform a qualification action.

(b) The degree of completeness indicates if all the operations that were to be performed in the process of performing an action have been actually completed. For example, in teaching the action of qualification of animals an operation to be performed is obtaining enough specific characteristics to be able to refer an object to a particular class. It is evident that sometimes all the answers can be correct but based on superficial characteristics which indicates that in the process of performing an action either wrong operations were made, or the order of operations was wrong, or not all of the necessary operations were performed. The common method of establishing the degree of completeness of an action is restoration of all the operations necessary to perform it.

The degree of assimilation, as a rule is connected with such indicators as the speed of performing an action, technical errors and mistakes, the level of automatism, etc. It should be noted that drill-and-practice software first of all is aimed at developing certain actions with a high degree of assimilation.

The SSDMA theory singles out five stages in the process of instruction. Detailed analysis of each of the stages in organizing a computer oriented learning environment is given in "Development of multifunctional dialogue CAT programs " (Bouniaev, 1991), therefore here we will provide just a brief outline of these stages.

The first stage deals with the presentation of the material to students and description of an action to be developed. Note that passive reception of knowledge by students is not performing an action. The second stage consists of developing actions in the materialized form. The third stage deals with developing an action in the speech form (both oral and written). The fourth stage is beginning interiorization. Each of us probably noticed that before performing an action to make it easier we tend to speak it out to ourselves. Speaking out to ourselves is the fourth stage of development. At the fifth, final stage, the action is developed in a mental form. Note that at each of the last four stages the action is developed at a certain given level of generalization, completeness and assimilation.
Construction of materialized objects in studying advanced mathematics

As it follows from most modern psychological theories, for example, constructivism or SSDMA theory, at the initial stage of instruction the object of action should be presented in a material or materialized form of action (Bouniaev & Connell, 1996). Moreover, this action should be developed at a high enough level of generalization, completeness and assimilation. As a rule it is not hard to do when we deal with development of arithmetic or algebraic actions. But the more abstract the material, the more difficult it is to present the object of action in a material or materialized form. Thus in organizing the instruction of more advanced math courses it is common practice to start right from developing the action in the mental form. This negatively affects the level of student’s knowledge in abstract math disciplines.

The math teacher curriculum traditionally includes such disciplines as College Algebra, Calculus, Linear Algebra, Foundations of Algebra and Analysis, Abstract Algebra and Advanced Calculus. In training a math teacher each of the above-mentioned courses plays its particular role. A change of this role in studying more advanced courses significantly affects the character of didactic goals to be achieved in the process of instruction. This change can be easily observed in changes in wording of the exercises of the above-mentioned courses.

Thus in College Algebra and Calculus I the majority of exercises deal with finding a new object. For example, find a sum of two algebraic fractions, find a derivative or an integral, etc. At the final stage of instruction of Calculus and in teaching Linear Algebra the number of problems dealing with finding new objects is balanced by the number of classification or attributing to the concept problems. For example, to prove that the given series converges (in Calculus), or to prove that the given system of vectors forms a basis (in Linear Algebra). So we see a new type of problems, however, as we already mentioned they deal with development of elementary logic actions.

As a rule, the object of action of this type of problems can be easily presented in the material or materialized form. For example, it is easy to represent the terms of converging series as a sequence of dots on the plane. However, it should be noted that a model presentation of an abstract notion that looks superficially good is not always helpful in doing a specific problem.

Development of logic actions such as classification is connected with construction of materialized models that physically may not look like the respective actions but present in the materialized form the structure of such actions. For instance, tables can be used that students fill in while doing specific problems. It is also expedient to use electronic text fragments, which can be moved to different places on the screen. The details of using IT in solving this type of problem can be found in (Bouniaev, 1999). Therefore we are not going to elaborate it here.

At the next stage in teaching such courses as Advanced Calculus and Abstract Algebra besides simplest logical actions such as classification and attributing to the concept we have to develop more complicated logic actions such as the action of proof. Bearing in mind that in studying Calculus students have mastered the simplest “transformation problems” like finding a derivative or an integral, then in Advanced Calculus development of the action of proof becomes the major goal of instruction. And not only development of the action of proof, but proof of statements applicable to the whole class or classes of objects. In this case the object of action is a theoretical abstract concept, which makes it significantly different from the situation when the object of action is a particular function even if the action itself is an action of proof.

Thus for example the task to prove that function six x is continuous is significantly different from the one to prove that any continuous on the closed interval function is bounded. In the first case the object of action has materialized representation both in the form of a formula connected with numerous trigonometric identities and in the form of a graphic using which all the actions performed in the course of proof can be “materialized”. In the second case the object of action is a math abstract notion for which it is difficult to find a materialized representation. Any continuous function viewed as an illustration is just an example of an object coming under this notion and thus cannot claim to be a materialized representation of a math abstract notion.

Besides that, math abstract notion itself significantly depends on the level of development of an individual in whose mind it exists. For example, the notion of continuity exists both in the mind of a
freshman before studying Calculus I and in the mind of a senior ready to study Advanced Calculus. At the same time in the framework of the studied course (Calculus or Advanced Calculus) further development of abstract notions determines different actions that are objects of these abstract concepts.

For example, in Calculus I to develop the notion of continuous function it is enough to use the action of classification of pictures illustrating graphics of continuous and discontinuous functions. We can also effectively use pictures in a formal proof of continuity. However, in the proof of theorems in which continuity is a premise or a result, an illustration may help but it cannot serve as a materialized model of proof. A model should reflect not a particular case of the proof of continuity but general characteristics of any proof. In the framework of the model needed for instruction, “proof” and “proof of continuity” are related as general and particular. As the conducted experiments showed databases or bases of knowledge can serve as materialized models in teaching proofs.

Databases in the Study of Advanced Calculus

A natural information model of any subject field including mathematical theories is a database or a base of knowledge. We consider databases a named complex of data reflecting a stage of an object or a number of objects, their properties and relationships. In fact a database can be viewed as an information model of a given object, and effectiveness of the control system of the object depends on its preciseness and authenticity.

Using databases or bases of knowledge in the process of instruction is not something new. Already ten years ago reference and information systems built within the framework of prevalent databases constituted about one third of all the databases used in teaching math. However, we offer much more than just using databases for reference and information purposes although we do not exclude it either. Let us consider the possibilities of using databases at every of the five recommended by SSDMA theory stages of developing mental actions based on the organized process of instruction of Advanced Calculus.

According to the SSDMA theory at the first stage of instruction a student gets necessary information about a goal of action and its objects. The instructor in familiar from previous courses terms explains a system of reference points (prompts that help the student to master the studied material.) He/she also discusses the content of the studied material. It should be mentioned that even at this early stage of instruction, certain difficulties arise first of all because it is hard to explain to a student what the goal and object of instruction are. The thing is that students have been studying Calculus for three semesters but they still have a very vague idea of theoretical math fundamentals thus making it very difficult for them to understand what kind of proof they are going to deal with in this course. For the majority of students at this level, math is associated first of all with such words as find, calculate, etc. Problems of existence and therefore of proof are still completely alien for them. It becomes even more confusing since in most traditional advanced calculus textbooks the problems (especially in the beginning) are worded in the same way as they are formulated in their Calculus textbooks.

Questionnaires to monitor the students response that we have been distributing and analyzing during the last ten years of teaching Advanced Calculus invariably indicate that even after two or three weeks of instruction students were confused about what is required from them to succeed. At the same time most Advanced Calculus students already took courses incorporating databases. Thus terms associated with them such as table, record, form, report, query, relationship, etc., are familiar to them and do not provoke psychological rejection.

Using this previous experience with databases as an advantage we determine the goals of instruction as structuring the material contained in the textbook and explained in class. By structuring we mean constructing databases using the studied material of the course. Naturally the structure of any database significantly depends on what kind of information this database is used for. Therefore as points of reference for constructing databases we offer students typical questions that will be part of the test. Naturally, the most important points of reference are the examples of proofs discussed in class. By no means we imply by this that this is enough to teach students the action of proof. At the same time we include into the system of prompts questions like: “how to build a database so that using it one could reproduce the proof presented in class?” We also linked questions that students had to answer using their own constructed databases to the points of references. It was mentioned that the tests would include the following questions.

1. Formulate the theorem. 2. What is the theorem’s premise? 3. What is its conclusion? 4. What
notions are used in the theorem’s formulation and what is their meaning? 5. What theorems were used in the proof of the given theorem? 6. Give examples of problems, which are based on solving this theorem. 7. What theorems need to be used to do this problem? 8. Is the conclusion true in absence of any of the premises? 9. Are all the premises necessary for the conclusion to be true? 10. If you answered, “yes” in 9, demonstrate it. 11. Give an example of an object that can be attributed to this concept. 12. Give an example of an object that cannot be attributed to this concept. 13. Prove this theorem. 14. Solve a proof problem.

It should be noted that at this stage of instruction students are not yet involved in performing the action or they perform it in a perceptive form, i.e. students just observe how it is performed. Besides, in the process of demonstration / observation points of reference (prompts) are determined that help to develop the action at the next stages. At this stage the instructor can also use his/her own prepared database as an information system to get illustrations of examples, links with respective sites in the Internet, etc. Certain fields in such a database can be “objects” representing different program packages. At the second stage proofs are developed in the materialized form. In the course of experiment the entire group (about 30 students) was divided into subgroups of three. Students took decisions concerning the structure and elements of databases independently. It was assumed that any member of the group could use this database during the test.

At the same time there were certain limitations to the base itself and ways of its use. First, none of the fields could contain more than 50 symbols; second, none of the fields should contain a statement that could be divided into two conjunctive statements. For example, none of the fields could contain the statement “continuous on the closed interval function”. Such field should be broken up into three: a) function domain is interval; b) function is continuous; c) interval is closed. This way the students could not record the whole theorem in one field. This requirement also makes students seriously contemplate the possibilities of structuring any material.

The next set of requirements deals with the possibility of using databases during tests. First, students should act quite fast since the number of problems presupposed certain operational speed. Second, to speed up the process, the students could print out certain forms from databases but only those that closely followed the question in the premise of the problem and contained no additional information. That demonstrates how at the second stage of developing the action of proof we used the materialized form to enhance the instruction process. Students worked with texts and databases. The texts were given but they constructed the databases independently. We also focused on all the characteristics of developing the action of proof in the materialized form to ensure its success – generalization, completeness, and assimilation.

A high enough degree of generalization was achieved by involving students in the action of determining for themselves fields of records in a universal way so that they accommodate analysis of all other theorems as well. If the fields of record determined for one group didn’t accommodate a new theorem then the whole group had to be reviewed. A high degree of completeness was provided by the process when all the activities were broken up into two classes - determining the structure of databases and creation of new records, queries, filters and relationships. The first part implied breaking up an action into all the included operations and the second enabled its performance in the automatic regime. And finally, a high degree of assimilation was provided by the necessity to structure quite a lot of instructional information. Besides, one of the factors of successful use of databases was the speed of acquiring and utilizing necessary information.

As we already noted, the students themselves determined the structure of databases, fields, records, etc. However, at the beginning of this experiment we had a certain database structure in mind. First of all since we deal with development of the action of proof, it seems expedient to have a table of theorems, with the following fields: “Name of the theorem” (for example “Intermediate value theorem”); “Object of the theorem” (for example “Domain is an interval <a, b>”); “Premise 1” (for example “Continuous on the interval”); “Premise 3” (for example “Domain is a closed set”); “Conclusion 1” (for example “f(a)<C<f(b)”).

It also seems useful to have a table “Theorem Proofs” including the following fields: “Name of the Theorem”; “Object of the Theorem”; “Definition of Concept 1 used in the proof”; “Definition of Concept N used in the theorem statement”; “Model Problem 1”; “Model Problem N”. We also believe it would be helpful to create such tables as “Concepts and their definitions”, “Model Problems”, etc. Creating queries plays an important role in the instruction process. As with tables the students...
make decisions what queries to create independently. It looks expedient to create queries that provide access to all the records (or their parts) that have the same conclusion; like "sequences converge". It is also useful to create queries enabling to find a model problem solution proceeding from the problem being solved.

The third and fourth stages of action devolvement are designed to develop an action in external and internal speech forms. As we already noted, results of students activity at this stage should be either articulated out loud or written down. If at the previous stages in organizing the instruction process we focused on determining the structure of databases and building them then at this stage it already played a secondary role. At the same time, naturally, in the course of study new records were created and added. As a task, the students were required more and more often to write a standard proof using information from the student databases. If in the first test questions 1-12 were prevalent, then in the second test we included questions immediately related to proofs (13-14) and the third test consisted mostly of proofs with access to databases.

At the last stage the action should be developed in the mental form. At this stage students continued to replenish their databases, however, their use as an information system was limited to an emergency. Using databases during the test was penalized, though insignificantly.

Abstract: A decisive factor for new technologies is always the added value with respect to the efficiency and capacity of traditional technologies. This also is true when considering the impact of new technologies in training applications. New types of applications have been developed along the last few years to incorporate information technology in the learning environment. The growing need for communication, visualisation and organisation features in the field of learning and training environments, the e-learning approach, has led to the application of virtual reality and the use of multi-user real-time communication platforms to support these needs. This paper presents the first approach of such a system as well as useful technologies and standards for its implementation.

Introduction

The implementation of an attractive, user-friendly and effective teamwork oriented learning environment, to offer synchronous and asynchronous training services, includes many technological and pedagogical issues. In this section a short description of the basic components, issues and requirements of Networked and Learning Virtual Environments (LVEs) are presented.

A simple Virtual Environment (VE) is a computer system, which generates a 3-D virtual environment, with which the user can interact and receive real time feedback (Normand et.al. 1999). If multiple are connected and interact to each other the above definition is extended to multi-user or Shared VE (SVE). A Collaborative VE-system (CVE) is an SVE aimed at a collaborative task. A Learning Virtual Environment is a CVE that is designed to offer additional educational tasks such as synchronous and asynchronous learning (Bouras & Philopoulos & Tsiatsos 2000) and (Bouras & Tsiatsos 2000). A LVE is a set of virtual worlds or a virtual world, enhanced with educational functionality.

The users are represented by avatars (graphically) that populate the LVE and can be provided with additional behaviour such as gestures, interaction, movements and sound. Every LVE must comply with a set of requirements in order to be used widely.

Users are offered a high level of presence through their representation by an avatar of his choice, which simulates some basic realistic actions, such as gestures and movement, giving them a shared sense of space, presence and time (Singhal & Zyda 1999). Users are also able to navigate in a 3D shared space in order to access the content provided, to examine their knowledge, to interact with each other, to exercise their skills and to
receive the information provided. Furthermore the user is informed for the presence of other users (avatars), of their arrival in the LVE and their leave.

A LVE must also provide their users with many types of interaction in order to enhance the development of users as autonomous active learners both in the immediate learning context and in the longer term. Two types of interaction is defined in a LVE:

- Multi-modal user-to-user interaction: chat, voice communication and gestures. This type of interaction is supported by manipulation of shared 3D objects. Real time applications such as audio communication, application sharing and whiteboard functionality are important features.

- User-system interaction, which is based on navigational aid and commands that the system provides to the user for a specific function as well as the manipulation of 3D objects. Furthermore, the users must be able to insert and change objects in the 3D world, sharing these activities with the other users. This type of interaction offers the user the capability to customise the total design and outlook of the VEs according to the needs of their specific themes. Therefore the user-system type of interaction satisfies the need for customisation.

Although immersive applications are more effective in the use of VR technology, the main feature of educational VR applications is the interactivity and not the immersion (Youngblut 1998, Sutherland 1968). Moreover, a VR application, which is designed for educational use should be suitable for widespread use and mature in the part of the technology. Considering these requirements, immersive VR technology is not mature and it is expensive. On the other hand desktop VR is more suitable for widespread use regarding the hardware and software requirements (Youngblut 1998).

A LVE must be scalable to a large number of users in order to support large virtual educational communities. This set of users can be divided in each virtual world that is a part of a virtual educational community, which is able to support a maximum number of simultaneous users. The LVE must be able to integrate any digital material into the platform.

Two other features of the LVEs are consistency and coherence. Consistency is realised by distributing and synchronising user input as well as user independent behaviour in order to achieve the impression of a single shared world. Coherence is used with the sense of a uniform structure of the provided services, concerning mainly the functional and operational characteristics rather than its visual representation in the VEs.

Except the advanced features that a LVE must support, it should also be able to run under a variety of hardware and software platforms, support different formats/protocols and provide adequate security mechanisms. The system must offer an easy and complete administration mechanism allowing easy management of training material and users.

The remainder of this paper is structured as follows. In the next section we describe a European project in the area of the collaborative learning environments for distance education and our vision for its implementation. We then present a review of tools, technologies and standards, which are useful for the implementation of such a project. Finally we present some concluding remarks.

**Intelligent Distributed Virtual Training Environment Project**

INVITE (Intelligent Distributed Virtual Training Environment) is a project in the framework of the Information Society Technology (IST) Programme of the European Commission. It started in February 2000, and it will run for almost 3 years.

The main aim of the project is to build a platform for synchronous tele-learning which can be interfaced with standardised content management and/or instructional management systems. In order to reach this aim the following objectives have been set:

- Identification of the relevant cognitive and social processes in collaborative learning situation and extraction of those factors into user requirements.

- Development of an integrated system based on distributed virtual environment technologies, including intelligent agents’ real-time translation facilities, realistic avatar representation and enhanced interactivity of avatars.

- Evaluation of the prototype within different learning contexts.

- Research results on social learning processes within virtual environments.
INVITE provides the user with VR experience so it will be built over a 3D VRML multi-user environment with smooth movements, extensive textures, 3D icons for manipulation and interaction within the environment and stereoscopic visualisation options. A virtual model will be used for the construction of the worlds. The user interface will be enhanced through the integration of 2D video and 3D worlds.

Full body-photo realistic avatars will be used for representing the user since they seem to be more effective when used in a collaborative environment offering gestures like waving, nodding, bowing, disagreeing etc. The possibility for using talking avatars (text-to-speech lip synchronisation, driven in real-time from voice) with movement capabilities and voice driven emotions will be investigated during the project.

In order to offer asynchronous learning services INVITE will integrate available asynchronous learning systems and support audio/video streaming of available content. Additionally, in order to manage the documents and other educational material a document repository will be implemented, to facilitate data visualisation and implementation of structured search engines. A common habit in training sessions is that all participants take notes on paper copies of the training material and usually the trainer presents his material in slides and allows access to it.

User interaction will be realised by voice/text chat, and online translation. Users will be supported through the application of intelligent knowledge based agents thus providing tools for personalised searching and facilitate the organisation of background information. In (Fig. 1) the main components of a virtual collaborative learning environment are presented (Triantafillou & Tsiatsos 2000).

![Diagram of Basic Components of Virtual Collaborative Learning Environment]

**Figure 1: Basic Components of Virtual Collaborative Learning environment**

**Technologies**

The range of technologies available for developing collaborative virtual learning environments is more varied than ever. The exchange and presentation of web based material, 3D content and the transmission of audio/video streams, of high quality, are now supported by a variety of technologies and tools. Integrated platforms consisting of a server for the virtual environment and a client for the presentation of the 3D graphics are now available. Efficient user-system interaction is supported by a variety of intelligent agents. On-line translation tools for text communication and text-to-speech translation allow multilingual user interaction.

VRML97 (Virtual Reality Modelling Language) and X3D (Extensible 3D) will be used for handling multimedia, 3D objects and shared virtual worlds over the Internet due to their platform independence and their capability to allow scripts to be embedded adding more functionality in the 3D scene. External user and 3D-scene interaction will be supported by VRML-EAI (External Authoring Interface).

In order to ensure maximum performance a commercial platform must be used. Such a platform should be open, allowing easy integration with other platforms and technologies, mature (since the whole project will be based
on the platform), offer full support of VRML and other relevant technologies (HTML, Java) and run on a variety of systems/servers without major modifications to the code. The most promising platform seems to be the blaxxun Community Platform that complies with main features such as: full compatibility with VRML, audio/visual interaction, chat facilities, Java, JavaScript and EAI, 3D rendering and SDK support. Rapid prototype development of the virtual environments can be supported by Parallel Graphics' ISB and ISA which seem to be the most suitable application tools to be used since they support the VRML 97 standard. X3D-Edit can be used as a graphics file editor for editing, authoring and validation of X3D files. AvatarMe's technology (AvatarBooth) will be used for the capturing and creation of photo-realistic avatars.

Educational material (except documents) involves pre-recorded audio and video (streaming media). Most of the tools that facilitate real time support and electronic conferencing can be used to support communication between participants in a learning session thus covering the user demand for additional synchronous learning support. Microsoft Exchange 2000 Conferencing Server and Meeting Point since are open, offer a variety of features, conform to conferencing standards and can run over various platforms. OnLive platform supports only audio conferencing but its client can be used as plug-in in a web page. RealNetworks solution can facilitate pre-recorded streaming multimedia delivery and synchronisation.

User-system interaction in computer based learning systems is provided through intelligent agents (Fabri et. al. 1999). In INVITE a set of functions, like avatar and object handling, mobile communication interaction and collaboration will be programmed through intelligent agents. Also agents can be reminders, guides, guards and translators of the users. The use of declarative language implementations provide more advantages than procedural ones and for that reason the tool to be used should support KQML (Knowledge Query and Manipulation Language) for communication between the different agents. Java based tools (JAFMAS, IBM Aglets and AgentBuilder) have an advantage over other tools since they have the ability to run over different platforms.

HTML and XML will be used for their capability to facilitate efficient document exchange over the Web. XML offers more capabilities than HTML and can be used to provide metadata and various types of data on the Web. An efficient database management system will be used in INVITE to manage documents, user profiles and educational material. Since one of the main objectives of INVITE is to provide a tool that can run over a number of different platforms this consideration limits our choices concerning the DBMS to be used in INVITE. Oracle's solution runs under different platforms and provides a number of important features like security, XML support, capabilities for producing dynamic XML or HTML documents from SQL queries over the Internet. On of the most attractive functionality, which must be provided, is the capability for multilingual text communication and text-to-speech translation. In order to provide such functionality the system will interact with text-to-text and text-to-speech engines. The most advanced text-to-speech translation tool seems to be Speech Cube with the capability of running under different platforms allowing a wide variety of languages but the actual choice of the tool to be applied will depend on its openness and the cost. The most common used system for text-to-text translation is SYSTRAN, which also can run under a variety of platforms and translate from and to a number of several languages. Linguatec offers a flexible solution for text-to-text translation that can be used over the Web.

Standards

The efficient integration of systems relies on the application of world wide accepted standards. A number of organisations (public, private) are active in this field of technical standards like sub committees of the Joint Technical Committee of ISO (SC24, SC29, SC34), IETF WebDAV group, and the World Wide Web Consortium (W3C). In learning technology, interoperability standards and models for learning systems specific recommendations have been suggested the last few years and a number of committees and projects have worked towards that direction (IEEE LTSC LOM, CEN/ISSS, CENELEC, ETSI, PROMETEUS).

XML will be used to facilitate the efficient document exchange over the Web and XSL will support the creation of virtual XML documents and the presentation of these documents of different media types. The distribution of interactive multimedia/hypermedia applications in client/server architecture across different platforms of different types and media will be based on MPEG 7 standard. MPEG-7 will be used to describe the various types of multimedia information and their relationships using a description language. Information retrieval will be based on the application of Metadata to identify features shared by different documents. Metadata for learning material have also been specified such as: LOM, Dublin Core and ARIADNE. The approach of XMI, which specifies an open interchange model, will support the ability to exchange
programming data between tools, applications and repositories. Learning technology standards will be used for the organisation and presentation of the learning material as well as a basis for the user interaction specifications. In this context the IMS specifications defined for easy discovering of data, data sharing over different platforms, operating systems and tools and ensure reusability will be considered.

User-system interaction will be based on the use of intelligent agents. KQML supports the communication between the different agents and the implementation of the performatives defined by KQML. KIF (Knowledge Interchange Format) (Ginsberg 1991) supports the interchange of knowledge among disparate programs. User-to-user interaction in a LVE will be mainly supported by avatars and chat communication. The integration of avatars in VE will take into account the specifications for a standard humanoid (H-anim Group). In case these capabilities are not available electronic conferencing can be used. ITU's T120 and H.323 will be used for audio, video and data conferencing over the Internet.

Asynchronous learning services to the users will be supported by the delivery of pre-recorded educational material (audio & video) through the application of real time protocols. (RSVP, RTP, RTSP).

The core module in INVITE is the virtual environment since it provides the main functionality and all modules will use this environment to interact through it. VRML standards for incorporating MPEG-4 technologies (face and body animation, streamed video and audio etc.) and the recommendations for SQL database access in VRML will be considered in the development practice of the project.

Communication between the different components of INVITE will lie on the protocols which support client, server, multicast streaming and network capabilities (VRTP) (Brutzman et. al. 1997), real time interaction (ISTP) (Waters et. al. 1997), and multi-user participation in virtual worlds (VIP).

Text-to-text and text-to-speech translation standards are set up for lexical resources and language engineering. In INVITE guidelines from currently advancing initiatives (e.g ISLE and XLT) which produce standards in the areas of multilingual lexicons, natural interaction, multi-modality, interchange of data among lexical resources from various translation systems will be used.

In the following table (Tab. 1) summarises the components of an LVE, useful technologies and tools for its implementation, as well as standards, protocols and specifications to ensure openness and interoperability.

Conclusion

INVITE aims at the development of a collaborative learning environment for distance education (reflecting real life collaboration) using distributed virtual environments. INVITE fills in a gap, concerning Networked Virtual Learning Environments, both in terms of functionality and technology approach. INVITE is a real-time educational environment, where presence and attendance to the lectures could be made compulsory for inscribed
students with Internet access. The students have the opportunity to participate at the real event of the lecture, with the ability to raise questions to real professors, or at a specially arranged and recorded event, where the lecturers are represented by intelligent agents that can be trained to ask commonly asked questions and problems. INVITE establishes virtual communities with a theme, rules, roles and moderation where useful services can be employed to facilitate educational procedures. INVITE will provide a tool aiming in reflecting real life collaboration into a network virtual environment.

The added value of INVITE is in both the technological and the pedagogical field. INVITE is capable of running on the average users' PC and is compatible with standards like VRML enduring openness and portability of the application. Also, INVITE will facilitate the inclusion of many real world features allowing manipulation of objects and exchange of information with objects and users. All interfaces between the different modules of the system are based on mature standards and INVITE is an open system, which can be interfaced with standard instructional management systems and data representation schemes.

Abstract: Universities are under increasing pressure to develop a virtual presence in the face of widespread global competition. Online courseware development and delivery presents many exciting opportunities, and brings with it a number of challenges to be overcome. This case study describes some of the experiences of the EU funded TISCAM project, which developed an online masters-level course in supply chain management for work-based learners. The project involved a number of partners and multiple development teams working in parallel. Some of the issues and challenges faced as a result of this development model will be discussed, and resulting lessons presented.

Introduction

This case study outlines the development of online course materials within the context of a virtual university. The transformation of traditionally delivered courses into online versions can be a steep learning curve for all concerned. This paper will illustrate some of the experiences and lessons that have emerged from this research project. It should provide valuable insights for those engaging in large-scale virtual university development and delivery.

There are a number of significant challenges that the project had to face.

- The scale of the project, involving a number of partners and universities in the UK and in Europe, with a number of authors developing the material.
- Many of the authors were subject specialists, but did not necessarily have experience of producing courseware that could be delivered effectively online.
- The materials had to be vocationally relevant, academically rigorous, and allow pathways for learners to seek accreditation for their studies. The resulting course had to be capable of online delivery to learners in their workplace.
- There is a tension between the desire to design innovative systems and materials, and at the same time to maintain a realistic and practical hold on the project and the achievement of its goals.

This paper will discuss these challenges and how they were tackled.

The TISCAM Project

The TISCAM project (Training for Innovation in Supply Chain Management) is a large European-funded initiative involving a number of partners. It offers masters-level courses in supply chain management to learners...
in the workplace. Delivered through a virtual university framework, learners have access to materials, expertise and tuition from some of the key university providers in this field, irrespective of their geographical location. The target learners are managers in small and medium sized enterprises (SMEs), who are generally characterised by having small training budgets and limited release time to study full-time or block release courses away from work. The modular structure devised, allows a number of study pathways to be followed. Managers may have a specific personal or organisational training need within the context of supply chain management, or they may want to gain an accredited award – either can be accommodated.

Course materials were developed by a series of expert teams (see Fig. 1 below for an illustration of this structure). A central management team was responsible for the overall management and scheduling of the project. Authors from a number of universities produced the material, with guidance and support from development teams. The pedagogy support team provided advice and quality control on the effectiveness of the learning materials produced. The academic review team approved material for its curriculum suitability, and monitored subject coverage from one module to another. The technical team developed the delivery system, and worked with authors on the technical development of their materials, transforming them for online delivery, after approval by the pedagogic and academic reviewers.

![Figure 1: The development and delivery model](image)

Learners receive support from a range of specialists, each with their own expertise (Anderson & Oliver, 1999). They register at a Regional Delivery Centre where guidance is provided. Online support is available from a tutor with subject-specific expertise, and also from specialists providing technical and administrative support. In-company support is provided by a mentor, who gives guidance and support on work-based issues, helping the learner complete work-based activities, and to apply what they are learning within their company.

Initially, 12 modules were developed. Each module constitutes 100 hours of study, and is broken down into 10 units, of approximately 10 hours study time each. This includes: working through the materials; carrying out and completing activities and assessments; building up a portfolio; engaging in online discussion groups; reading case studies and related materials.

In developing processes to meet these developmental aims and characteristics of the project, a number of issues emerged. The paper will discuss some of these issues and challenges and how they were met. This discussion is organised around two main themes: developing large-scale online courses, and the reality of developing materials for an innovative delivery system, given the scale and constraints of the project. It will then move on to describe the resulting system and materials, and conclude with the key lessons learnt.
Large-scale Distributed Development of Online Courses

The project required a development process that could accommodate large-scale distributed development. The expert teams were based in separate geographical locations, as were the authors. In some universities there was a team of authors working on each module, requiring a co-ordinator to liaise between the individual authors and the development teams. The development process adopted was an ‘industrialised model’, in which a chain of experts each plays their part in the process. This is in contrast to the ‘craft’ model more familiar to lecturers, who are accustomed to designing and delivering traditional courses themselves (Peters, 1998).

Authors were selected on the basis of their subject expertise, and were invariably lecturers or researchers, who lacked hands-on experience of online courseware design. In view of this, they required ongoing help and guidance during the authoring process. Early on in the project a series of meetings were held, in which the pedagogy support team, technical development team, authors and project managers met. These meetings began to formulate operational frameworks and agree methods of working. Communication and distribution of materials was largely conducted by email, with face-to-face meetings held in a central location at periodic intervals.

The development of a pedagogic framework was identified as being important to underpin development in what, for many authors, was a new medium for learning delivery, and this became a subject of much discussion in early meetings. The pedagogy support team presented a number of approaches that could be adopted by the project, following an analysis of learner needs. This emphasised the need for motivating, vocationally relevant learning that could be undertaken in short periods of ‘release’ time within the company environment. A socio-constructivist approach was eventually adopted, which drew on Laurillard’s conversational framework (Laurillard, 1993), but was adapted for course design (Conole & Oliver, 1998).

To enhance shared understanding amongst the project teams, a series of guidelines were produced for each key player: for authors (Oliver & Conole, 1999), tutors, in-company mentors, regional facilitators (Anderson & Oliver, 1999) and also for the learners (Anderson & Oliver, 2000). These guidelines gave an agreed description of each role, and acted as minimum specifications for delivery, based on existing good practice drawn from the field of distance and online learning.

The guidelines for authors were designed to perform a crucial role in helping them to work with the new challenges they faced in developing online courseware. They incorporated:

- The context of authoring for the project
- The pedagogic framework
- The learner support framework
- Guidance on preparing units, using multimedia, incorporating peer group discussion, designing activities and assessment methods
- A template for specifying the aims, objectives, learning outcomes, learning methods and assessment methods of each unit
- The process for submitting drafts and acceptable formats.

The authoring process devised incorporated a number of stages. Authors draft units were submitted to the pedagogic and academic review teams for approval that the required standards had been met. The academic reviewer checked that the subject matter was adequately covered, and didn’t overlap significantly with other modules. The pedagogic review examined the draft in terms of its effectiveness as learning material, and feedback was provided to reinforce successful attributes and suggest improvements to address weaknesses. At the same time the technical developers reviewed the material, to ensure that authors were making appropriate and realistic uses of the available technologies. If revisions were required, the author was responsible for undertaking them, and re-submitting the unit for approval. Once each unit had been ‘signed off’ by each reviewer, it was passed to the technical development team to transform it into online material. Peer review amongst authors was also encouraged, enabling them to share experiences and learn from each other’s practice.
The Reality of Developing Materials for an Innovative Delivery System

On receipt of the first few drafts, it became apparent that authors were not designing materials according to the guidelines, continuing to work in the style most familiar to them. Much of the material resembled extended text books or teaching notes, with notable exceptions from authors with wider experiences of different teaching and learning practices. This resulted in an interesting diversity of materials, but an overall lack of consistency from one module to another. It emerged that one reason for the lack of a common approach was that the pedagogic model adopted, based on Laurillard’s conversational framework, was unfamiliar to the authors (Laurillard, 1993). It was agreed that the model used should provide concrete recommendations on the structure of the materials, and should be familiar to all authors. Instead, Kolb’s experiential learning cycle was adopted as the basis for unit development (Kolb, 1984). However, even after this, authors differed significantly in the material they produced - a clear example of the difference between espoused theories and theories-in-use.

The whole drafting and review process took longer than was anticipated, and threatened to extend beyond the time-scale permitted by the project. Authors’ drafts took longer to produce, and the pedagogic reviewers found they needed to make a lot of suggestions for improvements to the materials. A number of solutions were devised to improve the situation. Firstly the author’s guidelines were tightened to incorporate a more clearly defined specification for authors, including structural considerations for the online delivery system, and criteria they should meet for the pedagogic and academic reviews. The amount of support and guidance for authors was increased. Meetings for authors and the development teams were held more frequently, giving opportunities for development workshops to be held and more time for the discussion of guidelines and issues being encountered. Examples of good practice were shared amongst authors, to help them to overcome common areas of difficulty, e.g. good examples of model activity answers and self-assessment questions.

A further development was that the technical team devised a set of templates for activities that could be re-used within the materials. This served three purposes. Firstly, it provided examples of how web technologies could be utilised to produce more interactive and visual forms of activities for authors who were struggling to make full use of the capabilities of the online medium. Secondly, it made it easier for authors to incorporate self-assessment activities which had computer generated feedback. Thirdly, it helped cut down the development time required for the technical team, as they could re-use the basic structure and code from one unit to another. Maintaining the schedule and balance of the workflow became critical at times during the development process. Authors had agreed deadlines for the submission of units with the project manager, and the whole process was designed on the premise that they would submit units on an individual and regular basis. This enabled the reviewers to complete their task within the agreed time-scale of 10 working days and the technical team to have a steady flow of material to develop. However, some authors submitted several units together, which for the pedagogic review could make the process easier, as authors invariably developed a style, and units were likely to have common strengths and weaknesses which enabled common feedback to be given across a number of units. Any corrective action required of authors however, could result in substantial revision across a number of units. Several authors also fell behind schedule, so that when the final submission deadline arrived, they suddenly submitted their outstanding units en masse. This created a bottleneck at the review stage, resulting in a delay in the provision of feedback. At times when the flow of materials was not steady, the result was that there was not enough material to keep the review and technical teams fully employed, or alternatively, there was too much. There was a need for tighter control of the workflow, coupled with a greater awareness amongst all the development teams of the effects of missing deadlines on the balance of the entire production process.

Any project of this scale which attempts to develop innovative delivery systems based on good practice models will inevitably need to keep a close eye on practical concerns as development progresses. Initial ideals may need to be scaled down to suit practical and operational requirements and plans will constantly need to be evaluated and refined as issues arise and deadlines approach.
The Results

The technical development team created a bespoke online delivery system, providing the course materials with an overall consistent structure and functionality. Each module unit was divided into a number of sections, ideally between 4 and 6, which provided manageable amounts of material for individual learning sessions, around a particular topic. Within each section the material is separated into content, related material, case studies and activities, each accessible through a series of ‘tabs’ along the top of the screen. Other tabs provide access to additional services for learners: ‘community’ includes communication facilities between the tutor and contains the learner’s portfolio compiled from their activity responses, a study guide and access to support services.

This structure enables learners to construct their own pathways through the materials. The author guides the learners through the material according to their suggested route, but learners can also make their own choices of what material they look at and when they look at it. Because content, activities and related materials are presented separately, learners can for example choose to attempt all the activities first if they have a lot of experience in that area, or they can skim through the content and go straight to the case studies to find out about real-life examples. The result is a hyperstructure, a highly user-centred model which allows the users to have considerable freedom of access through a network of nodes of content and to pursue non-linear pathways through it (Boyle, 1997).

Orientation is provided for users in a number of ways, helping them to identify their location within the materials. The system only allows access through the tabs to materials within that section, so the user can’t accidentally navigate off to another part of the unit. Information at the bottom of the screen tells the user which module, unit and section they are currently accessing.

Technically, the materials utilise widely available web technologies to enhance and support the learning process. Graphics are animated where this is appropriate, for example to illustrate process flows. Activities include text input boxes, or allow attached files to be uploaded to the system database. Learner’s responses to activities are automatically stored in their portfolio, which is available for them, their tutor, or their mentor to view through the ‘student services’ tab. The development of a portfolio allows learners to build up a record of their work on the course and their achievements, which is common practice in vocational training.

Conclusions

A number of lessons can be drawn from this project which will be helpful for anyone engaged in the large-scale development of on-line courses. The production and delivery of online courseware can impose a steep learning curve for all concerned. New skills and expertise may need to be developed by a number of participants in a range of areas, and the sharing of expertise, in conjunction with ongoing guidance and support is important to ensure success.

Development models and processes need to be established which meet the diverse needs of project partners and the project as a whole. However, these may be alien to some participants, and it is important that shared understanding is achieved, and to acknowledge that refinement may be necessary if this does not result. Participants also need to understand and respect the roles and requirements of others within the process, so that schedules and work flows are maintained and the shared goals of the project can be achieved.

Ultimately, compromises between the pursuit of innovation and the achievement of effective delivery inevitably have to be made, in order that such a project meets its objectives within the resources and time-scale permitted.

The HyperSkript Authoring Environment—An Integrated Approach for Producing, Maintaining, and Using Multimedia Lecture Material

Andreas Brennecke, Harald Selke
Heinz Nixdorf Institut, University of Paderborn
Fürstenallee 11, 33102 Paderborn, Germany
{anbrihase}@uni-paderborn.de

Abstract: Based on a technical infrastructure that supports face-to-face university teaching, we have developed an environment that enables small groups of lecturers to develop and maintain lecture material co-operatively. In order to allow for a flexible use, only few formal workflows are imposed on the users while co-operation is supported by easy-to-use mechanisms. We have extended the functionality of an existing web server to support and integrate individual, distributed, and co-operative processes that are involved in the production and maintenance of multimedia lecture material.

Introduction

Traditionally, multimedia material that is being used in university teaching has been pre-produced by a single author or a team of authors. Students may then work with this material independent of place and time. The main goals of using technology are on the one hand to produce material that fosters learning by providing interactive techniques, animations, and simulations. On the other hand, communication tools are used to improve the contact between lecturers and students. The authoring tools with which the multimedia material is produced usually impose a strict separation of production and reception. Communication channels, if they are established at all, only serve as means for the distribution of material and information.

In this contribution we present an approach that transcends the one-way street of creation and reception. Instead, it promotes the distributed, yet integrated production, maintenance, and use of multimedia material. The conventional group of authors who produce for unknown learners is replaced by a group of authors who are at the same time teachers that use the material which has been produced jointly. They use the material in their own lectures and improve it based on their teaching experiences—in nearly the same way as they would do with conventional lecture notes. Thus, in addition to enhance lecture material multimedia, an integrated environment is provided that enables lecturers and students to work with own as well as pre-produced material. Our distributed multimedia lecture material (or HyperSkript, for short) allows for more flexibility in the use without raising the expenditure of producing the material significantly.

In order to allow for a most flexible use of the HyperSkript, authors may largely use the tools they are accustomed to, which is to say that standard technologies are employed to the largest possible extent. In addition to the authoring environment described in this contribution, a teaching environment and a number of supplementary tools have been developed some of which support the production of multimedia material—like interactive animations or the audio annotations described in (Grimm & Hoff-Holtmanns 1999)—while others simplify the use of the material by allowing users to create their own views on the documents. Semantic maps for example enable users to create a graphical overview on a specific subject. They act as navigation tool. Individual copies of the maps can be modified by the learners and adopted to their actual knowledge (see Klemme et al. 1998 and Hampel & Selke 1999). The overall structure of the HyperSkript is shown in Fig. 1.
Figure 1: The HyperSkript environment extends standard web technology by providing functions for the co-operative production of documents (authoring environment), functions for the active use of material (learning environment), and supplementary tools for the production of multimedia documents. The authoring as well as the learning environment are accessed via standard web browsers.

Requirements for the authoring environment

The experiences made in several years of using new media in university teaching (as described in Brennecke & Keil-Slawik 1995, Brennecke et al. 1997, e.g.) served as a starting point for the implementation of a new authoring environment. After having established an infrastructure that enabled users to work with electronic material at all locations where learning takes place (at home or in the library as well as in the rooms where tutorials and lectures are held), the production and maintenance of this web based material should be supported efficiently. Additionally, there was the idea of co-operating with a lecturer from another university in a way that allowed to create and maintain the material for lectures and use it at different universities while still teaching students in an individual way.

The HyperSkript contains all documents necessary for a course on a specific subject. This material is produced by several authors and integrates documents that all authors have agreed upon as being relevant for the context as well as documents that reflect their particular competencies and preferences. In that way, the material may be used in different courses while still allowing to present individual lecturing approaches. To allow this, the lecturers create different views for each single course by selecting the appropriate material. The material within the document base remains unmodified but may be supplemented by additional documents.

Co-operative development and maintenance are also important factors in rationalising the process of producing multimedia material which is a crucial aspect when it comes to working with such material on an everyday basis. The material needs to be structured in a way that it can be easily adapted or extended to integrate new results from research or simply modify the course to better meet the students' goals. The latter goes along with the requirement that not only the lecturers but also the students may individualise the material according to their needs and preferences. Thus, the students should also be able to work with the documents within the HyperSkript while leaving the original material in a consistent state.

As a result, the lecture material is designed to incorporate a high-quality core of material that has been produced co-operatively. This core is then surrounded by individual, sometimes short-lived, material like additional documents for a particular course, complementary notes, personal annotations of the students, or audio-annotations of a lecture. The different user groups (authors and students of different courses) thus need to be presented different views onto the material. The material should be structured in a modular way to allow for easier maintenance on the one hand and multiple use in different contexts on the other hand.
HyperSkript Architecture

Like in a textbook written by a group of authors, the authors have to co-operate on the question which contents to include in the HyperSkript and on the way these are broken down into modules as well as the multimedia and pedagogic design. The topic modules may consist of documents of various types ranging from images and texts to sets of slides, animations, or even CBTs. However, to guarantee that the material may be used in flexible ways and easily combined with other modules, each module should be self-contained and contain all documents necessary for dealing with that particular topic. These modules are stored in the so-called compound layer of the HyperSkript which is being produced and maintained co-operatively by the participating authors. For each module a “main author“ may be specified who is responsible for editing the content of that module. However, a module may only be released, i.e. given read access by the students, when all authors have agreed on it. Each module may also contain meta-data, in order to generate data according to the LOM standard.

The material in the compound layer may be complemented by background material like, e.g., journal and conference papers, images, or movie clips illustrating a relevant aspect. As this material is “objective” in the sense that it does not use an approach but rather documents that have been produced in a different context, the authors need not agree on the content. The authors may thus decide to distribute the maintenance of these documents—stored in the so-called base layer—in order to reduce the amount of work for each single author. The base layer is therefore sub-divided into areas, each of which is administered by one responsible author who alone may change or update content in this area. The other participating authors are notified of all relevant changes in any area of the base layer.

Finally, the topic modules and the background material have to be integrated with course-specific documents which finally make up the particular course—usually held by one of the authors. The assembly is done within the so-called course layer which is administered individually by the respective author according to the context in which the course is given. The architecture is shown in Fig. 2. The HyperSkript authoring environment aims at efficiently supporting the authors in creating, maintaining and updating the shared documents within the compound layer co-operatively and within the base layer in a distributed manner.

![Figure 2: A HyperSkript consists of three layers which reflect different kinds of co-operation.](image)

As opposed to systems that support co-operation in large distributed organisations which aim at the co-ordination of work processes by the implementation of formal workflows, a HyperSkript is produced by a small team of authors who co-operate voluntarily to achieve a common goal: the efficient production and maintenance of lecture notes that make use of multimedia and are of a high quality. In that sense, producing a HyperSkript is comparable to a group of lecturers and their assistants editing a textbook for university teaching. Therefore, the HyperSkript authoring environment does not implement any formal procedures but rather guarantees that the processes of creating and updating the material are transparent to all participating authors. For small groups of authors who trust each others, an optimistic “relaxed mode” allows the authors, e.g., to agree on updating a particular piece of text while in a meeting or even when talking to each others on the phone. Within the authoring environment one of the authors may then sign the agreement in the name of another author. However, it will be stored who actually signed in the name of
which author. Where such informal co-operation seems inappropriate, a “strict mode” requires each of the authors to log in to the authoring environment and sign the agreement themselves.

In the co-operation, the authors may use software they are accustomed to to the largest possible extent. They may use any kind of synchronous or asynchronous communication; the authoring environment simply allows to easily access these external tools or the necessary contact information. While the production of material is external to the authoring environment, it allows the authors to efficiently manage the documents, guaranteeing that students always see a consistent version of the lecture notes while the authors may create new versions of topic modules in a special editing area. All documents—including those in the course layer which may also be produced by the students—need to be managed within the system.

Using the learning environment (cf. Bader et al. 1999 and Meier & Holl 2000), the students work with the material in a way very different from the way the authors edit the material with the authoring environment. They access the HyperSkript from an entry point in the course layer which the lecturer supplies. The learning environment then allows each student individually to restructure the documents according to their own preferences, complement them with their own documents, and annotate existing documents. Students may also form groups and create their own private workspaces. While they have read access to all material of the HyperSkript which the lecturer decides to present, the internal HyperSkript architecture with its three layers is invisible to them.

**HyperSkript Realisation**

The HyperSkript authoring environment has been implemented on top of the Hyperwave Information Server—a specialised web server—which was chosen because of its strong orientation towards document management, its support for asynchronous co-operation and its extensibility on the server side as well as the client side. The latter allows for different user interfaces reflecting the special needs of authors and readers respectively while managing all documents within a single database. The mechanisms needed have been implemented using the Hyperwave Application Programmer’s Interface in Server Side JavaScript.

In order to achieve an optimal integration into the authors’ workplace, all functions of the authoring environment can be accessed with web clients of the fourth generation. Documents can be integrated into the environment using any of the Hyperwave clients, which again means using a web browser or one of the extensions to MS Windows programmes like the Virtual Folders which allow to access a Hyperwave Server from the Windows Explorer in a way similar to accessing a file system.

Within the authoring environment, documents of different kinds can be maintained and edited co-operatively. In addition to atomic documents, like texts, images, or audio clips, complex objects consisting of several basic documents like multimedia applications or hypertexts are supported. The authoring environment only implements the mechanisms related to co-operative document management (finding new or modified documents, releasing documents, creating draft versions etc.). The editing of the individual documents is done using the usual tools like HTML editors or office suites.

<td>universal</td>
</tr>
</tbody>
</table>

**Table 1:** The layers within the HyperSkript architecture reflect different types of working and different levels of co-operation.

As depicted in Tab. 1, the HyperSkript layers each require different mechanisms to support the co-operation needs. Presenting and editing the material within the course layer is done individually and thus does not need any kind of co-operation within the authoring environment. However, it needs to be guaranteed that students always see the latest released version of any document. In addition to basic mechanisms such as access control and locking mechanisms to prevent simultaneous write accesses, both other layers require specific kinds of co-operation support. When editing documents of the compound layer, a draft version must be created which can then be worked upon. The older version remains visible to the readers of the HyperSkript as long as this draft has not been signed for.
release by all team members in a *co-operative* process. In a similar way, new topic modules are always created in a special area which is invisible to the readers. Because production and administration are *distributed* among the authors in the *base layer* by division of labour, there is basically the need for notification as described above.

In order to efficiently support the different aspects of co-operation, certain awareness information is needed. According to Gutwin and Greenberg (Gutwin & Greenberg 1997), the following questions are crucial:

- **Who is currently working with the system?** A list of the team members who are currently logged in is visible to the authors. These team members may then be contacted easily by synchronous communication means such as a chat, a phone call, or a video conference. Given appropriate conferencing software, synchronous editing using a shared application is also possible. The HyperSkript authoring environment itself allows to specify any such contact information within a special user object. It does not implement any tools for synchronous communication but rather allows to easily access them via external tools from within the environment.

- **Who is currently working on which documents?** An author might want to contact another team member who is working on a particular document synchronously, e.g. because both are working on documents that belong together. This kind of awareness information is currently not supported by the HyperSkript authoring environment.

- **Which documents have been modified or newly created by other authors?** This vital information can either be distributed by notifications to the other team members—e.g. by sending an e-mail with a list of new or modified documents—or be gathered by each of the team members individually by using an appropriate search query. Currently, the HyperSkript authoring environment only supports a manual notification mechanism in addition to a flag shown next to edited or new documents. Because we expect that there will be many minor changes—such as the correction of typos—we decided not to rely on an automatic notification mechanism but rather log important events and leave it to the authors to send this log to other team members when appropriate. However, a search mechanism will be provided in the next version. In contrast to ordinary workflow systems within our "relaxed mode" each author has to decide which modification may be important enough to inform the other authors.
authors respectively which one have to be agreed by the others. (The correction of orthographic mistakes typically requires no reaction from the co-authors e.g.)

- Which state is a document currently in? At any point, the team members need to be provided with versioning and editing information. For that purpose, draft (or experimental) versions carry a certain attribute and are stored in designated areas of the data base. For new and revised topic modules of the compound, a voting mechanism is supplied where each author can state their agreement or disagreement on including the document in the current version into the HyperSkript. An author can decide to release a topic module for which he is responsible within the compound layer at any time. However, before it is actually released, all other authors have to agree on releasing that version. In addition to the current vote (who has agreed, who has disagreed, who has not cast a vote yet), there is a basic type of discussion forum that allows to make comments and suggestions for improvement. As soon as all authors have agreed on releasing the module, it is integrated into the HyperSkript and thus becomes accessible for the readers. The discussion is stored in an archive; older versions or drafts that have not been released may be archived. Fig. 3 shows the discussion of a topic module within our HyperSkript authoring environment.

Conclusions

The HyperSkript authoring environment supports teams of university lecturers who wish to co-operate in the production of multimedia lecture notes emphasising the need for developing and maintaining documents on a long-term perspective. A web based document management server has been extended to support co-operation processes in distributed authoring. Important features include awareness information, notification and voting mechanisms, creation of draft versions and easy-to-use release mechanisms. By integrating these new functions into an environment of standard software that is used in the every-day work processes of the lecturers, the HyperSkript approach seems to be a suitable tool for individual, co-operative, and distributed production, maintenance, and use of multimedia lecture material.

The authoring environment described in this contribution is integrated into the HyperSkript project in which an additional learning environment and supplemental tools have been developed. A prototypical script for courses on software ergonomics and design of multimedia systems has been produced, improved continually over two years by two authors, and used at two universities in different courses. Evaluation so far shows that students rate the material as becoming better over time. However, this good result may also have been influenced by other improvements in the accessibility of the material and requires a more detailed evaluation.

The SALSA Animation System: 
Simply Generating Java Applets to Learn with Basic Animations

Andreas Brennecke, Jochen Greiving, Manfred Hußmann, Michael Wegener
Heinz Nixdorf Institut, University of Paderborn
Fürstenallee 11, 33102 Paderborn, Germany
anbr@uni-paderborn.de

Abstract: The effective preparation of multimedia applications still remains a problem when using new media in teaching and learning processes. When using the Java technology which becomes increasingly important within the internet, the programming of Java applets is especially expensive. To reduce this disadvantage, we have developed a tool which supports the easy production of Java applets for a special class of animations which we characterise as basic animations.

Basic animations are interactive two dimensional animations intended to visualise facts as well as dynamic processes and to make them easier to understand. They are dynamic and controllable illustrations. Basic animations are constructed hierarchically from simple objects in such a fashion that the animation as a whole, or parts thereof, can be used within other basic animations. (Greiving 1999) Such simple animations with illustrative and explanatory character are helpful to demonstrate temporal processes. Apart from being simple run downs they also should allow for interactive control. Therefore, the possibilities of basic animations lie between simple animation sequences and more complex multimedia applications such as CBT programs or explorations (Hampel, Keil-Slawik, Ferber 1999).

Although there are many authoring tools for multimedia applications, no single one fit our goal to implement a hierarchical animation concept. Furthermore, we wanted to use animations within the internet and, if possible, without special plugins. Java applets fulfil these demands but their development effort is enormous. Therefore, we built a tool which generates Java applets from simple textual descriptions. Our system is based on the concepts of programming language-like animation systems such as XTANGO, POLKA, Goofy, SAMBA, or Lambada (see Stasko 1990, Ford 1993, or Mitchener 1996). These were designed in the 1990's, mainly to visualise the actions of computer algorithms. At first, Lambada or the XtangoAnimator seemed suitable because of their implementation in Java. However, both are based on Java 1.x versions whereas our hierarchical concept as well as the desired interactivity required a modified structure. In addition, the Java platform 2 contains fundamentally useful extensions (JFC/Swing components and Java 2D API) which should be used.

Therefore, we designed a new Java class hierarchy which provides a set of instructions to implement our basic animation concept. For simplification, a translator was developed to convert textual descriptions of animations into Java code and to generate executable Java applets. Although the class hierarchy can, of course, be used within any Java program, the emphasis is on the simple creation of animations—also for non-programmers. In the tradition of the naming of POLKA, SAMBA, etc. (i.e. according to dances) we called our tool the SALSA animation system.

Basic animations should be small multimedia building blocks which can be described in a special SALSA syntax which defines and connects the different object types.

- **Basic objects** are the fundamental parts of SALSA animations. Geometric figures (squares, rectangles, circles, polygons, ...) are basic objects as are bitmaps or text. Their attributes (position, size, geometry, colour, texture, ...) are used to obtain animation effects.
- **Modifiers** are used to change the attributes of basic objects as well as of composed objects. The application of a modifier (moving, rotation, scaling, ..., or changing of colour, texture, transparency, and level) on a basic object already defines a simple animation.
- **Compositions** (spatial and temporal structures) allow the concatenation of objects and the production of complex animations. Spatial structures (groups, couples, collections) combine several objects and make it possible to apply modifiers to complex structures. The time flow of animations is controlled by temporal structures (synchronisation, asynchronous run, sequence).
Control elements enable the interactive manipulation of animations. Buttons can be used to start animations and sliders can control the time flow. Furthermore, objects and animations can be manipulated directly with the mouse if the corresponding attributes were set for interactive control.

The SALSA concept offers a proper hierarchical composition of animations. All objects represent executable animations. Modifiers, combinations, or control elements can be applied to every animation. Animations therefore can be described as a tree where modifiers, combinations, and control elements represent the nodes while basic objects represent the leaves. A special start object embodies the root of an animation tree. If parts of the tree are to be used several times, the tree can be extended to a directed acyclic graph (DAG). To illustrate its simplicity, Fig. 1 shows a simple SALSA animation and its defining textual description.

```java
appletsize 600 521
rectangle background 0 0 600 521
setFillColor background gray
bitmap sidewalk 0 0 sidewalk.jpg
bitmap manl 550 350 man.gif
setInteractive manl MOVE
bitmap man2 550 350 man.gif
setInteractive man2 MOVE
bitmap man3 550 350 man.gif
setInteractive man3 MOVE
bitmap ruler 550 120 ruler.gif
setInteractive ruler MOVE
collection collect background sidewalk
manl man2 man3 ruler
```

Figure 1: A Java applet generated with the SALSA system to show the size constancy illusion. (The human visual system assumes that figures in the upper right corner are larger because the background image feigns a three-dimensional scene.) Students can interactively move both the figures to different positions as well as the ruler in order to check their actual size. On the right, the SALSA code for the animation is shown. Each line begins with a SALSA command and is followed by object names and/or attribute values.

The SALSA translator was extended by a graphical interface, also implemented in Java. A special text editor supports the creation of SALSA code. Syntactical correct textual constructs can be chosen from a menu. A colour and a font chooser as well as a file selection box (e.g. for bitmaps) support the setting of attributes. Second, parsing, translating and testing can be controlled interactively. A special log screen shows all actions or syntactic errors. The execution of the animation can be tested in a special runtime environment. Finally, a graphical editor supports the drawing of basic objects as well as an interactive scaling or grouping instead of textual descriptions. In this manner, the building of graphical scenes is substantially simplified.

The SALSA animation system is not a universal authoring tool for multimedia applications. Especially the time control cannot yet be represented and defined graphically. So far, SALSA is restricted to the concept of basic animations but the consequent hierarchical structure seems to be a reasonable approach for more complex animations, too. Main advantages are the simple generation of Java applets and the reuseability of animations or parts thereof.

Learning Contracts – a Measure to Set Up a Framework for Communication and Cooperation in E-Learning?

Jens Breuer
University of Cologne, Germany
Chair of Economics & Business & Social Education
jens.breuer@uni-koeln.de

Abstract: In a learning contract concluded between learners and teachers resp. between learners, stipulated learning and teaching activities are fixed. The purpose of a learning contract for e-learning is to clarify the innovative organizational structure and to give hints about how learners and teachers have to behave, to communicate, and to cooperate. Cooperation becomes easier when all participants know to which forms of communication and cooperation learners and teachers/tutors have committed themselves. In two of our projects, we gained experiences with this didactical and organizational method.

Introduction

In the „Mercur“-project and in the project „Meisterassistent im Handwerk“ (assistant master craftsman), we utilize learning contracts in a telematics-based advanced vocational training measure. Our learning contract
- gives hints about how learners and teachers have to behave, to communicate, and to cooperate, thus establishes a framework for communication and cooperation between the learners as well as between learners and teachers/tutors,
- clarifies the innovative organizational structure with a combination of face-to-face sessions and phases of telelearning to the learners and the teachers as well as binds them to its didactical implications.

Cooperation and communication becomes easier when all participants know to which forms of communication and cooperation learners and teachers/tutors have committed themselves.

Even though the experiences we gained were gathered in the field of vocational training, they can easily be transformed and used for education at other levels and with different target groups.

In the “Mercur”-project (http://www.mercur.de), forward-looking possibilities and limits of the use of tele-communication technologies for further training in the craft trades have to be researched, developed and tested with the scheme „Betriebswirt/in des Handwerks“ (business administration in the craft trades). This course is aimed at master craftsmen and is held by several chambers of handicrafts and the guilds.

The project „Flexible Zusatzqualifizierung (Meisterassistent/in im Handwerk)“ (flexible additional qualification as assistant master craftsman; http://www.uni-koeln.de/wiso-fak/fbb/MAH.html) is designed to research, develop and test possibilities and limitations for the acquisition of additional qualifications in the course of initial vocational training for the craft trades with the use of ICT.

In both projects, the www-based learning platform ILIAS is used. ILIAS was developed by the University of Cologne, faculty for economics, business administration and social sciences. As a workplace on the web ILIAS brings together tools for learning, authoring, information access, and co-operative work. It is in use since summer 1998, and more than 5000 students are registered. ILIAS is an open source software since September 2000 and can be downloaded (http://www.ilias.uni-koeln.de) without costs.
Contract Learning in Theory and Practice

In general, learning contracts are agreements between a student and a teacher that provide a framework for describing what a student will learn as a result of a specified learning activity. Though not binding in a strictly legal sense, learning contracts are statements of agreement on at least four elements (see Asselmeyer 1981, Boak 1998, Brambleby & Coates 1997, Caffarella & Caffarella 1986, Dohmen 1999, Feeney & Riley 1975, Knowles 1986, O'Donnell & Caffarella, 1990):

- learning objectives
- learning resources and strategies
- evaluations of learning activities
- a time line for completion

The term contract learning is known since the beginning of the last century. Learning contracts demonstrably exist since the 1960s in the United States, where they are usually used in a university context. (see Chickering 1975, Weingartz 1991)

With the signature of the contract, both parties accept an obligation:

- the learner commits to work with the material and to learn the content
- the teacher/tutor commits to provide material, to be ready for support and consulting, and to answer to questions as previously agreed upon.

The contract can easily be modified during the runtime. By the use of the contract, learners and teachers/tutors appear formally as emancipated, what can improve their relationship. (see Holmberg 1989).

Learning Contracts and E-Learning

In addition to the "normal" problems of conventional trainings (e.g. newly learned skills of the employees are not transferred to the workplace), in e-learning individual learners as well as learners and teachers are spatially and temporally severed. Adult learners are often not used to learn in a self-directed way with telematics-based media. Furthermore, the problems of computer-mediated communication, e.g. the reduction of communication channels, the lack of social context cues (Kiesler & Siegel & McGuire 1984), or social information processing (Walther 1994) are well-known (Bruhn & Gräsel & Mandl 1997). A very busy adult learner will not send an e-mail with a question to another learner or to a teacher or tutor from whom he or she does not know when he or she reads it and answers the request. The acceptance of a new learning method depends strongly on reducing the incertitude of the learners. Also a lot of teachers are not used to utilize the new forms of teaching and communication in a telematics-based setting.

The learning contract we designed for our courses eliminates the obscurities right from the beginning by describing some of the attitudes of learners and teachers that differ in comparison to a conventional course. In both projects, face-to-face sessions and phases of telelearning are combined. Learners and teachers declare in the learning contract

- at which point of time the substitution of face-to-face sessions with telelearning is pronounced,
- what the learners are expected to do with regard to their communication and cooperation behaviour,
- what and when learners and teachers are expected to respond,
- when the teachers are to provide materials,
- which organizational rules learners and teachers have to observe, etc.

Experiences with Learning Contracts and E-Learning

According to the experiences in our courses, this using this method in e-learning achieves the following objectives (Breuer & Schaumann 2000, Breuer 2000b):
the constitution of an organizational model for the steering of the teaching and learning progress, that is declared by teachers and learners.

In the learning contracts, stipulated learning and teaching activities are fixed, e.g. appointments for the answer of questions posed by e-mail. Learners are provided with supplemental course information that outlines course objectives, concepts, and ideas.

intensification of the individualisation and the autonomy of the activities of the learners.

The learners are motivated to design their learning activities on their own. Learners in further trainings in the craft trades often do not attend and utilize the opportunities and the necessity to design their success in learning on their own. By the use of learning contracts, this can easily be demonstrated and requested.

support and maintenance of a suitable form of communication and cooperation between learners as well as between teachers and learners, particularly during phases of e-learning.

We combine face-to-face sessions and phases of e-learning. In our judgement, also with the possibilities of telecommunication, a great amount of face-to-face sessions is needed (Breuer 2000a). Because of this organizational division of the learning situation, a permanent synchronous communication between the learners and between learners and a teacher/tutor is neither possible nor intended. The asynchronous forms of communication have to establish a didactical added value concerning the achievement of a success in learning. In general, learners in telematics-based education forms think that timely feedback to assignments and questions is a significant factor of success (The Institute for Higher Education Policy 2000). In our courses, everybody knows to which forms of communication and cooperation learners and teachers/tutors have committed themselves. According to this, learners and teachers do use the possibilities of communication and cooperation (like e-mails, discussion boards) in our system.

We utilized learning contracts for the first time in a course that started in February 2000 and ended in February 2001. This course had very few participants, and the experiences concerning the achievement of the objectives we gained were gathered by interviews with the participants. Further empirical studies will follow with learners of a second course (start: July 2000, end: July 2001). At the conference in Tampere, further results will be presented.

In addition to the objectives mentioned above, learning contracts should not be used independent of an analysis of the target group. Against the background of specific didactical and organizational considerations, they always have to be adapted to the specific needs and requirements of the target group. For example, the learners in the project „Flexible Zusatzqualifizierung (Meisterassistent im Handwerk)” need more elements that stimulate their motivation and give orientation, because of their minor age and their smaller experiences with self-directed learning, both in comparison with the learners in the “Mercur”-Project. In the learning contract, such elements can be integrated.

Problem Solving Strategies – Is there a better way?

Gwyn Brickell, John Hedberg, Brian Ferry, Barry Harper

Faculty of Education, Research Centre for Interactive Learning Environments
University of Wollongong
Wollongong, Australia, 2522
e-mail: gwyn_brickell@uow.edu.au

Abstract: Research on strategy use in problem solving has undergone considerable development in the last decade with the emphasis on the solving of complex and ill-structured problems. In this study, the problem solving strategy used by novice learners was investigated. The purpose of such an investigation was to develop a better understanding of how learners engage problems in technology supported learning environments with the view of developing a cognitive tool(s) to support students in the problem solving process. The problems investigated focus on environmental issues in the context of river catchment systems. The problem solving process requires clarification and understanding of the problem, collection of supporting information and data, and the application of analysis and reasoning to generate a solution. This paper reports on the initial outcomes of the study and its implications for the development of supportive frameworks for problem solving.

Background to the Study

In recent years a major growth in the development and application of technology supported resources for learning has occurred through changes in information technology, specifically related to CD-ROM and Web based development. The development of these interactive learning environments has eventuated because of the belief that students need to be engaged in complex, authentic tasks that demand higher level thinking and active learning. By presenting scenarios containing ill-structured (Jonassen, 1997) or open-ended problems (Land & Hannafin, 1996) students define issue(s), create hypotheses, locate and evaluate information and present their argument(s). However, the development of such higher order thinking skills is a complex process that is currently the subject of much research and theorising. Constructs such as ‘active’ and ‘inert’ knowledge, learner scaffolding and metacognition are frameworks on which these ideas are being developed.

Initial investigations to examine student perceptions of the problem solving process and the strategies they employ in moving from novice learners to expert practitioners have indicated considerable differences in problem solving skills between students (Brickell, 1998). Even though the majority of students studied appeared to be competent users of the technology, difficulties were experienced in defining the problem and developing a plan of action towards achieving a ‘solution’. Little evidence of re-checking or detailed analysis of the problem was observed. Most students reported they had little difficulty in developing a solution and understood, from the introduction to the ill-structured problem, what the issues were. However, analysis of their ‘solutions’ did not support this view illustrating both a lack of structure and a lack of clarity of ideas in their written responses. This study sought to examine the ‘theories and actions’ (Land & Hannafin, 1996) learners use, in problem solving, when provided with a range of supportive mechanisms that help organise ideas and focus possible problem solving hypotheses.

Research Questions

The main emphasis of the research addressed the focus question:

How can learners be supported in problem solving within technology supported learning environments?

To support this objective the following sub-questions were used in guiding the research:

When provided with a supportive framework, what ‘theories and actions’ do learners use in solving ill-structured problems within a technology supported learning environment?

What variety of strategies do learners use in accessing and making effective use of information when completing a specific task?

Research Design

Participants of this study (N = 32) were volunteers drawn from a first year undergraduate information technology class in the Faculty of Education at the University of Wollongong during Spring Session. Of the participants in the study, 27 were female and 5 male. The age of the participants ranged from 18-45 years. The study used the software Exploring the Nardoo(1996) CD-ROM, a constructivist learning environment designed for high school students. This resource introduced scenarios that encourage students in developing a plan to solve the problem(s). Experimentation, lateral thinking, acquisition of stored information, reflection and analysis, or combinations of these processes, are involved in promoting the problem-solving approach and developing students with a higher level of cognitive skill.

The study took place over a ten-week period. Initially all subjects were given an overview of the CD-ROM and randomly assigned to one of four groups (see Table 1). The subjects were asked to participate in the following sessions as part of the data collection process:-
1. Strategy tutorial: each group was instructed on the basic principles of their designated support strategy through modelling by the researcher then practised by the participants, with guided instruction, using both paper-based and CD-ROM based examples. All group members were issued with the strategy tutorial outline in written form and given time to work on example problems using their assigned strategy.

2. CD-ROM tutorial: all groups were instructed on the use of the investigating tool to develop their skills, with both the software and their assigned strategy, using alternative problems to those used in the study.

3. Problem investigation: all participants were assigned two problems to solve on an individual basis. This was carried out in two stages with revision of the assigned strategy prior to each problem solving session.

Table 1. Time Allocation for Stages 1 & 2.

Data Collection
The research followed two stages of development. The first stage involved participant familiarisation with the assigned support framework and the operation of the CD-ROM. The second stage of the research involved the researcher as a participant observer within the student group. Each student was allocated the same problem to solve and asked to prepare her/his solution using the support of the CD-ROM and the paper-based support framework. During the process observational field notes on student activity and interaction were taken. The primary sources of data collection were: student work, audio transcripts of student comments, observational records and student interviews. Student work comprised answers submitted to the assigned problems together with field notes collected on their PDA, and hand written notes compiled while completing the problem.

Participants were asked to verbalise their actions in the methods they employed in 'solving' the problem.

Results.
Even though participants gathered a number of pieces of evidence it appeared that in constructing their responses they preferentially consider one or two pieces of information rather than a variety of issues. In addition not all supporting evidence was accessed by a number of students with essential articles being 'missed' in the information gathering process, resulting in the formation of 'weak' responses when developing an argument to support the solving of the problem. Participants used a combination of their personal and their assigned strategy. Many still exhibit underdeveloped skills in adopting a systematic approach to both information gathering and in the analysis and comparing of supporting information for the problem under investigation. However, both these skills tended to improve with the second problem under investigation. With both experiments, a variety of strategies were used in accessing information, in the pattern of exploration in developing mental representations of the problem, in the use of the media elements and in the use of the guides in directing the focus of investigation.

Based on the four problem solving frameworks used in the study, the following generalisations are made: the two strategies Six Hats and Critical Thinking provide stimulus for students to seek out data and make some preliminary analysis of the suitability of the data in addressing a possible solution to the problem. Participants using these strategies presented clearer representations and better argued solutions to the problem. The other two strategies, Venn Diagram and Concept Mapping, focussed more on the organization of ideas once they were identified. In either case, students, when taught one strategy and then asked to use it for problem solving, did so with greater allegiance for the first two strategies than the second two. It is conjectured that this was due to the focus of the strategy on data identification.

Tammy Chapman
College of Education
Lehigh University
Bethlehem, PA USA
tac7@lehigh.edu

Abstract: The emergence of the World Wide Web as a valued medium for delivering instruction is sparking an interesting change in education on all levels. Universities, in particular, are investigating ways to exploit the power of new technologies in education. Yet, few have engaged in empirically-based investigation of the true costs and benefits for students - and teachers - actively engaged in online course experiences. The Clipper Project is a research endeavor designed to study the effects of Web-based learning on pre-college students. The project coordinators hope to provide baseline information to inform future developers and providers of online education and guide them toward the provision of informed, responsible learning experiences for students. This paper describes the aims, goals, objectives, and design of this web-based research initiative.

Introduction
The acceptance of the World Wide Web as a reasonable medium for delivering instruction is sparking an interesting change in education on all levels. It has been argued that Web-based technology has a positive effect on student learning (see Oliver, Omari, & Herrington 1998; Magalhaes & Schiel 1997). Yet, despite the universal call for Web-enabled learning, there exists little research regarding what, exactly, constitutes effective and appropriate practice in online education.

Few have engaged in empirically-based investigation of the true costs and benefits for students - and teachers - actively engaged in online course experiences. A recent review (DiPerna & Volpe 2000) of evaluation of Web-based instruction found only a dozen articles (from a pool of nearly 250) that include some form of data-driven investigation. Of the twelve, all but one relied solely on students' self-reported attitudes or perceptions regarding Web-based instruction. Whereas anecdotal accounts of successful online classes and reports that draw upon commonly shared theory are useful, they are not sufficient alone as proof of effectiveness. The kind of understanding needed to make truly informed decisions about the value of online education requires more varied and rigorous investigation.

The Project
The Clipper Project is designed to study the effects of Web-based learning on pre-college students. High school students accepting early decision to Lehigh University are eligible while still in high school to complete college courses offered online. The students may take Web-based courses in chemistry, calculus, economics, engineering, and English. The courses are taught by Lehigh faculty, follow a semester schedule, and carry with them all of the responsibilities, activities and expectations one would find in a face-to-face course. The faculty member who designs the course is also responsible for interacting with students enrolled in the Web-based versions. This interaction is an imperative component of these courses, and is facilitated via a combination of discussion groups, chat rooms, email, and other media.
Researchers directing the project are carrying forth a longitudinal quasi-experimental study with both qualitative and quantitative measures to determine the behavior of students during the Web-based instruction, the extent to which this instruction has prepared them for advanced instruction, whether this vehicle indeed opens broader learning experiences to them, and the effects of such a project on the faculty engaged in the process. This project is intended to enhance the collegiate experience of Lehigh freshman students by accelerating their entry into advanced studies in their specialties and in complementary fields. The purpose of this project is to provide empirically-based insight into what factors impact success within a Web-based learning environment by investigating the following factors:

1. **Implementation/Transformation Considerations**—computer access, scheduling, assessment
2. **Cost Considerations**—time, money, and personnel budget impact during development and delivery
3. **Student Learning Outcomes**—grades, number/quality of online communications, achievement in consequent courses related to content area(s)
4. **Faculty Teaching Outcomes**—impact on pedagogy of on-campus as well as on-line courses

Researchers are utilizing transcripts, focus groups, journals, activity logs, observations and student performance artifacts (e.g., grades, transcripts, reports) as the primary sources of data for measuring student and faculty behaviors.

Participants include students (current and prospective) as well as faculty at Lehigh University. Across the lifespan of the project, no fewer than 900 students will participate. High school participants are solicited through informational brochures sent to seniors who are granted Early Decision status at Lehigh. Student participants on campus are solicited through a variety of means including information shared with advisors and emails distributed to first year students.

**The First Cohort**
The first cohort of students began in February 2001. Of the 309 students offered early admission, 88 applied to one of the two Clipper Project courses (course offerings are staggered, with Calculus and Economics online first and the other three to be added in year two). At the 10-week point, the Calculus course has a 90% retention rate, and the economics course maintained an 85% rate. Participation has been steady, as well. Each student has maintained an active access rate for the course materials and each has participated in the mandatory assignments, as well as the optional chat sessions.

An interesting impact point that has emerged is the value of the online community itself in promoting success within Web-based course environments. That is, the more facilitative structures provided, the more comfortable the participants appear to be with not only the courses themselves, but also with the impending transition to the university. As the project matures, it appears the construction and maintenance of an active community of learners among the online participants—a community that spans across the courses themselves and includes opportunities for students to interact with one another, as well as with students, faculty, and other campus leaders—before making the physical transition from high school to college life will be an important factor for success.

**Conclusion**
Many universities are spending a great deal of time and money augmenting traditional curricula with distance education classes and Web-based instruction without investigating the most effective ways to develop and deliver the courses. It is often assumed that technology will automatically expedite learning—making learning easier and faster. Yet, we have no reason to believe instruction has improved simply because course information has been placed on the Web and students are working on their computers. As more learning becomes digitized, it becomes imperative that we understand what factors influence success. Given the pace of change and potential impact of distributed learning on higher education, we must now undertake due diligence and begin investigating empirically the exact impacts—if any—technology-based coursework has on teaching and learning at the university.

The National Commission on the High School Senior Year (NCHSSY) recently reported that more than a quarter of the freshmen at four-year colleges do not make it to their sophomore year. In addition, at selective four-year colleges and universities, only about half of college freshmen earn a bachelor’s degree in about six years (NCHSSY, 2001). One of the problems the Commission focused on was how colleges can retain their students to improve graduation
rates. One aspect of introducing a program like the Clipper Project is getting students motivated and committed to college classes before moving to campus.

The next phase for the Clipper Project will be guided primarily by the students' interest in developing a community of learners. Establishing relationships between on-line classmates seems an important factor in facilitating success. As the Clipper Project moves forward, initial feedback suggests that efforts spent on forming informal chat sessions, Web-casts, and discussion boards that extend to topics outside course material is likely to contribute to the overall effectiveness of the online academic experience. We may find that Clipper students have less anxiety over classes (already having completed a Lehigh course), transition easier to living away from home, have parents less anxious about their children living away from home, or feel connected to their University earlier than traditional freshmen. As the Clipper Community continues to evolve, it is becoming clear that understanding these factors will be instrumental in providing a picture of the true impacts of learning online.

By examining the impact a Web-based course has on a student population, the Clipper Project can determine characteristics of successful online course offerings. We hope to provide baseline data to inform future developers and providers of online education and guide them toward the provision of informed, responsible learning experiences for students. Rather than investing time and money into instructional design that we hope works, we will be able to concentrate funds on what we know works. This is a constructive step towards effective Web-based instruction that will lead to a positive learning experience for students and faculty alike.

Abstract

The perceptions and practical experiences are important influences when creating and developing online learning experiences in cross-cultural contexts. In this study, fifteen educational designers studying for their Masters Degree were asked to contribute their interpretations to an ongoing study of what meaning and interpretations were generated from a series of different learning environments offered via the Web. Course materials were designed in Australia and delivered into Hong Kong, SAR, China. Students did not always interpret the visual information in the manner expected by the original designers. This paper discusses the outcomes of the investigation in relation to student’s perceptions of the appropriateness of the interface design guidelines when applied to a number of exemplary WWW sites, highlighting the cultural differences encountered.

As tertiary studies turn to on-line delivery and courses become truly global, educators, course designers and instructional designers must now transcend national boundaries and cater for their ‘new’ clients – those with backgrounds as diverse as the cultures they live in. The increasing popularity and utilisation of the World Wide Web (WWW), has led to a proliferation of course offerings which explore web design and construction. It is timely for principles, priorities and values to be examined closely in order to evaluate the appropriateness of the content presented. Questions can be raised whether meaning and communication between cultures can be achieved in relation to the material being presented. As Duffy and Cunningham (1996:171) warn ‘idiosyncrasies of construction lead to an inability to communicate’.

As educators we know that all students come to subjects with different thinking and learning styles but now as we approach this unique learning situation the diversity is much more transparent, as we attempt to realise the needs of students from other countries and cultures. At times the lack of shared meaning can make communication difficult for people of different cultures. (Duffy and Cunningham, 1996). Content is often developed for courses assuming that a common culture exists.

According to AlHunaiyyan, Hewitt and Jones (1999), ‘culture is a discernible variable in interface acceptance and interfaces should be designed to accommodate users’ cultures’. This sentiment has been echoed by several other authors including Del Galdo, 1996; Fernandes, 1995; Uren, E.; Howard, R.; & Perinotti, T. 1993. In an effort to examine whether this statement is true and, if the content and learning experiences presented for WWW courses is authentic and appropriate, this study sought to uncover any anomalies that may exist in the area of interface design. Within the post-graduate Master of Education program an on-line subject, Cognition and Interface Design, was presented for students from both the Wollongong, Australia campus and the Hong Kong, SAR campus. The study examined the appropriateness
of the content and the interface guidelines for web construction, which had been developed in the Australian context.

Theoretical Background

In recent years researchers of technology-supported learning environments have embraced constructivism by providing educators with sets of design guidelines and instructional design goals (Cunningham, Duffy and Knuth, 1993; Savery and Duffy, 1995; Duffy and Cunningham, 1996). At the same time researchers in the area of visualisation and interface design have developed and proposed design guidelines for computer interface (Laurel, 1990; Tognazzini, 1992; Misanchuk, Schwier & Boling, 2000).

Accepting the tenet that learning is the process of constructing knowledge, Duffy and Cunningham (1996) suggested, through a social constructivist framework, knowledge is context dependent and that learners are participants in the socio-cultural process. Therefore, taking into account the interactive nature and ability for knowledge construction of the Web, then this type of learning should also be context dependent with learners participating in a socio-cultural process.

This investigation firstly, examined the nature of the learning process from a cultural perspective to determine the extent that context plays, and secondly evaluated the applicability of the components or principles of computer interface design when they are applied in differing cultural settings, in particular, in contexts different from their North American original viewpoints. The questions that guided the study were:

1. Do cultural differences exist in guiding instructional designers as they undertaken webpage design and construction?
2. Can a set of web design principles developed in one cultural context be applied successfully in another cultural context?
3. What cultural differences or context issues should be considered when developing on-line courses for multi-cultural cohorts?
4. Is culture a discernible variable in interface design?

Methodology

The study has been implemented in 2000-2001 within the Cognition and Interface Design postgraduate subject. The first cohort has completed a preliminary pilot study in 2000 and the second implementation occurred in December-February 2000. Fifteen students from Hong Kong developed an evaluation tool, in the form of a rubric, which has been be applied to a number of WWW sites that were deemed exemplary. These sites were chosen with Chinese and English language origins. Sets of four design principles have been formulated based on current research and have formed the framework for this evaluation. A large number of design principles exist in the area of visual and interface design, such as, colour, layout, backgrounds, etc. For the purpose of this study only four design principles or premises were extracted from the work of Williams and Tollett (2001). They were alignment, contrast, proximity and repetition.

In summary, Williams and Tollett describe the four principles as:

Alignment simply means that items on the page are lined up with each, when aligned the page is cleaner and more organised therefore they communicate better;

Contrast is what draws your eye into a page, if two elements (such as type, rules, graphics, colour, texture) are not the same, make them very different, contrasting elements create a hierarchy of information allowing the user to skim the information;

Proximity: the principle of proximity refers to the relationship that items develop when they are close together, i.e. in close proximity, when two items are close they appear to have a relationship, to belong together, group items together that have some relationship, items that are not close in proximity appear as separate elements, spacing arrangements provide visual clues as to the meaning and importance of different information, the visual spaces create a hierarchy of information;
Repetition: The concept of repetition is that throughout the site you repeat certain elements that tie all the disparate parts together, items such as navigation buttons, colours, style, illustrations, format, layout, typography are all elements that can unify a site.

Fifteen students were asked to identify four Chinese WWW sites each that they considered exemplary in their visual design. The students all had prior experience in web design evaluation through previous coursework. Criteria for evaluation included items such as content and strategy, visual style, navigation and graphic design. The study was conducted in two phases. Firstly, students were asked to identify four exemplary Chinese WWW sites and second they were given the four Williams and Tollett design principles and asked to apply them to the first four web sites that they had chosen. They were then asked to identify any cultural differences evident.

Results

The results are discussed following the four design principles or premises proposed by Williams and Tollett (2001).

Alignment

It appears that alignment is a principle that may vary according to cultural context. In this study the alignment of text on the screen design used on the Chinese sites was an important factor. According to one student ‘owing to the cultural style and characters of Chinese, the left edge is not necessarily the beginning of the text’. While Williams and Tollett contend that indentation and left aligned text is preferable, traditionally Chinese characters for formal writing is presented in a vertical format with writing from right to left (although the Western influence has allowed in some instances for writing characters to be read from the left as well). Therefore, in this context the text would be generally centre aligned and indentation is not a requirement in Chinese writing. From the small sample of Chinese WWW sites chosen for evaluation, centre alignment was the preferred principle. Many sites also used a frame format where the screen was divided into either two or three segments with centre or left alignment within each cell. As another student responded ‘Chinese designers always centered the topic and the content for most Chinese thinks [sic]

Contrast

Generally, the sites chosen used bold contrasting elements with many animated effects. Many sites used a variety of font sizes, some headings quite large in relation text size. Colour was used in many of the sites to differentiate particular elements. Many students commented on the ‘bolding of topic headings and the significantly bigger font size to bring attention’. Within blocks of texts comments were added that ‘important information was appropriately bolded or coloured for focal points’.

Proximity

On the whole, the students commented that proximity in the web sites chosen followed the principle outlined by Williams and Tollett. Text was aligned closely to graphics and images that provided understanding. The centre alignment of the text did allow for space between the concepts but generally this was used in a vertical format and generally for headings only. A number of students commented on the ‘clumsy’ nature of the sites and the ‘crowding’ of the sites. As one student stated ‘the spacing arrangement is not strong enough to provide a visual clue to the meaning and importance of different information’.

Repetition

Generally, according to the student evaluations, the Chinese sites used repetition as described by Williams and Tollett. On the whole, a consistent and predictable set of navigation tools, graphics, colour and style was carried throughout the sites chosen allowing for ease of navigation. As one student stated of the sites chosen ‘the repeated approach simplified navigation and ensured that they were built with a consistent rhythm and unity across the sites’.
Conclusion

This study has resulted in a number of interesting findings that would be significant to on-line course developers, instructional designers and researchers of computer interface design.

Firstly, it appears from this study that there are cross-cultural differences existing between Western designed WWW sites and Chinese developed sites. This is significant for a number of reasons in relation to on-line learning and the content provided for off-shore students. Content is being presented to students from base educational institutions with vastly different cultural contexts. In this case, Western instructional designers using Western design principles being delivered to Chinese students.

Secondly, it is important to note that students were asked to choose the exemplary sites first, before being given to the principles by Williams and Tollett. This ensured that students did not purposefully seek sites that demonstrated the principles proposed. In fact, generally the students accepted the principles as ‘gospel’ and then commented that some of the sites chosen were not exemplary after all because they did not demonstrate the principles. For example one student stated ‘the page looks not so neat and not so clear to communicate by the users’ [sic] although this site was chosen by the student as exemplary. This is significant for two reasons. First, the reason the students may not have readily found agreement with the principles was because culturally the visual design was different and second, the Western-based principles proposed were being adopted without question because they were part of the course content delivered. The fact that the students noted discrepancies should indicate the tensions and difficulties in matching the visual design and navigation of the sites to the four principles.

Many students commented on the crowded nature of the screen design. Many elements, including animated graphics were added to the pages, generally for embellishment, as one student commented ‘flashing graphics caused distracting of users eyes’. Perhaps some parallel could be drawn between the visual impact of the often-cluttered neon explosion of the street signage and decorations experienced by first time visitors to Hong Kong. From experience with other web sites, this perception of more interesting visual appeal being equated with a number of “cute” visual effects appears to be culturally-based. In addition, the use of written Chinese on several sites has additional impact by virtue of the nature of the written language and how it is parsed into grammatical structures. As grammar is derived from the context in Chinese writing this also means that context is used to construct meaning as the text is read. This has immediate implications for how the text is laid out and designed for quick recognition and selection. In particular, web sites are designed to attract and focus attention rather than being “read” the visual representation of ideas through characters can be working in several ways and further studies are required to identify which factors are operating under which circumstances.

Collaborative Learning Environments: Integrating Informal Learning Experiences in the Home with Learning at School

Helen Brown
Research Project Manager
British Educational Communications and technology Agency (BECTa)
helen_brown@becta.org.uk

Abstract: This paper describes an array of research projects that explore the use of ICT within the home and other informal settings to enhance pupil motivation and learning outcomes and contribute to the attainment of children in school.

It is important for teachers; researches and policy makers to be more aware of the ways children are using computers in the home. More importantly early indications from longitudinal research projects suggest that effective integration of ICT within the school environment is constrained by:

- a narrow conception of knowledge and its construction
- a lack of appreciation of the power of collaborative environmental environments made possible by ICT
- an underestimate of Children's experience and facility with ICT
- lack of time and opportunity for teachers to explore the Internet and engage in purposeful but playful activities that contribute to confidence and vision.

Little evidence is currently available about the impact of informal learning on pupil attainment at school. Two major projects are underway with research teams from four UK Universities to develop a framework for measuring the ICT environment.

The learning environment in the digital age

Teams of researchers have found that the ways children learn to use computers at home are markedly different from the ways they use them at school. Alongside a huge investment of UK government funding in the National Grid for Learning (NGfL), new technologies are being adopted very rapidly in a majority of homes. Schools are currently coping with children who have an increasingly broad range of computer skills and very high expectations of ICT.

There are some important differences emerging in the ways in which adults and children experience this new technology. When children and young people use the computer for pleasure they learn by playful discovery and experimentation. They ask family, friends and use electronic help frequently such as chat rooms and web sites. Their use of computers at home tends not to include educational software but they do choose to write, design and play games (often in group situations on or offline).

It is of concern that many children and young people are positive about using computers in the home, but disillusioned with school ICT. Often they find the restrictions on Internet Access frustrating and the speed of individual PCs or networks are less efficient than they experience in the home.

Some exciting untapped potential exists in greater home-school linkage and collaboration. This is the wider learning environment in which children can flourish and which need to be understood more fully. Research projects are currently exploring the possibilities of raising pupil attainment through new forms of home school collaboration. It recognises the undervalued knowledge and skills of parents, peers, extended family and global www communities. In this context Music web sites and software user groups can be very motivating and a rich source of learning.
Although it is recognised that important forms of learning takes place both in homes and classrooms, teachers and parents and children rarely have the opportunity to share, discuss and use their experiences and skills.

Teachers are increasingly being asked to develop innovative ways of teaching with ICT. In particular they are asked to use the Web to develop new ways of communicating with parents, children and colleagues. There is a growing concern that teachers have little time to integrate ICT meaningfully into the school curriculum and ironically they feel that pressure of work prevents them for ‘surfing’ and exploring the www. Their experience of learning via the web is thus very different from that of children who tend to find serendipitous links and spend a lot of time discovering interesting resources and passing on links to friends.

There is a growing challenge for teachers who are then asked to mark computer produced homework. They are also facing the consequences of differential access in the home which can make it difficult to know how best to compensate for the digital divide within the school environment.

Previous research has strongly indicated the potential outcomes of using ICT in education. Factors such as learner engagement, enhanced enjoyment, increased commitment to the task; increased autonomy and self-esteem are frequently mentioned (Cox 1997, Someck 1996, Bonnet et al 1999, Davies & Somekh 1997 and Cole 2000). However there is a complex web of social, cultural and economic factors impacting on educational standards and attainment. This makes it very difficult to isolate or extrapolate the direct effects of ICT on teaching and learning.

ImpacT2 a major longitudinal study sponsored by the DfEE and managed by Becta. The study makes the assumption that there are new empirical and conceptual challenges involved in attempting to identify a causal relationship between children’s use of ICT and improvements in their attainment.

The researchers indicate in their early finding that exposure to networked technologies may impact on learning in ways that are not reflected in Standardized Attainment Tests at the end of Key Stages 2 & 3. Nevertheless the skills and attitudes acquired in informal settings may well be essential to developing effective learning strategies. Exciting possibilities for learning includes the development of higher level conceptualization, better problem solving, more complex small-group talk. However as yet there are no reliable measures for identifying and documenting these in relation to attainment in school.

A Concept Mapping Task has been developed as a research instrument, which could potentially be used as both a baseline measure and an outcome measure. The ImpacT2 research project (1999-2002) provides a fantastic opportunity to ‘get inside’ the child’s experience of ICT.

Hotel Simulation - a 2nd year student project

Henric Bundy, Linkoping Univ., Sweden; Robert Johansson, Linkoping Univ., Sweden; Bengt Lennartsson, Linkoping Univ., Sweden

We will present the experience from a 2nd year programming project for 60 electronic design students. Our conclusions from a number of case studies in software industry:
* Ability to learn new things rather than to memorize and repeat static knowledge
* Ability to communicate and to co-operate rather than individual brilliance
* Ability to understand totality rather than having a narrow deep knowledge
* Ability to act and ask questions rather than ability to follow detailed instructions.

We have designed this course to train the new capabilities. The content is computer networking and object oriented architectures. There is a requirement on a graphical user interface with animation and sound. The task this year was to implement a client-server based game-like hotel simulation system. The system implemented will be presented by two of the students. They are happy to discuss the course layout and the general experience from it.
Computer-Enhanced or Computer-Enchanted?  
The Magic and Mischief of Learning With Computers

Abstract: What is it about computers that makes them so hypnotic? How can we educators take advantage of the computer’s power to attract and hold our students’ attention? How can we ensure that our students are creatively engaged in learning, not merely mesmerized by swirling images and button-pushing? Is the computer wasting our students’ time more than it is enriching them? This paper will report on recent research in human-computer interactions, give examples of some of the most promising uses of educational technology, and categorize the effective and ineffective applications. With a focus on the elements of audience, interactivity, and creative integration, we will discuss the educational possibilities offered uniquely by the computer, arguing that we are neglecting the computer’s greatest potential that is, its ability to draw out our students’ creativity.

Introduction

A Mother’s View

My son Jonathan got a 3-dimensional puzzle for Christmas a few years ago. It was a 12 X 14 X 4 inch wooden box with a maze inside. The maze was built on a moveable platform, and you could tilt the box back and forth in an effort to get a little silver ball to roll through until it dropped out some hole. Holes closer to the end were worth more points. My son played with the gadget for about an hour, off and on. He has hardly touched it since.

I think that was the same year my son was introduced to PacMan on the computer. You all remember PacMan. A circle with a triangle mouth cut out on the side moved through a 2-dimensional maze, eating colored pellets while being chased by “ghosts.” The more pellets your PacMan ate, the more points you got. Jonathan played PacMan for hours, day after day.

What was the difference? Why was one of these activities so absorbing, and the other of such limited interest? Admittedly, my son is just one case, and perhaps his puzzling preferences don’t apply to your child or your students. But it represents a trend that’s all around us the proclivity of young people for electronic activities, their willingness to sit mesmerized for hours in front of a computer or video screen, when equal time concentrating on almost anything else would be unimaginable. If we could just get at this, if we could figure out exactly what it is that draws so many of them in so magnetically, educators and parents would have a powerful force within their grasp.

The Purpose of this Paper

The purpose of this paper is to provoke discussion about the problems and the potential benefits of computer use among young people. We begin our discussion in section two ("The Bad News") by
acknowledging the down-side to computer-enhanced learning. Our purpose is not to argue for the abandonment of educational technology, but to encourage a more tempered view. To this end, we attempt to analyze what makes computers so attractive and absorbing with an eye to harnessing them for better purposes. Section three (“The Good News”) continues by proposing types of computer activities that may be particularly valuable for college level students. We give examples of promising applications of educational technology and describe some original material developed by the authors and their collaborators. We conclude with some personal reflections from a parent’s perspective.

The Bad News

Far more has been written about the wonders of computer-enhanced learning than about the time wasted in front of the computer screen. The reasons are pretty clear. Those who don’t care to use computers in their teaching may grumble in the halls about all the money and attention thrown at technology, but they generally don’t write about it. On the other hand, the defenders of educational technology often have a vested interest that makes them reluctant to speak out in ways that seem contrary to their own professional commitments – for example, large investments in educational technology at their institutions, or publications in computer-enhanced learning that would be devalued if the field were repudiated. Nevertheless, it is important that those who believe in the potential of educational technology speak out clearly about its disadvantages as well. With a growing number of schools requiring that their students have computers, we have a responsibility to consider carefully how young people are spending time with the companion we have assigned to them.

In the face of the great enthusiasm for computer-enhanced learning, a backlash against the hype was inevitable, and in the past few years some notable books and articles have begun arguing for a more balanced view. Clifford Stoll in *Silicon Snake Oil* was one of the first to proclaim that the emperor had no clothes (Stoll 1995). Focusing primarily on our fascination with the Internet, Stoll warns, “You’re viewing a world that doesn’t exist. During that week you spend online, you could have planted a tomato garden, volunteered at a hospital, spoken with your child’s teacher, and taught the kid down the block how to shag fly balls.” His equation speaks the simple, disturbing truth. “Every hour that you’re behind the keyboard is sixty minutes that

In a 1999 report, the Kaiser Family Foundation added up the hours and gave us the facts with regard to our children (Kaiser Family Foundation 1999). Surveying 3155 young people between the ages of 2 and 18, they found that on the average 5 ½ hours of a child’s day is spent using media (including TV, video games, music, and computers). Nearly 70% of children have a computer in their home, and 45% percent have Internet access. On a typical day, 42% percent of these children will use their computer. When asked to choose the companion they would most like to have if they were stranded on a desert island, children generally prefer computers over TVs, CDs, tapes, radios, video movies, and video games.

Many parents would consider this good news. Computers are viewed as educational -- less passive and more enriching than television. But what are our young people doing during those hours at the computer? The Kaiser study reports that 60% of their time on the computer is devoted to games, email, Web browsing, and chat rooms, while only 22% percent is spent on schoolwork. For boys, shoot-em-up games like Doom or Duke Nukem are much preferred over educational programs.

Our greatest care should be toward the young children, who are being deeply influenced by electronic media at early stages in their development. In 1999, a group of concerned educators, physicians, psychologists, scientists, and philosophers founded the Alliance for Childhood, pooling their expertise in a study of the effects of computers on children (Alliance for Childhood 2000). Their results are well-researched and compellingly conveyed. They describe what many parents and educators have themselves observed – that “young students often seem to be mesmerized by, and some even addicted to, the action on their [computer] screens, rather than motivated to learn.” Educational psychologist Jane Healy notes that today’s children nurtured on swirling, colorful, quickly-changing, and instantly accessible electronic images -- often find it hard to exercise their own imaginations. (See also Healy 1998.) The report warns that computer use can undermine the sense of wonder and reverence that children typically bring to their encounters with the real world of pebbles, streams, mud, insects, and stars. “What happens to the capacity for quiet wonder,” they ask, “when children are regularly bombarded with cartoonish graphics that are far louder and flashier than the real thing, or sanitized, edited versions of reality that don’t give them a chance to get their hands dirty?” Nature needs to be approached by young people not as some virtual reality, but as its “raw, untidy self.”
The report arrives at the same conclusion drawn by Todd Oppenheimer in his 1997 *Atlantic Monthly* article, "The Computer Delusion" (Oppenheimer 1997): We are spending too much money in our public schools on computer technology without questioning carefully enough the premise that computers serve our children’s educational needs. Convincingly, they call for a restriction of the computer’s influence and more time with hands-on learning, nature, language, the arts, imaginative play, and most importantly, direct contact with caring adults.

What about college levels students? Are their educational needs being compromised as well? A growing number of universities are insisting that students be equipped with computers as they enter their freshman year. College students have passed through the crucial early developmental stages of their education, and we expect that they now have the maturity to benefit from the computer as an educational tool. But how are they really spending their time on the computer, and how can educators guide them to toward enriching rather than time-wasting activities? Our own experience with university students indicates that they are spending long hours exchanging email and instant messages, browsing the Web, playing games, and – perhaps the biggest time consumer – downloading games and music files. Much less time is spent on educational computer activities. Clearly, computers continue to have their hypnotic effect on many college age students. Perhaps if we understood better what attracts them so intensely, we might put that power to better use.

As a point of discussion and a call to further research, we offer our own analysis of the reasons behind the computer’s mesmerizing hold on young people. This list emerges only from personal observation, but it may help us to separate what enriches young computer users from what merely panders to them, and guide us more clearly to our educational goals.

Picture a young student focused for hours on a computer screen playing a game. What is it that holds the student’s attention so tightly? We see eight factors:

- a feeling of power and control at the push of a button
- competition
- frequent and quick feedback
- incremental successes and rewards
- instant gratification
- visual and auditory stimulation
- little physical exertion
- simple problem-solving, requiring relatively undemanding intellectual exertion

Web browsing shares many of the same attractions, but with the added element of readily accessible information, and without the element of competition. In the case of email and instant messaging, we see the following enticements:

- easy accessibility of friends
- the novelty and mystery of communication with strangers
- the comfort of anonymous or faceless communication
- the ease of informal communication, often in a fun, shorthand slang peculiar to young computer users
- the ease of capricious communication, less restricted by timing and convention (i.e., one can initiate, respond, or not respond to a message at whim)

As for the hours spent downloading games and music files, there is the natural attraction of young people for the popular music and games themselves, the delight of acquiring things free of charge, and the feeling of power and control at the touch of a button.

These attractions are enough to keep many young people tied to a computer for hours a day. But if this list matches your own observations, you would have to agree that computers are not speaking to our students’ deepest intellectual selves. How can we tap into these enticements and help guide them toward greater challenges and richer human experiences?

**The Good News**

This entanglement with educational technology is a Faustian bargain, warns Neil Postman in *The End of Education* (Postman 1995). And yes, we agree that our relationship with computers comes at a high price, but we need not sell our souls in the bargain.
In spite of the acknowledged pitfalls of computer use among young people, we believe that college educators are not selling out by requiring that every student have one of these infernal devices. There is enough essential utility in computers to justify them even if their use goes no further than email exchanges with professors, communication among classmates for collaborative work, word processing, and basic Web research. Ensuring that all students have computers is hardly more unusual than ensuring that they all have telephones.

The challenge of educators is to help students become more aware of their habits; talk with them about the pervasive influence of technology in their lives; frequently point them back to the messy, disorganized real world that won’t be changed with the click of a mouse; and focus them on computer activities that may truly develop their problem-solving skills, expand their world view, and foster their creativity.

We must consider both what attracts young people to computers as well as the unique capabilities that computers add to the educational environment, and pull the very best out of this mix. With this purpose in mind, we offer the following classification of promising computer activities.

**Rote Learning, Exercises, and Mastery of Information or Procedures**

Multimedia presentations and on-line exercises will never be a good substitute for the explanations and guidance of a talented human teacher, but they are an excellent supplement. Subjects such as foreign language, medicine, mathematics, and biology require a great deal of time outside the classroom in drill and exercise. Concepts, facts, and phenomena can be vividly conveyed and well-reinforced through a computer — building an electrical circuit, exploring visual allusions in the political cartoons of Thomas Nast, examining products of linear transformations, watching a 2D harmonic wave disturbance, experimenting with Fermat’s principle, designing a snowflake pattern, witnessing a cytoplasm egg donation, or solving a mystery in French, for example. (Excellent Web sites offering exercises such as these include Learner.org at [www.learner.org](http://www.learner.org); Exploratorium at [www.exploratorium.edu](http://www.exploratorium.edu); ExploreScience.com at [www.explorescience.com](http://www.explorescience.com); 7stones at [www.7stones.com](http://www.7stones.com), and — as one example among the host of foreign language resources — “Apprendre le français avec l’inspecteur Duflair” at [www.polarfle.ovh.org](http://www.polarfle.ovh.org).)

But what of the warnings against multimedia learning that we hear from both Clifford Stoll and Jane Healy? Stoll cautions against the Sesame Street approach, where students are taught by means of cartoons, gaudy numbers, and weird random noises, all of which are highly entertaining but give children the impression that they can learn “without work and without discipline.” Similarly, Healy warns of sugar-coated learning that may “spoil children’s appetite for the main course,” cheating them out of the joy of mastery that comes from hard work and real challenges.

There is truth to what they say, but perhaps they overstate the case. Audio/visual presentations need not be flashy to be effective, and they take advantage of the interactivity that young people enjoy. It is far more engaging to be able to select activities and see immediate feedback than to watch a non-interactive TV-program-style production. When used as a supplement to rather than a replacement for classroom instruction, multimedia exercises and presentations are clearly beneficial.

**Activities That Couldn’t Be Done Otherwise, Or That Are Done Better With Computers**

Computers are not a good substitute for real-world experience. However, they are valuable tools for activities that couldn’t be done otherwise, or for activities that are done better with computers. These include

- **Communication that would otherwise be difficult or impossible, such as long-distance conversations among students of different languages and cultures, or student interactions with artists and scholars.**

  In April of 2000, Secretary of Education acknowledged “The Growing Importance of International Education” and encouraged educators to use the Internet to foster “classroom-to-classroom exchanges that allow young people to learn about each other from each other.” Notable initiatives in this area include The Alliance for Global Learning ([www.global-learning.org](http://www.global-learning.org)), ePALS ([www.epals.com](http://www.epals.com)), iEARN ([www.iEARN.com](http://www.iEARN.com)), Intercultural Email Classroom Connections ([www.teaching.com/iecc](http://www.teaching.com/iecc)), International School Partnerships in Technology sponsored by UNC’s Center for International Understanding ([www.ca.unc.edu/NCCIU/isptl](http://www.ca.unc.edu/NCCIU/isptl)), and The Global Schoolhouse ([www.lightspan.com](http://www.lightspan.com)).

- **Experiments and demonstrations that are otherwise too dangerous, expensive, or impractical.** Simulations can rarely capture the random, difficult-to-measure elements of natural phenomena, and thus they are second best to real lab experiments. However, for experiments involving entities not visible to the human eye, or materials that are expensive, inaccessible, or dangerous, simulations
provide learning opportunities previously unavailable to students. With the aid of computers, students can now see astronomical views of the night sky from any location at any time; explore microscopic organisms; manipulate molecular structures; “walk through” architectural designs before they have been built; perform autopsies without cadavers; experiment with radioactive materials; or view graphical representations of mathematical functions.

- **Analysis and presentation of research results closely integrated with the research experiments.** A wide range of data capturing and input devices now exist that can be directly interfaced with computers. For example, sound or light waves, radioactive decay, magnetic fields, or temperature can be measured by hardware connected to a computer. Then the data can be analyzed and the results displayed both graphically and numerically within the same computer environment.

- **Accessibility to information for disabled students or for students at locations distant from learning materials and instructors.** On-line learning can minimize the impact of disabilities by delivering learning material directly to disabled students in an accessible format, and allowing these students to reveal their disabilities only if and when they choose. Access to PIVot (http://ncam.wgbh.org/webaccess/pivot) exemplifies the work being done in making multimedia learning material available to students with disabilities. A cooperative effort of MIT, CPB, the NSF, and Mitsubishi Electric American Foundation, PIVot (which stands for Physics Interactive Video Tutor) provides alternative graphical user interface devices for blind and deaf students. For students whose handicap consists solely in their isolation from educational material, the computer is an equally powerful support. For example, *The Power of the Internet for Learning: Moving from Promise to Practice*, a publication of the Web-Based Education Commission, tells of bringing on-line educational material to isolated native Indian communities behind Arizona canyon walls. These examples represent educational opportunities provided uniquely by computer technology.

### Logical Problem Solving with Intelligent Tutoring

Computers are built to be logical, and they are less prone to error than humans. It is no surprise, then, that they make excellent tutors in logical problem solving. Moreover, “intelligent” tutors can give well-targeted feedback based upon the student’s current mastery level. Progress in artificial intelligence has augmented the computer’s fundamental logic, giving it greater “creativity” in finding its own way to solutions. A single computer program can now be written so that it solves not just a single logical problem, but a whole class of problems – even to the extent of proving theorems in formal logic. To go a step further, the computer, equipped with basic problem solving ability, may “learn” better strategies of problem-solving over time. This opens the intriguing possibility of the human and the computer learning interactively and with each other’s help.

We have been exploring human/computer interactive learning in our own research. PLogic Tutor is a tutorial program designed to teach students the fundamentals of prepositional logic, including theorem-proving (http://www.cs.wfu.edu/~burg/). The goal of the project is to test the efficacy of tutorial programs that combine intelligent tutoring in the traditional sense (i.e., a tutor that monitors student activity and gives customized feedback) with intelligence in the machine learning sense (i.e., a tutor that learns better problem solving, and thus better teaching strategies, over repeated tutorial sessions).

The computer’s application to logical problem solving is natural and full of potential. Educators are well-advised to consider the existing software for development of problem solving skills, as well as pursue open research questions regarding how humans learn logical thinking and how their learning might be enhanced with their ultimately-logical companion, the computer.

### Creative Expression

The greatest untapped potential of computers lies in their ability to foster creativity. We have heard the warnings of educational psychologists who observe decreased imagination in students satiated on computer use. But this need not be the case if computer use is both limited and channeled.

---

Computers can encourage creativity. Perhaps the most powerful stimulant to creativity produced by technology is the world-wide audience that it opens up to anyone with something to share. There are few Emily Dickinson's among us, content to slip our poems quietly into a drawer. Art in any medium is a personal expression meant to be shared and appreciated. The World Wide Web — where students can post their writing, music, and art for international view — can motivate students with the possibility of an audience, and this is a stimulant that educators should draw upon.

Computers also give us powerful and easy-to-use tools for work in a variety of media. Beginning with word processors for writing, we now have progressed to sound editors, MIDI keyboards, CAD programs, photo-editing software, paint programs, virtual reality authoring tools, and multimedia programming languages.

Computer-generated art integrates various media and senses in a novel way that distinguishes it from traditional art. Combining multimedia and interactivity, computers are more than TV screens at close view. Rather, they give rise to a new art form — one with a unique, still-evolving vocabulary, and calling upon a mindset different from those inclined toward fine arts as we have previously known them. Computer-generated multimedia art has an appeal for the mathematically and scientifically inclined, and gives them an outlet for creative expression that they may not experience otherwise. It can be the meeting place of the Godels, the Eschers, and the Bachs.

In addition to giving students a new mode of creative expression, original computer-generated works can add dimension to a student's experience of traditional art, music, or literature. For example, consider how a student's understanding of a poem might be enriched by an interactive multimedia interpretation, one in which the resonances of a word's interpretations are represented through a vocabulary of hyperlinks, fade in/out, cursor navigation, visual and auditory metaphors, etc. A new form of literary criticism, or a mixture of criticism and creative interpretation through interactive multimedia, opens intriguing possibilities. The enrichment of artistic discovery via computer technology is well worth considering if we hope to tap into the creative reserves of our technologically-inclined students.

A Mother's View, Revisited

My son is 13 now, and he still would like to play at the computer more than I think he should. He has gone on to flashier, more complex games that have him building empires or searching out and destroying superhuman foes. I don't think there's much in these games to challenge his intellect, but nonetheless he can sit absorbed in them for hours. I'm encouraged, however, that there do exist computer-based activities for young people that can engage their interest as well as develop their creativity. Allow me to give an example from my parental perspective.

Last year, Jonathan was required to do an artistic composition for a school project. He chose to do music. His first efforts to compose a song at the piano were simple and child-like — smudged scribblings of alphabetic notes on a dog-eared scrap of paper. From there, he transcribed his song by hand into proper musical notation — still smudged and elementary, but with a few embellishments that came to him as he notated the score. It was then that he learned that he could get a trial version of a musical transcription computer program. Now Jonathan could "type" the musical score into the computer and print it out in perfect form. This basic computer tool made it much easier to note and play back the music. I watched with fascination as my son cut and pasted, made variations, and finally emerged with a piece so complex and interesting that his own fingers could hardly keep up with it any more. This, I thought, was time well-spent on the computer.

Jonathan still prefers empire building and superhuman foes. But I keep hoping that my young technophile — this used-to-be-little boy who always drew people as geometric shapes and lulled himself to sleep murmuring number patterns — will eventually be drawn to deeper intellectual and creative challenges, if I just keep laying them in his path. That's my job as a parent. That our job, as educators.

Abstract

Two major events require teachers to be knowledgeable about technology influenced learning and how to create learning environments leading to higher levels of student achievement. These events, the 21st century information technology explosion and increasing demands for accountability for teaching results, are changing the way 1) schools are responding to learners and 2) preservice teachers and school leaders are being prepared for the classroom. New millennium teachers and school leaders must have sufficient technology expertise to integrate technology into meaningful learning paradigms. The impact of technology on teaching, instructional delivery and school reform will require knowledge of technology as a cognitive tool which when used skillfully can bring diverse learners to higher levels of academic achievement and significantly change the way learning communities are developed. This paper will 1) discuss the impact of technology learning on teachers and school leaders, 2) highlight basic qualitative research from a group of graduate students in Educational Leadership, and 3) delineate technology readiness skills all teachers and school leaders should possess.

I. Impact on Teaching

Teachers report little or no use of computers for instruction. Despite the growing numbers of computers in the classroom and the increase in available training, teachers are still finding it difficult to use computers as part of daily classroom delivery of content. This results from a lack of development time along with a limited quantity of instructional materials.

According to a March 30, 2001, Atlanta Constitution news report, 84 percent of teachers in a national poll said computers and Internet access improve the quality of education, 78 percent said they are too busy to take full advantage of those technological tools, ninety-seven percent said they have Internet access school, and 78 percent feel comfortable using the Internet. Yet, two-thirds said the Internet hasn't been well integrated into their classroom activities, and 60 percent said they were online for less than 30 minutes a day (Mollison, 2001).

Technology has the capacity to positively impact teaching by: 1) being a resource for instruction. Technology as a resource can help teachers cope with a growing paperwork load. Teachers can become more productive as they are trained in the use of technology and can gain quick access to information to help them and their students by meeting individual needs. 2) changing the way teachers teach. Technology enables teachers to help students with the construction and integration of knowledge. The process of construction is not an easy one. The students need mentors with whom they can have effective
dialogue. 3) facilitating increased communications. On-line communication between teacher and student, teacher and parent, teacher and teacher, and teacher and information expands the dialog necessary to be effective. It is through this human interaction that ideas become creative thought and creative thought becomes a new product or service for humanity. 4) helping teachers use technology effectively. Instructional Technology is a systematic way of designing, carrying out, and evaluating the total process of learning and teaching in terms of specific objectives, based on research in human learning and communication and employing a combination of human and nonhuman resources to bring about more effective instruction. 5) improving Learning. The application of educational technologies to instruction has progressed beyond the use of basic drill and practice software, and now includes the use of complex multimedia products and advanced networking technologies. Today, students use multimedia to learn interactively and work on class projects. They use the Internet to do research, engage in projects, and to communicate. The new technologies allow students to have more control over their own learning, to think analytically and critically, and to work collaboratively. This "constructivist" approach is one effort at educational reform made easier by technology, and perhaps even driven by it. Since this type of instructional approach, and the technologies involved with it, are recent developments, it is hard to gauge their educational effects. Still, an increasing body of evidence as presented by Bialo and Sivin-Kachala (1996) for example, suggests positive results.

Another effort called the Buddy Project (Indiana's Fourth Grade, 1990) supplied students with home computers and modem access to school. Positive effects included: an increase in writing skills, better understanding and broader view of math, ability to teach others, and greater problem solving and critical thinking skills.

Effects of Technology on Students’ Attitudes. Numerous studies over the years, summarized by Bialo and Sivin-Kachala (1996), report other benefits enjoyed by students who use technology. These benefits involve attitudes toward self and toward learning. The studies reveal that students feel more successful in school, are more motivated to learn and have increased self-confidence and self-esteem when using technology-supported instruction. This is particularly true when the technology allows the students to control their own learning. It's also true across a variety of subject areas, and is especially noteworthy when students are in at-risk groups (special education, students from inner-city or rural schools). Also, students reported significantly increased use of computers in four different areas, gathering information, organizing and presenting information, doing multimedia projects, and obtaining help with basic skills.

II. Qualitative Research – A group of 20 graduate students at Albany State University in Educational Administration, many of them teachers, were given question “How will using technology improve teaching and learning in the classroom?” Eighteen of the twenty students returned results. The papers were then reviewed to identify several common threads including the students’ responses to the impact technology would have on teaching and learning. To make a difference in education, 94% of the students said that technology training must be provided for teachers. Technology training has been developed in Georgia as a staff development program. Nearly 27% of the state’s teachers have completed the program to date. Technologies influence of the classroom is further identified in the table 1. The largest influence identified by this group of teachers is that student motivation increases. Faculty needs to be aware of technologies influence in these areas as a minimum to ensure success.

Table 1 – Elements that influence classroom success

III. Technology Readiness Skills – The International Society Technology in Education (ISTE) under the National Educational Technology Standards project has identified core skills that new and experienced teachers are expected to know and be able to pass on to their students. Below is a sampling of skills teacher will be required to demonstrate. A full list is available at : [http://cnets.iste.org/](http://cnets.iste.org/)

- demonstrate a sound understanding of the nature an operation of technology systems, - use technology tools and information resources to increase productivity, promote creativity, and facilitate academic learning, - use content-specific tools (e.g., software, simulation, environmental robes, graphing calculators, exploratory environments, Web tools) to support learning and research, - use technology resources to facilitate higher order and complex thinking skills, including
problem solving, critical thinking, informed decision making, knowledge construction, and creativity, collaborate in other creative works using productivity tools, use technology to locate, evaluate, and collect information from a variety of sources. Use technology tools to process data and report results.

In order for teachers to create the most effective learning environments they must transform traditional approaches and new approaches in a way that makes learning relevant while addressing individual student needs. "The resulting learning environments should prepare students to:

- Communicate using a variety of media and formats
- Access and exchange information in a variety of ways
- Compile, organize, analyze, and synthesize information
- Draw conclusions and make generalizations based on information gathered
- Know content and be able to locate additional information as needed
- Become self-directed learners
- Collaborate and cooperate in team efforts
- Interact with others in ethical and appropriate ways (ISTE, 2001)."

IV. Conclusion - The U.S. Department of Education and Educational Testing Service (ETS) (Baker, 1998) report that new methods of evaluation that look at technology in context are being investigated. These methods will focus ideally not on the question "Does technology work?" but rather on how it impacts the various components of the educational process. One factor is that instruction can be more standardized. One section or one class taught by several teachers can have the same thread of knowledge by using technology. Because of the various elements of color and motion, learning can be more interesting. We can go places with video that would be too costly or too dangerous for our students. Yet, they can have the same vicarious experience as being there. Through the use of computers learning becomes interactive. Students can make choices and respond to those choices. Learning time can be reduced. Much research has been done in this area. Although there still remains some questions as to specifically why time is reduced, student learn faster when using technology...and perhaps as a result the over all quality of learning improves. We find, for example, that teachers take care to develop high quality overhead transparencies and other materials for student use that has been fully integrated into the learning process.

The role of the instructor changes from the possessor of knowledge to the facilitator of the learning environment. Teachers are free to develop instruction and to spend time with students in small groups, helping the ones who need help and enriching the ones who can absorb more. Technology has been shown to have positive effects on the instructional process, on basic and advanced skills. Technology is also changing the instructional process itself. To be effective, technology cannot exist in isolation. Technology is an essential part of the pedagogical skills and strategies that all teachers must possess. Technology must be made an integral part of the entire instructional process for schools to succeed.

X-Quest: An Open Tool to Support Evaluation in Distance Learning

J.C. Burguillo, J.V Benlloch*, J.M. Santos, D.A. Rodríguez, F.Buendía*
ETSI Telecomunicación. Universidade de Vigo.
36200-Vigo (SPAIN)
jrial@ait.uvigo.es
*Escuela Universitaria de Informática. Universidad Politécnica de Valencia.
46022-Valencia (SPAIN)
jbenlloc@disca.upv.es

Abstract: In proprietary distance learning environments it often results difficult to exchange educational resources among different systems. In this paper, we introduce X-Quest, an open tool to create and maintain IMS-compatible questionnaires. Two main modules compose the tool: the first one is a user-friendly graphical interface that deals with the questionnaire creation phase and produces a XML output, compatible with the Question & Test Interoperability specifications; the second module takes advantage of XML features to make a presentation of the questionnaire in the more suitable way. This work is part of a more challenging project that intends to apply the same approach in the development of an educational framework for authoring and publishing didactic resources.

The growth of the World Wide Web is transforming teaching and learning at all levels of education, in particular, at the Universities. In this context, a lot of educational environments have been developed all over the world. From a pedagogical point of view, a fundamental topic in any distance learning system design is to include an effective way to evaluate the student progress. In most cases, the student has to answer several questions at the end of every course section in order to assess his knowledge.

Frequently, the distance learning environments we find in the context of education technologies include its own authoring tool to create and use questionnaires. Nevertheless, a common problem in most of these proprietary environments is the difficulty to allow systems to exchange the educational resources, particularly the questionnaires. Because of this situation, several international institutions have created groups to research and elaborate standards, which allow the interchange of educational resources among different learning systems, developed for heterogeneous purposes and in different software platforms. In the field of evaluation resources, one of the most relevant is the one proposed by IMS Global Learning Consortium “Question & Test Interoperability” (QTI) specification (IMS, 2000) which describes a basic structure for the representation of question (item) and test (assessment) data. In this paper, we introduce the X-Quest, an open tool to create and maintain IMS-compatible questionnaires.

Two main modules compose the tool, as shown in Fig. 1. The first one is a user-friendly graphical interface that deals with questionnaire creation phase. This module produces a XML output compatible with the aforementioned QTI specifications and stores all the necessary data elements required to compose, render, score and
provide feedback from questions. The second module takes advantage of XML features to make a presentation of
the questionnaire in the more suitable way. For example, as HTML pages that can be displayed by any commercial
browser; as a PDF file that could be easily printed out or as any other format able to be processed automatically. The
current XML galaxy provides us with an enormous set of possibilities to carry out all these transformations.

The X-Quest tool has been completely developed in Java 2 (Gosling et al. 2000) in order to achieve the
platform independence concept. The tool offers the next features:
- Typical types of questionnaires: true/false, multiple choice, multiple response, fill in black, as well as
  heterogeneous combinations of these basic types.
- Questions may contain multimedia resources: text, images, audio, video, etc.
- It is possible to define different feedback messages for each question/response.
- It includes support to be easily portable to different natural languages.
- Displays an intuitive and user-friendly graphical interface (see Fig. 2).

Fig. 2: Main graphical interface and questionnaire editing

The X-Quest tool has already been developed and incorporated into a web site in order to test the
functionality offered. The tool has been linked with a database, where several questionnaires are stored. Clients may
access these resources through any commercial web browser.

This work is part of a more challenging project that intends to apply the same approach in the development
of an educational framework for authoring and publishing didactic resources as tutorials, slide presentations,
exercises, simulators, glossaries and, of course, questionnaires. One of the key ideas of this proposal is to represent
and organise them and their multiple relationships using a hypermedia model like Labyrinth (Diaz et al. 1997). One
of the advantages of that kind of models is the explicit support of structure and navigation. On the other hand, XML
is an adequate notation to represent different contents and publish them in a Web environment. Linking both aspects
is one of the main purposes of the project.

In the near future it is foreseen to include the questionnaire tool into the global framework and what it is
more important, to get complex didactic resources as simulators to dynamically generate related questions and their
corresponding responses.

Visualization of fundamental definitions in calculus

Du-Won Byun, Sunghee Lee, Dal Won Park, Yongsun Ro, Seung Dong Kim
Department of Mathematics Education
Kongju National University
Kongju 314-701, Korea
dwbyun@knu.kongju.ac.kr

Abstract: Some concepts in elementary calculus make students distressed because of abstraction of definitions. For examples, limit of sequences, continuity of functions and partial derivatives are difficult concepts for learners that consider mathematical process as only arithmetic one. Understanding mathematical definitions is the first step to learn mathematics. Most mathematical terminologies are not easy, but learners must understand them to study more advanced mathematics and to apply to many areas related to mathematics. For those reasons, many instructors of mathematics anguish to find the method that they make learners understand mathematical concepts easily and fast as soon as possible. Hence it is efficient to use visual tools in order to make common learners be familiar with mathematical definitions. By tools, some multimedia materials of instruction are prepared and we present some important topics that can be explained easily by using them.

Introduction

Calculus is one of mathematical subjects that are learned in the undergraduate course first of all. Though some concepts contained in this subject have been mastered in high school, many students feel difficult in learning calculus because of the difference of approaching method for every concepts and the strictness of logical process. For examples, limit of sequences, limit of functions and continuity of functions were learned in the previous step but most of learners fall in distress meeting with epsilon-delta argument that is expanded topologically. Hence we need to consider new method of instructing calculus and to prepare learning materials for learners' understanding.

This paper reports an instance of development of some multimedia materials and application of them in calculus instruction. Our materials are related to the following sections: limit of sequences, limit and continuity of functions, partial derivatives and differentials. They are made by use of Java applet and 3D Webmaster.

Contents and stressing parts

Limit of sequence

Concept of limit is introduced intuitively in high school mathematics. Though such an introducing method is understood easily it is not appropriate for students that want to study more advanced mathematics. Hence, for stable base, we must approach the definition of limit faithfully. The sequence \( \{a_n\} \) converges to \( a \) if and only if for any positive number \( \varepsilon \) there exits a natural number \( N \) such that \( |a_n - a| < \varepsilon \) for all \( n > N \). We adopt a statement equivalent with the definition mentioned above: every neighborhood of \( a \) contains \( a_n \) excluding at most finite terms. Visualization of this concept is realized by Java and the following topics must be stressed and observed during our instruction:

- existence of successor of each term
- existence of maximum value in finite set of real numbers

---

1)
meaning of "at most finite"
uniqueness of limit of convergent sequences
boundedness of convergent sequences

Limit and continuity of function

Let \( f(x) \) be defined for all values of \( x \) near \( x_0 \) with the possible exception of \( x = x_0 \) itself. We say that the number \( l \) is the limit of \( f(x) \) as \( x \) approaches \( x_0 \) if for any positive number \( \varepsilon \) we can find some positive number \( \delta \) such that \( |f(x) - l| < \varepsilon \) whenever \( 0 < |x - x_0| < \delta \). In word this means essentially that we can make the absolute value of the difference between \( f(x) \) and \( l \) as small as we wish by choosing \( x \) sufficiently close to \( x_0 \), i.e. by choosing the difference in absolute value between \( x \) and \( x_0 \) sufficiently small. Continuity of \( f \) at \( x = x_0 \) satisfies well-definition of \( f(x_0) \), \( l = f(x) \) and convergence of \( f \) at \( x = x_0 \). Our instruction materials are also made by Java program, and we must use them so as to make learners understand very important concepts:
- difference between definition of function and existence of limit
- existence of right limit and left limit and coincidence of them
- uniqueness of limit

Function of two variables

Instructing functions of several variables need different method from one variable function because of difficulty of drawing their graphs. Computer enables us to visualize the graph of function of two variables, and accumulating experience make us extend understand functions of more variables. Hence we must actively use computer graphics in instruction of function of several variables. Our materials are made by using 3D Webmaster that is one of authoring tools of 3D graphics. We focus on the followings.
- limit of sequence composed of points in plane
- limit and continuity of function of two variables
- definition of partial derivatives
- existence of functions that are partially differentiable but not continuous
- definition of differentials

Expecting effect

Mathematics is essentially a process of thinking that involves building and applying abstract, logically connected networks of ideas. These ideas often arise from the need to solve problems in science, technology, and every life. Specially, calculus has the widest applicable area, and learning this subject is necessary for students interesting in science and technology. Hence, our multimedia materials will help learners of calculus to understand some fundamental concepts more rapidly and more deeply. Also, this subject will be considered as an interesting one and they will be able to use calculus as more skillful tool for their works.

Computer Based Lab Methods in the Instruction of Probability and Statistics

P. Cabilio
Department of Mathematics and Statistics
Acadia University
Wolfville, Nova Scotia, Canada
cabilio@acadiau.ca

We describe the use of studio labs in the teaching of courses in probability and statistics. These labs augment material presented in lectures, providing students with an experiential context in which difficult ideas can become more tangible. Students generate small data sets from simple experiments involving beads, cards, ping-pong balls, poker chips, etc. The real-life context is given in which these experiments are applicable, thus providing the student with an understanding of the experiment as a simulation. Since the total number of replications of such experiments is too small for illustrating the connection between the model probabilities and the experimentally observed relative frequencies, the student is instructed to use the computer to conduct larger simulations. Thus the connection is made between the just completed small scale experiment and the computer simulation which represents it. We report the reactions of students who have taken these labs over the last few years.
Technology as Facilitator of Quality Education: A Model

William P. Callahan and Thomas J. Switzer
College of Education, University of Northern Iowa

Note: The authors would like to thank the following graduate students for their work on the project: Alex Spatariu; Corina Cimpoeru; Simona Boroianu; Madalina Tincu; Marius Boboc; Michelle Matz; and Nadia Solukhina.

Abstract: Few people would argue with the idea that information technologies have a major impact on how we view schooling, teaching, and learning at this point in time. If technology is indeed a facilitator of quality education, how will it be used? How can developments in information technology facilitate an education appropriate for the 21st century while enhancing student achievement in core areas deemed important to our democratic society? This chapter describes the Technology as Facilitator of Quality Education (TFQE) model currently being developed at the University of Northern Iowa. Technology as Facilitator of Quality Education: A Model. This model includes seven major dimensions: students at the center of their own learning; principles of good learning; aspects of information processing; standards from content disciplines; tenets of effective citizenship in a democratic society; teacher knowledge and behavior; and technology.

Few people would argue with the idea that information technologies have a major impact on how we view schooling, teaching, and learning. They may, however, argue about the kind of impact that we currently feel from the use of technology in our classrooms. Opinions range from those who see technology as the driving force for all that will be good about education in the future, to those who see information technology as a force that will destroy education as we now know it, driving us toward all of the negative aspects of consumerism.

Like most complicated technological developments and their associated social changes, the potential impact of information technology on education is somewhere between these two extreme positions. Decision-making is, of course, still the key to the impact that technology will have on education. One would hope that informed human beings would find a way to capitalize on the best of what information technology has to offer, while preserving the core components of our educational system. This blending of the new with the old is most likely to serve us well in the future and provide us with a foundation for effective citizenship in a democratic society.

People who fear the consequences of developments in information technology frequently do so not out of ignorance, but from the realization that these technologies present the possibility of a fundamental shift in how we think about the nature of schooling, teaching, and learning. They question the consequences of such a shift. Unfortunately, those who advocate this shift have not developed a persuasive rationale for their position. In their rush to support technology, they have failed to show how the shift can actually promote the core values of education in a democratic society.

If technology is indeed a facilitator of quality education, how will it be used? How can developments in information technology facilitate an education appropriate for the 21st century, while enhancing student achievement in core areas deemed important to our
democratic society? Technology as Facilitator of Quality Education (TFQE) is a model currently being developed at the University of Northern Iowa. It includes seven major dimensions:

1. Students at the center of their own learning
2. Principles of good learning
3. Aspects of information processing
4. Standards from content disciplines
5. Tenets of effective citizenship in a democratic society
6. Teacher knowledge and behavior
7. Technology

The seven dimensions of the model provide a way for educators to view the integration of technology-related tools into a robust educational environment and thus answer the hard questions regarding support for the shift in our educational activities toward technology. The model sets up a framework for this robust educational environment and identifies key points at which technology should be implemented and evaluated to determine its impact. It simultaneously allows for the integration of new research findings, while maintaining the structure to evaluate the impact of technology tools on these new findings as part of an ongoing evaluation process. In so doing, the model allows a variety of stakeholders to see the complex process that is education and how technology is affecting that process.

The TFQE model allows us to view the integration of technology as an essential set of tools being used appropriately in a robust educational environment, a democratic setting in which
students are at the center of their own learning. Addressing deficiencies in the use of technology in K-12 education using the TFQE model, a consortium of schools have developed the InTime project (Integrating New Technologies Into the Methods of Education, http://www.intime.uni.edu/), funded by a Catalyst grant from the U.S. Department of Education.

Drawing on the TFQE model, this project is intended to produce change in teacher education programs in three ways. First, new learning resources on the Web will be generated to support new teaching and learning processes in education methods courses. These resources will include development of video scenarios of pre-K-12 teachers effectively integrating technology, along with components of quality education, in a variety of grade levels and content areas. The videos will be stored on a video server already in place at the University of Northern Iowa and made accessible on-line nation wide.

Second, methods faculty will revise their courses to model technology integration using the video scenarios and on-line discussion forum, require students to apply technology, and implement the Preservice Teacher Technology Competencies as exit criteria for their courses. Finally, methods faculty will share strategies for integrating technology and course revisions with other faculty involved in the grant through a variety of activities. Each participating university will ensure that faculty members have access to adequate resources that support the integration of technology into methods courses, providing one-on-one technical support to those faculty members who are revising their courses to integrate technology. Methods faculty members will also participate in faculty development programs to revise their methods courses to incorporate new learning resources and new standards. A professional evaluation team will assess the overall effects of the project on teaching and learning, as new learning resources are developed and implemented, along with new standards, into methods courses.

The Technology as Facilitator of Quality Education model within the context of the InTime project is intended to provide teachers and instructors of teaching methods classes with a rich resource for integrating technology throughout the school curriculum. It is only through full integration and use throughout the curriculum that the full potential of technology will be realized.

William Callahan is the Associate Dean of the College of Education at the University of Northern Iowa. He has served as Executive Director of the Renaissance Group, as a professor in the Department of Special Education. As a consultant, he has worked in both the public and private sector improving professional performance, and organizational learning.

Thomas Switzer is a Professor of Curriculum and Instruction and Dean of the College of Education at the University of Northern Iowa. As Dean of the College of Education at UNI, Switzer has served on the Board of Directors for the American Association of Colleges for Teacher Education [AACTE], as President of the Teacher Education Council of State Colleges and Universities [TECSCU], as Chair of the Technology Committee for AACTE, and on numerous state boards and commissions.
Evolution of an Intelligent Web Tutor

David Callear
University of Portsmouth
Department of Information Systems
6-8 Burnaby Terrace,
Portsmouth, PO1 3AE, UK
David.Callear@port.ac.uk

As distance learning courses proliferate on the internet, there is a problem in providing human tutors to manage students' learning and carry out the marking of their work, and also a problem of providing structured tuition for students. WITS, a Whole-course Intelligent Teaching System, addresses these problems.

WITS is essentially an Expert System shell which simulates the expertise of the teacher. The original system was written in Prolog and used an original form of assessment based on probabilities. It taught Solid State Electronics from a commercially produced videodisc, but a new prototype version uses digital materials on CD-ROM and has been built to run in a web browser. It will be used as the basis of an intelligent, multimedia internet system.

Research funding is currently being sought to validate the probability assessment technique and to develop WITS further, and evaluate its effectiveness as a distance learning tool.
Who Uses the Internet for Educational Purposes?  
A National Demographic Study in the United States

Xiaoli Cao, Ph.D., Kenneth Gray D.Ed.,  
Workforce Education and Development, College of Education,  
Penn State University, State College, PA, 16802, USA,  
gty@psu.edu

Abstract  
The purpose of this study was to determine the demographic and socioeconomic characteristics of adults, ages 19-60, that use the Internet to take educational courses or to do research at home for traditional classroom courses. Results suggest that the Internet is not expanding the education market but simply segmenting the traditional market.

Background  
Among the various types of educational media, the Internet is perhaps the most often touted. The ability to take educational courses "on line" or use the web to conduct research for formal education is alleged to be altering the way degree programs are delivered and instruction is conducted. Importantly, many institutions of higher education are now investing significant resources in the development of "world campuses" in hopes of tapping new markets of non-traditional students thus expanding enrollments.

While the Internet has made it technically possible to take courses and do research at home, it does not automatically follow that it will attract a new group of non-traditional students. The Price Waterhouse Coopers' 1999 Consumer Technology survey found, for example, that 48 percent of US users polled said they went online for email but only 28 percent said they went online to do research of any kind. Importantly in 1998, those figures were the exact opposite suggesting that perhaps the demand for Internet based formal education may be overstated or not growing as anticipated.

The purpose of this study was first to investigate the degree of Internet use to take educational courses or to do research at home for traditional classroom courses and second to determine the demographic and socioeconomic characteristics of these users.

Methodology  
The data for this study was extracted from The Current Population Survey (CPS), a US government funded monthly survey of about 50,000 households conducted by the Bureau of the Census for the Bureau of Labor Statistics. The sample is scientifically selected to represent the civilian non-institutional population. Data collection involves face to face interviews. The data for this study came from the December 1998 Current Population Survey (CPS) in which interviewers asked supplementary questions regarding
Computer and Internet use. A dichotomous logistic regression model was used to determine characteristics that differentiate those who use the Internet for educational purposes from Internet users in general.

Findings and Conclusions

There were 18,003 adults (age 16-60) Internet users in the final data set of which 3,620 or 20% reported that they used the Internet for educational purposes. This data suggests that among all those who reported using the Internet at home, about one in five use it for academic course taking.

Being unmarried, younger, having some higher education, income lower relative to other Internet users, employed in managerial professional occupations, and working part-time, were all associated with using the Internet for education purposes. Race, gender, citizenship, and geographic region of the respondents had no practical significant relationship to using the Internet for education purposes at home. The characteristics of these users mirror traditional college students. Specifically they tend to be young, single adults, who - if employed - are in professional occupations, and who are either college graduates or trying to finish a college degree.

These findings suggest that the use of Internet based education is significant among traditional college students but not widespread among other segments of the population. While the data used in this study is now two years old, findings suggest it is valid to suspect that the Internet might be only segmenting the traditional higher education market and not making inroads in expanding the market to non-traditional students as hoped or prophesized.
Methodologies of distance invigilation to support distance education*

*This work was supported in part by a China national key fundamental research grant G1999032708.

Abstract: In this paper, we present four methodologies for distance invigilation; i.e., tutor-based, surveillance-based, software-based, and network-based invigilation. These methodologies form a new invigilation framework to support distance examination. Based on the four methodologies, we have developed a distance invigilation system in which three apparatus-based methodologies are implemented by separate subsystems. Our system has been successfully applied to a nationwide professional examination on a wide area network. As a result, the system performs quite well.

I. Introduction
Invigilation is a necessary way to prevent dishonesty for a fair examination. Along with the development of modern education, especially for distance education, distance examination becomes a sort of new method to evaluate students' performance through network, which demands new invigilation methodologies for such an examination. Unlike the traditional examination forms (i.e., examination on paper), distance examination, especially on a wide area network (WAN), could face several problems that do not exist in traditional invigilation, which leads to some new research topics in distance education.

In this paper, we present four methodologies for distance invigilation; i.e., tutor-based, surveillance-based, software-based, and network-based invigilation. Based on the four methodologies, we develop a distance invigilation system that has been applied to a nationwide examination. In the sequel, we describe our distance invigilation framework and present our implementation in details.

II. Methodologies

II.1. Tutor-based invigilation
Tutor-based invigilation is a typical way used for preventing dishonesty in traditional examinations. In this way, one or more tutors are needed to monitor students' behaviors on site during examination in order to spot any behaviors violating examination rules. This method provides an immediate and direct way to recognize those apparent cheating behaviors, e.g., the use of teacher's book and sneaking other people's answers. Although the environment of distance examination is different from the traditional one, this method is still effective to be taken in distance examination if possible. Here, we suggest that it should also be one of the basic methodologies in distance invigilation.

II.2. Surveillance-based invigilation
Surveillance-based invigilation is a complement to the tutor-based invigilation since one or more cameras can objectively record the real situation that happens in an examination site. Furthermore, a video taken on site can be used as substantial evidence to charge those students violating the examination rules, which also leads to an off-line way for invigilation. Thus, it provides a method to remedy the shortage of the tutor-based invigilation.

On the other hand, the video taken by a surveillance system can be transmitted to a remote place through network, which provides an off-site way for invigilation. This salient feature makes the surveillance-based invigilation be one of choices in distance invigilation.

II.3. Software-based invigilation
For modern education, especially distance education, computer plays a critical role in the process of education. In particular, computer has been used as a tool for diversified forms of examinations. Therefore, there appear new dishonest behaviors by means of computers themselves. In order to prevent such a sort of dishonest behaviors, an electronic invigilation method is demanded. Basically, an invigilation software package is designed to record the subject operations on computers and alarm for those illegal operations. In contrast to the above two methodologies, the software-based invigilation provides a more effective way to prevent possible cheating behaviors by means of computer.

II.4. Network-based invigilation

As a basis of distance education, network provides infrastructure for diversified distance education activities. However, it is of potential weakness that can be utilized by hacker-like people for their own purpose. Such a problem is unavoidable yet in distance invigilation. Thus, the network-related equipment should be managed in order to avoid illegally accessing the resources on local or remote computers, including those servers located in the examination center, through network. The technical support for this methodology lies in the use of network administration functions and its related security technology, which needs to develop a special management package based on system functions. In contrast to the software-based invigilation, the network-based invigilation provides a more global way to preventing the dishonest behaviors through the use of network.

III. System overview

We have developed an invigilation system for distance examination based on a Microsoft Windows NT platform under a WAN environment. The aforementioned four methodologies are applied to our distance invigilation. Except the tutor-based invigilation, other apparatus-based methodologies are carried out by three separate subsystems.

In our surveillance-based invigilation subsystem, some multimedia data sampling instruments are installed in the testing rooms located in different areas. The instruments include video camera, microphone, platform, and multimedia data compression apparatuses, e.g. encoder and decoder. Considering students' distribution in a testing room, we adopt two different ways to spot the situation of testing rooms, i.e. capturing pictures from designate areas and taking pictures for a whole testing room, which may enable us to monitor situation of both an individual and the whole testing room. In our subsystem, all the multimedia data collected are first compressed and then transmitted to an examination monitor center through the WAN with an IP-based transmission technology. For efficient transmission, our subsystem can adjust transmission rate to maintain smoothness and fidelity of visual signals to adapt to different channel bandwidths and qualities. At an examination monitor center, all the multimedia data acquired are used for invigilation.

In our software-based invigilation subsystem, a monitor procedure is running to monitor every student’s operations on his/her computer during examination. As a result, those data are buffered and transmitted to a server through a WAN. In the client side, our software-based invigilation subsystem is able to capture the following students’ operations during examination: a) resident application programs opened by an individual, b) files opened, c) an operating interface, d) data in clipboard, e) keyboard operations, f) mouse operations. In the server side, our software-based invigilation subsystem can provide data for system administrators to identify whether an operation is illegal or not. For implementing our subsystem, we adopt the client/server technology where the UDP (user datagram protocol) network communication protocol is used. The client package spots the related operation of candidate computers and delivers the information to a server, while the server package receives the data coming from suspect’s computers on the corresponding UDP ports and displays those operations on screen after processing.

In our network-based subsystem, we take advantage of the technology of virtual private network for network security. Binding IP address and the MAC address of candidate computer together in CISCO routers prevents from the access to the WAN by anyone without authority. In addition, a network management system is employed to monitor the whole network in order to detect and prevent from any illegal apparatus linked to the network. During examination, every student’s name, password, and IP address are recorded and checked by a server located in the examination center such that only a legal student can commit to examination.

IV. Conclusion

We have presented four methodologies of invigilation to support distance examination, and three apparatus-based methodologies are implemented by separate subsystems. Our system has been successfully applied to a nationwide WAN-based professional examination covering over ten provinces and cities (around 1/4 areas) in China. As a result, it has effectively prevented miscellaneous dishonest behaviors during this examination.
An Educational Evaluation of WebCT; a Case Study using the Conversational Framework

Dawn E Carmichael
School of Computing,
University of Abertay Dundee
Dundee, Scotland.
d.carmichael@abertay.ac.uk

Abstract: This paper details a study into the development of a WebCT based learning resource, which was used to augment the delivery of a second year degree level module. The development of the learning resource was informed by the educational theories expounded in the conversational framework, Laurillard (1993). Subsequently the resource was evaluated using criteria extracted from the conversational framework as a set of guidelines. It was found that all of the criteria could be supported to some extent, although in some areas the support was marginal. The learning resource was then evaluated by students who were asked to give details about which of the individual facilities were used, and beyond this which were useful. The results of this student centered evaluation showed that the students did not consider several key facilities 'useful'. It is suggested that further work be done on developing a method for determining criteria, implementing a resource and evaluating the facilities for successfulness, as determined by students.

Introduction

The process of defining educational criteria with which to inform the development of a computer based learning resource is well known. There are a wide range of criteria, informed for the most part by the theoretical assertions of a variety of pedagogic traditions and paradigms. Most of us involved in developing computer based learning resources will be familiar to some extent with one or more of these traditions. The process of choosing criteria, developing the resource and analysing the extent to which the attributes in the learning resource support the criteria is also well known. In addition to this, many of us are familiar with evaluative measures that seek to shed light on the successfulness of the resultant learning resource in general terms. Often these take the form of questionnaires seeking to elicit student attitudes to the learning resource as a whole. Thus we have on the one hand pedagogic objectives, and on the other hand student evaluation as to the success overall of the learning resource. However these two elements are not necessarily directly connected. It is possible to have met a set of criteria in creating a successfully learning resource, without those criteria having had significant bearing upon the outcome.

This paper is based upon a case study learning resource, constructed using WebCT. The design of the learning resources was informed making use of criteria taken from the conversational Framework devised by Laurillard (1993). The case study is described in the next section, followed by an explanation of the criteria taken from the conversational framework.

The case study

The case study module under consideration is IC240 module, 'IT in business', a second year module provided by the division of Information and Communication Technologies, which is part of the University of Abertay Dundee. The students of IC240 are studying for degrees in accountancy, tourism, business, management and a range of other courses. This diverse mixture of student backgrounds means that there is a wide range in levels of previous experience in IT. In practical terms this diversity of student experience suggests that a flexible learning resource would be beneficial to students. For this reason a learning resource making use of the Virtual Learning Environment (VLE) WebCT was developed.
WebCT is an integrated web based learning environment. It was devised at the university of British Columbia, www.webct.com. The software is based upon web technology, offering a number of facilities running as Java scripts or applets. In this study the vast majority of WebCT facilities available were deployed, Table 1 outlines the facilities and how they were used.

The case study learning resource was the subject of a two-fold evaluation. Firstly the learning resource was evaluated heuristically against the criteria extracted from the conversational framework. Subsequently the individual facilities comprising the learning resource were tested by means of a survey of student opinion.

The Conversational Framework

The heuristic evaluation made use of the Conversational Framework developed by Laurillard (1993) as an evaluation tool for WebCT. This framework was chosen as the work encapsulated in the framework has pioneered the evaluation of hypermedia based learning resources. Authors such as Brittain (1999) have argued that whether the VLE is being used for distance learning or to enhance learning within institutions, their most important role is as a medium for supporting constructivist and conversational approaches to learning (Brittain 1999). Therefore Laurillard's conversational model offers itself as an interesting candidate for providing the basis of a heuristic pedagogical evaluation framework for WebCT.

The roots of the framework lie in the Conversation Theory developed by Gordon Pask (1976), although Laurillard traces the need for dialogue in the learning process back to the Socratic method of philosophical enquiry. The centrality of dialogue in the model comes from the need for the teacher to unearth the student's mental constructs about a topic before negotiating the path to the target conception that is the goal of learning from the teacher's perspective.

The teaching strategy advocated in the model is based on interaction between lecturer and student and not solely on the actions required of the student. The model advocates that action on the part of the student is constructed around the dialogue and should be supplemented by constructive and meaningful feedback from the teacher. There are a number of key characteristics of the conversational model as applied to academic learning. These are drawn from Laurillard, (1993, pp.94-95).

1. T(eacher) can describe conception
2. S(tudent) can describe conception
3. T can redescribe in the light of S's conception or action
4. S can redescribe in light of T's redescription or action
5. T can adapt task goal in light of S's description or action.
6. T can set task goal
7. S can act to achieve task goal
8. T can set up world to give intrinsic feedback on actions
9. S can modify in light of feedback on action
10. S can adapt actions in light of T's description
11. S can reflect on interaction to modify redescription
12. T can reflect on S's action to modify redescription
It is important to note that these criteria are not necessarily sequential, but it is suggested that they should be supported by WebCT if it is to be judged compliant with this educational model. In the next section we will explore the extent to which the case study module is successful in delivering the criteria, but before this we will examine an important new revision of the conversational framework.

**Conversational Framework revision 1999**

The first version of the conversational framework (Laurillard, 1993) described the learning process and was used as an analytic tool for information technology media and methods. However, the original framework did not indicate a process whereby the student internalised their learning, rather it focuses entirely upon a dialogue between student and teacher. This omission has been dealt with in an article 'A conversational framework for individual learning applied to the 'learning organisation' and the learning society.' (Laurillard, 1999). Clearly this revision addresses a crucial part of learning, and as such it is suggested that the evaluative criteria be expanded to encompass this element. Therefore for the purposes of this evaluation the full set of criteria will be numbers 1-12 as indicated above and in addition;

13. S can internalise articulation/action.

**The Heuristic Evaluation**

A suitable evaluation framework for WebCT using the conversational model could be constructed in a variety of ways. The way suggested in this study involved constructing a table that describes the tools that are available for each of the stages of interaction described in the model (see Table 2). Table 2 shows the evaluation framework for WebCT using the interactions in the conversational model as criteria against which to identify the tools provided by WebCT. For each element a WebCT tool is identified along with a description of how it was used in the case study module.

This relatively simple approach offers much potential as a methodology for evaluating virtual learning environments (VLE) such as WebCT. A similar proposal has been recently put forward by Crawley, (1999). However, the major emphasis in this study is the way the evaluation by students, given in the next section, is used to validate the findings put forward by the theoretical evaluation.

In order to evaluate WebCT using the conversational framework we need to establish which tools are provided within the software to allow dialogue and action to mutually influence each other to allow modification of both conceptions and actions on the part of the student as described above. Another issue that quickly becomes apparent is that the notion of a 'micro-world', takes on a different meaning in the case of WebCT than more traditional forms of courseware, Britain (1999). In essence, WebCT provides the tools for a lecturer to build a micro-world by allowing the teacher to construct learning activities enriched by the resources.

</table>
The points described in the table show that WebCT as used for the module in this study has, at least to some extent, the facilities to support all of the features laid out by the conversational model. However it is important to consider how successful the learning resource is at delivering the requirements specified in the conversational framework. It is the results of this evaluation, given in the next section, that will be used to make a judgement as to whether this particular resource is successfully compliant with the criteria in this educational evaluation.

### Student centered evaluation

In this study the evaluative measures included an 'exit survey'. The rationale for the exit survey was to find out directly what the experience of using WebCT was like for the students. The students were asked about their experience in general, where it was discovered that 13 of the 15 students taking part in the evaluation, found the resource as a whole useful, 2 were neutral, none negative. It is important to note that only fifteen students were involved in the survey, representing around a quarter of the total number of student studying the module. These numbers mean that the findings can only be regarded as indicative, carried out within the context of a pilot study. The next two questions in the survey sought to shed light into which facilities the students used, and beyond this which they found useful. This distinction between used and useful is crucial for this study. It is suggested that it is not sufficient to say that a theory indicates the use of a facility, and consequently its inclusion validates the learning resource. If students do not find the facilities useful it throws into doubt the voracity of using the facility to achieve a particular educational objective. The questions and findings where as follows:

- From the list of WebCT facilities which have you USED?
- From the list of WebCT facilities which did you find USEFUL?

#### Table 3 The results of the student evaluation 'exit survey'

</tr>
</tbody>
</table>
These results indicate that some facilities were used but not found to be useful, in particular the note editor, discussion forum, chat, whiteboard, check progress and targets were not useful to all of the students who used them. In addition, some of the students elected to not use some of the facilities. As some of these facilities were key to supporting the conversational framework, this finding poses questions about the context for their use. Further analyses of the findings regarding the usefulness of the facilities are shown in Table 4 on the next page. Table 4 shows the numbered items from the educational criteria along the top (listed in Table 5), whilst the WebCT facilities are listed down the left hand side. This form of analysis i.e. the conversational framework analysed against the facilities in a VLE was used by Conole (1998). It is suggested however, that this analysis goes a step further, in so far as it makes use of student evaluation to inform the rate of successfulness. The table highlights the points discussed earlier, for example some of the requirements are not being successfully met.

Table 4, on the next page, shows that as the module content display was useful to 100% of students, therefore criteria 1, 5 and 6 of the conversational framework were successfully implemented. On the other hand, the note editor facility was useful to only 7% of students, therefore criteria 13 cannot be said to be successfully implemented. Reading the table starting from the criteria, we can see criteria 6 Teacher set task goal, is successfully implemented by the module content facility if not entirely by the goal setting facility. Perhaps most significantly for the conversational framework the facilities being used to support interaction between Student and Teacher, for example criteria 2, 3 and 4, are not being entirely successfully implemented by tools such as the discussion forum.

Table 5 Conversational framework Criteria

| 1. T(eacher) can describe conception | 8. T can set up world to give intrinsic feedback on actions |
| 2. S(tudent) can describe conception | 9. S can modify in light of feedback on action |
| 3. T can re-describe in the light of S's conception or action | 10. S can adapt actions in light of T's description |
| 4. S can re-describe in light of T's re-description or action | 11. S can reflect on interaction to modify re-description |
| 5. T can adapt task goal in light of S's description or action | 12. T can reflect on S's action to modify re-description |
| 6. T can set task goal | 13. S can internalize articulation/action |
| 7. S can act to achieve task goal |

Conclusion

In conclusion it is suggested that whilst the WebCT software supports the design and development of a learning resource that can be compliant with an educational evaluation based upon the conversational framework, it can not, however, be taken for granted that any individual learning resource is entirely successful in delivering the aims of the conversational framework. The results of this study indicate that success maybe illusive, even in terms of the fundamental requirements. In respect of the IC240 module, it is suggested that the learning resource be redeveloped, in order to leverage more successfully key facilities in the learning resources. In more general terms, it is suggested that the process of developing pedagogically informed learning resources, going from criteria, to facilities and then to evaluation, should be refined into a methodology that focuses upon the student as the main arbiter of successfulness.

For the evolution the knowledge also changes. One of the changes is the denial of one of the agents for doing a task belonging to a role, the coordinator is in charge of choosing a new one among the other free agents and teaching him if no other agent is found, that has done a similar or related task before. In the case of a new task that is to be carried out, the coordinator shows the coordinated agent how to execute the tasks belonging to his role, going first through a teaching and understanding of the new functions stage. For example, when the process coordinator receives new information that affects him, he must analyze it and check what tasks and functions must evolve, teaching his own to execute the new tasks to his coordinates so they can also teach their auxiliaries (if they have any) or to train in such functions. After the teaching process, the coordinated agents change their role, because they are now able to do a set of tasks that the coordinator may assign him later.
Behind the MASK Project

Helen, CARTER, University of Wollongong, Australia

The Media Appraisal/Selection Kit (MASK) Project is about identifying and organising the various ‘tools’ we use in the process of developing educational media. We may not think of them as tools but over the years we have used our experience and training in educational design, programming, graphic design, video and print production to guide clients through the development process using these various mechanisms.

A ‘toolkit’ would aid this process of educational materials development by:
* identifying possible media types and answering some typical questions about them;
* highlighting features of the alignment of technology and educational purpose through annotated case studies; and
* providing checklists to aid project specification.

The MASK project is not about determining whether or not to use interactive multimedia instruction but is about informing the client of possibilities. It is recognised that this can be heavily influenced by the learning problem being presented but MASK does not take this responsibility.
A Survey of Academic Use of Information Technology

Abstract: Wollongong is recognized as a top performing regional university in Australia. Its leading edge approach in introducing its students into the 'e-world', acknowledged in the accolade of joint 2000-2001 Australian University of the Year award, underlines the significance of information technology in our educational environment and the activities we perform within it.

A cross-disciplinary working party was given the task of developing a framework to inform future planning and policy on information technology at the University of Wollongong. Information gathered by the working party was used to develop a survey. This paper presents some results of this survey of Wollongong academics.

To maintain an edge in information technology (IT) in our current educational environment, requires effective: IT infrastructure; Management of IT; Implementation plan for IT; and Methods for monitoring progress and adaptability. From an academic perspective, we need all this in place to optimise our use of IT in support of our primary functions in research, teaching and professional activities. We need significant input to these – and to facilitate these processes, we need effective administrative systems.

A cross-disciplinary, academic working party was given the task of developing a framework to inform future planning and policy on information technology for academics at the University of Wollongong. Information gathered by the working party, in particular, from focused user groups, interviews with key stakeholders and appraisal of available information technology policies, was used to develop a survey. A sample survey was trialed with a number of faculties and the feedback received used to modify survey questions.

The final survey incorporated and examined. Academic and personal profile; IT proficiency; Use of IT in the work of academics; Structural information, such as types and age of computers; Rating of IT support; Areas of IT need; Communication on matters of IT and a call for independent opinion – both positive and negative on IT at the University of Wollongong.

Over one third of the academics in the University completed the Survey - even though by necessity conducted at that time of year when marking, administration, looming summer conference papers, planning days, and student appeals...
converge. Overall this was a phenomenal response. It was as if the academic community was grateful for an opportunity to have their needs heard - and this represented a vehicle to get that message through. A testament to the importance and the preparedness of academics at the University to be involved, was that when asked "If they would be willing to serve on a University-wide IT committee?", approximately 50% said 'Yes'.

Preliminary results
At this stage, only a preliminary analysis has been made of the substantial data collected. Some results are presented here.

An analysis of a survey question relating to type and age of computers, showed an even split between Macintosh and IBM-compatible (PC) personal computers. However, on average, desktop PC's on campus were reported as younger at 1.75 years and for Macintoshs older, at 2.4 years. Interestingly the survey pointed to lots of overtime going on - 75% of academics reported that more than half of their home computer use was for work purposes.

In overall computer use, academics rated their IT proficiency at a high level, with 52% feeling very comfortable to virtual experts and 28% comfortable. Macintosh users rated their IT comfort at higher proficiency levels with 52% in the very comfortable to expert regions compared to 46% of PC users. This may explain why Macintosh users may be reticent to change to another platform with the vision of having to rebuild their IT proficiency.

When asked their chances of getting release time to develop subject teaching material involving IT, the answer was less than a 10% chance. The same level of response was given to getting release time to develop any other area that involves IT. Respondents indicated there was a better chance, about 20%, of gaining release time to undertake technical training. This may account for the previously reported high degree of comfort with IT proficiency.

On the last page of the survey was an opportunity to write about any issues that academics felt impeded or facilitated their use of information technology at the University. These responses were categorised and in the 15 positive categories, the top response was for Faculty IT support. This comment was listed by 25% of academic staff and therefore rated as the most commonly unsolicited comment in the area of a feature that facilitated IT. It should also be noted that this response was dichotomous, as the same comment was made by 6% of academics in the negative.

Conclusion
There are many issues which deserve deeper consideration. It was a surprise to the researchers that the overall rating of information technology satisfaction across the university was skewed to the right, with a peak response between 60 - 90% approval. Also we saw that 90% of academics saw themselves as having at least satisfactory competency in IT - but the most significant impediment to IT was a strongly felt lack of time for familiarisation and training in new systems and/or processes. Such seeming paradoxes deserve closer attention.

The purpose of the working party was to provide insights into the most important IT requirements of academics at the University of Wollongong. This information would be used to inform future information technology planning and policy at the University of Wollongong so that academic work would be even better facilitated.

The survey has provided a rich source of data, which may provide insights into the most important information technology requirements of academics both at Wollongong and similar institutions. From a more detailed analysis we should be able to more clearly define the aspects of information technology which will facilitate rather than impede our academic effort. Can we identify core values which are central, and articulate them with Faculty and academic imperatives? Can we evaluate how this can be matched to other policy needs - like all good policies we must ensure information technology policy is congruent with other University of Wollongong policies?

(1997) University of Wollongong 'Strategic Plan 1997 - 2005', Wollongong, Australia
Abstract: This paper reports on the applications of Computer-mediated Communication (CMC) tool, eGroups.com (currently known as groups.yahoo.com) in English as a second language learning in a vocational education setting in Hong Kong. CMC is playing an important role in creating a learning environment that encourages interaction and communication which are crucial in language learning. The purpose of this investigation is to ascertain the usefulness of CMC in supporting third year computing majors in the VTC in the learning of the English module.

Introduction

CMC refers to “computer applications for direct human-to-human communication. This includes electronic mail, group conferencing systems, and interactive ‘chat’ systems.” Santoro (1995). Hart’s (1999) definition is that interaction between people, using computer or computer networks as the medium of communication. This communication can be synchronous or asynchronous.” December (1997) -Mediated Communication is a process of human communication via computers, involving people, situated in particular contexts, engaging in processes to shape media for a variety of purposes.” Regardless of the definition, communication is the key issue of CMC.

Lane (1994) collected and summarized the advantages of CMC in education. Some of them are: “enhances flow of information; sharing ideas; provides the capabilities to store, process and transmit messages; breaks down barriers to communication; fosters more participation and contribution; convenient; flexible.” Codde (1996) believed that “The biggest advantage of CMC is that it encourages student to be active in the creation of knowledge rather than passive reactors to instruction.” Warschauer (1997) suggested that the potential contribution of CMC is that it results in “more equal participation among learners” and “communication is time-and place-independent”.

The Study

The CMC tool used in this experiment was an egroup, 2000CM3, at eGroups.com. A group ‘2000CM3’ was founded on 26 September 2000 in eGroups.com. Students started to sign in and subscribe to the group in early October. The actual duration for students using the egroup was about 10 weeks. eGroups.com (http://www.egroups.com/info/features.html) provides a web based communication environment for users. Its major instructional features are: teacher to students asynchronous communication, teacher to students synchronous communication. Other features include: Message Archive, Files, Calendar, Chat and Polls.

The goals of the integration of the egroup into the English language module are to support students’ English and Communication learning by providing links to resources, giving supplementary information of assignments, announcing news about the course, sending reminders of deadlines or events. Above all it is a channel of communication between teacher and students and among students themselves. The integration of CMC tool aligns with constructivist perspective of learning, communicative language teaching methodology as well as the circumstances of the students. According to constructivism, learners take an initiative role in knowledge building through negotiation and collaboration in their learning process. (Jonassen, Peck and Wilson, 1999). CMC supports active learning (Shield, Weininger and Davies, 1999). The communicative language teaching approach emphasises active interaction in meaningful use of the target language (Littlewood, 1981). CMC “can provide authentic communication and can foster awareness of both the language learner and the languages they are learning.” (Singhal, 1998). Holliday (1999) proposed that “CMC is highly motivating as students have a real purpose for
communicating, using authentic language and receive peer group support in their language learning endeavours.” The duration of the module is short and class time is quite limited. However, CMC tools overcome such distance barrier. (Codde, 1996; Fishman, 1999) “Computer mediated communication (CMC) provides a third platform where L2 students can transcend the spatial and temporal confines of the classroom via the Internet” (Blake, 1999).

Findings and Evaluation

Data was collected by means of pre and post investigation questionnaires, interviews, qualitative comments posted and teacher’s reflection. 101 students became members of the egroup. The number of messages recorded was 275. The questionnaire results showed that the use of the egroup did not have much effect on the enhancement of professional speaking abilities, professional writing abilities nor did it result in an increase in students’ confidence when communicating in English. Positive comments were posted. Positive feedback was also obtained from interviews with students. Most of the students agreed that the egroup supported their learning in the following ways: link to resources, get supplementary information of assignments, get announcement about the course and get reminders about deadlines.

There is no doubt that the egroup provides a very convenient tool for communication between teacher and students. Students who actively take part have chance to practice the language and students who lurk can gain insight from reading the messages. However, the workload of the teacher increases tremendously as it is time consuming to respond to students’ messages. It is difficult to foster changes in students’ attitude towards the facilitating role of their teacher. The duration of implementation should be longer in order to help students to get used to the new form of learning. Language enhancement is a long-term process so it would be more appropriate to integrate egroup in a year long module. In this investigation, egroup is mainly used as a support. Therefore some students are not actively using the egroup. If the aim is to enhance the language abilities of the students, the use of the egroup should be incorporated into the curriculum. Modification of the scheme of work of the course may be necessary as one student suggested having some discussion tasks scheduled in class to be conducted through the egroup.

The investigation provides encouraging results to the supporting role of integrating CMC in the English learning of students in a vocational setting. The egroup is a very useful communication channel for both teacher and students. The effect of whether the use of CMC enhances the language abilities of students has not been confirmed. Further investigation and modification of the instruction design are needed. The integration of CMC will be more fruitful if students take a more active role, put more time and effort in their learning, and if students accept the facilitating role of the teacher.

Building A Virtual Learning Community of Distributed Knowledge on Web for University Students

Chi-Cheng Chang
Graduate Institute of Technological and Vocational Education
National Taipei University of Technology
Taipei, Taiwan, ROC
f10980@ntut.edu.tw

Abstract: This paper mainly tries to explore and grapple with some of the key issues of building Web-based learning community. We have completed the construction of knowledge distributed learning community (KnowDisLC). Development tools paving the way for building KnowDisLC are presented. Challenging issues associated with effective system building are discussed. A model involving systematic process of effectively building Web-based learning community is proposed. Lessons learned are subsequently discussed.

Research background

The new wave of Web-based teaching and learning has given rise to various Web-based teaching and learning systems. In Taiwan, some emphasize hypermedia and distance collaborative learning such as the CORAL (Cooperative Remotely Accessible Learning) (Chiao Tung University, 1996). Some emphasize constructive learning and peer assessments such as the Albatross system (Chiao Tung University, 1999); and still others emphasize active and social learning such as the LISA (Learning is Active) system, which is comprised of both the intelligent educational agent and the virtual learning buddy. The Earth Science Learning Environment was founded on project-based learning (Central University, 1999); the Pathfinder system on the integrated functions (Tainan Teacher College, 1999); the DALE (Distance-assisted Learning Environment) on the will to overcome learning barriers for teachers, parents and students (Hsinchu Teacher College, 1999). A few even focus on creative learning like the Taiwan University's Management Forum, in which students will not need to go to school (Taiwan University, 1999).

Some are designated for student teachers to enrich their knowledge in academics and counseling practice, such as the distance counseling and instructional resource systems developed by the normal universities and teacher colleges. The target user groups of these systems include students of colleges, high schools, middle schools, elementary schools and teachers of middle and elementary schools. There is a large variety, and each one has its own characteristics. They are vivid and interactive. However, it is a fact that there are many other Web-based learning systems that only provide static Web page material and lack any interaction to motivate students. Some of these are also very seldom visited. The widespread application of the WWW and learning technology has raised the awareness of WBL/WBI developers to the potential of virtual learning community on the Web. Though some domestic research in Taiwan on the Web-based learning environment and knowledge guidance systems for in-service teacher has noted the concepts of a learning community, none of them have developed any system based on the complete idea of a learning community. Actually, there are a lot of related documents and research overseas.

Founded on the concept of community of practice, CoVis (Learning through Collaborative Visualization) aims at research related to science learning (climatology and geology) (Pea, 1993). It provides online discussion, e-mail, teleconferencing and other WWW tools to link experts, teachers, students and field workers to form a collaborative learning community. CSILE is a kind of collaborative database style of learning community which aims at providing students with strategic tools that can stimulate thinking. Therefore, it is designed for a wide variety of knowledge (Scardamalia, Bereiter & Lamon, 1994). A student can access the thoughts of the present or former students and can leave his own for other students. As a kind of asynchronous data sharing, CSILE emphasizes that the context of the learning community, and its knowledge building should be more effective than knowledge telling. During the building of knowledge, a student will continue to confirm what he does not know and to expand his own knowledge system through the sharing of thoughts and assistance from the others.

We have built a Web-based knowledge distributed learning community (KnowDisLC) based on the concepts of knowledge distribution and sharing. The system has been experimented on subjects of the university to evaluate its functions and effectiveness. The purpose of this paper is mainly to explore and grapple with some of the key issues of building Web-based learning community (WBLC). Meanwhile we are also intend to explore the design considerations...
paving the way for building WBLC, as well as challenging issues associated with effective construction and implementation of WBLC. Finally, a feasible model involving systematic process of effectively building WBLC is expected to propose for helping guiding further modeling efforts.

Construction of System functions

The KnowDisLC provides access to utilities that include news bulletin board, discussion board, curriculum center, learning activity bulletin, learning resources sharing and provision, user profile center, expert consultation, website resource search, opinion bulletin board, point accumulation system, web-based learning record, system management. KnowDisLC enables synchronous and asynchronous interactivity. KnowDisLC includes students, instructors, field experts, and practitioners among its memberships. It supports tele-discussing, tele-mentoring, teleconferencing, tele-sharing, tele-instruction, and access to communal resource bases and information bases for learning enhancement and enrichment.

News bulletin board provides dynamic up-to-date information, including a 'system bulletin', 'school bulletin', 'class bulletin', and 'information bulletin'. Bulletins that have been posted for over one week will be automatically moved to the 'old bulletin box'; users can browse old news or information there. Dynamic HTML flexible menu has been adopted in the system to avoid a problem of long screen resulting from too many sub-menus. Discussion board provides 'synchronous online conferencing', 'host conferencing', 'asynchronous discussion', 'online calling' and 'host list' functions. Users may partake in distance conferencing, or they may publish and discuss articles through asynchronous discussion board. In addition, the discussion board provides a conference/discussion host, system manager, online assistant and teacher with management functions. For instance, a host may use the conference-record function button for the host conference to take down all the contents of the discussion as a reference for teachers and students. A host can also announce or remove the time and topic of a web conference. The host may also modify or remove from the academic discussion all articles of an improper issue or content which have been put online.

Curriculum center provides online curricular outlines and multimedia presentation materials for users to online browse or download for offline reading, which can be used for preparation before class and revision after school. Learning activity bulletin allows teachers to announce the newest learning activities, such as personal assignment, project-based assignment, collaborative learning, group list, examination information. The bulletin includes 'bulletin announcement' and 'bulletin browse'. The 'bulletin announcement' function is only assigned to the system manager, teacher, and online assistant); while the 'bulletin browse' function is assigned to students. Learning resources share and provision is designed in stays true to the spirit of 'knowledge share and provision and distributed knowledge'. Provide 'website-resources share', 'website-resources provision', 'files-resources download' and 'files-resources upload' functions. Users may enter information and URL address of related websites or link to related websites and upload or download related materials for knowledge sharing, resource sharing and information exchange.

User profile center provides 'personal data inquiry', 'personal data edit', 'user inquiry' and 'user data list' functions to enable a user to query and modify his own data, view the data of other users, browse the learning status of his own or other users and accumulated point record. The 'user data list' contains information such as user ID, Chinese name, nickname, log-in frequency, last-log-in date, last-log-in time, total accumulated points. This enables users to know the log-in status of other users. Expert consultation provides three functional modules including 'expert list', 'expert registration', and 'management' module. The term 'Expert' refers to both 'experts' (students); users may ask them questions through e-mail. A user may become an expert or little teacher by using the expert registration function provided by the system once his log-in accumulated points have reached a certain standard and he is interested in becoming one to help other students. Users who are given system management authority (teachers, system manager, and online assistant) can remove data provided by unqualified experts.

Website resource search including search engines are provided to enable users to run a remote search by inputting key words. In addition, the function enables users to link to websites not directly related to curricula (such as libraries, related organizations and institutions, net bookstores, and other websites), so that a user may use other resources from within the system. Opinion bulletin board enables users to state their own opinions and to browse the opinions of others in order to establish a humanistic virtual community. A user may choose from within a set of 16 emotional patterns provided by the system to express his feelings. The system will automatically display a week's worth of contents on the bulletin board when a user logs in.

Point accumulation system is used to encourage user involvement in learning activities. When a user participates in any of the community activities, he will be given a set number of points. Furthermore, the point accumulation system will provide a reference for teachers to evaluate student involvement and to open advanced functions. Web-based learning record provides information about a user's learning status on web, including 'learning record
statistics’, ‘browse conferencing record’, ‘assignment upload statistics’, and ‘host performance’ to enable students to understand their own progress, learning status, and performance by viewing other users’ learning activity records and summaries. This will stimulate the visit of log-in and revision of learning. The current problem, however, is that the system is unable to detect what students are doing when they are actually on the site, including what and when they are browsing. This is what we are trying to improve the KnowDisLC at the moment. System management provides online system management to teachers, online assistants and system managers, and includes ‘news announcements’, ‘user log analysis’, ‘user data maintenance’, ‘upload data reviews’, ‘mail delivery center’, and ‘web conferencing record’ functions. The system can automatically identify a user's account authority level according to his user ID, and no additional password is needed.

System development

Development tools

The KnowDisLC system is constructed on the MS Windows NT Server 4.0 Chinese version platform, and uses MS IIS (Internet Information Server) 4.0 as the site server. On the server side, site database tables are created with the MS Access 97 database management system, using the ASP (Active Server Page) which is used in application programming. On the client side, applications are programmed using HTML, Dynamic HTML, VB Script, and Java Script. In Web page editing, MS FrontPage 98 is used to create the basic architecture and static data of the site, and the dynamic Web pages and applications are edited and programmed using MS Visual InterDev 6.0, which is a very handy and visualized tool for dynamic Web page and application development, including built-in HTML and script editors, database development tools, ODBC (Open Data Base Connectivity) support, and Website management tools. It also allows developers to integrate other programming components (ActiveX controls, VB Script, Java Script) with the developing system.

Other system development supporting tools include SA-FileUp software for ActiveX-based active server components by Software Artisans; without its programmable object module, the Web-based FTP module would not have been developed for timesaving and laborsaving goals. In image processing, Ulead Photolmpact 4.2 was used for special text effects, the Web page image, GIF animator, button, and object production. On the client side, the commonly used MS IE 4.0 was chosen to be the target browser.

Prototype

The prototype of the KnowDisLC system first used the MS FrontPage 98 to create the format for the system, including its page layout, screen background, Web page hyperlink of main functional buttons, form/table design, and Web teaching material (PowerPoint presentation). However, since the prototype is an HTML-based model with some sections designed with Dynamic HTML, VB Script and Java Script, which are all client script languages, (i.e., program commands are embedded in the HTML files and are interpreted by the browser after it is transferred to the client. It is unable to output different Web page contents or results according to different environments and data requirements.) therefore, having static Web pages is still the major concern of the prototype, and the majority of the system functions are not covered.

Model of Building WBLC

The process of our building KnowDisLC follows the ISD and ADDIE frameworks that are consisted of analysis, design, development, implementation, and evaluation components. The construction of KnowDisLC is focused on finding out how to incorporate the increasingly powerful Web application and multimedia technologies and content development tools into developing and producing a feasible online learning environment, as well as enhancing the system functionalities and performance so as to improve its applicability. In order to establish basal theory of Web-based learning, a commonly accepted construction model of Web-based learning community is imperative to explore. A feasible model of building Web-based learning community is proposed as Figure 1. The proposed model is based upon our experiences of design and development as well as the evaluation results of the KnowDisLC. This model involves systematic process and tasks of building Web-based learning community. It is observed that effective design and construction of a Web-based learning community can be facilitated through systematic process and prototyping approach. Moreover, integration of ISD and prototyping approach may be employed to find opportunities
for establishing a derivative framework for enhancing Web-based learning. Internet and multimedia technology may be applied within the framework of ISD and ADDIE as a systematic approach for building Web-based learning community. In this manner, effective integration of an adaptable ISD approach along with Internet technology may contribute to learning experiences in the current instructional framework.

Figure 1: The model of building Web-based learning community

Issues of Building WBLC

Building a learning community network on the Web is accomplished by installing, executing and maintaining a Web server. Support of standard network protocols is needed for providing server with high access performance. Construction of learning community generally involves funding, resources, and time as well as is associated with budgetary, technical, design, production, testing, operational, and implementation issues. There are numerous challenges in building KnowDisLC that include the following:

1. What are the common goals, objectives, missions, and visions of the learning community for incorporating members together to form a tight-knit community consortium.
2. What is the main intent of the learning community?
3. What types of memberships will compose the learning community? What are the target groups of the learning community?
4. What are the technical requirements for developing and producing the learning community system?
5. What are hardware and software requirements for accessing and executing the learning community?
6. What software tools will be used for developing and producing the learning community?
7. What are the tools for creating Web pages and HTML documents?
8. How to enable the learning community to be multi-courses platform?
9. What are the contents of database for supporting the learning community? What types of data will be made available?

10. How will the information in the learning community be presented? Will the information be in textual or graphical format?

11. How will the course materials be presented and delivered? Will the course materials be supported by multimedia such as audio and video?

12. What are the tasks and responsibilities for building the learning community?

13. Who are the team members for building the learning community? Who will be responsible for the instructional design, system design, programming, multimedia production, course design, Web-page design, database design, evaluation and so forth?

14. How will operations of the learning community be sustained over the long time?

15. Are there sufficient funds available for building the learning community?

16. What types of learning resources will be appropriate to support learning? How will the learning resources be presented? How to gather and manage learning resources such as Websites related to courses?

17. How to create portfolios for monitoring students' learning processes?

18. What amount of time is needed to setup and run the learning community?

19. How will rapid prototype be created for correctly developing final system?

20. How to compartmentalize, build, and integrate programming modules that constitute the codes of learning community?

**Lessons Learned of Building WBLC**

The context of telecommunication offers validation, encouragement, interaction which researchers have found absent in tradition learning experiences. Consequently, this may facilitate design and construction of Web-based learning community. Reliable communication performance, rapid response time, favorable operations, and ease of maintenance are key factors of effective implementation for Web-based learning community. Participants in Web community may find themselves sharing knowledge and exchanging experiences in an online discussion/forum. As Goodyear (1995) observes, this is so called information, expertise, knowledge and intelligence distribution. Participants in the Web community share common goals and visions as well as show the diversity of memberships. Participants may vary in gender, age, education, interest, experience, and occupation background and can comprise students, teachers, field experts, and practitioners.

Students used a great deal of discussion to clarify their understanding of not only the contents of course materials, but also interactions among peers. Discussion in the forum of the learning community opened up students' views on the depth of the interesting issues. Students indicated that they had sensed participating in and penetrating the very constructing of new knowledge. The virtual community was created to captivate events, in turn leading to learning experiences gleaned in participation. Bandwidth of telecommunications and access to acceptably reliable Internet technologies continue to distract from Web-based virtual community. Nevertheless, limitations of effective learning may be minimized through adaptable instructional design of course materials and congruous applications of communication mechanisms. Just like Palloff and Pratt (1999) state, distance learning will not replace traditional face-to-face learning. Whereas, it sustains to enwrap nontraditional learners for the main reasons that the structure and confines of the traditional classroom simply do not work.

Regardless of adequate support of technologies, effective Web-based learning requires appropriate design, sufficient interaction, good course materials, and meaningful communication. As HerrNeckar (1999) observe, availability of course content, interactivity of telecommunication, and alleviation of time and place constraints provide basal implications for access to virtual community. It is necessary for successful implementation of a learning community to include training for its online assistant, forum moderator, and instructor in the process of online learning. Online assistant and instructor training involve an introduction to the hardware and software being used to deliver course materials. Forum moderator training involves skills of presiding over online conference or discussion. What we have learned from our experiences of building and executing KnowDisLC is that regardless of the environment, the establishment of learning community aplenty promotes the quality of learning experiences.

**Conclusions and Future Works**

Based on building the KnowDisLC supported by the Web, this paper covers experiences regarding design
considerations and issues of building system, deemed crucial to electronic community building. It is an examination of systematic processes uses through which the KnowDisLC was created, constructed, and evaluated. Recent advances in Internet technology have afforded flexibility in building Web-based learning environment. Network technologies and services and Internet popularity contribute to the Web-based learning whereas, there are still many obstacles to the integration of technology and Web-based learning into curriculum. Worldwide acceptance of the Web as a medium for knowledge share, experience exchange, information distribution, and resource access contributes to the development of the KnowDisLC. Nonetheless, merits and liabilities of Internet technology in Web community domain are not yet fully documented (Littman, 1999). Despite the obstacles, establishment of KnowDisLC, a virtual learning community on the Web, can happen.

KnowDisLC involves virtual reflections of activities taking place in real life. It provides a common cyberspace for the interaction, exchange, and retrieval of information and enables participants to access, share, and update information from variety of resources. Its socially oriented activities transcend tradition learning; heighten interactions among participants; serve as forum for discussing common issues; promote collaborative capabilities; and increase knowledge creations. As Herrmann (1998) observes, Web community is one such social structure and that this structure has a strong affective dimension. Participants in the learning community gain more attention from instructors and online assistants. Additionally, they may spend more time thinking about, responding to, and exploring on, whatever question peers or instructors give. We discussed a number of issues as we found them based upon the experiences of building KnowDisLC. Whereas, we are attempting to create points for further discussion rather than offering solutions. The question of wider applicability and effects of the KnowDisLC may be left open to corroboration and further investigation in varying contexts.

Discover Sequential Patterns of Learning Concepts for Behavioral Diagnosis by Interpreting Web Page Contents

Chih-Kai Chang and Kuen-Shan Wang
Department of Information Management
Da-Yeh University, Taiwan
Email: chihkai@mail.dyu.edu.tw

Abstract: As Web-based course become popular, the Web system accumulates a large amount of log data. Because the log data was generated by learners' behavior on the Web-based course, many researchers agree that analyzing the Web logs will bring benefits for learners, instructors, and the Web site manager. In general, one record of Web logs can specify "the filename of the Web page that was accessed", "who access that Web page", and "when the Web page was accessed". Although many interesting results can be derived merely depending on the general Web logs, some important meanings of the Web logs were not considered in previous researches. In our opinions, the content, represented by the Web page format, is not included in the general Web logs. For instance, a Web page may present a project work, a discussion article, a section of curriculum, or a grade report. However, previous researches did not consider the represented content of a Web page in the Web logs, in which only the file name of the accessed Web page is generally identified. This paper proposes system architecture to analyze learners' online behaviors for mining learner's patterns by transforming general Web logs to a content perspective. Hence, the methods of previous research still can be used to find the more meaningful results. Most important of all, this methodology finds patterns based on learning behaviors instead of browsing behaviors.

Introduction

As Web-based course becomes popular, various learning activities can be running on the Web (Herrington, Sparrow, and Herrington, 2000; Chang and Chen, 1997). The asynchronous discussion activity, homework assignment and submission, announcement, grade reports, and almost anything students expecting to do can be executed on the Web. Because all the learning activities are represented as Web pages, the Web server will accumulate a large amount of log data for every Web page. One record of the Web logs can indicate which page was access by someone in sometime. Hence, many researches analyzed the Web server logs to figure out users' motivation, users' response, browsing pattern, and the network traffic (Sullivan, 1997; Sun and Ching, 1995). Furthermore, analyzing students' on-line learning behaviors and on-line problem solving activities can also discovery meaningful results (Jehng, 1999).

There are many products of Web log analysis for commercial web sites. The technologies used for analyzing Web server logs evolve from traffic-based or time-based assessment to user access pattern analysis. For example, Perkowitz uses access patterns to construct an adaptive Web site (Perkowitz and Etzioni, 1997). Hence, the interested Web pages will be linked and organized as a proper view for every user according his/her access patterns. The path concept, users' sequential Web page access records, is important for constructing user access pattern for Web logs. For instance, Stuart Schechter (Schechter, Krishnan, and Smith, 1998) create users' path profile to predicate users' browsing behavior. Consequently, the field of Web log analysis is growing for the purpose of custom services.

Recently, applications of Web log analysis integrate data mining techniques to focus on the customer behavior patterns. It is because the predictive modeling and link analysis operations in data mining techniques can be used to answer questions such as "Which of my customers will prove to be good, long-term valuable customers and which will not?", "How can I sell more to my existing customers?", "Is there a recognizable pattern in which my customers acquire products or use services so I can market to them just-in-time?", and so on. Although there is no universal approval definition of data mining, it generally indicates the process of extracting previously unknown information from a huge amount of data. Then, the discovered information can support users make decisions, develop a predictive model, or do something benefit from it. Consequently, we intuitively apply data mining.
and ‘from where the learner come’, but also should know ‘what the Web page contains’. However, it is difficult to represent the content of a Web page with symbols. The reason is that the content of a Web page may contain many concepts. Consequently, the first step for understanding the pedagogical meaning is reconstructing the Web pages in the site of a Web-based course by endowing only one topic or concept for each Web page. While breaking a Web page into single concept Web pages, one would find that some concepts are not atomic concepts. That is because a major concept will contain many sub concepts. Hence, the second step for understanding the pedagogical meaning of a Web page is to identify its location within a concept hierarchy, which is a special case of a concept map, instead of its location within the hypertext hierarchy.

Concept mapping is a technique widely used to represent knowledge in graph (Johannessen, Beissner, Yacci, 1993; Roberts, 1999). Some researches demonstrate that teaching materials are more easily assimilated if a concept map of teaching materials can be consulted (McAleese, 1998; Wang, 2000). Although concept mapping could be used for diagnose misconceptions or assess understandings, current applications of concept mapping technique on the WWW do not focus on that purpose. After Web pages interpretation, the following issue is what a concept hierarchy can support for assessing learners’ understandings. Therefore, the second requirement, referred as mining concept patterns, for discovering learners’ learning pattern is to mining sequential access paths on previous aforementioned concept hierarchy. Learners’ navigating tours on a course web, also called hypertext paths, are an important issue in hypertext. Generally, hypertext paths are related to two major problems: user disorientation and cognitive overhead (Conklin, 1987). However, the users’ access (navigate) pattern can only help Web site manager improving Web site schema because a Web instructor still can not figure out learners’ intention. The proposed concept hierarchy presents a feasible style for supports of interpreting the Web page content. After learners’ navigating paths on a Web site are transforming to navigating paths on the concept hierarchy, a Web instructor can comprehensive how learners learn from the information of what learners read.

The third requirement, coming from the founded concept patterns, is to infer students’ internal concept states for explaining students’ behavior. This requirement is referred as behavioral diagnosis. Inferences, interpretation, and classification are three types of behavioral diagnostic activities in literature (Wenger, 1987). The classification type of behavioral diagnosis is used to characterize or evaluate observations of learners’ behaviors. The interpretation type of behavioral diagnosis will explain observations of learners’ behaviors. In this paper, the requirement of behavioral diagnosis is inferences types because the goal of our data mining effort is to provide the instructor with results that are interesting or unusual. For example, the assertion can be made that a novice of a programming language is likely to visit the synopsis of language syntax often. In other words, a learner’s internal states, that are concept patterns, produce his/her behaviors in determinism. If a concept pattern of a learner is “surprising” to an instructor, it means that the instructor’s expectancy of the learner differs from real learning state. Consequently, an instructor can posit learners’ concept structures to account for observed learners’ behaviors.

This paper proposes a methodology to mining learners’ learning pattern by transforming learners’ Web page access sequences to sequences of learning a concept in Web logs. Traditional web logs mining algorithms, which is designed for discovering users’ access pattern on a Web site, can support the methodology. This methodology is not used to replace traditional web logs mining algorithms nor is arguing that concept hierarchy is a suitable web site schema. Rather, this methodology presents a framework for integrating traditional web logs mining algorithms with pedagogical meanings of web pages to support Web instructor get more feedback from learners’ navigation on the Web course site. Broadly speaking, this methodology contribute to apply traditional web logs mining algorithms to a specific domain in the technical aspect and progress assessment skills in the Web-based distance learning aspect.

System Architecture

To apply data mining methods for concept sequential patterns discovery, a distance learning instructor should first construct the concept hierarchy of a learning Web site and link every Web page to a related concept in the concept hierarchy. Then, the system can implement the mechanism for mining concept sequential patterns by general sequential pattern discovery techniques. Finally, an
instructor will get a report of interested or unusual concept sequential patterns. Thus, the instructor can refine learning strategies or diagnosis learners’ behaviors after assimilating the mined results. Meanwhile, the Web site manager can evolve the schema of learning Web site according a distance learning instructor’s pedagogic ideas.

There are three phases for mining sequential concept patterns by general sequential pattern discovery techniques in the system architecture. First, data preparation phase is responsible for constructing a concept hierarchy. This phase also links every Web page to a node in a concept hierarchy and prepares a logging mechanism to record learners’ behaviors on a concept hierarchy. Then, the second phase begins to transform Web logs after the learning Web site for a group accumulates many Web logs. Because the only way to access a Web page is through the concept hierarchy, a sequence of accessing Web pages can be transform to a sequence of learning concepts. Third, a general technique for sequential patterns discovery is used for mining both concept sequential patterns and Web page access patterns. Hence, a distance learning instructor can use the mined information to diagnosis whether any special behavior is happening in a group. For instance, learners are debating a topic in a long time. Consequently, a distance learning instructor can intermediate in time. Furthermore, a distance learning instructor can also review the arrangement of Web pages according the reported portions of learning Web site.

Figure 1 illustrates the system framework for mining sequential concept patterns by interpreting the Web page content. The portfolios block denotes a database containing Web logs, discussion articles, and project works so on. First, a distance learning instructor should construct a concept hierarchy and reorganize Web site schema according the concept hierarchy. Then, learners will be asked to use the concept hierarchy to access all pages in the learning. For instance, the system will forbid a learner’s browsing behaviors if the learner uses an URL to access a Web page directly. Implementation of this part can be easily archived by using the Session object of Microsoft’s ASP (Active Server Pages) technique. After learners use the concept hierarchy to access Web pages, the logs of his/her browsing behaviors can be endowed additional meanings. For instance, an instructor can find out the members who have not read summaries of a discussion activity posted by the moderator of a group. Consequently, a distance learning instructor can diagnose learners’ behaviors from concept level instead of browsing behavior level.

A distance learning instructor now has a concept hierarchy to support interpreting Web page contents. Interpreting Web page contents can support the system operations in two aspects. For data preparation, every Web page is linked to a symbol that denotes a concept. Then, a filename in Web logs can be transformed to a symbol of a concept. For data mining, only a general method for sequential pattern discovery (the up arrow in Figure 1) is needed to mining concept sequential patterns because a symbol in Web logs represent a 'node' in a concept hierarchy instead of a filename. Hence, the results of mining sequential patterns may reveal a ‘path’, that is a sequential pattern, in a concept hierarchy. A sequential pattern of learning concepts is more useful for behavior diagnosis than a Web page access pattern. For instance, ‘80% of learners who accessed page A will thereon access page B’ is less clear than ‘80% of learners who read discussion summaries will thereon access’ Furthermore, an instructor is easier to assimilate a sequential pattern of learning concepts than a Web page access pattern.

Figure 1: System framework for mining concept sequential patterns.
Illustrative Example

In overview, there are two steps in this illustrative example of detecting learning status. The first step is data preparation. We design a sophisticated structure of a Web site so that we can recognize the content of the accessed Web page. The second steps will find pedagogical meanings from the contents of the preferred Web pages. In this illustrative example, the result of step two will show that learner is not familiar with the learning topic.

Data Preparation

The required data was collected from the students in an undergraduate course of Perl programming. Perl is a high-level programming language written by Larry Wall. Perl is a very popular programming language for system administrators and CGI script authors. After a brief introduction of Perl, students were asked to study the Web pages extracted from Perl manual. There are three topics in the prepared Web pages. First topic of Web pages demonstrates how to execute the Perl interpreter, called Perlrun in Perl manual. Second topic of Web pages explains the Perl model for declaring importing, and calling a subroutine, called Perlsub in Perl manual. Third topic of Web pages describes associativity and precedence of Perl operators, called Perlop in Perl manual. Consequently, learners' behaviors recorded by Web logs can be recognized by the topic of accessing Web page.

Synopsis and description compose each topic of Web pages. Synopsis is a summary of a topic and generally contains no more than one page. Description explains the details of a topic in original Perl manual. For illustration, description for each topic was reorganized into two Web pages. In general, synopsis of a topic is prepared for learners who are familiar with that topic. Learners who are learning a topic will prefer the description of that topic. Hence, we can help a learner just in time if he/she is always looking around the detail of a topic.

Aforementioned structure is content structure of learning materials. To present learning materials in a hypertext style, a hyperlink structure is required. We use the full connection style to link all Web pages. Hence, learners can navigate to any destination in any Web page.

Figure 2 shows the concept structure of the learning materials on the Web site. The notation $P_i$ indicates the Web pages. Although the overview structure is composed of concept hierarchy and contents of learning materials without hyperlink information, the tree structure above the $P_i$ can be used to interpret the content in the page. For instance, the $P_7$ belongs to concept synopsis, which is the partial content of the Perlrun topic.

![Figure 2: The concept hierarchy of a Web site.](image)

Mining Processes
There are three learning topics in the Web site, denoted as Perlrun, Perlsub, and Perlop. Each learning topic has two sub concepts, denoted as synopsis and description. The word "synopsis" is used to indicate the Web page for summarizing a topic and the word "description" represents the Web pages that explain a topic in detail. There is an index Web page linking every Web pages to serve as communicating interface with learners. Hence, learners can study any topic in any order through the index Web page. Assume that there is a learner who prefers the "description" Web pages of any topic. In other word, that learner is not familiar with all topics. Hence, the logs of that learner's browsing behavior on the Web site may be like the sequence:

p2, p3...p2, p8, p9...p5, p8...p5, p1...p2, p5, p6

Because learning can happen in any time, only time nearly browsing behaviors will be related in a learning pattern. Hence, the transaction idea, used in database theory, is involved to cluster learners' browsing behavior. The Ti means a transaction of the learner's browsing behavior. The content of every Web page can be interpreted as a pair of topic and representation style. For instance, p2 belongs to topic Perlrun and is a description of the topic. Hence, p2 is interpreted as (Perlrun, description). After interpreting the transaction data of learner's behavior, the results are follows.

T1: (Perlrun, description), (Perlrun, description)
T2: (Perlrun, description), (Perlop, description), (Perlop, description)
T3: (Perlsub, description), (Perlop, description)
T4: (Perlsub, synopsis), (Perlrun, synopsis)
T5: (Perlrun, description), (Perlsub, description), (Perlsub, description)

Most of algorithms for mining pattern are derived from aprior (Agrawal, et al., 1996). A general description of aprior is presented as following four phases.

1. Find the items with minimum support (threshold) by a length.
2. Increase the length by one.
3. Recalculate the items with minimum support.
4. Repeat step two and step three until no new item is found.

Finally, the maximal phase will find the most meaningful pattern from large-2 itemsset and large-3 itemset. Initially, the union of large-2 itemsset and large-3 itemset is used as the result. Then, some items will be eliminated because they are the subsets of some larger items. For instance, the meaning of \{5, 4, 4\} is more than its subset \{5, 4\} and \{4, 4\}. Hence, the large-2 items, \{5, 4\} and \{4, 4\}, will not be deleted from the initial result. Finally, some items will be eliminated because they are less meaningful then items in the result. For instance, the \{4, 3\} will be deleted because \{4, 7\} implies \{4, 3\}. Similarly, the \{2, 4\} will be deleted because \{6, 4\} implies \{2, 4\}. The following table illustrates the result.

<table>
<thead>
<tr>
<th>Maximal itemset</th>
<th>Real patterns</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>{6, 4}</td>
<td>{(Perlsub, description), (**, description)}</td>
<td>2</td>
</tr>
<tr>
<td>{4, 7}</td>
<td>{(**, description), (Perlop, description)}</td>
<td>2</td>
</tr>
<tr>
<td>{5, 4, 4}</td>
<td>{(Perlrun, description), (<strong>, description), (</strong>, description)}</td>
<td>2</td>
</tr>
</tbody>
</table>

Table 1. Maximal itemset.

Assimilation of Knowledge

The goal aforementioned data mining efforts is to provide the instructor with results that are interesting or unusual. In other words, an instructor may be interested to understand a concept pattern that contradicts to general beliefs. Beliefs of domain knowledge and beliefs of instruction knowledge are two important types of beliefs for behavior diagnosis. Consequently, the pedagogical meanings of mined concept patterns can be depicted from two different aspects. First, if the mined concept patterns contradict to general beliefs of domain knowledge, those mined concept patterns may imply the learner's misconception. For instance, a learner's browsing behaviors will generate a pattern of irrelative concepts when applying wrong concepts to solve exercises in problem solving activities. Second, if the mined concept patterns contradict to general beliefs of instruction knowledge, those mined concept patterns may imply the learner's disorientation. For instance, the "array" concept should be learned before the "pointer" concept in C programming language. If a learner is studying the "array" concept, any "pointer" related concept pattern would contradict to beliefs of instruction knowledge.

Conclusion

The Web-based learning environment offers opportunities to precisely observe learning processes.
However, it is tedious for a Web instructor to discovery useful information from the huge amount of Web logs. Traditionally, a Web instructor uses the Web log analysis products to realize the unusual parts of a Web site. From the pedagogical standpoint, the results of the Web log mining algorithms are not very useful for figure out learners’ learning process because the contents of Web pages are not considered. This paper proposes a methodology to mining learners’ learning pattern, which is related with the Web page contents, from Web logs. The methodology uses Web log mining algorithms, which is used in Web log analysis products, and the concept structure embedded in Web pages to mining patterns with learning and pedagogical meanings, so called concept patterns. In our opinions, this methodology presents a framework for integrating traditional Web log mining algorithms with pedagogical meanings of web pages to support Web instructor figure out learners’ navigation on the Web course site from the concept hierarchy perspective. Consequently, the approach presented here may be not only a feasible application of traditional Web log mining algorithms, but also a possible direction of Web-based learning assessment research.

Chung-Yuan Christian Univ., Chung-Li, Taiwan, 320
maiga@ms2.hinet.net, rita@mcsl.ice.cycu.edu.tw, jsheh@ice.cycu.edu.tw
http://ivc.cycu.edu.tw

Abstract: With the navigation mechanism designed in this paper, an intelligent agent then can learn how to solve a specific experiment in a virtual experiment environment such as IVC (Internet Virtual Community), through reading those XML-style experiment teaching materials alone. After storing the mind of experiment agents with knowledge, an agent can capture users' actions and send corresponding commands to Virtual Lab to help learners completed their tasks. Besides, this mechanism could also be used in solving problems, for example, learners can ask for instructions from agents.

Keywords: Virtual Experiment Environment, XML, Agent, Teaching Materials, Interactive Protocols

1. Introduction

A Virtual Experiment Environment (V.E.E) in distance learning systems provides a visualized social learning environment by creating experiment situation on Internet. [Tung95][JCCH96] A set of simulated virtual equipment for doing experiment is also included in V.E.E. [HSCX98][HHCH99] Recently, V.E.E. on WWW (World-Wide Web) categorized as three major types, Real Lab, Virtual Lab and Visual Lab,

1. Real Lab: needs a set of external experiment devices and software kit. [JJYH97]
2. Virtual Lab: simulated experiment through software. [CCJH96]
3. Visual Lab: using video-media and some manipulation toolboxes. [WCHH00]

Although V.E.E. offers an environment for learners doing lab on Internet, there is difficult for learners to ask question/demonstration or find out what is going wrong when they are doing exercise inside V.E.E. Hence, many researchers proposed some interactive intelligent tutors or environment solutions. [GSCX92][FuL92] In this paper, not only the model of interactive intelligent experiment agent is implemented, but also the mechanism of reading and understanding teaching materials is well analyzed and designed.

2. Analysis of Interactive V.E.E.

Architecture of Interactive V.E.E.

According to V.E.E. mentioned in previous Section, an interactive virtual experiment environment consists of four major components, including teaching materials, user interfaces - UI (visual lab, in this paper), interactive protocols and knowledge base. As Figure 1 shown below, those four components operate cooperatively.

Learners do any scientific experiments as they like with appropriate visual lab interface (UI) and teaching materials, of course, these materials and UI should obey some basic educational concepts such as the seven problem solving stages and science process skills. An experiment agent (or agent, in shortly) might be able to read the teaching materials directly without supervising, and store some well-organized knowledge (or information) into their artificial brains, which is so-called knowledge base. After understanding specific experiment, an agent owns capability to be a navigator as learners processing a lab exercise, agents can provide instructions for next step, demonstrate the whole experiment process through UI and even predict whether a learner's doing will go wrong or not.

User interfaces provide some interactive methodologies to learners for studying materials and doing experiments; Although teaching materials seem easily to develop, how agents can understand it is a big issue;
Interactive protocols include learner-UI (experiment), agent-UI (experiment), agent-material and learner-agent; knowledge base can be divided into two parts, knowledge structure and inference engine.

Figure 1. Four components in V.E.E.

The user interfaces, including study interface and experiment interface (visual lab, we called) are well built on WWW during these several years. [HCHH99][WCHH00] Therefore, this paper focuses on the XML-style teaching materials analyzing for reading by experiment agents, and the design of the four interactive protocols described above. Based on the CLIPS and JESS a simple version of knowledge base is also applied to the experiment system implementing in the paper.

Next on this Section we will analyze the protocols between agents and teaching material, agent and user interface (visual lab) at first. Secondly, a flow diagram for the interactions among agents, UI and teaching materials in the instructional system can be designed. About those interactions between learners-Uls and learners-agents are quite simple, and we had done a lots in past, hence, there will not discuss too much in this paper but you can still get some ideas in the experiment system constructed by this paper.

Interactive Protocols and Knowledge Base

Since the agent-material protocol requires the understanding of experiment agents in teaching materials, the W3C standard, XML, is taken into consideration of constructing the experiment teaching material on WWW. XML has capability to form a HTML style document within the concept of object oriented. It is so important to have some properties in the specific learning concept and experiment, take a free-falling experiment for example. We will need both a ruler and a timer when doing this experiment, a ruler should have length property and timer should be able to let us get current time. Following is an XML-style example for the free-falling experiment.

```
<VLaction act="adjust" obj="Ruler">Adjust
    <Obj id="VRuler">Vertical Ruler</Obj>'s as
    <length 1="13">13</length>
</VLaction>

<VLaction act="getvalue" obj="Timer">Get
    <Obj id="Timer">Timer</Obj>'s current time
</VLaction>
```

List 1. XML-style teaching material
Where the “<VLaction>” tag indicates an action in the visual lab, “<Obj>” and “</Obj>” create a timer or a ruler object with a special id. We may have some actions, such like adjust and get value, using these actions the properties belong to object can be obtain and modify simply. Besides, agents can read and understand this sort of standard XML-style teaching material by parsing those tags in the document.

After understanding the teaching materials, agent might need to interact with UIs such as visual lab. Through operates equipment and observe data, an agent can demonstrate the whole process of doing an experiment for learners. Hence, to design a communication language for the interaction between agent/UI is necessary. Here we try to design a lisp-like language to simulate what teaching materials tell as List 1 show above.

```
(adjust VRuler 13)
(getvalue Timer1)
```

List 2. Communication language between agents and UIs

Now, flows between these four components in V.E.E. can be drawing down as Figure 2 below.

In Figure 2, a learner should acquire and read teaching materials at first through the material reading UI, and doing experiment with the visual lab UI. Similar to learners, an agent also can use its agent-material interactive protocol to read teaching material, and then with agent-UI protocol to manipulate lab equipment and obtain experiment data from visual lab. Besides, depends on the learner-agent protocol a learner can ask an experiment agent for help, and agent can also provide either instruction or demonstration to learner through this protocol.

3. Visual Lab within Navigation Agent

Navigation Agents

Although everything seems going fine as Figure 2 shown above, there is still important issue needed to design. The very important issue is, how to let agents can understand what they read from XML-style teaching
materials, remember it and even inference. As we talk about previously, some exist systems and languages, JESS and CLIPS, are used to achieve this final goal.

Java Expert System Shell (JESS) is a system provides an expert environment in which rules or knowledge can be stored/inferred in CLIPS form. Therefore, a java agent constructed with JESS/CLIPS can direct store/recall/inference relative knowledge/rules from those teaching materials it read. The knowledge structure and inference methodology of agents for navigation in the instruction systems such as V.E.E. is illustrated in Figure 3.

In Figure 3, an experiment agent first use Microsoft Browser Helper Objects (BHO), which can be found in almost Windows operating systems (Windows 95 or above), to get the specific XML-style teaching material. Then the experiment agent can parse the XML-style documents and store some information and rules into knowledge base. When either it needs for demonstrating or learner asks for instructions, JESS can recall these rules/information for inferring and producing results to agent.

Figure 3. Knowledge structure in the JESS based agent

Figure 4. Visual lab without experiment agent
Visual Lab

To extend our past researches, the visual lab in IVC has been modified with those four interactive protocols, knowledge base and navigation mechanism we analyzed and designed in previous Section.[LCH00][CCH00] Figure 4 demonstrates the visual lab in Internet Virtual Classroom, and there is no experiment agent in it but only some equipment as visual lab UI provided for learners. An experiment agent with navigation capability looks like Figure 5. When a learner ask agent for help through the learner-agent UI (protocol), the experiment agent can either demonstrate, tell or explain instructions for learner as Figure 6 shown following.

Figure 5. Experiment agent for navigation

Figure 6. Experiment agent explains for learners in visual lab

4. Summary and Future Works

In this paper we have done the following things,
1. Analyze four components in a V.E.E., including learners, user interfaces, experiment agents and teaching materials.
2. Four interactive protocols, including learner-UI, learner-agent, agent-material and agent-UI.
3. Design specific XML tags for XML-style physical teaching materials.
5. Integrate both JESS/CLIPS and Database.
6. Implement an experiment agent in V.E.E. for demonstrating experiment process, diagnosing errors and making suggestion for next step to learners.

Beside those contributions summarized above, there are still several issues can be taken into consideration,
1. More general XML tags for courses in other fields should be analyzed.
2. Can the knowledge structure inside knowledge base be concept map?
3. Operations for acquiring knowledge base.
4. Knowledge exchange among learning systems.

Considerations of Spatial Ability in Learning from Animation

Lih-Juan ChanLin,
Department of Library and Information Science
Fu-Jen Catholic University
Lins1005@mails.fju.edu.tw

Abstract: The study explored the use of animation in facilitating descriptive and procedural learning in a scientific instruction. Spatial ability was used as a variable to observe students' learning of different knowledge. Both quantitative and qualitative data were analyzed. It was found that the effects of animation were different among students with different spatial ability. Compared with the control group, students with high-spatial ability learned better with animation in descriptive learning tasks, whereas, students with low-spatial ability learned better with still graphics in procedural learning tasks.

Introduction

When designing interactive multimedia applications, animation is often seen as an important component in presenting information. Animation provides potential visual interest for presenting computer-based materials, which makes scientific learning more interesting and enjoyable to learners. Learning under multimedia instruction requires students to integrate various types of information, which involves complex processes constrained by properties of the learner's cognitive operation, and especially by the capacity of working memory (Gyselinck, Ehrlich, Cornoldi, de Beni & Dubois, 2000). The most effective arrangement of animated visual aids may vary with the differing spatial abilities of students. Literature suggests that students scoring high in spatial abilities should be able to conceptualize the processes of diffusion in animation more completely or to a deeper elaboration (Hay, 1996). Individual differences in the use of their perception and visual strategies have become an indicator for analyzing students' learning patterns, especially in hypermedia learning environments. It therefore seems useful to determine whether the use of visual strategies produces different effects on different learner groups. The ultimate aim is to design learning materials optimized for the preferred modes of presentation among groups with differing characteristics to improve their performance. How users employ an appropriate strategy during the process of learning is also highlighted in the study.

Static and Dynamic Graphics

In design of scientific multimedia lesson, graphics and animation are often used to present instructional information. The terms, "static visual display" and "dynamic visual display" are used to differentiate between graphics and animation (Park and Hopkins, 1993). By definition, "graphics" refers to representations that do not rely solely on the use of text or numbers to provide informational content, while animation is the combination of a series of graphics and motions to form a visual scenario to represent information. Rieber & Hannafin (1988) define animation as a series of rapidly changing computer screen displays that represent the illusion of movement. In recent years, the increased availability of design tools has also permitted the design of instructional materials that incorporate unlimited variations and forms of verbal and visual information to fulfill our visual need (Parkash & Mathur, 2001; Rieber, 1995). The representation of motion provides potential learning interest and stimulates viewer's attention.

One note of caution should be sounded when using animation to present information. A number of researchers have identified individual differences among learners as influencing the effectiveness of animation. For example, Mayer & Sims (1994) concluded that learners with either high- or low-spatial abilities used different cognitive activities in processing visual information. Discrepancy in individual differences might influence the way given visual information is processed, and the degree to which related concepts and information are triggered and connected (ChanLin, 1999). Further study on individual differences in perceiving visual information is required before any firm conclusions can be drawn.
Spatial Ability

In mathematics and science learning, "spatial ability" is one of the most important indicators used for differentiating students' individual differences. Animation is also often used in current instructional materials to enhance visual skills (Holliday-Darr, Blasko, & Dwyer, 2001). The term "spatial ability" identifies what has also been labeled as the spatial sense, spatial perception, visual imagery, spatial visualization, visual skills, spatial reasoning, mental rotations, and visual processes (Davey & Holliday, 1992; Dixon, 1995). Spatial ability also refers to the ability to rotate or fold objects in two or three dimensions and to imagine the changing configurations or objects that would result from such manipulation (Mayer & Sims, 1994). In a study investigating the relation between the factors of gender, spatial visualization, mathematical confidence, basic ability, and classroom graphing utilization to conceptual mathematical performance with graphing calculators in college algebra, Cassity (1997) found that spatial visualization is related to conceptual mathematical performance.

Although from a design aspect, visualization is a fundamental component of presenting information on the computer screen, different presentation formats (non-graphics, still graphics, and animated graphics) may facilitate learner encoding of information differently for students with different levels of spatial reasoning ability. For example, Mayer and Sims (1994) explored high- and low-spatial ability students learning from computer-based instruction. They concluded that spatial ability allowed high spatial learners to devote more cognitive resources to building referential connections between visual (graphical) and verbal representations of the presented material, whereas low-spatial ability learners had to devote more cognitive resources to building representational connections between visually presented materials and its internal representation (Mayer & Sims, 1994). Large et al. (1996) found that primary school students with higher spatial ability gained more benefit from the presence of animation with text than students with lower spatial ability. Supporting evidence also comes from Hegarty and Sims (1994). They found that visual representations appeared to help those subjects who already had good visualization skills more than those subjects who had more difficulty in visualizing. Although the use of visual treatments to facilitate effective mental processing, individual differences in processing spatial information may be a fundamental factor requiring consideration.

Specifically, the purposes of this research were to: (a) study the effects of visual treatment and differences in spatial ability in learning from scientific multimedia instruction; (b) observe how individuals differ in navigating and processing visual information in a hypermedia environment; and (c) examine how differing visual treatments influence learning in students with different degrees of spatial ability.

Methods and Procedures

Subjects and Instructional Materials

The study consisted of three hundred and fifty seven students. There were nine classes of eighth-grade and ninth-grade students, randomly assigned to different visual treatments on a class basis. The material used for teaching physics was a computer-based learning program, covering problem about force. Students studied the instructional materials individually. After a period of study, a criterion reference test was conducted to assess students’ learning performance.

With an emphasis on using meaningful representations, which would encourage thinking, the lesson was designed with various scenarios for interaction. Several physics problems were embedded in the scenarios, which had adventures to draw students into becoming actively involved in finding the solutions. The lesson covered descriptive and procedural knowledge. Descriptive knowledge referred to knowledge that could be communicated through a recital of facts or the description of objects or events. In the learning and application of scientific concepts, it is essential for providing the basic information to be remembered. For example, the definition of “resultant” and “force vector” provided in the lesson was considered descriptive knowledge. As opposed to descriptive knowledge, procedural knowledge referred to learning and construction of the problem-solving procedures related to physics concepts. Learners needed to relate rules...
and facts to formulate a problem solving procedure. For example, the step-by-step problem-solving procedures were provided to help students construct a problem-solving concept.

The lesson was designed in three versions. The following is a description of the three different treatments:

1. **Treatment 1. Text (Control group):** In this version, only textual information was presented to explain scientific concepts.
2. **Treatment 2. Graphics with Text:** In this version, static graphics with textual information were presented to explain scientific concepts.
3. **Treatment 3. Animation with Text:** In this version, the instructional materials contain textual instructions and animated graphics.

**Instruments**

Classification of students as to their spatial ability was determined by a spatial ability test. This test had several sub-test which were part of the educational testing services package, “Multiple Factor Test” (Lu, et al, 1994). The spatial test involves several visualizing tasks that require students identify the specific three-dimensional shapes that result after an object rotates to a certain angle. This kit of spatial tests was selected for a variety of reasons. The first was because the visualizing tasks involved in the test were related to learning the spatial concepts in the lesson. Also, through official assessment, the test has been determined to be a reliable indicator of spatial ability.

To assess students' performance, a criterion reference test was created based on the content provided. The criterion reference test contained 25 testing items. Twelve of them were to assess students' learning of descriptive knowledge, and thirteen were to assess students' learning of procedural knowledge. Kuder-Richardson Reliability (KR21) for the criterion test items used in this study was 0.76.

**Results**

Among the 357 subjects, 182 were classified as being high in spatial abilities, and 175 were classified as low in spatial abilities based on the spatial ability test. To determine the effects of visual treatments and students' spatial ability in descriptive and procedural learning, a 3 (Text/Graphics/Animation) X 2 (High/Low Spatial Ability) ANCOVA was employed to examine the effects of these two factors. Separate ANCOVAs were also used to describe the effects of visual treatments on different spatial groups. Since in the Pearson correlation analysis, students' grade levels, prior physics, and mathematics scores were significantly correlated with post-test scores for both descriptive and procedural knowledge (p<0.05), all of these factors were used as covariates for controlling the initial differences among groups.

**Descriptive Learning**

In descriptive learning, the 3 X 2 ANCOVA indicated insignificant effects for both spatial ability \[ F(1, 348) = 0.675, p = 0.412 \] and visual treatment \[ F(2,348) = 2.429, p = 0.090 \]. No interaction was found between the two variables \( p = 0.572 \) (= 0.05 level).

In order to see whether animation or still graphics assist learning of descriptive texts, separate analyses were conducted within each spatial level group for treatment-to-treatment comparisons. It was found that among high-spatial ability learners, only the group using animation was better than text group \( p = 0.039 \); while among low-spatial ability learners there were no significant differences in any of the tests \( p>0.05 \) (= 0.05 level).

**Procedural Learning**

For procedural learning, the 3 X 2 ANCONA indicated an insignificant effect for spatial ability \[ F(1, 348) = 0.000, p = 0.988 \] and a significant effect for visual treatment \[ F(2,348) = 3.582, p = 0.029 \] (= 0.05 level). No interaction was found between the two variables \( p = 0.548 \). Overall, students learning with animation and still graphics performed significantly better than those learning with text did \( p = 0.035 \) and \( p = 0.013 \) respectively. No significant difference
was found between the animation and the still graphics group (p > 0.05) (≤ 0.05 level).

Treatment-to-treatment comparisons within each spatial level group were conducted. It was found that among high-spatial ability learners, there were no significant differences in any of the tests (p > 0.05); while among low-spatial ability learners, only the group using still graphics did better than the text group (p = 0.031) (≤ 0.05 level).

**Observation**

It was found that when learning spatial concepts, the use of processing strategies can be categorized into three kinds: external visual representation, internal visual representation, and combination of both types of visual representations. Employing external visual representations, students often used their own drawings as well as the graphics and animation provided by the teaching materials in the lesson to construct their own understanding of the meaning. By contrast, with internal representation, students used the images created in their minds with the description or concepts presented in the lesson to construct their own internal meaning. Even when graphics were not provided, they translated the verbal information into internal spatial representations for further processing. Some students shifted their spatial strategies either from external to internal or from internal to external visual representations in order to process and assimilate complex information.

In spite of the differences in the use of external visualization and internal visualization strategies among learners, learning spatial concepts does require internalization of the external representations provided by the graphics or animation. The difference between students' spatial performance is determined by their ability to create, rotate, and manipulate objects in their minds, and their knowledge of how to use these abilities to perform the spatial tasks given.

**Conclusions**

In the study, the main effect of visual treatment was observed significant for procedural learning, but not for descriptive learning, revealing that differences in visual treatment (the use of animation, still graphic, and text) were an important concern in procedural learning. Overall comparisons among different visual treatments indicated still graphics and animation were both better than text for learning procedural knowledge (not for descriptive knowledge). Although literature reveals that spatial differences might favor students with higher spatial abilities in scientific learning (Cassity, 1997), insignificant effect of spatial ability was observed in the study. The effect of spatial differences might be tempered by the factors within the training and instructional setting. The use and training of various spatial strategies within the classroom setting also served as a function of gaining experiences of solving problems in descriptive and procedural learning.

The analysis of different visual treatments among different spatial-ability learners shows that the use of animation promotes descriptive learning among those with high spatial abilities, while the use of still graphics promotes procedural learning among those with low spatial abilities (compared with control group). Inconsistent with other studies (Hay, 1996; Hegarty and Sims, 1994), which concluded that lower spatial-ability learners benefit more from animation, the study found that those with lower spatial-abilities learned better with still graphics in the procedural tasks. For those with low spatial abilities, the element of motion in animation might require extra effort in constructing the procedural links among rules and steps. Motion might not be suitable for students when the procedural links among rules and concepts can be presented with sufficient clarity in a still graphic form. In addition, the limited capacity of working memory in processing animation among lower spatial-ability learners might be worth noting.

Learning descriptive facts requires deciphering and encoding the rules and verbal information. For students with higher spatial ability, the deciphering process is automatic. Animation might provide some level of elaboration for encoding process. As a result, learning of descriptive tasks was facilitated with the motion cues embedded in animation, high spatial learners might devote more cognitive resources to building mental connections for elaboration. However, low-spatial ability learners must devote more cognitive resources to deciphering the visual information. They did
not benefit from animation in descriptive learning as high spatial-ability learners.

In summary, this research points to the theoretical and practical benefits of visual treatment. Different treatment effects among different learners imply the need for considering the cognitive processes in different learning tasks. On the theoretical level, this study concluded that the use of animated and graphic representations facilitates assimilation of scientific knowledge. On a practical level, this study raises the issue of differing mental processes for different learning tasks among different learners. From the qualitative assessment, it was concluded that learning requires internalization of the external visualization. Cognitive overload and spatial meta-cognition among learners when performing the spatial tasks was worth noting. Animation should be used with some caution, especially when internalized visual strategies are not an automatic process employed by most learners.

The Role Of Exports In Economic Growth With Reference To Ethiopian Economy

Faye Ensermu Chemeda

Abstract: This study applies the Cobb-Douglas function model to analyze the effects of exports on economic growth in context of Ethiopian economy. To determine the relationship between export and economic growth, an attempt will be made to use econometrics techniques of analysis (co-integration system) by using the RATES software package for the time series data from 1950 to 1989. The lack of capital stock data is overcome by using the ratio of real investment to real gross domestic product (I/Y), in place of capital stock while lack of labour force data is overcome by using the real gross domestic product per capita. The results suggest that the real export and (I/Y) are co-integrated with real GDP per capita. These results support the idea that the rate of growth of real exports has a positive effect on the rate of economic growth in context of the Ethiopian economy. Even strong positive relationship exists between real export and real growth domestic product per capita in long run rather than in short run when I compare real exports with that of (I/Y). Thus, the contribution of real exports to economic growth in context of Ethiopian economy is greater in long run than in short run.

Introduction

There are two extreme views which have attempted to assess the relationship between exports and economic growth, i.e., some have regarded export as it contributed positively to economic growth. Others have regarded export as it does not have contribution to economic growth. Even some have regarded export as it has contributed negatively to economic growth. For example, H.V. Berg and J.R. Schmidt (1994:p:250-51), O.A. Onafiwara (1996:p:346) and D.E.A. Giles, J.A. Giles and E. McCann (1992:p:196) suggest that growth of export stimulates economic growth. In other words, there is a positive association between the growth of export and economic growth. The reasons most of them give are:

First, export growth may reflect a rise in the demand for the country’s outputs, and this in turn will be realised in economic growth.

Second, by raising the level of exports, additional foreign exchange will be generated, and this facilitates the purchase of productive intermediate goods.

Third, a growth in exports may lead to greater productive efficiency (perhaps through economies of scale or technical improvements as a result of contract with foreign competitors and enhanced output. Productivity growth is also assumed to be the result of specific policy choices, namely policies that expand exports.

Fourth, there are externalities associated with export sectors; export earnings allow a country to use external capital without running into difficulties servicing foreign debt.

On the other hand, arguments have also been made (see, for example, D.E.A. Giles, J.A. Giles and E. McCann (1992:p:196) in support of the opposite view point; i.e., it has been argued that export hinders the development of country. The reason some authors give for the fallacy of the export as the contribution to economic growth is that the strategy the country may depend crucially on the type of good that is being traded like primary commodities exporting. Moreover, D.E.A. Giles, J.A. Giles and E. McCann (1992:p:196) also stated that there is no effect of export on economic growth. Their hypothesis is rejected the existence of the effect of export on economic growth. As some of them stated, the positive relationship between real gross domestic product and real exports does not exist in developing countries like Ethiopia, which depend on exporting primary commodities.

In general the empirical evidence associated with the effect of export on economic growth is very mixed. Accordingly, the objective of this paper is to test the validity of the hypothesis, i.e., the effects of exports on economic growth in context of Ethiopian economy. In other words, the aim of this study is to investigate the magnitude of the link between exports and economic growth of the country in question.

Thus, this paper uses the data on Ethiopia to investigate the effects of exports on economic growth using the cointegration system. Since Engle and Yoo (1987, p:143) stated that a co-integrated system can be represented in an error correction structure which incorporates both changes and levels of variables such that all the elements are stationary. This error correction structure provides the framework of estimation, forecasting and testing of co-integrated system.

The paper comprises three major parts. The first part examines the methodology and the data used while the second part presents the result from the data. Finally, it is summarised.
Migration, Income and Employment Linkage in Ethiopia
With Special Reference to Bahir Dar Town

Faye Ensermu Chemeda

Abstract

In both developed and developing countries, cities have been attractive centers to human settlement. As such, the rate of urbanization has been increasingly higher. In other words, the urban population in general and population of cities in particular are growing substantially faster than the total population. Moreover, this differential is widening in several countries. As a result, urbanization continues at a rapid, and sometimes at an accelerating pace. For example, in 1950, there were only two cities, London and New York, with populations of more than 10 million. By 1994, in the world the number of cities which had populations of more than 10 million were 14 of which 10 were in developing countries. It is also anticipated that there will be 27 largest cities in the world with population of 10 million or more two decades from now, of which 23 will be in developing countries, and only 4 in industrialized countries.

This has recreated a situation of incompatibility between urban facilities and the people who need them. This problem though prevalent in both developed and developing countries is more prominent among and within towns of Third World countries like Ethiopia.

This study examines and contributes to an enhancement of understanding of the urban situation in Ethiopia with special references to Baherdar town.

This town, one of the towns, which are found in Ethiopia, has an important role that is changing from time to time. The town was the capital of Bahirdar Province among Gojjam Administrative Divisions, latter it become the capital of West Gojjam Administrative Division.

Now it is a special zone and the capital of Region 3 and also serves as the capital of West Gojam Zone, which is one of the administrative zones within the region. This Region consists of ten zones and one special zone, Bahirdar itself, 106 weredas, and 208 towns (location that had 1000 or more persons whose inhabitants were primarily engaged in non agricultural activities were identified as towns irrespective of whether urban Kebele Administration has been established or not. Similarly capitals of weredas were also identified as town even if urban Kebele Administration has not been established). From these administratively importance, it is assumed that the population growth (as a result of natural and in migration) increased rapidly and leads to face a considerable socio-economic problems.

Among demographic factors, migration stands out as having strong and immediate political, social and economic effects. It is no wonder that many governments around the world rank (put) migration as the most pressing demographic related problem. For example, G. Standing (1984, p:1) stated that, according to the 1978 survey, the overwhelming majority of “developing” country governments saw population distribution as a greater source of development problem than population growth. He also stated that, by the 1980 survey in every part of the world, more governments regarded the special distribution of their population as cause of the development problem than their fertility levels.

But there are two extreme views {see, for example, G.Standing (1984, p:1)} which have attempted to assess the relationship between migration and socio-economic aspects.

2 Amhara Region is one of the National Regional States form the nine National Regional States of Ethiopia. It is found in the north western part of the country.
Some have regarded migration as growing at a rapid rate in recent years, contributing to “excessive urbanization” and the growth of huge “mega-cities”, to chronic urban open unemployment, worsening income inequality, ecological stress, population maldistribution and a growing threat to the social fabric.

Others have regarded migration (see also G. Standing (1984, p:1)) as a necessary part of economic growth, evidence of equilibrating tendencies, a factor facilitating industrialization, improving income distribution, inducing technical change in agriculture, reducing population growth and easing social tensions, mainly but not only in those areas from which the migrants move.

The approach used is to make the analysis of comparison of socio-economic characteristics of migrants and non-migrants to determine the linkage of employment, income and migration. Thus, based on this approach and relying primarily on secondary data of census survey of 1984 and 1994 and primary data of sample survey, which was carried out by NUPI on Bahirdar town in 1994, this study seeks to investigate the relationships among them.

Throughout the study, to determine the relationship among migration, income and employment, an attempt will be made to use statistical techniques of analysis (cross section data and qualitative response model like probit model) by using the SPSS software package.

The facts & figures presented in this study indicate that relationships among migration, employment & income are, in most cases, positive. For example, the high proportions of the migrants that non-migrants were working age (15-39 years). In addition to this, on the average, more of migrants were better educated than non-migrants. The evidence also shows that, in the town, the migrant's contribution to the labor supply is not strictly proportional to their total number because the age sex proportion of employment rates are higher among migrants than among the non-migrants and the migrants have a higher proportion in the working ages.

What do all these facts add up to for the migrants and for the town affected by migration? Numerous studies (See K.C.Zachariah & J.Conde, (1981, P:12) have shown that migration improves the Well-being of the migrants it is also stated that migrants who stay in the town seem to be better off, on average, than people who remain in the place of origin. The income distribution of the town indicates that relatively more proportion of the migrants was in higher income bracket than non-migrants.

Finally, the result of probit analysis also shows that the linkage of employment, migration and income is in most case positive though there is a few exceptions.
Online assessment decision supports in electronic portfolio systems using data mining technologies

Abstract: A teacher can use student portfolios to evaluate learning performance and promote learning outcomes. The portfolios can also be used as a communication channel among students and teachers as students implement them on the web. However, it is burdensome for teachers to obtain the required information to determine student learning status. This study describes a web portfolio system that enables teachers to use information technologies to guide and evaluate student learning processes. Teachers can utilize this design to analyze the web portfolios online to improve instruction, understand the progress of students, and guide their learning.

Introduction

Educators have increasing interest in authentic and performance-based assessment to actively assess and manage students' learning performance. Authentic or performance assessment are used to describe a series of assessment practices that evaluate students in the process of performing real tasks with relevance to their education (Mcafee&Leong 1994). Portfolio assessment, one of authentic and performance assessment manners. According to Northwest Evaluation Association, portfolio is a purposeful collection of student work that exhibit the student's effort, progress, and achievement. That is, portfolios must contain students’ learning products, learning processes, and learning perceptions (Lankes 1995). Such performance-based, realistic, contextualized assessment may be used to be applied to decision making about instruction (Shaklee et al. 1997). Electronic and web portfolios (Niguidula 1997) are increasingly being used in education applications as computer networks become more widespread. Integration of such portfolio with data mining tools enable teachers to not only comprehend student learning processes, but also make decision to assess students’ learning performance.

Support of decision making with data mining tools

This work presents a web-based portfolio system to elucidate teachers’ role in inducing and using student model and the method used to assess students’ learning performance. Teachers desire to comprehend students’ learning performances at application, analysis, evaluation levels for enforcing peer support strategy in the web learning system since teachers world prefer to recommend students only with application, analysis, and evaluation abilities to help others with analyzing and providing a solution to a problem. Therefore, the teachers and the learning system require the performance database that records the students’ ability in each learning concept at the application, analysis, evaluation assessment levels. Constructing a performance database entails observing students’ states by analyzing the quality of portfolios, inferring the ability of application, analysis, evaluation level from observed learning states, and updating student performance in the database. Figure 1 schematically depicts the architecture of constructing a performance database.
For a portfolio of a certain concept, teachers assess the quality of the portfolio to assert the learning state that a student has reached after developing the portfolio. The teachers assert the following states from portfolios:

- **Known**: The student knows the definition and basic constructs of a learning concept.
- **Used**: The student has correctly utilized the learned constructs to solve problems.
- **Analyzed**: The student has correctly analyzed the effectiveness and performance of a solution to a problem.

Bayesian network software are applied Bayesian network technology to infer students' abilities from observed states. Table 1 lists the probabilities of inferring the application ability from Known and Used states in our experiment.

Table 1. Inferring application ability from Known and Used states

**Conclusion**

Database and data mining technologies enable teachers to assess learning performance and enhance student learning with web portfolios. The web logs can record student portfolio development processes and facilitate teachers to query student learning processes via a clear frame of portfolios. In addition, data mining tools such as Bayesian network tools assist teachers to extract rules to infer student ability level from observable state in portfolios. Thereby, teachers can go online to utilize the valuable information in web portfolios to predict students' performance, and hence regulate proper strategies for promoting performance.

Abstract: Because students can not interact face to face with each other in an asynchronous learning situation, they are difficult to know who is able to help them. Thus, teachers or teaching assistants should put many efforts in solving students' questions. Besides, students have no chance to learn by teaching others. In this paper, we use existing commercial machine learning tools to construct a mechanism for suggesting peer mentors for students according to their questions and preference. The mechanism will locate peer mentors who not only perform better than the student in the area of the proposed questions but also can possibly provide solutions that can be understood by the student that issues the questions. Experiment data is provided to demonstrate that the mechanism also distributes the mentors equally without putting all the efforts on some particular well perform students.

Introduction

Peer support becomes an important method for students to involve their learning process (Baker & Dillon 1999). Acquiring such an understanding through experiential learning facilitated by student mentors is offered by London Guildhall University Student’s Union. When students encounter learning problems in the web-based learning system, finding suitable companion mentors for them to help each other is a good way in both reducing teacher’s effort and solving students’ learning problems. However, two things need to take into consideration for choosing a mentor. One is that the mentor should be able to solve the problems. The other is that the student should understand the explanation of the helper. Moreover, the student should be willing to accept the helper. In Flower and Hayes (Flower, & Hayes, 1981), they proposed an important writing progress model, which indicates that everyone has a different writing style. Students may have different preference to select article/answers proposed by others. In other words, reader’s acceptances on article writing styles depend on individual’s preference. Article writing on the same topic is not always suitable for each reader because of different writing preferences. Therefore, finding a mentor whose knowledge is good enough and suitable for learner’s preference is the key points to peer support in web-based learning system. Some systems have designed effective mechanisms for finding experts. For instance, Expert Finder (Vivacqua, 1999) helps users to locate expert in Java programming. It determines the expertise of Java language according to the frequency of object classes used in java programs developed by the expert candidates. Although this model could get the student’s learning states, but student’s preference are not considered in this model. Referral Web (Kautz et al. 1996) utilized personal email to identify users’ interest and employed the social network in the email to search the expert for helping users. This method uses the classification methodology to locate the helper with the same interests. However, this method does not immediately detect everyone’s status and preference.

Finding companion mentors for students in web learning systems involves detecting learning status and getting students’ preference. While using web-based learning systems, there are several difficulties about how to find mentors for students. For instance, the mentor finder system should sustain a list of learners, who master a specific learning topic, before suggesting suitable mentor companions for a learner, who encounter problems in learning the specific learning problem. Moreover, the mentor finder system should know how to rank those qualified
mentor companions by prediction of the pupil's progress. Hence, the mentor finder system can suggest a most appropriate mentor companion from whom the pupil will most benefit. To finding a most suitable mentor for a learner, the difficulties that a collaborative learning system will encounter are summarized as the following three problems.

**Learning Status Awareness Problem**
In order to understand who has the ability to help other classmates, the teachers of learning systems must detect students' learning states immediately. When students encounter learning problems, the mentor finder system can suggest mentors who have the capabilities to solve their question. In other words, the mentor finder system should know how to get every learner's current learning states. However, it is not trivial to immediately detect learning states in an asynchronous, for instance Web-based, collaborative learning environment. A behavior monitoring mechanism is a postulation to solve this problem, but it is not enough. For instance, we do not know that a learner is browsing, reading, or studying a Web page when he/she accesses the Web page. This difficulty is denoted as a learning status awareness problem.

**Preference Detect Problem**
Because of learning through web learning systems, students have less chance to have direct interaction with others. The system is not easy to capture the students' preference among their classmates. Therefore, the mentor finder system needs a mechanism to collect students' predilections from all aspects to know student's preference about other classmates. In order to get all students' preference without adding too many loads for students, a feedback assessment mechanism is needed for students to decide preference level in discussion board. By this way, we can collect each student's preference. A preference detect mechanism is needed to suggest mentors that the students with problems will be highly possible to provide solution or explanation that can be accepted by them. This is a preference detect problem.

**Preference Classification Problem**
In order to find out suitable mentors for students, the mentor finder system needs to consider student's ability and preference about each other. Besides, the mentor finder system also should avoid suggesting mentors from a small pool of students who have good learning performance in all aspects. For instance, a student's test grade within the top 10% of students can help the other 90% of students. However, it is not a reasonable obligation for the top 10% of students to dedicate to teaching others. In other words, the mentor finder program should suggest mentors that not only qualify to answer the questions for the student, but also learn something by teaching others. Consequently, both a pupil and the suggested mentor can benefit from the mentor finder mechanism. To sum up, learners' preferences compounded the difficulties of finding out the most suitable mentors. A preference classification problem represents aforementioned difficulties.

![Figure 1. Mentor finder with portfolio assessment and RBF technology.](image-url)
This paper presents a novel methodology to assist teachers in finding companion mentors for the students requiring help in the web-based learning systems. The methodology utilizes machine-learning technology on web portfolios to solve the problem. To classify students’ preferences, the mentor finder system uses one of the tools provided by "IBM Intelligent Miner for Data", which is a famous commercial product of machine-learning technology. RBF (Radial Basis Function) technique in the set of intelligent mining tools is used to classify all students to categories of preferences. After classification, all students can be ranked by two dimensions, the students’ preferences and the learning performances of a topic. By using the results, the mentor finder can suggest suitable mentors for who needs help. With the mentor finder system, the processes of collaborative learning is more efficient than traditional heterogeneous grouping strategy for collaborative learning. Furthermore, an innovative method of using learning portfolios on a collaborative learning system is proposed to assess students’ learning status by integrating with students’ preferences. Consequently, student can support with each other by the mentor finder system, and thus reduce an instructor’s efforts of answering students’ questions. Figure 1 illustrates how teachers of web-based learning systems utilize portfolio assessment to analyze and observe learning status and preference via a discussion board feedback and RBF technologies.

Reasons for using portfolio assessment and RBF technology

Teachers require automatic mechanism to detect student’s learning progress to know who is excellent to teach other students. Expert Finder (Vivacqua, 1999) helps users to locate expert of Java programming. It helps teachers to find out lists of learners who are excellent in a learning topic of Java programming. In other words, the key of finding suitable mentors for a student is their degrees of mastering a learning topic. However, few students with good learning performances will be burdened with answering questions if results of learning assessment are the only referable factor for finding mentors. Consequently, students’ preferences about authors of discussion articles can disperse the opportunity of playing the mentor role to most students.

The web learning system allows multiple students to learn and interact with peers on the Internet. In order to let students help with each other, when students encounter learning problem, teachers of the web learning system need to know which student is good enough to consult. For not to concentrate on few excellent students, every student will have a chance to be the mentor by using RBF technology to take into account students’ preferences about other classmates. Therefore, in addition to using domain knowledge to assess student’s portfolio, RBF technology provides an inference mechanism for the instructor to find mentor who is suitable for a learner’s preferences. Integrating portfolio assessment and RBF technology can help teachers to locate suitable mentors for a student from two perspectives.

Portfolio assessment for detecting students’ learning progress

In order to get students’ learning status of every learning topic, the first task is to determine what learning topics should be included in the C programming course. The contents of a C programming textbook are reorganized to a style of learning topic oriented, called a topic map. It is worthy to be noticed that a learning topic may contain many concepts. Hence, it is not proper to refer the topic map as a concept hierarchy because every node of a topic map represents a learning topic, which may be composed by many sections, in textbook. Fig 3 illustrates the topic map of a student’s learning status that is denoted by skill levels.

![Figure 2. A student’s topic map with skill level.](image)
We build a topic map for each student to record his/her skill level about each topic in textbook. In order to detect student’s skill level about each topic, there is homework or online test next to each node in topic map represented in Fig 2. The system will ask student to do homework or online test on web learning system to detect student’s learning status. After students have finished homework or online test on time, teachers then assess students’ homework or the system will grade students’ answer of an online test immediately. Consequently, the portfolio assessment mechanism can completely record every student’s grades of every learning topic (node) in his/her topic map. Furthermore, an instructor can shortly know a student’s learning status of every learning topic by maintaining every student’s topic map.

Collecting students’ preference feedback from discussion board
Because of less contact with classmates during distance learning environment, we build a feedback mechanism in discussion board. In our system, we have logged the author who post articles in discussion board. When student browsed each article on the same page, we set a questionnaire for student to express his preference. Through questionnaire in discussion board, our system logged all attributes as follow table.

<table>
<thead>
<tr>
<th>Student Name</th>
<th>Reading Time</th>
<th>Article requested</th>
<th>Author</th>
<th>Preference Grade</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linms</td>
<td>11/Oct/1999/11:02:41</td>
<td>/cgi/vc/Read.exe?article=990242</td>
<td>Robert</td>
<td>3</td>
</tr>
<tr>
<td>Linms</td>
<td>11/Oct/1999/11:03:05</td>
<td>/cgi/vc/Read.exe?article=990231</td>
<td>Christia</td>
<td>4</td>
</tr>
</tbody>
</table>

Table 1. Example of preference log about students from discussion board questionnaire

We log student’s name, each article’s reading time, each article’s ID, article’s author and the grade of preference that indicate reader’s preference. We set five degree 1~5 in preference grade for student to express their preference about other classmates’ article. For example, in second row of table 2 represented that student Linms read an article, which ID is 990242 and the article author is Robert. The reader’s preference about this article is at level 3. In table 1, we can see that Linms likes Christia’s article more.

Inference all students’ preferences about other classmates
Because of less contact with classmates and most learning behavior is performing in web site, student has less chance to read every classmates’ article and portfolio. Therefore, teachers of learning system feel hard to know students’ preference on all other classmates without using inference mechanism. Here we use a machine learning skill RBF(Radial Basis Function) which is a conditional probability inference method. Radial Basis Function is used to find nearest students who have the common preference. Because RBF just has one layer inference function in his network, it infers rapidly to help student to find out who are the suitable mentors for him.

Figure 3. RBF inference network example
Figure 3 is a RBF influence network example. RBF, which looks like a neural network, influence each node from one to one through direct arrows. In figure 4, f(x) is the result function that RBF can find out from students’ preferences. The final f(x) is the summation, formally called a linear combination, of all \( w_j h_j(x) \) where \( j \) ranges from 1 to \( m \). If the f(x) function is calculated, it can be used to rank classmates for a student by preference perspective. In other words, the f(x) function will score a candidate from preference perspective. For instance, the priority of student S1 is higher than student S2 if the value of f(S1) is greater than the value of f(S2). Hence, the mentor finder system can use RBF as an indicator of a student’s preferences about his/her classmates to suggest learning companions, who are qualified by portfolio assessments.

Each \( x_i \) in Figure 3 represents a student and each \( h_j(x) \), formally called radial function, represents the feedback mechanism attached to a discussion article. The mentor finder system sets up a RBF inference network for every student to represent the preference. For example, every student, who is illustrated by \( x_1, x_2, \) and \( x_n \) in Figure 4 has read three articles in discussion board. The feedback parameters coming from those three students’ preferences compose the vector \( <h_1(x_1), h_2(x_1), h_3(x_1)> \) where using a typical style of radial function to represent \( h_j(x) \), that is Gauss Function. The other two vectors are \( <h_1(x_2), h_1(x_2), h_1(x_2)> \) and \( <h_1(x_3), h_1(x_3), h_1(x_3)> \). The goal is to find a f(x) and its “distance” to the three vector is as close as possible. In other words, the problem is theoretically like determining the least squares function, which has been proven to have at least one solution, in linear algebra.

\( <w_1, ..., w_k, ..., w_m> \) in Figure 3 is an optimal weight vector used to linearly combine all radial functions to get the experience function f(x). After the optimal weight vector is founded, the experience function can be used to help students find favorite classmate. When a student encounters learning problems, we input all classmates’ preferences with three qualified students in experiment function like figure 4 to derive how much does the learner prefer about each mentor. The basic inference rule is that if a C-student likes A-student’s articles and B-student likes A-student’s articles then the C-student have more probability to like B-student’s articles.

**Evaluation Result**

An experiment is conducted herein to evaluate the mentor finding system. The experiment engages 54 undergraduate students electing the one-semester course, *Introduction to Computer Science*, in National Central University. After learn in the conventional classrooms, students are required to discuss in the learning system. The collaborative learning environment for programming results about 2993 discussion articles in four months. A native approach of finding peer mentors is to recommend the top ten students in the learning program to students who need help. However, one issue of recommendation is that a student should not assign to solve others’ learning questions too frequently. Therefore, the recommendation experts should not converge on a certain group students who have expertise in the learning program. The recommendation expert should distribute on any students who are able to answer the question. An evaluation is made to clarify the effect of the learning system to distribute loads of excellent students in the learning program. The system recommended experts in terms of only the required knowledge level and students’ preference, rather than the expertise in the whole learning program. Therefore, any student who is master of the proposed learning questions, even he/she is not the top ten students, may be recommended.

Figure 4 lists the loads of every student. A vertical bar indicates the frequency of suggesting a student as a mentor. There are 54 vertical bar in Figure 4 because there are 54 students involved in the experiment. When a student plays the mentor role to support a pupil, the pupil will be inquired about whether the mentor is suitable for him/her. The frequency of pupils’ agreements about a student is shown by the white part of a vertical bar. Regardless of students’ rank in the whole learning program, each student is possibly to be recommended to solve others’ questions. The experiment result in fig. 4 shows that the recommendation times for each student as well as the times students regard him/her as an expert for a learning topic. The result indicates that although the top ten students are generally considered as experts to solve others’ problems, other students are possible to be capable of solving peers’ learning problems. A sophisticated mentor finder system is required to distribute the workloads of excellent student and accurately locate experts not only in excellent students.
Conclusion

To experiment with the idea of suggesting mentor, a Web-based collaborative learning environment was constructed. Then, a novel sub system, called mentor finder system, was designed and implemented to support students find suitable mentors among learning companions. To properly suggest mentors for a student, the mentor finder system uses a discussion board to collect students' preferences and use portfolio assessment to get students' learning status. The topic map is introduced as a repository for every student’s learning status of every learning topic. Moreover, a feedback mechanism for collecting preferences can automatically attach to every discussion article when a student reads it. Besides, the mentor finder system successfully integrates a machine-learning tool, RBF (Radial Basis Function) technique coming from IBM Intelligent Miner for Data, to classify students by similar preferences. The operation of calculated RBF functions as an indicator in view of a student’s preferences before the mentor finder system suggests learning companions. Most important of all, the experimental results show that using students’ preferences as a bias to suggest suitable mentor is more acceptable than what without considering students’ preferences. Hence, the mentor finder system can let everyone have a chance to be the mentor that makes the best students won’t be too busy resolving other students' questions.

The Development of A Hypermedia Language Learning Environment
For Teaching Academic English

Abstract: Considerable research has shown that academic language is more difficult and takes longer to learn than social language. Comparatively, there are two factors affecting language comprehension: context and cognitive complexity. With these two factors in mind, the paper describes how hypermedia and web-technology can be deployed to support academic English learning. Based on these considerations, we developed an interactive hypermedia language-learning environment, called "AcademicEnglish", based on communicative approach in second language acquisition (SLA), for EFL/ESL academicians to improve their basic communication abilities in academic contexts. To support our hypotheses in building such an environment, we conducted a questionnaire survey of the difficulties in academic language learning. Moreover, we have explored the research findings of SLA from the educators' and learners' points of view. The focus is to present our approach in communicative-oriented courseware development. Based on the new hypotheses that emerged from the preliminary study and the literature, we built an illustrative prototype system, which intends to allow learning goals communication, learning activities negotiation and collaboration between learners.

Introduction

The effectiveness of computer-assisted language learning (CALL) systems has been proven by many previous studies (e.g., Yang, 1997). However, the main weakness of current CALL systems is that most of the video-based multimedia materials treat language as a set of linguistic structures. Thus, language is taught as words and sentences, not as discourses and interactions in context (Duranti &Goodwin, 1992). A communicative focus on the appropriate and meaningful use of language in a variety of contexts is still in its struggle in a computer environment, although hypermedia tools have offered a context for the successful acquisition of communicative competence with the aid of CALL. Another problem in present CALL systems is that there is little courseware for non-native English speakers to learn English for their academic purposes (Jarvis, 1997). Even if some systems provide examples, words, etc., from the academic life, there is no major difference between the support for social language learning and academic language learning in their courseware implementations. Context and cognitive complexity will be the two main factors that affect academic language comprehension. So the current CALL systems cannot meet the academicians' requirements and needs. Therefore, our research goal is to respond to these needs, by building a hypermedia language-learning environment for teaching academic English via the World Wide Web. We intend to find the best ways to organize, present, and index multimedia information to maximize effective academic English learning for academicians.

This paper is organized as follows: in section 2, we start by presenting the research goals of our system; then, in section 3, we show the results of our preliminary tests, and in section 4 the new constructive hypotheses that emerged from it. Section 5 is dedicated to the illustrative prototype system that we have built, based on these new hypotheses. This section presents the general overview of our system, as well as the AcademicEnglish courseware that we built, based on the communicative language teaching approach. Section 6 presents a discussion about our work. Finally, in section 7, we draw some conclusions.

Goals

Our study has four purposes: the first one is that academic language modalities are developed for content area activities, as they are needed, rather than being taught sequentially; the second one is that students should learn academic language and content more effectively with the explicit instruction of the learning strategy and communication skills; another one is that the simplification, comprehension and visualization of the domain content will allow students to focus more on language learning; the last one is
that the hypermedia learning environment access methods should be “cognitively relevant” to the learning, reasoning, and information seeking goals of the user.

Pre-experiment

In order to achieve our goals, we have done some preliminary experiment before actually designing our system. In this way, we could determine what kinds of components affect a student’s learning process, and how the various elements fit together. This study was conducted by a questionnaire survey of 20 ESL/EFL students majoring in computer science. The test was designed to examine the difficulties influencing the academic contents learning and language acquiring.

We interviewed 20 students by questionnaire. The questionnaire consisted of 20 questions, including close-ended questions and open-ended questions, like “What are your language problems when you read and listen to academic materials in English?”, “What type of words cause problems when you read and listen to academic materials in English?”, and others. The subjects questioned were all students at university level. In short, the test results showed that students who learn and use academic English might experience content-related problems and language-related difficulties as well (see table 1 and figure 1 for more details).

Resulting Hypotheses

The learning environment and courseware that will be presented in this work is based on the following four hypotheses derived from our preliminary tests (for more detail, see, Chen, 2000) and from various other research studies (e.g., Brett, 1998): 1) interaction and negotiation are important features of communication, and therefore of second language learning; 2) students learn academic language via domain content more effectively with the explicit instruction of learning strategies and communication skills; 3) hypermedia environment with well-defined courseware can play a mediating role between academicians and their context; 4) learning should be communicative, active, and dynamic.
The four hypotheses above are used as the springboard for an examination of the possibilities and pragmatics of developing a communicative-oriented hypermedia-language learning environment for the delivery of academic English learning courses via the web.

**Academic English: an illustrative system**

Based on our hypothesis, we have developed a hypermedia language-learning environment called Academic English, which contains multimedia material targeted at undergraduate artificial intelligence (AI) and knowledge computing students. The environment allows students with some background knowledge structure of artificial intelligence (AI) and education technologies (ET) in their own native language to learn to express and use this knowledge in English in academic context. The subject materials for the environment are topic-based conversations, which came from introductory AI courses, which are delivered via hypermedia language learning environment in accordance with the improvement of students' listening comprehension and furthermore with their academic language competence.

**System structure**

The architecture of Academic English consists of three layers (see figure 2): visualization layer, logic layer, and data store layer. The visualization layer presents the actual learning material and interacts with the user or a group of users through the Internet. The logic layer serves for the processing logic and allows the users to access the teaching resources in the data store layer via the search mechanism and to check answer and get feedback via the assessment mechanism (for more detail, see the next section) as

![System Structure Diagram](image)

well. The last layer is the data store layer, consisting of two databases; one is the teaching resources database (for more details, see Chen, 2001) and the other one is the student profiles, in which students' personal data, learning behaviour, learning and communicative strategies, and actual performance will be stored. Furthermore, during the learning, we provide three types of interactions: interaction between the user and the system, interaction between the user and other users in the same group, and interaction between user and the human teacher.

**Assessment mechanism**

In analyzing student input, the environment contains additional assessment modules, which get evoked when processing a student's answer. Figure 3 illustrates the modules of the simple natural language processing.

The first module in analyzing student input, the system extracts the base forms of each word. When defining an activity, we anticipate and store possible answers of a given task. The Answer Check module matches the extracted base forms with the anticipated answer. If any of the words in the task are not contained in the student answer, the system will report an error.

The Error Check is the most elaborate of the modules. Here the sentence is analyzed by the semantic parser according to the rules and a corpus of language.

The assessment mechanism is organized in a way that if a module detects an error, further processing is blocked. As a result, only one error at a time will be displayed to the learner. This was
implemented mainly to avoid overloading the student with extensive error reports in the case of multiple errors. After correcting the error, the student restarts the checking mechanism by clicked the “Continue” button. Then all of the data will be stored into the student learning history and update student profile.

![Student Profiles](image)

Figure 3. A diagram of the assessment mechanism

**Courseware structure**

When this environment is used, in the beginning, registration details, such as name, email address, and level of English learning of the user is required. After the registration, the user has two choices: to search the course via the VOD search mechanism (*autonomous study*), and to access the course via a placement-test (*automatic study*). When the user chooses one of them, the activity with VOD corresponding to the user’s choice appears on a newly generated page. Each activity session consists of three modules: pre-viewing module, while-viewing module, and follow-up module (for more detail, see activity design section). After each session, the environment will update the relevant attributes of the student profile (e.g., current progress, learning behavior, communicative strategies, etc.). Then it generates a plan of remedial actions and presents it to the student in the form of suggestions for further sessions and learning, and the user him-/herself can decide whether to continue the study or end it.

**VOD-support dialogue linking**

We edited some complicated AI and ET course-book into oral conversations, and then recorded them as video resources. The whole courseware consists of ten topics, and each topic is subdivided into several subtopics, and each subtopic has three levels of dialogues. In total, our present courseware contains one hundred dialogues, and each dialogue corresponds to one video resource. The dialogues in a topic are internally presented in a form of a directed acyclic graph that we call “concept map”.

![Concept Map](image)

Figure 4: A sample concept map

Each dialogue is presented as a small hypertext document, which represents a node in the graph, and arcs define the prerequisite relations between the dialogues. The prerequisite relations are attributes that are defined as video numbers. The inputs of the nodes are constraints to activate the actual node, thus user can begin with any of the node via Search mechanism. Figure 4 illustrates an example of a simple knowledge graph of a topic and its subtopics, where a student must understand the concepts *state* and *operator* to understand search (a fundamental technique in AI).
Activity design

The academic language function acquiring, language learning strategies and communicative strategies are naturally embedded in content activities. We defined the activities with three language levels: 1) intermediate, 2) upper-intermediate and 3) advanced, in addition, there is a continuum in the activities in and among each level, which are graded according to the cognitive and performance demands made upon the learner, moving from comprehension based activities to controlled production activities and finally ones which require the learner to engage in real communicative interaction, which are hierarchically organized into three modules: (a) pre-viewing module, (b) while-viewing module, (c) follow-up module. Student’s performance in each activity contributes to the student profile.

In the present courseware, we used communicative teaching strategies, like eliciting, personalization, information gap, problem solving, and game playing, etc., to promote opportunities to use language meaningfully. Here we give the information gap activity as an illustration:

Information gap activity

These types of activity are focused on extracting, recording and sharing information in various class groupings. This is exemplified as follows, where we see a unit, which is built around an information gap task. The activity contains the following steps.

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. <strong>The activity goal:</strong> Plan a project</td>
<td></td>
</tr>
<tr>
<td>2. <strong>The description of the activity:</strong> In this activity, you will watch two videos describing various concepts of AI Search technique. Your task is to use the information you heard to produce a project based on the AI Search technique.</td>
<td></td>
</tr>
<tr>
<td>3. <strong>Activity contents:</strong></td>
<td></td>
</tr>
<tr>
<td><strong>Pre-viewing module:</strong></td>
<td>Instruction: please write five subject-specific vocabularies about the AI Search technique in two minutes, and click the “Hidden” button to compare yours with the vocabulary list. (The “Hidden” button displays subject-specific vocabularies and academic language functions involved in the conversations.)</td>
</tr>
<tr>
<td><strong>While-viewing module:</strong></td>
<td>Instruction2: Step one: here are two videos describing some concepts of the AI Search technique. Please listen to one, and then inform your partner to watch the other. And then answer to the questions relating to the conversation you heard individually. You may replay the tape as often as you need in order to find answers to the questions. Then press the “Check” button to check the answer. Step two: exchange video information with your partner by asking five questions via dialogue box and then fill in the information table. After finishing, press the “Continue” button. Step three: watch your partner’s video, and check the information you got from your partner, and you can reverse it according to your understanding. And then press the “Check” button to check your answer and read the feedback (see the assessment mechanism for more detail). Write an evaluation to your partner via the dialogue box.</td>
</tr>
<tr>
<td><strong>Follow-up module:</strong></td>
<td>Instruction 3: Step one: below are a diagram and a title for the project. Use the information in the information table to write an abstract of a project based on the AI Search technique within 300 words. The subject-specific vocabularies should be included in the abstract. Step two: press “Publish” button to publish your essay online, and then select the “View” button to share your partner’s abstract; if there are some language problems, please correct it and send it to your partner. Step three: now reread your own abstract carefully, especially your partner’s correction, if you disagree, you can negotiate with your partner who corrected your abstract. Step four: rewrite your abstract and send your final version to your personal teacher.</td>
</tr>
</tbody>
</table>

Table 2: A scenario of information gap activity

Discussions

In view of our research purpose, the analysis and descriptions we have just offered have attempted to present the full potential of our illustrative system. Our methodologies involve designing CALL systems based on our hypotheses, conducting empirical studies with students, and building an interactive hypermedia language-learning environment.

Related to the system development, we intend to provide the users with a dynamic, flexible and communicative learning environment. The three types of interactions provided allow the user to negotiate
the meaning in her or his academic language competence development. The selection and realization are
based on our five hypotheses above.

Related to dialogue editing, since academic course text is decontextualized, we put our emphasis
on the simplification, comprehension, and visualization of the domain content, which, we believe, results
in SLA. Research on comprehension outcomes using written or spoken input texts, which contained large
amounts of these features (i.e., a slower speech rate, bimodal input, and elaborative modification of the
discourse (Conrad (1989)) in non-interactive input, have consistently showed greater resulting
comprehension.

Related to dialogue arrangement, we adopt an approach of using relatively small, linked
knowledge elements, which has many advantages. Firstly, it makes it possible to effectively define
specific goals for studying. Secondly, student's knowledge of each topic can be estimated separately by
enabling automated navigation guidance, and thirdly, the hierarchical structure of information is stated
explicitly. In a learning context, students bring to bear a variety of knowledge, goals, and strategies.
These can result in a considerable variability in the nature of the activity that arises while interacting with
computational artifacts. Our intention is to provide different types of access methods so that individual
learners can make appropriate choices.

Related to activity design, following our hypotheses, we put emphasis on the need to relate the
new concepts and knowledge with the learners' existing knowledge, comprehensive input, and
authenticity of language use. We expect that language learning can become a "communicative practice".
The pre-viewing activity follows Schmidt and Forta's (1986) findings that by 'noticing the gap' between
the state of one's current language knowledge and output, and then by consciously comparing this with
what has been experienced in input, learners will realize language gains. In the while-viewing module,
we believe that listening comprehension tasks, coupled with feedback, may help learners to "notice the
gap" in their comprehension. Furthermore, the hypermedia environment may provide access to the
linguistic phenomena that have caused comprehension breakdown and the resources to facilitate a
negotiated understanding of these problematic linguistic items. Finally, the follow-up module provides
communicative activities for users to monitor what they have learned and furthermore to intake what they
have learned. The selects and realizations are based on the assumptions about SLA of Krashen (1977)
and on the hypotheses about communicative competence of Hymes (1972).

Conclusions

In this paper, we proposed a hypermedia language-learning environment based on the
communicative approach. Our work is in the analysis and design phase and the actual system is in
progress. What we need to do in the next steps is to implement the courseware, including assessment
mechanism. We also need to continue to develop the collaborative learning functions. Finally, we plan to
do real-life experiments to evaluate the effectiveness of our academic English teaching environment.

Intranet is a local group of computers where each terminal can communicate between each other. The main theme of this project is to convert voice message into text format and pass it to all the terminals in Intranet. This system is developed in RMI (Remote Method Invocation). This system deals with the communication in the Company. In this model one system will act as a Server and the other system will be clients. Server should be turned on always. Accounts should be created for all the clients in the Concern. Client has to log into the Server to get response for its request. Database is been maintained by the Server to evaluate the user id. Server will provide the details of the active clients connection and all the members of the concern.

Server spoke the messages and it is converted into text format using the IBM Via Voice Software and placed into the message box of the Server. And the Server can make corrections if required. Finally the Server will pass these messages to all the members of the company through Intranet. During the data transfer if the client is not connected then the message will be stored in the client's inbox. Later when the client log into the system all the messages will be listed in the inbox which can be downloaded like in E-mail.

In Server side, maintenance modules are added. They are New User, Change Password and Disconnect. New User module helps the Server to register the new client. And for each new user a separate inbox (directory) is created. To tight the security Change Password module is used. Server can also disconnect the active client by sending the tokens to the client, using Disconnect module. So the user has to get connection once again.

The Client can also disconnect from the server and Server will receive immediate notice of the client disconnection. Client send acknowledge message to the server about its message receivable. Help is also provided which will guide the user to use the package efficiently.

All the distributed system uses the registry to keep track of the addresses of remote objects that are being exported by their application. In RMI, stub and skeleton are created for the server. The stub is a client side proxy of the remote object. The skeleton is a Server side proxy of the remote object. RMI Registry application should run continuously as the background process. It can add or remove the object to or from the registry.
NetKnowledge Presenter and Content Reuse

Abstract: Streaming technologies, with the introduction of synchronized media support, are now able to produce a more faithful copy of classroom lectures, and hence, meet better the distance education needs. At the same time, streaming content creation and distribution tools are also widely available. However, many of these tools are not designed to allow users to edit, reuse, and share contents. Without such flexibility, authors' productivity and opportunities for incremental content refinement are greatly constrained. For example, users cannot import parts from an existing web presentation into another one. In this paper, we describe a streaming authoring tool that we have developed to facilitate the editing of the parts of a slideshow presentation and assembly of those parts into future presentations.

Introduction

Recent developments of streaming media technologies have dramatically improved the Internet's capacity to serve as an effective medium for sharing multimedia contents. Nowadays the viewer can start watching a presentation as it downloads and the streaming content can contain different media types that are synchronized in time and space. This is attracting individuals and organizations to make use of the new opportunities for reaching a wider global audience. Education is one of the fields that can benefit directly from this potential.

There are already many lectures available on the Web and many others are published everyday. Probably the most popular format of web lectures is slideshow, where audio/video narrations are correlated in time with slide images. Such lectures are usually generated by recording continuously the live presentation and capturing timing information of the slide transitions. Although there are tools that assist users in creating and publishing their digital presentations, only few of them offer a reasonably practical solution and an even smaller number provide means for flexible editing of content as well as facilitating sharing and reuse. In this paper, we propose NetKnowledge Presenter, a web presentation authoring tool that realizes content reusability by maintaining the parts (i.e., slides and narrations) of a presentation separate. The audio/video part of the presentation is encoded into one single stream and built from assembling the individual audio/video narration files produced for each slide. Slides are static image files that match to each change in the original slide (e.g., animation effects). Our framework, by enforcing the separation of a lecture into independent editable units from the creation stage, allows content producers to incrementally add new parts to a presentation or replace existing parts with new ones.

Discussion

RealNetworks RealPresenter [1] is currently one of the most known and complete web presentation tools. It takes advantage of RealNetworks' client-server tool suite, providing a solution that ranges from presentation recording to publishing. Nevertheless, editing options are limited - you can change the narration for a particular slide, remove a slide or otherwise start over. There are no provided facilities to insert new slides or reuse previously prepared ones. Furthermore, the editing model maintains the complete original audio/video encoded file and for each re-recorded narration, which corresponds to a particular slide, creates a new audio/video encoded file. This new file is then linked to the original file through SMIL [2] based on timing information. In the worst case, a n-slide presentation which has had (n - 1) of its slide narrations replaced, will result in a total of n audio/video encoded files that need to be uploaded to a streaming media server. In contrast, our approach guarantees that a single audio/video encoded file is uploaded which will be as big as if it were produced in a single live presentation using RealPresenter...
without editing. In other words, our upload file is independent from the number of slide narrations being replaced. We achieve this by merging the individual slide narrations after all editing is done. This is possible because we store every slide narration separately which is reflected in the way the presenter records his/her narration. Apart from the fundamental difference in capturing the presentation, our tool provides additional capabilities not available in RealPresenter [1]. A brief comparison table can be seen at http://vulab.ias.unu.edu/research/publications/nkpresenter/table1.shtml.

User Environment

Given the wide availability of Microsoft PowerPoint, it has been selected as the host application for our system. As soon as the user has finished composing the slides and is ready for augmenting them with narration and other features, he/she may start NetKnowledge Presenter and fill in the metadata for the presentation. Next, the user is taken to the main editing interface, which contains an ordered list of the slides, a preview of the slide image and all the recording and playback controls. To record a narration, all the user has to do is select the desired slide and press the record button. Individual narrations may be previewed at any time. The user may also choose to watch a full preview of all the available narrations. In this case, the system will provide automatic synchronization with the correspondent slides, to maximize the presenter’s sense of what his/her audience is going to be watching.

The interface allows many other manipulations such as reshuffling the slides order, deleting and inserting new slides. Slides may also be imported from other PowerPoint presentations or from the user’s NetKnowledge slide library. This is one example of the reusability power offered by our tool. Slides are stored in a categorized way, so that retrieval is made easy. Similarly, at a later time, the author may modify or reuse parts of the presentations.

Implementation Details

We have implemented the system as a PowerPoint add-in. NetKnowledge Presenter is automatically available to the user, as long as he/she is logged in to his/her Windows account.

Slides are exported into a portable graphics format and scaled down so that it can be streamed more effectively. While many tools use the JPEG format, which is optimal for compressing images with great color amplitude (e.g. photographs), we have adopted the GIF format, since our analysis has shown that most slides are made of simple shapes and text, with a limited number of colors. The result is that the GIF files are smaller and they do not lose slide information.

The presentation publishing process works in conjunction with a server application also developed in our institute. NetKnowledge Presenter is responsible for packaging the presentation’s metadata, slide images, narration and synchronization information and upload them to our server, which takes care of updating the online media catalog.

Conclusion and Future Directions

We have presented a new approach to produce web lectures, using existing technologies. Unlike past and ongoing developments, our work focuses on reusability by re-conceptualizing the way presentations are captured. The main strategy is to incrementally record the lecture in reusable pieces rather than in one pass. The result is ease of editing and scalability that helps delineate division of responsibilities, especially in the case of multi-author presentations. At the same time, it can be the basis for building a library of reusable multimedia contents. We have started using the prototype in our institute and so far, preliminary feedback has been positive. Our next enhancement is to allow the presentation to be recorded in a continuous mode yet without the knowledge of the user that it is being decomposed transparently.

Abstract: The Four Directions Project has been working with American Indian Schools to explore the uses of technology for culturally responsive teaching. One approach Four Directions is exploring is school-museum collaborations for student-created virtual museum projects. A Four Directions Model for school-museum partnerships has emerged from these experiences. Two example projects are described and the benefits of virtual museum projects is discussed.

Museums and Schools in a Pluralistic Society

Museums have long been the repository of important cultural items. They make these items available to public view in exhibitions in specially designed architectural spaces, and more recently in the virtual spaces provided on the World Wide Web and on CD-ROM. By making their collections accessible to the public in carefully crafted and coherent presentations, museums serve an important mission of perpetuating our cultural heritage through the educational experiences they offer to the public.

Schools share a mission of cultural preservation with museums, making them natural partners in the development of effective educational experiences for young citizens. Schools are also responding to the challenges of the 21st century by integrating new technologies into classroom practice. The creation of virtual museums as classroom learning projects is one emerging strategy schools have explored that makes use of new digital media, the World Wide Web and multimedia authoring. Some of these projects have been created in collaboration with public museums (McKenzie, 1996; McKenzie, 1997; Roy & Christal, 2000).

Because of its history of colonialism and immigration, the culture of the United States is pluralistic, reflecting throughout vital contributions from hundreds of indigenous American cultures as well as from countries in every area of the world. American education, however, remains staunchly Eurocentric. It largely fails at being truly American, reflecting the diversity of the nation and diversity of learning styles (Banks, 1997). As a consequence, schools fail to take advantage of the cultural knowledge many non-European American children bring to school that can be used to advance academic success. Also, by not embracing the contributions to America’s pluralistic culture made by non-European American students’ communities, educators fail to motivate these students to excel at school. Culturally responsive teaching involves taking strategic advantage of the cultural knowledge and contributions of students’ home communities to promote academic success (Gay, 2000; Pewewardy, 1999).
Many museums in the United States have collections that do reflect the cultural diversity of the nation. However, much of the interpretation that is presented in museum exhibitions tends to reflect the dominant Eurocentric world view. To resist this trend, the Smithsonian National Museum of the American Indian (NMAI) is setting a standard for interpretation of Native American collections by Native Americans. The museum brings Indian people to facilities as respected representatives of their cultures. Museum staff members collaborate with Native Americans in the interpretation of the items in its collections that came from their communities. For the NMAI, contemporary Native Americans, as direct descendants of the creators of its collections, act as culture bearers who have the most direct experience of the meaning that the objects hold. It is an expertise the museum values and relies upon.

This paper will present a culturally responsive emerging model for school-museum collaboration. The model has grown out of experiences of Native American schools working with museums with significant American Indian collections to create virtual museums that reflect their cultures and serve to present and preserve the students’ indigenous heritage.

The Four Directions Model for School-Museum Partnerships

Four Directions is a five-year project funded through a U. S. Department of Education Challenge grant. Its purpose is to promote the development of technology-supported culturally responsive teaching for Native American students. The partners in the project include nineteen American Indian schools in ten states that are part of the Bureau of Indian Affairs school system, four university partners, and two museum partners.

The Four Directions project has been motivated by the lack of available curriculum that is responsive to the cultures of Native American children and the recognition that technology can provide a way to empower local communities to create curriculum that fits their needs (Allen et al., 1999). The need for culturally responsive approaches has been heightened by the historical circumstances of American Indian education. From the 16th century beginnings of formal education for North American Indians, education was seen as a way to coerce Indians into giving up their culture. By the late 19th century, forced assimilation was the official government policy. This policy was enforced in various ways including removing Indian people from their homelands and setting up boarding schools for Indian students that were located far from student’s family and where students were forbidden to speak their language, practice their religion, or to express anything of their traditional cultures. (Adams, 1995).

Many Native Americans clung to their cultures the best they could under the circumstances. In the 20th century European-Americans gradually learned to value the cultures of the continent’s First Peoples and to celebrate the cultural diversity of the nation. American Indian schools began to include aspects of Native cultures in their curriculum, and since the mid-1960s, an increasing number of American Indian schools have come under direct tribal control (Szasz, 1977; Tippeconnic III, 1999). However, because of these historical circumstances, much of what remains of American Indian material culture resides away from their homelands in museums across the nation and in private collections.

The Four Directions project has been fortunate in having two museum partners that have allowed project participants to explore the potential of school-museum collaborations that give Native American students access to the important cultural property that remains in museum collections. These experiences are providing an evolving concept for museum-school-community collaboration that serves the missions and needs of all participants—what we are calling the Four Directions model for virtual museum collaborations. Three aspects of our experiences with virtual museum projects guide the Four Directions model:

- **Cultural Responsive Teaching** – Virtual museum projects are culturally responsive, because they teach to and through the culture of the child and bring community concerns and values to the center of the teaching-learning process. Students are motivated to excel because they are doing important, authentic work to recover and preserve their heritage. They gain from the knowledge of museum professionals and the wisdom of community elders. They develop skills in research, writing, social studies, science, mathematics, information literacy, and twenty-first century information technology.

- **Cultural Revitalization** – A common concern among Native American peoples is the recovery and preservation of cultures and languages. Much of what remains of traditional material cultures resides in museum collections far from Native American communities. Virtual museum projects provide a way for communities to “digitally repatriate” precious items of cultural heritage. In the Four Directions Model, virtual museum activities also take place in the Native American communities, where students research and record local materials that supplement the museum’s resources for the virtual museum. Local resources such as oral histories, cherished heirlooms, traditional stories, dances, and songs, native language and contemporary arts get combined with museum materials to present the vision of a vital, living culture.
Cultural Collaboration – Museums exist to preserve heritage and educate the public, but Native Americans sometimes object to the way museum exhibitions appropriate cultural property. Native Americans want the public to have access to authentic knowledge of their histories and cultures, but they believe that some aspects of their cultures should not be shared with outsiders. Virtual museum collaborations provide a venue where thorny issues of cultural property rights may be addressed and protocols for cultural collaboration may be designed and levels of accessibility decided.

The Model in Action: Two Examples

In the fall of 1998, three of the Four Directions partner institutions—the Pueblo of Laguna Department of Education, the University of Texas, and the Smithsonian National Museum of the American Indian (NMAI), began the first collaboration that brought Native American students, teachers, and community members to the NMAI George Gustav Heye Center Museum in New York City to create virtual museums. To help guide this first virtual museum project, Dr. Paul Resta drafted a concept paper, which is the first explicit example of the Four Directions model for school-museum collaboration. In it, he explains the rationale for the collaboration in the following way:

For many years, Native American culture was undervalued and suppressed in America. Although the richness of Native American historical and contemporary cultures has begun to be recognized, exemplary curricular materials based on this richness are rare. In addition, in a rapidly changing world, much traditional wisdom will be lost before there is an opportunity for Native American students to learn about their own history and culture, and to share what is sharable with the world community. Teachers trained in methods of cultural sensitivity and in the use of technology may provide leadership in the accessing, preserving, and sharing of Native American culture with the world community. One means of doing so is for Indian schools and communities to use technology to collaboratively develop virtual museums (Resta, 1998, p. 3).

Objects from the museum collections were to be selected by students and teachers in close consultation with community elders, who would help determine which objects were sharable and to add their own knowledge, and perhaps their own voices, to the virtual exhibition.

Local community participation and development were priorities in the original concept paper. Each school community that was to participate in the virtual museum project would send a team of students, teachers, and community elders to the museum to work on selecting, recording, and researching the materials to be included in the virtual museum. In addition, a summer program was proposed for each participating school community. In the summer program, community members would bring valuable cultural materials to the school so they may be recorded in digital photographs or QuickTime Virtual Reality for a local virtual museum. Local landmarks, natural settings, and historical sites would also be recorded. Students could record tribal elders speaking about important objects, people, events and places in English and their Native language to add to the local virtual museum. Some of the sharable locally-created materials may be used to supplement the materials offered on the virtual museum offered on the museum’s server. In exchange, the media created at the museum could be “digitally repatriated” to the local community for use within the community. Thus, there were potentially two virtual museums emerging from each museum-school community partnership. One offered by the museum and accessible on the World Wide Web that offered only materials that tribal leaders had deemed sharable in that venue. And a second, local virtual museum that was to remain within the community that may include more sensitive materials for community access only (Resta, 1998).

For this first school-museum collaboration, every aspect of Resta’s concept could not be met strictly, demonstrating the flexibility of the partnership. The NMAI was in the process of moving its entire collection to a new facility in Suitland, Maryland, which made the full collection inaccessible at the time of the proposed project. The items in the museum’s current exhibitions, however, were accessible to the project. This meant that very few artifacts that reflected a given student’s specific Native American culture would be available. A compromise was struck whereby students from several of the Four Directions schools would decide which items from the exhibitions would be featured in a virtual tour of the museum as seen through the eyes of American Indian children.

In the spring of 1999 two school teams, one from Santa Clara School (Pueblo, New Mexico) and one from Hannahville School (Potawatomi, Michigan), traveled to New York to digitally record and research the student-selected items from the NMAI exhibitions. These materials were assembled into the Virtual Tour of the National Museum of the American Indian, which has been accessible via the World Wide Web since February, 2000 (http://www.conexus.si.edu/VRTour). In May, 2000, Marty Indian School (Lakota, South Dakota) sent another team to extend the tour. The additional material will appear in the tour in fall 2000.

The virtual tour makes extensive use of QuickTime Virtual Reality (QTVR), which had been identified at the beginning of the Four Directions project as having a unique potential in educational applications. Training in the
creation of QTVR media has been offered to all of the Four Directions schools. There are two types of QTVR movies, panoramas and object movies. QTVR panoramas (panos) are made from a series of overlapping photographs taken from a tripod using a specially designed panning head. Software “stitches” the photographs into one seamless 360° scene. To interact with a panorama, one depresses the mouse button when the cursor is on the movie and moves the mouse cursor in the direction one wishes to “look” and the panorama scrolls in that direction.

The second type of QTVR media is the object movie. It is made by placing an object on a turntable and taking a series of pictures at evenly spaced angles as the object is turned. To interact with a finished object movie, one depresses the mouse button when the cursor is over the movies and moves the mouse in the direction one wishes to rotate the object. A specially designed object rig enables the QTVR photographer to move a camera around an object vertically in order to make more complex object movies with both vertical and horizontal rotation. One may zoom in or zoom out of both types of QTVR movies. Also, invisible regions called hot spots may be painted anywhere on QTVR movies. Hot spots trigger special actions when clicked on, such as launching a new web page, labeling a spot on an object or in a pano, or bringing up close details of an object.

Figure 1: NMAI Virtual Tour Screen Shot

Both types of QTVR were used in the finished Virtual Tour, with the panoramas of the exhibition space serving as an interface for accessing the featured objects selected by the students. Clicking on a hot spot over the museum display of a featured object will cause the QTVR object to load in a separate frame, accompanied by an interpretive essay written by a student. Clickable floor plans of the exhibition space offer another method of navigating the virtual tour and accessing the virtual objects (see Figure 1).

Of the three schools participating in the NMAI virtual museum project, Hannahville has been the most successful in involving the local community in the creation of a local virtual museum using local resources. In a three-day open house session at the school, community members brought native arts, crafts, costumes, and cultural items that students recorded in digital photography and QTVR. Students wrote essays on the objects and used digital sound recording to add their voices to annotate their virtual exhibits. They used oral history techniques to record community members’ renditions of traditional stories for their virtual museum. A year later, the school found a private museum in the region that gave them full access to its collection of Anishnaabe and historical items to add to their ongoing virtual museum efforts, an interdisciplinary effort which now involves the school at all grade levels. A publicly accessible component of the school’s virtual museum activities is on the World Wide Web (http://www.hvl.bia.edu).
The Heard Museum in Phoenix, Arizona, is another Four Directions museum partner that has been involved in virtual museum projects with three other schools. In May, 2000, students and teachers from Dilcon Boarding School (Navajo, Arizona), Seba Dalkai School (Navajo, Arizona), and Laguna Elementary School (Pueblo, New Mexico) spent four days at the museum, documenting items for the purpose of illustrating virtual museum projects in their communities. Dilcon Boarding School and Seba Dalkai School combined the media that students created at the Heard with oral histories, QTVR panoramas and photographs created locally to make a virtual museum of the schools histories. Laguna Elementary School will use the media its students created for a virtual tour of the Pueblo of Laguna community. Teachers and project partners used HyperStudio to author the virtual museums, which were distributed to the Heard Museum and the three schools on CD-ROM. The Heard Museum plans to use the CD-ROM as part of an exhibition on American Indian boarding schools.

The Benefits of Virtual Museum Projects

Since these initial virtual museum projects, several other schools in the Four Directions project have been actively planning to implement similar partnerships with local and regional museums that have cultural items which hold special meaning for the school communities. Four Directions students, teachers, and school communities are modeling how other Native American schools can plan and develop virtual museums that inform the world at-large while they return images of objects to their cultural homelands. Created by Native people, these projects provide a venue for cultural collaboration and cultural exchange. It is an act of cultural recovery as it returns to the Native community objects long removed from their origins.

The Four Directions model also holds important benefits for the museum community. As professionals at the National Museum of the American Indian testify, the Four Directions project benefits the museum in several ways. First, it provides a way to fulfill part of the museum’s mission, which is to be of service to its constituents (Native Americans) and to reach out beyond the walls of the museum to teach the museum’s public (non-Indians) about the culture and histories of the Native people of the Western Hemisphere. The NMAI recognizes that it has a special responsibility to the people whose ancestors made the objects in the collections. Native Americans have said they want the museum to help them preserve their cultural heritage and to share its resources with Native communities. The Four Directions Project provides a collaborative framework in which to leverage the vast cultural and human resources of the NMAI. The NMAI, in collaboration with the University of Texas and with other Four Directions partners can help Native American students learn new technologies, contribute to cultural preservation and share the resulting project with people all over the world, many of whom will not be able to visit the exhibitions.
in New York. One of the exhibitions in the Virtual Tour has been dismantled to make way for a new exhibition. It is now only available on the World Wide Web.

The Four Directions model may also be adapted to other student populations with different cultural backgrounds. The contributions that minority and subordinated cultures make to the rich tapestry that is America are not given their full significance in the standard curriculum. Museums and local communities have resources that can rectify this shortcoming. The Four Directions model of school-museum collaboration for the creation of virtual museum is one culturally responsive strategy for taking advantage of those resources.

Acknowledgements

The authors gratefully acknowledge financial support from the Four Directions Technology Challenge Grant (#R303A50083). The grant is sponsored by the U.S. Department of Education and managed by the Pueblo of Laguna (New Mexico) Department of Education. We also wish to acknowledge the support of the Four Directions museum partners: the Smithsonian National Museum of the American Indian, and the Heard Museum.

An expert authoring tool for dynamic scenarios

{pacini}@di.unipi.it

Abstract: The problem of constructing meaningful examples to teach about dynamic objects environments is complex enough to justify the construction of an expert authoring tool, which knows about the physical constraints and the rules governing the dynamic world. Such a tool can be used by teachers, preparing example scenarios and exercises, and by students for online active training. We describe the software architecture for the expert authoring tool, which has been implemented taking as test bed the domain of sail boats racing.

Motivations

Dynamic object environments can be conceived as environments where objects move according to rules that can be physical/mechanical on one hand and artificial on the other (e.g. authoritative regulations, sport or game rules). This is typical of games and sport environments based on skilful operation of mechanical apparatuses (e.g. sail boats racing). In this case, movements are subject the effects of the wind on boat speed, the result of steering actions etc. Moreover, specific rules exist to ensure a fair interaction with competitors. Racing rules issued by the International Sailing Federation are an example of a well-defined body of non-trivial behavioural constraints. Finally, a number of tactical rules and suggestions are usually available for achieving good performances and often determine the outcome of the competition.

Our purpose is to devise and experiment with general techniques in order to realize advanced authoring tools to be used in the construction of dynamic object scenarios, as defined above. Such tools, in order to be effective, will have to act as expert assistants, exploiting knowledge of the specific dynamic domain. The intended use is both for teachers preparing lectures and exercises, as well as for students engaged in online interactive learning. As our case study we have chosen the context of sail racing scenarios, which is in fact a well-tailored domain for experimentation. Detailed mechanical aspects such as boat rolling and pitching, which are normally of little interest when speaking about racing rules and tactics, can be disregarded. Moreover, even if the complete text of The Racing Rules of Sailing (ISF, 1997) expands over nearly a hundred of pages, there exist a limited number of core rules, involving several non-trivial and challenging concepts, which can be considered an ideal starting point.

The underlying idea is that both learning and teaching can be based on a common paradigm, i.e. the preparation and the analysis of suitable dynamic scenarios in collaboration with the expert authoring tool. The teacher uses the automatic assistant to compose meaningful examples to be shown during classroom lessons as well as exercises for students, the students to invent specific scenarios to be investigated. For teaching purposes, example scenarios must be prepared with special care in order to focus on critical aspects of dynamic effects and/or subtleties of behavioural rules, more difficult for the student to grasp. In fact it is possible that even small changes in the scenario may cause large variations in the final outcomes.

The expert authoring tool is composed of three different modules: an editor of sailing scenarios, tightly coupled with a simulator, and an expert commentator working in close cooperation in order to give the user suitable comments and advice since the early phases of scenario composition.

Our tool, in its present form, is tailored to the sail racing domain, and does not face the issue of domain knowledge acquisition, which is a major concern of authoring system for ITS (Murray, 1999). The combination of the editor and the simulator reminds of an authoring tool for preparing scenes in a multi-dimensional world (such a CAD systems or a 3D modelling system). A key advantage is that it is task oriented and that dynamic scenarios can be created and immediately analysed by the user with the help of the expert commentator, thus offering the functionalities of an intelligent training tool.
General architecture

The architecture of the system (see Figure 1) is inspired to the one used in simulated soccer within the RoboCup initiative (Kitano, 1997). The two domains have similar characteristics: there is a simulator of a specific dynamic world where actors (players in the soccer case) need to act in respect of physical and environmental constraints and learn to achieve a goal (winning the game or the race). Looking at the two different domains allowed us to design an architecture that is general enough to simplify the overall system design when moving to other similar domains. Each module is implemented as a program interacting with other modules using a TCP connection.

The simulation history, which is the output of the Editor module, consists of a stream of instantaneous snapshots of the dynamic scene, one for each simulation cycle.

Each snapshot describes the current situation of the world: the position of the boats, the wind direction and intensity, and so on. The scene description is bi-dimensional, i.e. the positions of objects are given in terms of planar coordinates. The dynamics of the scene complies with the typical behaviour of sailing boats, since it is produced by means of a specially tailored editor, which works in close cooperation with a simulator, taking care of enforcing physical constraints. The editor understands high-level concepts of the domain, such as trajectories, and offers advanced and task oriented editing functionalities such as reuse and composition of large pieces of previously created dynamic scenarios, and the ability to apply desired adjustments and modifications.

The role of the Expert commentator module is to annotate with comments histories received by the editor. Some aspects of the racing rules knowledge deal with single snapshots, for example in the case of concepts such as windward or leeward boats. However, in general, an analysis of sequences of snapshots is required, in order to discover critical conditions in the dynamics of scenario evolution. In some cases, in order to check the rules, the Expert commentator needs to ask the simulator how a given situation will possibly evolve (this is the reason for the back arrow between the first two modules). The output of the Expert commentator is an annotated history, a sequence of snapshots with proper comments attached to them.

The 3D player takes the annotated history as input and produces a 3D movie of the dynamic scenario. Comments generated by the Expert commentator are output as text and/or as speech, exploiting the technology of Microsoft agents (Microsoft, 1999). The architecture allows for multiple players receiving the same data in multicast mode: this feature may be useful for displaying a simulation to a class during a lecture.

All communication among modules is based on a text protocol, in view of simplifying extensions. The architecture is modular and flexible: each module can be hosted on a different machine or replicated as needed. Modules can be implemented using different languages and technologies, provided they comply with the communication protocol. We have used DELPHI Pascal for the editor/simulator, C++ and CLIPS (Giarratano, 1998) for the expert commentator, Java and VRML for the 3D player. Modularity also enables extensibility: it would be easy to add a new module, as shown in Figure 1, if we wanted to do some more editorial work on the output of the Expert commentator module, prior to its rendering as a 3D movie. Another advantage of the proposed architecture is that modules can be made to-work together in pipeline, with a module feeding a stream of data to the next in real-time, or they can be decoupled redirecting the output to a file, which can later on be used as input to next module.

Improving assessment: Rubrics in a tertiary multimedia course

Barney Clarkson, Edith Cowan University, School of Communications & Multimedia, Australia
b.clarkson@ecu.edu.au

Joe Luca, Edith Cowan University, School of Communications & Multimedia, Australia
j.luca@ecu.edu.au

Abstract: This paper explains how alternative assessment methods were implemented in a first-year tertiary course on web design. The aim was to make assessment clearer for the students to understand, and more focussed, using a rubric—a detailed, criterion-referenced marking guide. The results of a post-course evaluation of this action research showed that students strongly appreciated the use of this type of assessment. Our conclusion is that the rubric approach improves student satisfaction and can save lecturers time when marking.

Introduction
Assessment is a critical part of the learning cycle in a tertiary institution, but is sometimes treated as an extra burden rather than an integral part of course design. In addition, at a time of increasingly constructivist orientations in course design and presentation (eg. Duffy & Jonassen, 1992), course designers are reviewing their instructional regimens yet ignoring their assessment techniques. This misses the opportunity to make the linkage between assessment and instruction 'more natural, ongoing, and constructive', (Tierney, Readence, & Dishner, 1995, p. 482). Rubrics are part of a trend towards a greater variety and more authenticity in assessment. By integrating assessment into their instruction educators are both servicing their students better and making their teaching more satisfying (Yell, 1999).

Assessment has both summative and formative purposes — the summative purpose includes providing grades and feedback to students after the learning cycle. The formative purpose can enhance learning during a course, for example using rubrics:

Highly competent teachers use assessment measures to inform their instruction and ... as a means of instruction. Rubrics are frequently the tools used to identify key elements of proficiency [in that instruction].... These rubrics assist both the teacher and the learner in determining the necessary elements for each level of performance. (Skillings & Ferrell, 2000, p. 452)

There is often a conspicuous discrepancy between the student-centredness of some courses, and the isolated nature of their assessment. As Skillings suggests, changes towards more student-friendly assessment can improve learning. In fact the evidence that a rubric—a structured, elaborated appraisal tool—can lead to greater student participation, greater satisfaction for the instructor and better student performance, is the reason for the action research reported in this paper.

All about rubrics
A rubric is sometimes called a marking guide or a scoring guide. In cynical mode Popham (1997) argues that the name was carefully chosen because of its decisive lack of opacity, since less opaque descriptors like scoring guide are therefore less technically attractive. There are many differing definitions of rubrics and their usage (Brudnak, 1998; Wenzlaff, Fager, & Coleman, 1999), nevertheless there is still some agreement on the content (Morgan, 1999). As ways of assessing student work have begun to change, rubrics are becoming increasingly popular. They are sufficiently popular in schools that they are now mandated by education departments across parts of Australia, UK and educational districts in the US, at both class and system level.

In its simplest form a rubric is a rating table which allows comparison of student work against important content listed in a table (Tab. 1). The essential characteristics can be summarised as follows:

- a set of content or standards which are being assessed — here arranged in rows;
- a set of levels of proficiency, for example from beginning to developing through to accomplished (see columns in Table 1), or even sad to neutral to smiley faces;
each level contains specific, measurable performance characteristics, such as 'made regular/ some/ few pauses to check notes'; and
any descriptor used in any cell should normally appear in all cells on that row – in a 'good' rubric there should be no hidden skills that magically appear (or disappear) as the level changes, under normal circumstances.

<td>made some pauses to check notes</td>
<td>made few pauses to check notes</td>
</tr>
</tbody>
</table>

Table 1: Rudimentary example of a rubric for rating Notes Use in some public speaking activity

Some parts of the rubric are flexible. It is possible to have either detailed descriptors or checklist items in each cell; and the number of rating levels (three are used here) can range up from two, though less than six is strongly recommended (Schincariol & Radford, 1998).

Other parts of the rubric are less flexible. For example notice that the rating scale is not normative, like 'Good, Better, Best', but is explicitly measurable. The intention of the rubric is to rate student performance against some standards rather than simply comparing them with their peers. Creating rubrics is both an art and a science—just like all teaching—and a number of writers describe the detail of how rubrics can be developed (eg Montgomery, 2000; Morgan, 1999; Rose, 1999; Yell, 1999).

Assessment based on performance has become a popular alternative to traditional assessment (eg pencil and paper) in recent years, particularly with complex and subjective criteria (Schincariol & Radford, 1998). Instead of taking a traditional test with right and wrong answers, students are asked to demonstrate a skill by perform an oral presentation, create a web page or design a rubber-band-powered vehicle. These efforts cannot be graded by counting right and wrong answers, and that is where rubrics are powerful. They simplify appraisal in situations more closely resembling 'real life' than less authentic and isolated traditional tests. Unlike traditional marking keys, rubrics are provided before rather than after any student assessment point, and are intended to be a unified part within a teaching program. Rubrics are therefore public, composed of clear measurable language and integral to the learning process.

The role of rubrics in learning
Because rubrics convey clearly and explicitly what is expected in terms of content and performance standards (Rose, 1999, p.30), they are a useful and motivating assessment tool. But Germaine (1995, p.1) argues that rubrics can also be powerful teaching tools, since they:

- promote unanxious expectations; make grading criteria known to students; drive curriculum and pedagogy;
- reduce teacher subjectivity; ensure accountability; and maintain focus on content and performance standards and student work. (p.1)

Students given explicit, embellished, measurable guidelines for their assessments are working on the outcomes that have already been determined as important for their success, and that focus can improve their learning effort considerably. They also provide clear guidelines for the course instructor and hence focus the teaching directive (Rose, 1999).

Traditional marking keys are the hidden runes whose contents students guess at, whereas rubrics are public. This has a two-edged benefit, namely students can evaluate the evaluating tool before it is used on them. Hence students can now think and talk about their assessments, and even examine their own expectations and standards. Such metacognitive actions extend the role of rubrics as powerful tools for learning (Skillings & Ferrell, 2000, p.455). Furthermore, as writers like Abbott (1997) have pointed out, metacognition supports the transferability of these skills to other, different learning situations.

A rubric would appear to have a particular advantage over less elaborated methods of assessment for non-native language speaking students. The repetition of language in the rubric and clear development of conceptual levels across a rubric table mean that there are more opportunities for language pattern recognition than occur in a narrative or unstructured assessment format. In fact such improvements, eg in motivation for weak students, have already been noted in school environments (Custer, 1996; Skillings & Ferrell, 2000).
It is possible to integrate rubrics further into the teaching and learning process. Much of the literature on rubrics talks of a student role in their design. There is merit in involving students not just in the fine-tuning but the total design of their assessment rubrics because of the evident value engendered by their participation, argues Stiggins (1997):

> Involving students in the development of performance targets can be an effective instructional tool because students who are given the task of analysing quality work and its crucial components become better performers themselves. (p. 452)

Rubrics advantages are not without a price. Firstly they still only address only a part of the spectrum of student performance and should not be overrated. Although they appear to have broad educational justifications, they are not a replacement for a rich appraisal program says Yell (1999). Nevertheless he also points out that educators will find more and more uses for them as their proficiency improves. Secondly Wenzlaff et al. (1999) argue that there is no ‘best’ format for a rubric, and that “perhaps there should not be” (p. 43), which might explain why some teachers seem to ‘fine-tune’ their rubrics endlessly. They point out that the expertise of the user is at least as important as the actual rubric format. Still, if a rubric focuses an instructor’s attention on course-relevant processes and performances, then time spent fine-tuning is easily justified.

Thirdly students who meet rubrics for the first time can find them overwhelming and even confusing. ‘I liked the idea but as a "first off", was not clear about its purpose until assignment 2‘, complained one student. We realised in hindsight that rubrics need even more careful introduction than we expected.

Fourthly, because they tend to be standards-oriented rather than normative, rubrics represent a shift in philosophy from the traditional norm-referenced methods. In fact rubrics are not intentionally a grading system but simply a way of identifying weaknesses and strengths. It is true that a student who scored, say, ‘Accomplished’ on all criteria could argue that they deserved a high grade, but this is a trivial example. After all, grading students whose marks are extreme is always much easier than grading the rest. The issue of grading is critical because if the rubric is to be useful in a tertiary setting, it must allow marks to be compressed somehow into a single grade. Our method uses the principle of ‘conjoint progress’ — no student should be awarded, say, a D (for distinction) unless they had satisfied all the criteria for the D in all the content areas. In other words there should be no ‘averaging out’, just as making a cup of coffee cannot be averaged— missing a single step, eg ‘adding a teaspoon of coffee’ fails to complete the act of making the cup of coffee.

Consider three students S1, S2 and S3, whose three marked rubrics look like the table below (Tab. 2). The table uses blocks to represent cells from a rubric. For example, a row which consisted of a single filled block would represent a Beginning Level performance for that student, eg S2 on Criterion 3. Multiple filled blocks mean improved levels. The likely grade for S1 is the same as S2 and S3, since none have conjointly made progress of more than one cell to the right. Whilst S2 and S3 are clearly better than S1 in some areas, overall each has a weakness in a critical area already identified by the rubric, which undermines their overall ‘value’ (perhaps employability). So, in this case, all these students should be awarded the same grade.

Table 2: The 'conjoint progress' principle allocates students S1, S2 & S3 the same grade (see text).

In essence, then, rubrics provide a way to improve the meshing between the appraisal and teaching parts of the learning process. So called ‘objective tests’ require effort in their construction, but can speed marking. Similarly rubric development can be laborious but it can reduce the qualitative dilemmas at marking time, especially when considering performance-based measurements. As well as guiding and motivating the learner, their detailed structure is helpful for weaker students. Also, they serve as an elaborated reminder of the instructor, and there is evidence that they support metacognition and transferability of thinking skills as well. Novices will find, as we did, that their skills improve with use. Their advantages need to be weighed against the effort of construction, the need for explanation, and the likelihood of continual fine-tuning. Our conclusion was that a satisfactory assessment rubric would therefore meet six criteria, listed below (Tab. 3).
An n x 3(?) table of Standards (Rows?) against Levels of proficiency (3 columns?)

1. Contain specific, measurable performance characteristics in each level
2. That a descriptor appearing in any row ought appear in all or most cells on that row
3. Be available well beforehand so as to guide the learning as well as the assessment
4. Be student-constructed or at least student-adjustable
5. Be amenable to some marks compression process ie to produce a grade

Table 3: Rubrics Criteria — derived design criteria for a satisfactory rubric

Action research case study
IMM 1122 ‘Publishing on the Web’ is a first year elective in a course for students studying multimedia at Edith Cowan University in Western Australia. It has around 110 enrolments each year, covers introductory html, web pages, site design, and introduces vector graphics enhancements using Flash™. This unit was designed by the staff involved for the first semester of 2000. All the resources and an on-line bulletin board were made available via the unit web-site. At the first lecture, students were introduced to all aspects of the course, including the concept of an assessment rubric for their two assignments. The rubric was made available on the unit web-site some weeks before each of the two assignments. It was planned to provide it earlier, but it proved challenging for novices to construct, and satisfying to keep adjusting.

In an attempt to involve the students in the process of rubric design, assignment one had two submission dates, a week apart. Initially a paper design and their personal extensions to the standard rubric were sought. A week later the final electronic assignment was due in, to be marked according to the initial rubric as well as their additions to the rubric. A printed version of the rubric was used to mark their assignment—see extract below (Tab. 4).

Since each cell of the rubric was composed of mainly exhaustive criteria (eg: ‘☐ at least one working image map’) rather than examples, it was decided assignment two’s rubric should include a summative item in each cell, saying ‘☐ meets criteria for lower rating’ (see bold text in the right hand cells of Table 4). This had two consequences. First it meant that there was less repetition needed across the cells. Although this contravened one of the Table 3 rubrics’ criteria, it also made it a more manageable size. Secondly it meant a marker could make a rapid judgement more readily during the grading process.

Table 4: Extract from the Assignment 1 rubric, with summative entries in bold text in the right-hand cells.

It was realised that the checklist rubric approach would allow either a detailed marking scheme or an impressionistic global one. The detailed one simply added ticks, assuming, quite unreasonably, that the items were of equivalent value. The global marking method was supported by noting the volume of ticks in each cell and making a judgement about progress towards the higher ratings. Tutors were free to use either format for marking, within the constraints of the principle of conjoint progress, described above. Students were reminded of the mastery principle with the anecdote about flying with the pilot who passed, with 50%, by scoring 100%
of her take-offs and scoring 0% on her landings. By making this issue clear beforehand, it was felt that some potential misunderstandings were avoided.

**Student feedback**

All students at their first practical class were asked to complete a short pre-course questionnaire and at the last practical class were asked to complete a similar post-course one (35 collected). It is not possible to ascertain the views of those from whom no form was received, which includes those who chose not to attend the practicals, but we can think of no abnormal reasons for their lack of data to skew the results we report here.

Students were asked to rate a range of questions from 0 (low) to 10 (high); and were then given space for a comment. The average rating for the rubric idea was 7.1 and pleasingly the most common score was 10. Almost 80% of students rated the idea of using a rubric at a 6 or better, whilst 17% rated it from 0 to 4. Their rating for the course overall was similar, with 7.2 as the average satisfaction rating.

The range of positive responses ranged from observations like ‘helpful’ (with a rating of 7), to ‘great idea’ (with a rating of 10). A further sampling of their ratings and their associated comments follows:

- **6** Good idea, very helpful (if you use it)
- **8** I think it works well in a lot of ways
- **8** Good, I could check off things as I did them
- **7** Good for those who had NO idea (what was wanted)
- **8** Really gives you good indicator of what to include in the assnt instead of just guessing

It appears that some understood it better than others, but their judgements are largely supportive. Although one comment in the list suggests a student who was taking a rather mechanistic and unthinking approach ('I could check off things'), it is nevertheless true that they are working on priorities which the rubric writers have already identified as important. Without such a list they might not have any confidence that they were addressing consequential topics in their assignments.

It would be improper to ignore poor evaluations, as they are the students that have to be ‘turned around’ for assessment averages to improve. Here are comments from the (fewer) negative evaluations:

- **1** Criteria far too high for a 1st year unit
- **1** Didn’t know about it until the second assnt
- **0** Pointless since you do not evaluate according to a criteria but rather one student against another
- **2** Makes it more mechanical and less creative - you just put stuff in for marks

It is sometimes harder to summarise negative comments than positive ones, as there are many reasons for the state of dissatisfaction but all satisfied people are in approximately the same—ie satisfied—state. Two observations are in order. Student 3 seems to have made a philosophical judgement that is at odds with our stated aims. As before, there is a student (#4) with no interest in the rubric as a learning tool, and sees it as simply an elaborate checklist. Allowing such students more say in the content of the rubric (criterion 5 in Tab. 3) may address this concern. Overall it would seem that scrupulous explanations may improve student understanding, when introducing rubrics concepts.

Our attempts to allow students a more significant role in the extension of the rubric, though laudable, were judged as unsuccessful. At marking time, we found we were ‘juggling’ both the assignment rubric and the assignment itself, which we rated as unsatisfactory. Until we feel greater confidence in the use of rubrics, we sense that such a facility needs to be treated differently. Fortuitously the second assignment had only one deadline, and tutors rated this as preferable, feeling that it had not seriously undermined the extra value that the rubric had brought to the unit.

The completed rubrics were handed back to students with their assignments. Student comments after each assignment indicated general contentedness, and later strongly supported the approach, but there were some concerns by the students about tutors’ ability to use them properly. For example in the course evaluation one student commented, ‘useful, but my tutor did not seem to mark by it, so rather pointless’.

349

Page 301
Conclusions and recommendations
This paper demonstrates one way that tertiary courses can successfully utilise less instructivist approaches to assessment. The identified Rubrics Criteria (Tab. 3) were implemented with relative ease, especially after experience gained designing the first rubric. Although it seems that the rubrics concept needs careful utilisation, both to improve staff skills in its implementation as well as student understanding in its use, its robustness is comparatively obvious.

It appears that students enjoyed this unit's use of rubrics, although it was the first time they had seen such a device and even though it caused some difficulty for a small number of students. The strong balance of student support for the rubric concept and their overall satisfaction with the course suggest that the rubrics were a helpful part. Indeed, we assert that the rubrics helped many students better focus their effort on the delineated criteria in this unit on web publishing.

Eventually we envisage both staff and students having better procedural and conceptual understandings of rubrics. Immediate improvements could include better introduction of the rubric and its role; a tutorial activity where the students jointly mark some provided representative work samples; we can imagine students reviewing the unit's rubrics (displayed on a web-site) and suggesting improvements and additions—this might be handled by providing a specific on-line bulletin board on the topic, perhaps even for marks.

Change processes like this take time and need review, so it was ironic to read one of the criticisms of rubrics was that they encourage fine-tuning. We argue they warrant continued refinement, since they are as satisfying to the educators as they are educationally useful to the students involved. The reason is that rubrics can precisely centre your attention on what is and is not important.

Abstract

The paper describes the present state of the WWW & Over project to design techniques for the remote control of hypermedia teaching materials. It reviews the main features of the new version of the prototype for distance teaching, where teacher and students interact at a distance in real time on teaching materials created by the teacher. Also described are the first experiments in real distance-teaching processes during a university course, the results of which show that transmitting the video image of the teacher – which is normally regarded as crucial for recreation of the ‘real’ classroom – is not in fact indispensable. It was found instead that the teacher’s voice and its coordination with his/her actions is essential for the success of a distance lesson. Since the project has applicative purposes in environments consisting of low-cost and low-performance networks, this finding on the one hand encourages experimentation with the techniques adopted by WWW & Over, while on the other it rules out the use of numerous systems based on audio/video streaming in view of the substantial delay that arises between the real event and its perception by users.

Introduction

Perhaps still to be found in Sicilian popular culture are the cantastorie, strolling minstrels who comment in song on news events depicted on painted placards. Teachers who project slides during a classroom lesson are in the same technical situation as the cantastorie. Though there is a substantial difference between them, we shall show that it has no bearing on our argument. The cantastorie uses his voice to sing, while a teacher more simply performs an oration in prose. In the beginning was the blackboard; then came film strips, OHP transparencies, slides, the video recorder, and finally, and inevitably, the computer. Each of these devices has its place in the expounding of arguments for didactic purposes. If we concentrate on the applied context in which topics are expounded by means of computer, we find that the lecturer, like the Sicilian street singer, manoeuvres the visualization of images to reinforce the arguments expounded in his/her oration. At the same time the lecturer, again like the cantastorie, uses images to give coherence to his/her discourse. In this case, the images provide guidance for the lecturer during his/her oration. During the lecture, the lights in the room are usually dimmed to give sharpness to the images projected, and the lecturer is usually hidden behind a computer monitor. It is generally believed that this state of affairs does not greatly affect the nature of a frontal lesson characterized by the physical presence of the teacher in the room. As a consequence, the majority of the approaches tend to virtualize the teacher’s image by transmitting television pictures in order to recreate direct classroom communication between teacher and students at a distance.

The results presented in this paper suggest, however, that the teacher’s virtual presence depends much less on his/her image than on his/her voice [Land et al, 1999]. [Kötter et al, 1999]. During the last academic year, part of a course at our University was taught entirely at a distance. The students were from two different faculties but they attended the same course (Introduction to Databases), one-third of which was taught without the lecturer being physically present in the classroom. The teacher was alternately present in one of the two classrooms in the two faculties, and his image was projected in the other classroom (30 kilometres away) by means of a simple telephone link. The lesson was piloted by the prototype briefly described in section 2 of this paper. Besides the technical results, the feature that we believe warrants most detailed analysis is the feedback provided by the students (around 50 of them) at the end of the course. Put briefly, it emerged that the role of the lecturer as cantastorie (image, expressions, gestures) is less influential than, and because of, the interest aroused in the listeners by his/her voice.

2. A prototype for real-time online learning

Distance teaching has for years been a central concern of the training community, but it is still not as widely used as would be desirable. The association between the World Wide Web and distance learning is by now well-established, and many products for the creation and management of teaching materials for use on the WWW are now available [Becher et al., 1999]. [Mioduser et al., 1999]. Thanks to the growth of the Internet, numerous users are able to exploit the potential of the Web [Bos et al., 1996]. But although the Web allows the rapid transmission of multimedia lessons and the easy and rapid updating of information and materials, it does not solve the problem of lesson management. Besides the speed of transmission lines, the technology amply meets the needs of the large-scale use of distance learning, but there are still numerous problems connected with the "pull" metaphor typical of the WWW [Colazzo et al., 1996]. A further critical aspect is the difficulty faced by teachers in the rapid production of teaching materials, if they are not IT experts and are unacquainted with specialized tools [Ibrahim et al., 1995]. [Ehner et al, 1999]. The distance between teacher and student creates obvious problems, because the physical relationship that arises in a 'real' classroom cannot be easily recreated in a 'virtual' one where teacher and student
are not in physical contact. But the main criticism of the model of distance education that predominates today, based mainly on the WWW, springs from the following simple consideration. Students cannot be assigned control over their learning process by being allowed to navigate unsupervised among the teaching materials. This is because the students' lack of knowledge prevents them from distinguishing the most important concepts and from navigating in accordance with the teacher's wishes [Ping-Jer Yeh et al., 1996]. Only the teacher who has prepared the lesson knows which is the best route, which concepts should be memorized, which points may be ambiguous, and so on.

The aim of the WWW &Over project is to create a tool for the delivery of multimedia lessons via Internet which enables the teacher to exert more direct control over them. The system derives from a project begun in 1993 [Colazzo et al., 1995] in which the interactivity is created via a TCP/IP peer-to-peer network comprising the teacher's computer and the student computers linked thereto. This type of link is currently enjoying enormous success, especially in the area of file-sharing via Internet (Napster being a case in point). Under our approach, teacher and students are able to interact during a lesson without being physically present in the same place. The system enables the teacher to intervene in his/her multimedia lesson from his/her workstation, while the students' computer screens show the slides and the teacher's actions at that particular point of the lesson. It thus simulates physical presence in the classroom, flanked by the broadcast voice and image of the teacher via videoconference and by an events management system (control console) used only by the teacher during the lesson. Our initial preoccupation when flanking our prototype with a videoconferencing system to broadcast the teacher's image/voice naturally concerned the bandwidth of the latter. In fact, although the purpose of the prototype was to minimize this aspect, the broadcasting of video in real time proved to be a problem. The findings of the experiment are interesting, given that it used was a 160x120 pixel image. The main impact of the prototype was the creation of a lesson environment which approximated a 'real' classroom as closely as possible, and thereby enabled the teacher to use multimedia technology without having to equip the classroom with videoconferencing equipment that the majority of teaching institutions are unable to afford. The solution was based on the use of standard communication protocols like TCP/IP. This makes it possible to distribute a single version of the application to both teacher and students and to use the teaching hypermedia differently according to the role chosen. In this way, all the material used during the lesson is directly available to the students on their hard disks, so they do not have wait, for example, while an animation is being downloaded, as instead happens with Web-based courses. The WWW &Over project is a multi-year project and therefore consists of numerous components. Here we shall analyse only its part relating to real-time lessons. This part has been called the 'Control Console/Panel', the distinctive features of which are now listed:

- the possibility of creating a remote lesson as similar as possible to the traditional frontal lesson by connecting a telecamera to the student computers to gain visual surveillance of the whole class;
- the limited use of network resources made possible by the presence already in the student computers of the multimedia teaching materials (sounds, images, film clips, etc.); these are not transferred, merely 'piloted';
- the use of de facto standards for the transmission (TCP/IP) and of an ad hoc protocol for managing the distance lesson;
- simplification of on-line connections by users;
- different modes of use (on-line, off-line, teacher mode, student mode): this allows the student to use the materials for self-study as well;
- different visualizations on the teacher's application and the student's screen, so that the former can monitor the current state of the latter;
- multi-user integrated electronic communication system (Chat), with messages differentiated for all students or for only some groups, or person-to-person communications;
- interaction on the materials between teacher and students, with role reversals, direct question-asking via the slides, the highlighting of parts of the slides, etc.;
- recording the actions made by the teacher and/or students on the teaching materials.

2.1 Salient aspects of the prototype
The system comprises two distinct parts.

- The authoring system, where lessons are created using an editor similar to Powerpoint but simplified in those parts less suited to didactic purposes and with emphasis on giving dynamism to the lesson. The authoring system was created with Toolbook, a widely-used multimedia authoring system of which the multimedia creation functions have been utilized. This part of the system is not described here.
- The reader system, i.e. the component of the prototype which reads the lesson and enables the teacher to use it. This component is described in what follows.

For the moment the prototype is in Italian. As said, the multimedia teaching materials produced by the authoring system are previously distributed to the students. Thus, when the application is opened, the system asks the user what type of role s/he wants to perform during the lesson (fig. 1). The student is also asked for his/her IP address or the name of the remote host with which the teacher is waiting to be connected. The system is therefore heavily based on the idea which is today called peer-to-peer, also because we believe this to be a winning approach in a didactic environment. Already in its early versions [Colazzo et al., 1998] the system used a 'push' approach, given that, as said, the pull model is unsuited to on-line training environments.
The prototype's network configurations are of substantially two types:

- in the first, the students', i.e. the 'clients' are directly connected to the server, the teacher's application;
- in the second, there is an intermediate node – the Repeater – between client and server.

In the former case, a star-shaped structure is used which concentrates all the connection management operations on the server (the teacher's computer). This structure can be used efficiently only when there are a few clients. In the presence of numerous clients, transmissions between server and clients can be mediated by the Repeater. The latter is an application which sends the messages from the Server to the clients and vice versa. By means of the Repeater, the teacher's application can handle the transmission of data more efficiently and rapidly, given that the number of connections is relatively small. Most of the workload, in fact, is borne by the Repeater, the sole function of which is to handle connections and to duplicate data for each client.

2.2 Managing the lesson in real time

Once the lesson has been created and its dynamism established by the prototype author, at the beginning of the lesson the teacher exercises complete control (should s/he want it) over everything in the work environment depicted in figure 1 by means of the 'control console' shown in figure 5. The teacher can also use a navigation bar, which is naturally not visible to the student until s/he asks to intervene. Besides the navigation bar, the teacher can use the sequencer, which is the lesson 'control panel' real and proper (fig. 6). The Sequencer organizes the lesson pages with their objects into the sequence defined by the teacher. Each item in the sequence can be easily identified by the name given to it by the teacher or created automatically by the system.

An icon determines the visualization status of an object, so that an object in the sequence can be:

The teacher can therefore use the sequencer to follow the sequence of objects created at the authoring stage, or s/he can vary it according to his/her wishes. When a particular slide is being shown, the situations on the computer
screens of the teacher and students may be the ones presented in fig 7 and 8. Note the highlighting of the elements already visualized, and also of the next element in the sequence. This gives the teacher a series of advantages while s/he conducts the lesson and transmits information to the students.

- The teacher can choose what to let the students see and what not to let them see.
- All the elements on the slide can be visualized to maintain the sequence of the argument, unlike in the case of presentation products, where what the speaker sees is also what the audience sees. This engenders less cognitive overhead for the audience because they only see the objects being discussed by the teacher at that moment.
- The lesson control tools are only visualized on the teacher’s computer, so that the students’ screens are not cluttered with buttons, arrows, cursors, and so on. This, too, reduces the students’ cognitive overhead and enables them to concentrate solely on the slide.
- Only some of the elements on the slide can be re-viewed, an option which is extremely useful in the management of animations, for example.
- The teacher can jump to slides other than those in the sequence without the student noticing. S/he can thus change the route through the material without the students realizing, deciding impromptu the next slide to show.
- The presence on the teacher’s computer of other software for example a word processor program with the written text of the lesson – without disturbance to the student.

3. The experiment

The experiment in teaching the ‘Introduction to Databases’ course at a distance was conducted at the University of Trento’s two campuses located in Trento and Rovereto. Involved in the sessions were around 50 students, who divided between economics/business studies and information engineering. The students were attending the course for completely different reasons, given that it was a compulsory course with compulsory attendance for the information engineering students and an optional subsidiary course for those attending the economics faculty. This radical difference in motivation was extremely useful for creating a sample of potential online learners that was as heterogeneous and complete as possible. During the sessions the teacher was assisted by three other persons (two of them in the remote classroom) who helped with preparation and management of the lesson and dealt with technical problems without interrupting its progress.

3.1. Technical data on the experiment

As said, one of the purposes of the project is to enable the use of low-cost technology, so that students who do not have costly videoconferencing equipment or fast communication lines can take part in lessons. Used for the experiment, therefore, were standard hardware and software components and low-speed communication lines: two Pentium II 350 PCs, a 64 Kb/s ISDN line, two standard low-cost webcams, two video projectors for slides and videos, NetMeeting™ 3.0 for the videoconference. Used to collect the data was a questionnaire comprising twelve open-ended questions designed to yield the following:

1. a general evaluation of the method and its suitability for teaching purposes;
2. a qualitative assessment of the teaching materials used by the teacher, in particular of the language used, the clarity of the slides and animations;
3. assessment of the quality of the audio component and of the importance or otherwise of the video component;
4. assessment of the pace and duration of the lesson: this being crucial for students accustomed to taking notes, etc., at the pace typical of a traditional lecture;
5. criticisms of aspects to be improved or changed;
6. an overall evaluation of the experiment and its improvement or otherwise between the first and last session;
7. judgements by the students according to their faculty and number of lessons attended: different backgrounds and different types of course may have introduced biases in assessments of the experiment.

4. Analysis of the replies to the questionnaire

Analysis of the (anonymous) replies to the questionnaire revealed considerable interest in, and appreciation of, the method and advantages of distance teaching. Detailed analysis of these aspects would be inappropriate here, given the evident disturbance effects arising from the novelty of the experiment and the close match between the experiment and the students' interests. Rather, we briefly review some aspects emerged from the questionnaire.

a. It was very apparent that a poor-quality audio signal was distracting for the students. By contrast, the quality of the video signal was less important than we had expected. It should be borne in mind that the quality of the video was rather unsatisfactory, given that the transmission rate was around 2/3 frames per second, and the size of the window was 160x120 pixels. This poor video quality was deliberately introduced so that we could ascertain the student's real interest in being able to see/distinguish the teacher's gestures, face and expressions. It seems as if the teacher's image was a contact with reality and nothing more, and that its non-intrusiveness was appreciated because it did not interfere with concentration on the contents of the slides.

b. The duration of the lesson (around 2 hours) was judged to be about right, although numerous students asked for a short break after the first hour, especially when complex matters were being dealt with. The information flow and stimuli were indubitably greater than those of a conventional lesson. Unfortunately, it was here that errors in gauging the pace of the lesson were most apparent, as explained below.

c. The tools for management of the lesson enabled the teacher to 'navigate' rapidly and efficiently through the teaching materials while supplementing them with a large amount of further information. The pace of the teacher's exposition should be carefully assessed and tested. The computer medium accelerates the transmission of information but hampers focusing on it by the students, and it does not give them enough time to take notes.

d. Again with regard to the pace of the lesson, the multimedia materials on the slides (generally images and animations) were regarded as essential for clarification, but the teacher was urged to synchronize the presentation of these materials with the time taken to read and understand them.

e. A large number of students said that it was important to have printed materials on the topics addressed during the lesson, probably so that they could cope with the above-mentioned problem of note-taking.

f. The respondents stressed the importance of reducing communication via the microphone in the classroom or through a chat facility to the minimum. They also asked for interaction on the materials being used by the teacher. Instead, there was no request at all for some form of visual interaction, which confirms that video is only an accessory and unidirectional (teacher-to-student) aid.

g. Curiously but significantly, the students were reluctant to interrupt the teacher when he was present in the classroom, because this was deemed to clash with the purposes of distance teaching. Interruptions in a real classroom give the students time to pick up the thread of the argument, but in distance learning situations this 're-boot' is time-consuming and distracting.

We now provide some details concerning the analysis of the questionnaire replies. The teaching method used was judged to be 'satisfactory' or 'very satisfactory' by around 94% of the respondents, without marked differences between the two faculties. Most criticisms were expressed by those who had taken part in all four sessions: in this case, in fact, the students had sufficient information with which to express an opinion closer to the reality and less conditioned by the novelty of the method. The language used in the slides was regarded on average to be clear. The use of pictures, diagrams and animations was particularly appreciated (especially by the economics students). However, the replies highlighted the students' difficulties in taking notes while simultaneously following the teacher's explanations. This was because the pace of the simulations was much faster than that required to write examples on a blackboard. Consequently, the teacher had to alter the pace of his exposition so that the students had time to copy and understand the principles or concepts being presented.

The time aspect is generally little considered by electronic presentations. Moreover, the prototype for the remote control of lessons, given its technical characteristics, introduces practically no time-lag between the two remote components of the lesson. As a consequence, the delays that normally occur in distance communication are not possible in this case. As to the video transmission, this was regarded as useful but not indispensable by 79% of the economics students, but by only 50% of the engineering students. When opinions of the quality of the audio were analysed, account had to be taken of environmental conditions and of technical aspects. The two classrooms were of different sizes, the acoustics were also different, and a 64 Kb/s ISDN line was used for both the audio-video flow and the prototypes. This latter aspect was dictated by the need to verify the minimum conditions for satisfactory functioning of the system, this being indispensable for assessment of whether the lesson could be
followed by students at home, where the transmission band of the channel used is certainly not comparable to that of university networks. The data collected show that synchronization of the audio with the teacher’s actions is of key importance. This is a very significant aspect, in that it makes the distribution of the audio in streaming format rather complicated. We had decided, in fact, to distribute audio/video in streaming format, due to the evident advantage of being able to exploit the multicasting characteristics of these technologies, and thereby reach a number of users with a single transmission. In the light of our preliminary experiments, and above all in view of the questionnaire results, we realized that besides the normal delay deriving from the remote transmission, streaming products introduce a further (and substantial) delay due to the streaming algorithms, which make this delay unacceptable. The assessments of the audio were decidedly positive, especially among the Economics students, whose classroom had better acoustics. Of course, the last thing we thought of in this complex experiment was to analyse the sound quality in the room where the students were sitting. Also interesting is an analysis of the pace of the lesson and the speed at which arguments are expounded. There was a certain divergence between the opinions expressed on these aspects by the two groups: according to 35% of the economics students thought that the pace of the lesson was too fast, while the percentage fell to 13% among the engineering students. 4% of whom indeed declared it to be too slow (obviously influential here is the different levels of background knowledge in the two groups). One of the twelve questions on the questionnaire asked the respondent to indicate aspects to be improved, those to be changed, and functions to be added. The replies can be summarized as follows:

- To improve: the quality of the audio, synchronization between what the teacher is explaining and the slide being shown; some students wanted better video quality (but not a larger-sized window).
- Change: the pace of the lesson (according to the economics students), the characteristics of the rooms used for the sessions, the transmission band.
- Add: verbal interaction with the teacher, hard copies of slides to use during the session.

Conclusions

The paper has described the main results of an experiment in real-time distance teaching in which the teacher and learners interacted on teaching materials from physically distant classrooms. Used for the experiment was a prototype currently under development at the University of Trento, the aim of which is to set up an environment for the creation and management of on-line teaching materials. The experiment was positively evaluated by the students involved (21% very positive, 79% positive). None of the respondents expressed negative assessments of the experiment, and there were no significant differences between the results for the two faculties involved (Economics and Engineering). The experiment yielded some surprising findings on the usability of these systems with low-cost IT infrastructures. The students did not find fault with the extremely limited and qualitatively poor use of video, but they emphasised the need for improvement in the quality of the audio, and for adjustment in the pace of lessons. This clearly indicates that also the teacher should be ‘trained’ in how to manage lessons of this kind. Although they seem entirely similar to their traditional counterparts, the remoteness of the students and teacher interferes with the efficient conduct of the lesson, so that the teacher should learn how to overcome the differences in speed between the classrooms and his/her delivery.

Abstract: This paper considers the student use of electronic communications in two second-year university Biology courses. Over a three-year period, student contributions to a Web-based discussion forum, an e-mail list serve, and e-mail directly to the instructor, were recorded. A number of characteristics of these electronic communications such as the number of student users, time of day used, types of use, and differences in student performance between the on-campus lecture, distance education correspondence, and Web-based versions of these courses will be discussed.

Introduction

While computers, by themselves, have not yet revolutionized education any more than previous educational technologies such as the motion picture, educational radio, teaching machines, and television, they have become useful tools, which are beginning to change the face of education. One area which has seen such change is Computer-Mediated Communication (CMC). The types of CMC analyzed in this paper are e-mail and Web-based discussion forums.

The Courses

Biology 2040 (Human Biology) and 2041 (Environmental Science) are second-year, non-major, non-laboratory courses which are regularly offered in on-campus lecture and off-campus correspondence formats. Biology 2040 is also available as a Web-based course.

Characteristics of CMC Use in the Courses

An analysis of the time of day students used CMC showed that there was some use of CMC throughout the 24-hour period (divided into 4 hour time blocks), and in fact over 45% occurred at times outside of regular classroom hours. These findings seem to support Cavalier's (1992) contention that CMC allows students to participate in 'round-the-clock' dialogues.

The levels of use of CMC in the different formats of the two courses varied considerably. While the percentage of students using CMC in the Web-based format of 2040 was much higher (61%) than for any other format (8.9-23.1%), it is interesting to note that almost 40% of the students in the Web section made no use of CMC. An earlier study (Collins 2000b) tends to suggest that students who are frequent users of CMC tend to achieve...
higher final course scores than infrequent users. While use of CMC in the on-campus formats was predictably lower (23.1% in 2040; 17.3% in 2041) than for the Web-based format, CMC in the off-campus correspondence classes was even lower (8.9% in 2040; 11.7% in 2041). This is surprising given the fact that distance education students’ main method of communication with the instructor is by e-mail, while on-campus students have access to the instructor both in the classroom and in his office.

The main use of e-mail in all three instructional formats is for questions relating to test and exams. The second most common use for both correspondence and Web-based formats is for administrative purposes (i.e. scheduling meetings etc.). In the on-campus sections the second most frequent use is for questions relating to assignments, but this is merely a reflection of the fact that assignments are more often used in these sections. It is interesting to note that in an earlier study (Collins 1998) the percentage of e-mails about administrative and other matters amounted to only 2% but has grown to 20% in the present study.

In an earlier study (Collins 1998) there were also differences in the types of use related to student postings in the discussion forums. In the 1994 2040 class, content-related items accounted for 45% of postings, while class discussions accounted for only about 20%. In 1995 these percentages had changed dramatically, with the content-related items only accounting for 8% of postings, while class discussion accounted for almost 70%. During the period of this present study content-related items, class discussions, and assignment-related queries accounted for 70% of the postings in the on-campus classes. In the same period in the Web-based 2040 classes, however, items relating to tests and exams accounted for over one-third of the postings, with content-related items making up 18% of postings, and student discussions accounting for only 15%.

**Student Performance**

The results of an analysis of final course scores indicate that students in the Web-based sections generally perform at a lower level (mean = 71.4) than those in the traditional classroom format (mean = 76.9), and these in turn perform at a lower level than students in the correspondence sections (mean = 78.5). The findings from this study then are in marked contrast to other similar studies (Navarro and Shoemaker 1999; Wideman and Owston 1999) which found that students in Web-based courses did better than those in both on-campus and correspondence courses. Several explanations have been advanced for the differences (Collins 2000a).

Linking Organizational Knowledge and Learning

Betty Collis
Faculty of Educational Science and Technology
University of Twente
The Netherlands
collis@edte.utwente.nl

Abstract: Universities and corporate training centers are under pressure to offer increasingly flexible as well as individually relevant learning. Instead of trying to develop a stream of Web-based courses to run parallel to "business as usual" courses, a department can focus on gradually building a knowledge base in which key resources from individuals in the department or organization, from external sources, produced by learners, or re-used from previous courses can all be available for re-use in various combinations and in different views for different learning situations including learners in varying locations. With a focus that changes from "distributing content" to "building and (re)using resources" a new way of thinking about "courses" occurs. These processes require good technology; agreement on locally relevant standards; simple procedures for adding, finding, managing, and re-using resources; and a change in mindset for all those involved. How we are doing this is described.

Types of Learning and Pressures for Change

Within organizations, four general types of learning can be identified, as shown in Fig.1:

<table>
<thead>
<tr>
<th>Type 1: Structured information; informal access</th>
<th>Type 2: Structured information; organized access</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type 3: Unstructured information; informal access</td>
<td>Type 4: Unstructured information; organized access</td>
</tr>
</tbody>
</table>

Figure 1. Four types of learning in organizations

In universities, Category 1 is typically represented by the library; in companies, by the knowledge management system in place in the organization. In both universities and companies, Category 2 is represented by courses, where learning materials are prepared or selected, and learner interaction with those materials is pre-determined by the course designer. Category 3 occurs for learners less often in universities, until learners are senior enough to have informal contact with those having knowledge and experience. For the professional staff in universities and companies, Category 3 learning occurs most frequently; on the job, via contacts with one's colleagues in house and outside or by casual contact with resources, such as via e-mail between colleagues or via borrowing a document one sees in a colleague's office when dropping in for a chat. Category 4 occurs in universities most often in a graduate or professional seminars; when the opportunity is created for a small group to share and discuss experiences with each other, led by a knowledgeable leader who can relate those experiences to a broader concept or issue and stimulate reflection and transfer. In companies, such seminar-type learning situations may also be organized but they are usually not explicitly planned by the training department. The best examples of Category 4 in companies may be management-trainee seminars.
Each of the categories in Table 1 has its strengths, but also its limitations. Traditionally those responsible for Category 1 in both universities and companies are not those responsible for Categories 2 and 4. No one is responsible for Category 3; it just happens. In universities, "courses" fall mostly in Category 2, until the graduate level, when Category 4 predominates. In company training departments, Category 2 predominates. Category 2 is most often translated as content delivery, with the participants on the receiving end of the transfer.

In this context, two pressures are being experienced. (a) The first is the case for both universities and company training: the pressure for more flexibility. Particularly for the Category 2 experiences, learners may differ in when, where, and how they can optimize their acquisition of this knowledge. In universities, this pressure has led to more and more "distance education" and in companies to "e-learning". In both cases, it is assumed that knowledge will be pre-organized and delivered; what needs to happen is to release the learner from the constraint of having to be in a certain room at a certain time for this to occur. A less-understood aspect of flexibility is the need of learners to identify what forms of prestructured learning experiences are best for them. (b) The second pressure relates to relevance. The need for university courses to be relevant in the future careers of the students is becoming sharper as more and more students are already established in those careers and have an immediate basis from which to judge relevance. In companies, the need to relate formal learning to issues of importance in the workplace is also clear. In companies, where courses tend to be short in duration and chosen on a somewhat individual basis, the relevance problem is seen to be solved by the "voting by their feet" method: learners will enroll in the course that they need. If portions of the course are not useful to them is not much considered. In a two- or three-day course (typical in companies), as long as something is learned, the time spent unnecessarily is usually not seen as a concern.

Relevance in company training is easier to establish than in university settings. Real problems and issues facing employees in the company exist, and can be used as the basis for training. This occurs, but often in an abstract way. Courses are often seen as transfer of facts and concepts, with the presumption that the learner will be able to apply those in his work. The strengths of Categories 1 and 3—enterprise-specific experience—appear to be rarely used as the basis of Category 2 learning events, particularly those "on the Web". This tendency is increasing due to the pressures for time- and distance-learning. To offer courses at a distance and at learner-determined times, courses are being "bought" from the cheapest (often external) source, the criteria are that the courses be "standards compliant" and put on the Web. Explicit use of in-house experience, particularly the experiences of the learners, is unlikely to occur in a course acquired externally. By offering some access to a "tutor" who can answer questions about the pre-determined course material, it is assumed that a good substitution for a face-to-face setting has occurred.

But there are problems with this "solution". How can all these courses be found? How long does it take to develop them? How can this occur while "business as usual" still goes on within the traditional university or company training center? Is the expertise of the in-house course leader and of the participants being exploited? Is the learning experience good enough? What is the return on the investment in the short and long term? Are any of the benefits of Categories 1, 3, and 4 being integrated into Category 3? And do the results of the learning that occurs in a Web-based Category 2 course become available for others in the organization?

In our experience, in both university and company settings, the answer to providing more flexibility in learning is generally interpreted as pertaining to Category 2, and is generally being answered by making or finding pre-structured, organizational-neutral courses available via the Web with little or none of the strengths involved with Categories 1, 3, and 4. Particularly in companies, the connection between "e-learning courses" (Category 2) and Categories 1 and 3 is almost non-existent, and Category 4 barely exists in the first place. In universities, Category 1 becomes peripheral, as in-house libraries can never offer so much as portals on the Web. Category 3, "informal learning from colleagues", is hoped to occur through some entries on a discussion board, and Category 4 is outside the range of instructional designers of Web-based courses.

In our approach, we want to turn these tendencies around. Flexibility in terms of time and distance is important, but not our first aim. Pre-structured content is important, but not our first aim. What is our first aim? Learning from experiences, from one's own and from those in one's organization, and building upon these experiences for all four different types of learning categories. With learning from experience as a guiding theme, the boundaries between the four cells in Figure 1 start to blur, and "distance education" and "e-learning" take on new forms. A course becomes a guided opportunity to learn from experience, and to contribute one's own experience as learning materials for others.
Key Points for Learning from Experience

There are several key differences in the "learning from experience" approach compared to the "learning from neutral content" approach. These are identified in Table 1.

<table>
<thead>
<tr>
<th>Learning from content transfer</th>
<th>Learning from experiences</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content is preselected, prestructured, and delivered</td>
<td>Content is encountered from a variety of sources, and partially is contributed out of one's own experiences</td>
</tr>
<tr>
<td>Learning relates to hours of time spent on reading or</td>
<td>Learning relates to finding and interpreting examples from practice, seeing how they relate to important competencies and objectives, and contributing to the collective knowledge base.</td>
</tr>
<tr>
<td>listening or attending face-to-face sessions.</td>
<td></td>
</tr>
<tr>
<td>The starting point of a course is its content, prepared by in</td>
<td>The starting point of a course is the activities that learners will do, in order to bring new resources into the learning setting.</td>
</tr>
<tr>
<td>advance by professionals, perhaps not even having any contact</td>
<td></td>
</tr>
<tr>
<td>with the organization.</td>
<td></td>
</tr>
<tr>
<td>To be time and distance independent, a course must be instructor</td>
<td>The good instructor should be extended over time and distance. His main task is to lead learners to making the connection between theory and practice, starting with their own practice. He is not replaced, but extended.</td>
</tr>
<tr>
<td>independent; tutors need to be available to answer questions</td>
<td></td>
</tr>
<tr>
<td>relating to the pre-defined study material.</td>
<td></td>
</tr>
<tr>
<td>Perhaps a forum can be available if some wish to use it (must will not).</td>
<td></td>
</tr>
<tr>
<td>Content and standards determine quality.</td>
<td>Building on and contributing to the learning resources and learning community of the organization determines quality.</td>
</tr>
<tr>
<td>Standards are necessary to make use of materials produced</td>
<td>Standards are necessary but need to be a combination of external indexes and also locally meaningful indexes.</td>
</tr>
<tr>
<td>elsewhere, and to sell your own materials elsewhere.</td>
<td></td>
</tr>
<tr>
<td>&quot;Offering instructor-neutral courses on the Web&quot; is the</td>
<td>Building on and using the experience base of the organization is the guiding theme of learning activities.</td>
</tr>
<tr>
<td>guiding theme.</td>
<td></td>
</tr>
<tr>
<td>Learning is completing courses.</td>
<td>Learning is becoming an active member of a professional community, knowing how to locate appropriate knowledge (also in human form) and apply it in one's work.</td>
</tr>
<tr>
<td>Learning is studying pre-written content.</td>
<td>Peer-to-peer learning is central; pre-written content is a resource, but may also sometimes be written by one's peers.</td>
</tr>
</tbody>
</table>

How do these principles work in practice? They involve technology, pedagogy, and new ideas about instructional design (Collis & Moonen, 2001). "The only way to keep pace...is by rebuilding business processes to take advantage of the collective knowledge base" (Eckhouse, 1999). They involve the convergence of courses and professional development, of formal and informal learning. "The advantages in technology and changes in the organizational infrastructure have increased the significance of virtual knowledge sharing, knowledge refining, new knowledge building and virtual networked learning for professional development." (Vånskä 2001). "Potentially explicable knowledge that has not been articulated represents a lost opportunity to efficiently share and leverage that knowledge" (Zack, 1999). "People to people" connections (Hinrichs, Kelly, & Bakia, 2000) are critical. An "experience management" architecture (Layton, 1999) needs to replace a "course management system". Figure 2 shows such an architecture, based on an object-oriented database.
Making it Happen

How does this happen in practice? We know, in that we have been working in this direction in our own institution, the University of Twente, for several years and also are implementing these ideas in various company settings. The following steps (Table 2) are the ones we have used; each is based on a considerable amount of literature and experience (see Collis & Moonen, 2001; see also http://teletop.edte.utwente.nl).

Table 2. From content delivery to building on experience

<table>
<thead>
<tr>
<th>Steps</th>
<th>Strategies and tools</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Start where instructors are at; extend their strongest skills so 1. Begin by extending an existing course, not &quot;creating&quot; or &quot;buying&quot; a &quot;Web-based course&quot;</td>
<td></td>
</tr>
<tr>
<td>that learners who are not present can also take advantage of these skills.</td>
<td></td>
</tr>
<tr>
<td>2. Shift the focus from content to activities</td>
<td>2. Assume you can go on, for awhile at least, with the existing textbook or course reader; don’t start by trying to put it &quot;on line&quot;. Focus instead on new forms of activities that will bring new resources into the course.</td>
</tr>
<tr>
<td>3. Plan activities around learner contribution, and learner (re)use of resources contributed from a variety of sources</td>
<td>3. Use a Web system that makes upload and download of resources easy, for both instructor and learners. Uploaded resources need to become objects in a database, indexed or managed on the fly to make them immediately available for re-use.</td>
</tr>
<tr>
<td>4. Plan activities so that learners who are present in a face-to-face session create a base set of resources, which can be built upon by learners who are not present.</td>
<td>4. Use a Web system linked to a database; write activity descriptions that involve building upon the inputs of others; commenting, synthesizing, adding to, comparing to one’s own ideas, etc.</td>
</tr>
</tbody>
</table>

Table continues

Figure 2. Building on experience. Use of an object-oriented database to both acquire new records of experience and also to offer different views and combinations of experiences for different learning settings. (De Boer, 2000).

<td>Make activities meaningful, and required.</td>
</tr>
<tr>
<td>7</td>
<td>Assess via contributions</td>
</tr>
<tr>
<td>8</td>
<td>Plan activities so that each participant’s contribution is visible, valuable, and needed in order to continue with the learning activities. Activities are aimed at contributing to the learning resources, not individual practice exercises.</td>
</tr>
<tr>
<td>9</td>
<td>Think of content as coming from a variety of sources.</td>
</tr>
<tr>
<td>10</td>
<td>Be less concerned about the &quot;perfection&quot; of the content objects and more concerned about the contribution and re-use processes</td>
</tr>
</tbody>
</table>

Figure 2 shows how the building process of a course can occur as the course progresses, with on-going input from both the instructor and other participants. In this approach, the course environment grows with each learner.

**Figure 2.** Building as the course progresses. The key is in the activities for the participants.
And the Technology?

What is needed for this approach? The technology is a main and indispensible factor. A system built upon an object-oriented database that offers flexibility in terms of the templates that can be developed to support input and output from the database is critical. Tools for easy download and upload, in page designs of the instructor's choice, are necessary. An easy-to-use method to index, find, and re-use contributions and resources from a variety of sources, and to present these via different views generated by the database is important. A system for metadata that integrates external standards (as far as they are meaningful to the organization) and also local tags, such as those relating to competencies in an organization or objectives in an university program is important.

These requirements are not utopian. They are part of our own TeleTOP system for a number of years (http://teletop.edte.utwente.nl). TeleTOP is not so much a "course management system" as a flexible way to make use of a database. We have, in our courses at the University of Twente, moved to universal use of the TeleTOP system, and toward an increasing amount and variety of "learning by contribution" methods. We are continually researching how to carry out these new pedagogies, what their impacts are on the instructor and learners, and how to streamline these sorts of approaches via a combination of new didactic strategies and continually improving technologies (Gervedink Nijhuis, 2000; Strijker, 2001; Van der Veen, J., De Boer, W. F., & Collis, B., 2000). We see these changes as both evolutionary and revolutionary. But without the technology, standardized throughout the organization and built around the "building on contributions and experiences" ideas we would be very much handicapped in moving forward.

Planning for E-Course Success

Leon L. Combs, Ph.D.
Department of Chemistry and Biochemistry
Kennesaw State University
Kennesaw, GA, 30144

Abstract
This presentation will present a rather unique method of planning and designing a web site for e-learning. The following phases will be discussed: trouble shooting the project, initial overview of entire project, dividing the project into small portions and assigning people to each of these portions, periodic studies of the entire project in light of the development of each small portion and how the entire project is fitting together, periodic beta testing by students, the first launching of the project, and assessment of the project. One of the unusual aspects of this planning is trouble-shooting using a strategic planning process. Learning styles are used to determine the course elements for the web site, and Newton's second law is used as a basis for the distribution of assignments to various team members for the development of the web site.

We start with a basic law of physics, Newton's Second Law: F = ma. In this equation F is the force, m is the mass, and a is the acceleration. Solving this equation for the acceleration we have a = F/m and we see that for the same amount of force, the smaller the mass the greater the acceleration. Applying this equation to web-site design and development, we have the important principle that to achieve the maximum acceleration of development we need to have the mass at any given time as small as possible. Recognizing the mass as the amount of material on which we are working and the force as our efforts, I think that everyone now quickly recognizes the principle. If we have everyone working on many aspects of the site, the site development will not be achieved at maximum acceleration. We must have the individual team members working on a series of small contributions. However we have to plan initially so that everyone is working on the appropriate assignments in the appropriate order. Therefore planning must be done initially on the project as a whole. After the initial planning, the team needs to have most people concentrating on small portions of the project with periodic reviews of progress as well as periodic reviews of the appropriateness of each component in light of the entire project. Of course if the team consists of one person, the person must divide his/her time wisely so that he/she concentrates on just small portions at a time. Regardless of the team size, the project must consist of the following phases: trouble shooting the project, initial overview of entire project, dividing the project into small portions and assigning people to each of these portions, periodic studies of the entire project in light of the development of each small portion and how the entire project is fitting together, periodic beta testing by students, the first launching of the project, and assessment of the project.

Trouble Shooting
The trouble shooting of the project is a phase that is often ignored or just dealt with as the problems arise. It is much preferable to do a thorough examination of the project initially, in which the strengths, weaknesses, and possible trouble spots are studied. We have found that strategic planning is a tool that lends itself well to this initial phase. Strategic planning is a management tool that was very popular in the late 1970's and early 1980's and is now becoming a popular tool again (McNamara 1999; McNamara 1995). It is a method of managing an organization so that it can do its job better. It is used to determine mission, vision, values, goals, objectives, roles and responsibilities, etc. The process of strategic planning involves intentionally setting goals and developing an approach to achieving those goals. However I have found the process to be very useful in systematically developing an approach to most any application, including web-site design and development. Before proceeding to demonstrate and discuss the application
to this topic, we need to define some terms within the strategic planning process. While defining these aspects of strategic planning, we will also look at some hypothetical examples of each.

I. Goals
Specific targets or results the group wants to achieve in a short time period of usually one year or less. Goals should be specific, quantifiable, concise, acceptable, and compatible with higher organizational goals. Example: CH 1 web site must be ready for use on Jan. 1, 2002.

II. Objectives
Objectives are specific targets or results the group wants to achieve in a longer time period of usually more than one year. Objectives should be specific, quantifiable, concise, acceptable, and compatible with higher organizational goals. As time tables progress, objectives will become goals. Example: All core chemistry classes (CH 2, CH 3, CH 4 in addition to CH 1) must be on-line by Jan. 1 2003. This objective is compatible with university goals.

III. Strengths (S)
Strengths are factors internal to the group that are considered relevant to the group's competence and over which the group has direct control. Examples: The group is very capable with some members having web development experience. All but one of the group members has tenure.

IV. Weaknesses (W)
Weaknesses are factors internal to the group that are considered in need of improvement or change and are detrimental to the group's competence. The group has direct control over these factors. Examples: Group members do not have workload allotted to the development of the site by the department chair. One member of the group is not tenured. Not all pieces of the development puzzle are in the group (no one is a programmer).

V. Opportunities (O)
Opportunities are environmental factors external to the group that can directly influence the group's competence in a positive manner if utilized, but over which the group has no direct control. Examples: The Presentation Technology Services (PTS) group on campus has much of the software and hardware available for web site development. The university wants publicity portraying the university as technologically savvy.

VI. Threats (T)
Threats are environmental factors external to the group that can directly influence the group's competence in a negative manner if not reacted to, but over which the group has no direct control. Examples: PTS is very busy and has an inflexible schedule. There are no university funds for new servers. Time spent on web site development does not count toward tenure or promotion.

VII. SWOT Matrix
Now we can make SWOT matrices, which will be SWOT items applicable to each goal and objective. Note that the S & W are items over which the group has direct control and the O & T are items which impact the department but over which the department has no direct control. We don't actually have to construct the explicit SWOT matrices; the important point is to be able to construct all of the SWOT elements and then to analyze them for a particular application.

Briefly analyzing the above, we see that we have a pretty good team except that we don't have a programmer and that need must be addressed. The programming can be done off-site (expensive) or the team could hire a programmer from an undergraduate or graduate student pool. We see that PTS has the equipment and software needed but we can't depend upon them to provide for people time help. A server must be obtained, so someone needs to determine if another server on campus has available space for the project (usually the case) or if space can be rented. Also the type of material will dictate some particular needs of the server, such as if it needs to be a Real server. One member is not tenured and time spent on
web development does not count toward tenure. This is not an uncommon problem and is a major problem for which we need a solution. We can try to change the departmental and college tenure and promotion committee about the validity of such work toward tenure and promotion in the area of teaching. Also since the university is interested in having publicity about being technically savvy, it seems that the best short term solution is to see if the administrators will allow the work to count in the category of university service, for that category usually does exist in a tenure document.

The time spent in identifying the above specific portions of strategic planning and planning for overall success of the project is very valuable and should never be overlooked. Typically the time required to do the strategic planning is two weeks and this can be very effective use of time. In this hypothetical case, the items have been identified and solutions for possible problems offered. We know that now we are going to develop CH 1 and the other courses will be developed in the designated time line.

Determining Project Components

The second overall step is to determine the specifics about the development of the course. We have to first know our audience (Herrington & Oliver 1995; Kolb 1976; Kolb 1985). Knowing the learner styles of our audience will allow us to develop a web site that appeals to all of those learner styles. This is a critical stage of development that often is overlooked. Once we have determined the needed course elements to fit the learner styles that we will probably have in our course, then we will be ready to begin the web site development. The time to analyze the needed course elements is usually only one week, however the time to then determine which of each element will fit into a particular portion of the web site can be another week. Below is included a portion of a presentation made by the author at EdMedia00 (Combs 2000). This table can save people time in determining which elements are needed for a particular audience.

<table>
<thead>
<tr>
<th>Learner Type</th>
<th>Needed Course Elements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Visual Learners:</td>
<td>Graphics (illustrations, films, slides, and diagrams), flow charts, discussion bulletin boards, and animations.</td>
</tr>
<tr>
<td>Auditory Learners:</td>
<td>Films, sound-enhanced slides, Microsoft Net Meeting</td>
</tr>
<tr>
<td>Read/Write Learners:</td>
<td>Written web material, referrals to other web sites, written assignments such as chapter summaries, suggested exam questions, etc.</td>
</tr>
<tr>
<td>Kinesthetic Learners:</td>
<td>Different web pages for different materials (makes them take a needed break), short web pages, memorization drills, animations requiring input, non-web assignments (surveys, lab experiments).</td>
</tr>
<tr>
<td>Sequential or Global Learning:</td>
<td>Give a good overview of each section and provide a logical progression through the material that can be chosen by the learner.</td>
</tr>
<tr>
<td>Inductive Approach:</td>
<td>Facts and observations given, principles developed</td>
</tr>
<tr>
<td>Deductive Approach:</td>
<td>Principles given, consequences and applications deduced</td>
</tr>
<tr>
<td>Active Learners:</td>
<td>These learners need group work. We can make assignments to groups of students and require presentation of results over the web using a course management system such as WebCT. Case studies appropriate to the discipline can be used very</td>
</tr>
</tbody>
</table>

367
Reflective Learners: These learners need time to think over the material before trying it out. On-line quizzes that are taken at the time of the student's choosing appeals to these learners. A thorough assignment due at the end of the semester also appeals to these students.

Now if we want to develop the course for all types of learners – which we should – we see that we need on-line quizzes, bulletin boards, chat rooms, e-mail, overview of each section, appropriate graphics, flow charts, animations, films, sound-enhanced slides, and written material corresponding to the requirements listed above. All of this material also needs to be set up in such a way that students can easily choose which sections they need to attend at any given point in their study – student-centered direction.

As it is very important that we understand the learning styles of students, it is equally important that students understand their learning styles. We recommend the establishment of a web site that can be used by the students to understand various aspects of their learning styles. We set up a learner skill evaluation site that can be used by others as well: http://erkki.kennesaw.edu/skills/.

Task Assignment

Now the trouble-shooting has been completed, the types of material needed for the entire course has been determined, and we are now ready to assign tasks to various members of the team to continue our design process (Demeester 1999; Henke 1997; Mackintosh 1999). Content experts need to begin writing the content along the guidelines developed during the study of learning skills of students. The content experts then are not to just reproduce their notes. The written material needs to concisely explain some topics in each chapter and each section needs to have web-based material such as other web sites pertaining to the same material, videos of selected material, animations appropriate to the section, interactive java applets helping the students to practice their understanding, an audio slide presentation of an overview of each chapter, and quizzes placed appropriately in each section of each chapter. Some of these content items will be created by other team members so the content experts will have some means of communicating to such members the exact type and content of the needed additional material. Also everyone must remember the a = F/m principle so that although everyone knows the overall project, all team members are individually working on small pieces of the project. Such projects are rather massive, and the completion of small pieces is very rewarding feedback to each member.

Project Production

Timelines need to be established for every portion of the project with dates also established for a comprehensive examination of the total project during development (Oliver, Herrington, Omari 1996). Teams of student volunteers need to be established that will serve as beta testers for the project as it is being developed. The development team must never forget that the project is being developed for student success. This must also be considered an iterative phase for as pieces of the project are developed, modifications of the flow of the project may be envisioned that were not determinable before beginning the project. Every team member must stay flexible and be willing to modify content and flow as the project matures.

Product Launch

After the process of Trouble Shooting → Component Planning → Task Assignments → Project Production → Beta Testing, comes the long awaited day of launch. It is recommended that the first formal offering of
the course be to a small group of students who will also be involved in recommending changes and/or additions to the project. However the process is never over as the site will have to be continually monitored for updating web references and for monitoring each area for learning effectiveness.

When Good Courses Go Bad: The Anguish of Online Dysfunctionality

Dianne L. Conrad
University of Alberta
Edmonton, Alberta, Canada
dianne.conrad@ualberta.ca

Abstract: An online course dies a miserable death amidst learner, instructor, and administrative angst, its brief life illustrating not only the importance of online community but also the conditions in which it can exist. Students' limited energies must be nurtured in a focussed environment and supported by teaching expertise that understands the delicacy of this balance.

Introduction

In the short, dramatic history of online learning, we, the believers, revel in our success stories. Watching our risks bear fruit brings satisfying moments for deserving educational pioneers. This narrative tells the story of an online course gone wrong, resulting in dysfunctional community. It uses as a backdrop the literature of social learning theory, community, and constructivism and demonstrates the critical importance of design, emphasizing key differences between assumptions underlying classroom teaching and those underlying online teaching. It also highlights the delicacy of the learner-instructor-content interaction and the trust and respect that bind it together.

Setting the Stage: Design Issues

The course was developed by a seasoned classroom instructor in collaboration with an experienced distance educator for an online master's program at a large Canadian university. A group of 13 adult learners, all professionals in their fields, embarked on their learning quest with enthusiasm and passion.

But their energies quickly paled, their participation all-but-died, their ultimate evaluative responses were disheartening. What happened?

The course looked good online. WebCT was the platform. Modularized online notes were supplemented with a text and a package of readings. We had attended to the design features that are understood to be necessary to online success (Anderson & Garrison, 1998; Bullen, 1998; Stacey, 1999) and we built in interactive activities to instill "community." Among other things, WebCT allows for a social discussion forum, a calendar, and private in-course email exchange. Each of these features was utilized to aid coherence, community and clarity.

Materials were sent out early with a letter from the instructor outlining the course, his expectations of learners, reading, assignments, and important dates. Because the major assignment involved learners forming into project groups, detailed project instructions were set forth at the outset with an exhortation from the instructor to begin forming groups. This information was delivered to learners both in hard copy and on the course website.

Learning activities for each module included short “Notes” sections, written by the instructor specifically for this version of the course; relevant discussion questions, drawn from the assigned readings; and reminders of the ongoing course assignment tasks. Overarching the weekly content modules and discussion was a major group project. As a part of the project, groups were to post bi-weekly progress reports for all to see. An individual research paper, due at the end of the course, comprised the final assignment.

Lights, Camera, Action: And Then What Happened?

Student evaluations described an unsatisfactory learning experience, a poor distribution of energies (theirs and the instructor's) and a resultant impatience with online learning. Samples of responses included:

- I did not learn as much from this course as I hoped. Perhaps it is because the WebCT forums were rather sparsely contributed to.
I needed more timely feedback. Where is the instructor? I have to proceed without him.

The instructor tried to increase online discussion but people were generally not responsive.

Instructor did not offer enough direction or advice. Online discussion was not well facilitated.

Online forum should be been more structured to motivate students to participate.

Instructor must be more involved and certainly be more helpful.

The conferences on WebCT did not have good continuity.

Denouement: The Analysis of Failure

One month into this 13-week course, the instructor issued an impassioned “Help! Input Requested” message to students, realizing both intuitively and from feedback that the course was struggling. Complicating the fall-out from an inherent design problem, a series of interpersonal dramas began to unfold – the result of instructor inexperience with online teaching. Both issues are examined below.

A basic design flaw in the course’s assignments resulted in a strident fracturing of students’ attentions and learning energies. A type of “community schizophrenia” developed. In short, students were asked to undertake a major group project that got underway at the beginning of the course. Their allegiance to time and creativity was thereby funnelled into sets of small groups from the outset. At the same time, their attention was requested to develop a sense of community in fora created for large-group discourse. While building community online is recognized as advantageous to constructive learning (Jonassen, 1992) in this case its development was fatally thwarted: subset communities that fulfilled learners’ needs for interaction were established at the small-group level; learners with finite amounts of time to devote to their learning activities chose to invest their time where the greatest payoff of marks lay – in the group project. Student interaction with community, measured in postings, was very low: 54% of the students posted less than 10 messages; 31% posted 10-20 messages; only 15% posted more than 20 messages. Total postings were 173. (Courses of comparable length and size can easily engender 2000+ postings in a semester.)

A second, damning contribution to the downswing could be described as the “cult of the personality”: faculty previously successful in F2F venues, skilled in the application of personal power to learning situations, perceive themselves to be suddenly rendered impotent without the physicality of experiencing learners visually and personally.

In this case, the struggling instructor threw his teaching energies into supervision of the small-group projects, himself jumping ship from the poorly-attended forum discussions, giving them the appearance of virtual ghost towns. Students and instructor became increasingly disheartened and lonely.

A new book on communications by Peters contends that “In the end, the presence of others, their proximity and available to touch, is what matters.” Those of us who have created and taught successfully online know that we can work around the absence of traditional “touch.” However, the downward spiral of this course would probably not have occurred in a F2F environment, where the physical presence of the instructor would have mitigated the first signs of dysfunction within the group. Trapped by distance, with no solidarity and good faith waning, the course unraveled like a ball of wool – design, learners and instructor scattered like anguished pieces of yarn across the unforgiving Internet.

Abstract: The purpose of this study was to examine whether the use of a computer system developed to support informal interactions in an online learning environment increases the interaction among course participants and helps reduce their feeling of isolation while working in an online course. The universe used in this experiment consisted of five graduate students who agreed to participate in this research given their interest in the subject and their academic profile. The course was centered on the discussion of selected readings and mandatory assignments related to those readings. In general, participants affirmed that the educational experience using the system was satisfactory and were willing to take more online courses using the system, since they considered that the experience had been enriching when compared to other distance education they had taken in the past.

I. INTRODUCTION

The lack of interaction between students and professors, particularly in online courses, is stressed by the fact that students do not have well-defined schedules nor specific places to access course materials and engage in learning activities. In fact, Blanchard (1989) states that the lack of direct interaction between students and professors is a severe limitation of distance courses, even if compensated by other benefits. In traditional learning environments, interaction among students and professors can have an important influence in student performance (Chickering, 1969; Endo & Harpel, 1981; Feldman & Newcomb, 1969; Jacob, 1957; Terenzini, Theophilides & Lorang, 1984; in Lamport, 1993). In remote courses the opportunities for these interactions are limited even though their importance has been highlighted (Barnes & Lowery, 1998).

Traditional learning environments provide opportunities for formal interaction, mostly during regular lecture hours. In addition to this, hallways and cafeterias as well as in the classroom while waiting for a class to begin provide opportunities for informal interaction. These opportunities are generally non-existent in distance education.

According to Kraut et al. (1990), informal interactions are those that do not have a defined schedule or place, are spontaneous and not planned. In distance learning environments, besides the formal interactions, mentioned by Gunawardena (1995), informal interactions are of great importance since they provide the means for the establishment of a social presence favorable to learning (Gunawardena, 1995; Gunawardena and Zittle, 1997). The use of computer-mediated communication in these learning environments allows for all students, regardless of their gender, ethnic group, social class, or with special physical or emotional challenges, the same opportunity to interact with their classmates (Mower, 1996). Pascarella et al. (1978) found evidence that in traditional learning environments students with frequent informal interactions had better academic performance than predicted from their pre-enrollment characteristics, whereas students with few informal interactions tended more often to perform below expectations.

In distance education, asynchronous electronic tools play an important role, allowing interactions among students and between students and the professor. Some of their advantages are: flexibility in the continuous communication of the group and freedom from restrictions of space and time, but the same asynchrony presents a serious disadvantage in terms of the response time required by the instructor or student to
respond to a request. Student interest might decrease because of these delays while fostering feelings of frustration and loneliness.

One of the main challenges of distance education is to alleviate the isolation felt by students. Face to face encounters and telephone calls have been used in the past to maintain personal communication among participants. These solutions however, require additional resources and might be difficult to implement in large distributed groups.

Based on our experience with this problem of limited communication and interaction among participants in online courses, we designed, developed and currently use a software tool meant to encourage informal interaction and reduce the feeling of isolation among students.

II. INFORMAL INTERACTION SYSTEM

CENTERS (Collaborative INformal InTERaction System) allows students and instructors who access a course's web site, to be aware of, and interact with, others visiting the site at the same time. The following is a typical scenario that illustrates the characteristics of the system:

A student logs into the system and reads the task assigned to him for the day. While reading the assignment, he gets confused with part of the material but realizes that one of his classmates is consulting the site and sends him a message, asking if he can clarify the doubt. The other student responds with his opinion while mentioning that he is not sure whether his answer is correct. Then they notice that the instructor of the course logs into the system and send him a request for interaction, consulting him on the issue they are discussing. The instructor responds clarifying the matter. The characteristics of CENTERS are the following:

1. It allows lightweight interactions in the context of online courses. These interactions do not require the additional overhead found even in e-mail or discussion forums.
2. It allows web navigation in a completely natural way, without interferences, since the display of the system occupies only a small amount of space in the screen and the user can decide to navigate anonymously if so he wishes.
3. It displays and updates information about users connected at the same time. When a new user enters the site all current users are notified of his presence while their names are displayed on his own screen (see left frame in Figure 1).
4. It provides two mechanisms for textual communication with other people who are connected to the site: a chat and sending instant messages.
5. The user can use the two communication forms simultaneously; that is, he can send and receive instant messages from one user while in the middle of a conversation with another one using the chat.
6. It allows a user to quickly load the page that another user is currently looking at, this allows for synchronous navigation and facilitates the discussion of online material.

To help evaluate the use of the system the following features are included:

7. Stores the frequency of user access to the site with the following data: Name of the user, date and time of login and log-out, and IP address of the computer from which the connection is made
8. Keeps record of all messages, including the sender's and receiver's name and date and time when the message was sent.
9. Keeps a log of acceptance and rejections of chat requests.

Besides increasing the opportunities for informal interaction the system offers the advantages of its ease of use; its ability to synchronize users to the same web page, and its integration within the course documents, thus not requiring user intervention to install or configure any software. Figure 1 shows the main screen of one of the web sites in which we installed the system with four users connected at the time. The following section describes our experience with the use of the CENTERS system in an online course.

III. EXPERIMENT
The purpose of the study was to examine whether the use of CENTERS increases the interaction among course participants and helps reduce their feeling of isolation while working in an online course.

The universe used in this experiment consisted of five students from the Masters in Education and Technology at the University of Colima, Mexico. These students agreed to participate in this research given their interest in the subject and their academic profile. The online course: Models of communication in distance education, is an elective within the masters program and lasted five weeks.

The course was centered on the discussion of selected readings and mandatory assignments related to these readings. Students were required to write summaries of each reading in preparation for their discussion and publish them in the course's web site. At the beginning of the course, students were asked to access the course's web site at least once a day.

The students were asked to complete two questionnaires, one at the beginning of the course, which allowed us to characterize the students enrolled in the class, and the second one at the end of the course designed to gather the students' impressions about the course and the system. The first questionnaire asked students their age, gender, and previous experience with online courses and electronic tools, as well as their expected needs of interaction with instructor and classmates for their successful completion of the course. The second questionnaire required students to evaluate the course, and give their opinion on the interaction opportunities provided by the system and its relation with their progress in the course as well as whether they felt in touch with the rest of the group. This questionnaire consisted of 25 questions, 12 with two possible answers (yes or not), 10 that used likert scales and 3 open questions.

The frequency of access and number of messages sent per student per week, obtained from the system's reports, is shown in Figures 2 and 3. The answers to the questionnaires revealed the following:

Figure 1. Screenshot of the online course with the CENTERS system.

IV. RESULTS

The frequency of access and number of messages sent per student per week, obtained from the system's reports, is shown in Figures 2 and 3. The answers to the questionnaires revealed the following:
Four out of five students estimated that the opportunities of informal interaction provided by the system were sufficient to solve their doubts, and one considered these opportunities to be scarce. The system’s records indicated that this last student had the lowest number of accesses and interactions.

All five students indicated that the possibility of interacting with their classmates and course instructor facilitated the group’s integration.

When asked to rate the quality of their interaction with the instructor on the scale: Excellent, Good, Regular, Limited, Null, all students judged their interaction as Good.

All five students reported that knowing who else was connected to the site at the same time helped them to feel like an active part of a group and to reduce the feeling of loneliness while working in the course activities. They rated as high the frequency with which they verified who else was simultaneously connected in the scale: Continuously (5), very often (4), some times (3), scarcely (2), never (1), the average was 4.2 or very often.

Four of the five students considered CENTERS to be useful in supporting group and individual activities. In addition, they qualified the system as an excellent aid for consulting doubt synchronously.

All five students considered that the informal interactions they had during the course helped them to better understand the study materials, since they could discuss their doubts with their classmates and instructor at the moment when doubts arose, since very often somebody else was connected at the same time.

In general, the participants affirmed that the educational experience using the system was satisfactory and were willing to take more online courses using the system, since they considered that the experience had been enriching when compared to other distance courses they had taken in the past. The answers to the open
questions indicate that the students considered that the informal interaction system was useful in the context of that particular class, but depending on the class activities, the system would have different levels of usefulness.

V. DISCUSSION

The course participants considered that the informal interaction opportunities provided by the system proved to be sufficient to satisfy their needs for interaction with classmates and the instructor. In addition, they considered that the system allowed them to participate in a greater number of interactions and that these interactions helped them increase their comprehension of the course and establish better social relationships with their instructor and classmates. The previous assertions became evident when analyzing the records generated by the system during the course and the answers to the questionnaire applied at the end of the course.

Additional comments provided by the students about their interactions in this course were that when they realized that somebody else was accessing the site they often sent messages with social content to that person. In the case of the instructor, they sent messages to greet and welcome him, which enriched the interaction student - instructor. In addition, the records of the system show that briefly after a student entered the system, several messages were sent to him by other students, and these greeting messages were always answered. In many cases, these messages worked as a preamble to a conversation related to the course, and students considered this educational experience as satisfactory. Quoting one student "this course was an enriching experience that changed my impressions about distance learning education and my study and collaboration patterns."

These results are in agreement with those reported by Pascarella, Terenzini and Hibel (1978) for traditional learning environments. They found that the informal interactions that students had with the instructors in some cases caused them to change the way they approached learning. Also, they support Spady's (1970) hypothesis, which states that informal interactions between students and professors have a positive influence on the academic performance of the former.

Among others, Jacquinot-Delaunay (1999) and Froissart (2000) emphasize the fundamental role of the variable "loneliness" or "isolation" among the causes for students abandoning distance learning programs, attributing it even greater importance than to a poor academic background. The results of the present study indicate that students in this course felt less isolated than in other distance courses that they had taken which provided only asynchronous means for interaction. If these results were generalized, this kind of tools could help lower the high attrition rate of this type of courses.

The results obtained in this study are encouraging, although not yet conclusive due to the limitations of the study, among other reasons by the small study sample, the profile of the participants (graduate students, specialists in educational technology), the short duration of the course, as well as the novelty of the system that might have contributed to its frequent use. Nevertheless, this pilot study encourages us to continue with the development of tools that allow and encourage informal interaction in distance learning.

Future work will consist of exhaustive testing of the system in online courses of different disciplines and academic levels in order to obtain and analyze patterns of informal interaction, if they exist, as well as to make comparisons between the requirements for interaction and the degree of satisfaction provided by the system.

NOTE: The documents for the online course described in this paper will be available at:

Abstract

In this paper, a model is presented that uses educational dialogues to support the design process for learning support systems. This model assumes an iterative life cycle model of software design, in which dialogue can be both an input (in the form of data for analysis) and an output (the result of learners using a well-designed system). The model has been derived from analysis of patterns of system development, and is related to approaches to cyclic models in educational theory and research methods. Two contrasting studies are used as illustrative examples of this iterative life cycle. The paper concludes by presenting a comparison between this approach and related developmental models: Kolb’s experiential learning and Action Research.

Introduction

In this paper, a model that uses dialogue to support the design of systems for learning is presented. This model is argued to provide a structure that links pedagogically motivated empirical studies of student-tutor-system interactions to problem specification and system design, and to result in the creation of learning technology systems capable of supporting learning. Contrasting case studies are presented to support this claim.

The importance attached to dialogue in this model stems in part from the work of Lipman (1991), who has argued that dialogue with a ‘community’, including teachers and other learners, can play an important role as part of an interactive learning mechanism. As well as articulating and explaining a concept to peers and tutor, the learner will also internalise these dialogues. Self-reflection on these concepts can be fine-tuned and regulated by reference to a history of external dialogues that the learner has been exposed to. Furthermore, new conceptual understanding can be ‘tested-out’ by exposing them to further external dialogue within the ‘community of learning’.

The model described in this paper has emerged from an analysis of ongoing development work. Its proposed strength is based on the realisation that common structures appear in a diverse range of development activities. In particular, this methodological framework has been synthesised from developmental work in subjects as diverse as Musical Composition (Cook, 2000) and curriculum design (Oliver and Conole, 1998; Kewell et. al., 1999b), demonstrating its transferability and validity. Our life cycle involves five steps: 1) problem specification, 2) educational dialogues and interactions are analysed and modelled, 3) results from dialogue analysis can be used as the basis for the design of technology-based educational systems and/or can be used to inform our educational practice, 4) a system is implemented that can be used to foster informed or principled educational dialogues, and 5) the system is evaluated with users. There are various issues involved with each step:

- At step 1 we need to decide if the application area is domain specific or more generic.
- Step 2 requires us to decide on what dialogue analysis and modelling techniques to use. There is a great number of techniques available, a discussion of which is beyond the
The scope of this paper (see http://www2.unl.ac.uk/~exbzcookj/workshop/workshop.htm for the proceedings from a workshop that included talks on some of the approaches that are possible).

- It is not a question of direct transfer of expertise from human to machine, but rather to use human expertise, when modulated (rather than transferred) to the computational medium, as an appropriate starting point for system design, which can then be refined on the basis of evaluation with users.

- When moving from design to implementation two possible choices are that of going for an implementation of the whole design in one go (the big bang) or of adopting an incremental approach that involves the repeated use of prototypes to elicit user requirements. In our model we favour the latter approach.

- Evaluation can also be problematic. As has been discussed, a common problem with evaluation is that designer will adopt a familiar strategy, as opposed to the most appropriate strategy, and hence will not be able to address key issues. In addition, it may prove appropriate to use different evaluation strategies at different iterations within the cycle (Oliver, Conole et al., 1998).

The purpose of this paper is not to provide solutions to all of the above issues. Rather, we make use of two studies to explore aspects of these design issues and develop a deeper understanding of this model. To this end, the paper concludes by presenting a comparison between this approach and related developmental models: Action Research and Kolb’s experiential learning.

The first study: a support tool for musical creativity and reflection

The first study used steps ‘1 through 5 and back to step 2’ of our life cycle to develop a learning support tool for musical creative reflection. Cook (1998) has used a dialogue analysis and modelling methodology to develop a computer-based pedagogical agent for supporting musical composition learning. Cook has explored the life cycle as follows:

1. **Problem specification.** Evidence supports the view that the use of sequencer software in the current training of composers in higher education appears to limit creative thinking in some learners.
2. **Dialogue analysis and modelling.** Cook (1998) has analysed teacher-learner dialogues in a formal manner; one outcome of this analysis being prescriptive models of interactions described at the level of participants’ goals and communicative acts (the latter being seen as a way of achieving goals).
3. **Design of technology-based educational systems.** These dialogue models (generated by step 2) were then used in the design of an computer-based pedagogical agent called MetaMuse (Cook, 2000) that was able to engage in interactions that aimed to promote creative reflection.
4. **Implementation.** MetaMuse, a pedagogical agent for supporting undergraduate musical composition learning, has been developed as a result of employing the design approach described above.
5. **Evaluation of the system with users.** MetaMuse has been evaluated with users (Cook, 2000). The sample size of users used in the evaluation, at 17, was small and so some caution is required when attaching significance to these results. Given this reservation, however, the results seem favourable: the total average response score for user attitudes to MetaMuse — elicited by questionnaire following a session with the system — was
3.63 (out of 5). However, a question that asked users to evaluate the help screens and messages provided by MetaMuse received the lowest average score (2.76 out of 5). The help screens and the language used by MetaMuse clearly need improving. (Provision of help was not a focus for the initial version of MetaMuse.)

Current work involves two related projects. The first project aims to improve the guidance and explanations provided by MetaMuse by incorporating model-based training techniques (new problem, step 1 of the life cycle). The goal of such an undertaking is to provide enhanced access to learning over the Internet in a domain (musical composition learning) that has traditionally had little computer-assisted support (i.e. training in musical composition). The second project involves an analyses of transcriptions of pairs of collaborating learners using MetaMuse (generated by the study described by Cook, 2000). The initial evaluation of the MetaMuse pedagogical agent (i.e. step 5 above) did not provide adequate insight into the following question (new problem, step 1 of the life cycle): what are the interactive means by which learning agents engage in cooperative problem-seeking? This second project will, therefore, commence from step 2 initiating a second loop around the life cycle (i.e. more dialogue analysis and modelling).

The second study: pedagogic re-engineering

In contrast to the first case study, the second project started from a different point in the model. This work concerns Media Adviser (Kewell et. al., 1999a), a software tool that supports “pedagogic re-engineering” (Nikolova and Collis, 1998): changing the structure of a course and the nature of its activities in order to take advantage of Learning Technology. The software supports a five-stage process of course description, analysis to identify strengths and weaknesses, identification of alternative teaching techniques, the creation of revised curriculum plan(s), and a planning process that identifies the steps needed to implement the new curriculum. Media Adviser comes into its own when used as a discussion artefact (Kewell et. al., 1999b), and consequently dialogue has been used as an integral part of the tool’s development (Oliver and Conole, 1998).

The project involved implementing a software tool based on an existing design, and then testing this with users. This then led to the refinement of the software tool, involving an analysis of users’ dialogue, redesign and re-implementation.

4. Implementation. The specification for the functionality of Media Advisor and a high-level design outline was given to the project team, who implemented a prototype.

5. Evaluation of the system with users. The software was used as part of a professional development programme, in which users worked together to address problems of curriculum design. This process was observed and video recorded, and the data was subsequently transcribed.

2. Dialogue analysis and modelling. The dialogues that were observed in the evaluation phase were analysed in order to identify strategies for use, potential refinements and unanticipated needs or issues.

3. Design of technology-based educational systems. The software tool was refined and extended to address the findings of the analysis phase. This included enhancing the visual feedback on course profiles provided by the tool, increasing the flexibility of its modelling component, and allowing users to customise content with a ‘save and load’ facility. In addition, the navigation through the software was re-thought.
4. Re-implementation. Following the design of additional functionality and revisions to the interface, the software was re-implemented.

In summary, then, this second study started at step 4 of the model, progressed to step 5, looped back to step 2, and then moved on through steps 3 and 4. Current work on this project involves a second round of empirical evaluation of the software tool.

It is worth noting, however, that this project work built on existing research that can be mapped onto steps 1, 2 and 3 of the first cycle of the model. What this illustrates is that any research or design process is likely to draw on the full range of steps in the process, but that these may be carried out by separate researchers or project teams. Consequently, any self-contained team may only be aware of their progress through sub-sections of the model.

Discussion

The cases described above illustrate the model elaborated in this paper. However, it is useful to consider whether this model is actually innovative, or if it is simply a re-naming of an existing approach. To demonstrate the distinctiveness of this model, this section includes a comparison between it and two other models, each of which relates to a different aspect of its process: Kolb’s experiential learning and Action Research.

Kolb’s experiential learning cycle

Just as systems design has shifted from system- to user-centred models, current theories of learning have moved from teacher-oriented to learner-oriented. Particularly relevant to this discussion is the model provided by Kolb’s experiential learning cycle (Kolb, 1984). This model can be taken to explain the process whereby the designer learns, through experience, how to improve their system. Importantly, the “experience” phase of this model relies on first-hand immersion in (or observation of) real use.

This cycle fails to capture key elements of the model described in this paper. At a simple level, the mapping between stages (e.g. abstract reconceptualisation and design, experimentation and implementation, concrete experience and evaluation) highlights that the process in this paper is geared towards a practical process, rather than reconceptualisation. It is a process that deals with creation and development, as opposed to being purely concerned with the development of knowledge.

Additionally, the design process involves a ‘scoping’ element (problem specification) that is missing from Kolb’s cycle. The experiential learning cycle assumes that the remit for learning is given; the model in this paper places the responsibility for this scoping with the designer.

Finally, experiential learning also leaves the nature of “experience” undefined; in this model, a tighter focus is presented. The purpose of this is to concentrate on dialogue as a key indication of learning and development (e.g. Lipman, 1991). This reflects the aim of this model, which is to design systems that successfully support and structure learning through dialogue.

Action Research

Action Research is closely related to experiential learning, and follows a similar cyclic model (see, e.g., Zuber-Skerrit, 1992). The key difference between the two approaches can be argued to be one of emphasis. Experiential learning is closely linked to personal development (sometimes in the guise of Action Learning; e.g. Peters, 1998), particularly through reflective practice. It also focuses on the acquisition and development of concepts. By contrast, Action Research normally includes an element of dissemination (making it
partly a public process, rather than an exclusively private one) and is concerned with the identification and development of theories. In particular, it is viewed as one method of building grounded theories, and has been linked to Habermas’ conception of the organisation of enlightenment in critical communities (Zuber-Skerrit, 1992).

This model described in this paper does not place such predetermined restrictions on the designer, but instead responds to their personal interests. As a consequence, the process could lead to either type of output, depending on the focus of the work and the context in which it is carried out. For example, immediate, local solutions can be created through the design process. In addition, more general schemas for design can evolve through the repeated application of this process, and through reflections on problems that emerge.

One way of determining which of these emphases will emerge lies in the choice of evaluation strategy employed during the cycle. Traditional assumptions about transferability of evaluation findings suggest that highly authentic approaches will be best suited to local solutions, whilst controlled evaluations will support generalisations (Oliver et. al., 1998). Either approach could be adopted within this model.

One commonality between all of the models discussed in this paper is the use of iteration. One of the strengths proposed for Action Research, for example, is that the process is incremental and iterative, leading to a process of continual improvement. A similar argument is made for the model outlined here. This is particularly true given its emphasis on users and learning, rather than systems and teaching, which lies at the heart of improving the usability of learning technology.

However, one key difference between these models concerns the scope of their iterations. Action Research, as with experiential learning, assumes that iterations will involve complete repetitions of the four-stage process. The model proposed here is more versatile; in it, iterations may occur at one of four levels:

1. Re-implementation of the tool, necessitated by the identification of bugs or errors
2. Revisions at the level of design, aimed at improving usability (a link back from evaluation to design)
3. Reformulations that respond to unexpected patterns of use or to the recognition that current analytical techniques have not adequately explained the structure of the dialogue (a link back from evaluation to analysis)
4. The identification of a completely new (but probably related) problem, requiring a distinct project that may replace or run in parallel with the original one (a link back to the start of the process)

Conclusions

In this paper, a range of cyclic models for development or the identification of good practice have been identified. A further cyclic model has been elaborated which focuses on the role of dialogue in design. This has been shown to be distinct from existing models, in particular in terms of the flexibility of its iterations and its focus. Two key features of this model are worth emphasising.

Firstly, it is iterative in nature, which necessarily engenders a continuous process of research and development. Above we have described how our model has already investigated a limited set of cognitive and social processes that underpin the process of creative system design and innovation.

Secondly, it illustrates how existing models can be adapted and customised in order to provide a detailed and relevant step-through for design processes in specific areas. Indeed,
because of the diverse domains presented in our two studies, we claim that our model has a high degree of transferability and validity.

The current version of this model represents at least one iteration through a reflective cycle, such as that of Action Research, for the authors. It draws on the identified models, and on experiences of applying these in a research context. Reflections on these experiences identified refinements and changes, and also commonalities between practice in different research projects. These reflections lead, in turn, to the model described above. This can be viewed as an attempt to develop a theory that can be used to explain and structure the design of systems. The next step will be to undertake further iterations of self-reflection in order to refine the model further. One aspect of this will be to consider how this model relates to project management and to the structure of research projects. The work will involve applying the refined model, both to further iterations of the cases described in this paper and to new projects, and then further developing the model based on these experiences.

Building Tissues: Computer-based experimentation in plant tissue design

Glynis Cron, School of Animal, Plant & Environmental Sciences, Univ. of the Witwatersrand, South Africa; Tim House, South Africa.

"Building Tissues" is part of a hypermedia package "Constructa Plant" that aims to address some of the conceptual difficulties students have with understanding plant anatomy and provide an interactive tool for learning about the structure and function of plant tissues and organs. The "Building Tissues" section of the package allows students to experiment with (in the sense of trying out) various design elements for tissues created to perform a particular function. Students are required to select a function that their tissue should perform, choose the most suitable shape for the cells, cell wall thickening agents and cell contents (i.e. the presence of organelles such as plastids, mitochondria and golgi bodies and a single vacuole, such as is normally found in plant cells). Alternatively, the student may decide that the cells making up a particular tissue should be empty/hollow (i.e. dead, containing no protoplasm). Cell arrangement and connection must also be specified and the size and position of pores, if required to allow for flow of substances between the components of the tissue. Feedback on the completed design is given concerning its performance and suitability for carrying out the specified function. Students may then, on the basis of the feedback, go back and alter specifications and "retest" these changed features. This design trialing activity aims to move away from students rote-learning tissue structure and to rather promote understanding of the relationship between structure and function.

Students proto-testing the package enjoyed the creative nature of the Building Tissues section of the package and felt that it had promoted and/or reinforced their understanding of structure-function relationship in plant tissues. Pre- and post-testing of the students' recognition of important structural features in tissues carrying out specific functions confirmed this perception.
One-to-One Technology: 
A Model for 21st Century Education?

By Jerry Crystal 
Director of Technology Integration 
Bloomfield Connecticut School District, USA

Abstract – This paper outlines, in an in-depth manner, how Carmen Arace Middle School in Bloomfield, Connecticut transformed itself from an 90% minority underachieving school with “bright flight” and very little technology into a nationally recognized technology innovator. The “digital divide” has been conquered through every student and teacher using the One-to-One NETSchools Laptop system through a school-wide infrared network. This report documents some of the dramatic changes in instructional methodology, professional development for staff, improvements in achievement test scores, attendance and reductions in discipline incidences. Samples of the school’s laptop curriculum can be found at http://www.blmfld.org/araceweb/cazine.htm.

The Community - Bloomfield, Connecticut is a town of unexpected contradictions and unfulfilled potentials that is working to create a school system for the 21st Century. Located in the north central part of Connecticut, it contains rural vegetable, tobacco and dairy farms as well as one of the best known insurance companies in the nation, Cigna. Adjacent to the state capitol of Hartford, it is a racially isolated town with a 90% minority school-age population. While having a long history as a racially diverse community, stretching back to being an original stop on the Underground Railroad, today its population is a dichotomy of white senior citizens and African American families and their children living side-by-side in quiet neighborhoods.

The Problems - But unfortunately, Connecticut Mastery Test (CMT) scores in the 1990’s showed a low level of educational proficiency that was reflected across all grade levels. On the CMT’s of Reading, Writing and Math Bloomfield’s failure rate was abysmal. 1996 Statistics showed that only 33% of our fourth graders, 17% of the sixth graders and 15% of our eighth graders met state goals on all three CMT tests. This highlighted that there was a major problem in our schools, especially in the middle school.

The Solution - That solution turned out to be the NETSchools laptop program. NETSchools Corporation, a private corporation founded by retired IBM executives, had a pilot program involving a specially designed student laptop called the StudyPro™. This infrared linked laptop was capable of surfing the Internet, providing email, word processing, and spreadsheet capabilities in a Windows95 framework and it was virtually kid-proof as well. With a magnesium case, water resistant keyboard, wireless network capability, and six hour battery life, students would be able to have an all purpose tool that could not only extend technology access in school but also at home beyond the normal school day. This technological tool gives students a 24 hour-a-day educational resource.

The Project - After extensive research, and serious discussion, it was decided to attempt this pilot project. But this tool would not be for just a small group of students and teachers, boldly it was decided to provide the program for the entire population of Carmen Arace Middle School, 800+ students 5th through 8th grade and the staff of 70+ teachers. It was an expensive undertaking, but from the minute it’s potential and promise were explained to our students and families, support began to build.

The Parent Teacher Organization spearheaded a community-wide intensive effort to bridge the “digital divide in our community. Through their diligent efforts support grew by leaps and bounds. That support culminated in a unanimous vote by the school board, in front of a standing room only crowd, to fund the two million-dollar price tag over a five-year period. The school board of Bloomfield had made a decision to silence the skeptics through a decisive commitment to reverse the backward slide and redefine the culture of education in our schools.

The Program in Action - Since that vote three years ago, dramatic changes have taken place in the middle school. But
this was not change for change’s sake; it was a comprehensive and detailed plan to ensure the success of the pilot project. Before a single student laptop was issued, teachers were provided with their own laptops and received six-months of intensive and ongoing professional development. This training addressed not only how to use the technology, but the most effective ways to use this new tool for changing instruction. NETSchools created a bank of Internet resources, the Automated Information System™ (AIS) that matched Bloomfield’s curriculum objectives as well as the state’s Connecticut Mastery Test (CMT) and CAPT objectives. They provided further training in effectively utilizing these resources.

The First Three Years - As we look at the time frame 1998-2001 we see that the culture of learning in the school has been redefined by this technology. We have moved away from the traditional idea of using technology for technologies sake and have moved toward creating a school-wide culture of using the technology as just another tool used to create an end product.

There has been a significant increase in “on-task” time with problem solving and higher order thinking skills becoming a daily part of the student’s routine. Students daily conduct research on the Internet during their classes. We have moved toward the concept of the “online textbook” that consists of websites that precisely match the curriculum and the teacher’s objectives for that day. Often a class may begin with a teacher saying “open the email I sent you today and click on the first link”. Using the NETSchools Desktop Monitor™ teachers can then “lock” students into a particular web page and avoid off task surfing of web sites. Students use the resources of the Net to download trade books a chapter at a time to their laptops thereby saving the cost of yearly purchasing of paperbacks.

The laptops change our instructional techniques dramatically. In accordance with the latest research lessons are performance based with well-defined product outcomes. Students use standard word processors to take notes and write reports; they construct a wide variety of schematic drawings, data charts and graphs using paint and spreadsheet programs. The finished product is then emailed to their teachers. Teachers see an improvement in the thinking skills and the technology skills of students. There is increased excitement from students and teachers.

Communication between school and home now takes place in the form of weekly emails from the school to parents via the student laptop. We also send out this Thursday Family Email to over 250 home and work email addresses. This process brings a three to five page email directly to parents. The email system has also created a new way for parents to communicate with their students. Parents can email their children in school to confirm plans or changes in plans and this lessens the workload on over-burdened secretaries in the main office.

The Internet has provided a wealth of opportunities to transform the traditional activities of our school. Our school website, http://www.blmfld.org/araceweb/cazine.htm is a constantly changing resource that is directly tied to what is being taught in our classrooms that week or that day. Students have designed web projects which get posted to the school’s website, as well as examples of quality work. Our teachers have started posting lesson plans with performance-based objectives as well, enhancing peer-to-peer professional development. Teacher teams have weekly technology professional development times in which they are constantly improving ways to use the technology in the instructional environment.

The Initial Results - These dramatic changes in instruction have helped bring about dramatic changes in the CMT scores at the middle school, this year 50% of our sixth graders and 58% of our eighth graders met the state goals in reading, a 35% increase over the previous year. Writing and Math scores have increased as well with comparable increases of approximately 25% in both areas (See charts on CMT Results four-year Comparison and Degrees of Reading Power 3-Year Progression).

Our students feel better about themselves as learners and the evidence shows that those feelings are justified. Recent achievements include:

- A team of our 7th grade girls placed first in the 1998-99 National History Day Contest, their topic “How Technology has effected Archeology” they had conducted email interviews with archeologists in the field as well finding 60 original source documents ion the internet. In 1999 -2000 another team placed first in the Connecticut History Day Contest for their project on the “1964 Voting Rights Bill” which included an email
interview with Rosa Parks.

- We have had numerous students take honors and first place awards in the BrainQuest and WORDMASTERS national competitions. On a daily basis our students interact and compete in online math and other subject area quiz sites. In each activity they build their own abilities and confidence that they have what it takes to succeed.

Unexpected Benefits for School Climate - Beyond pure academic indicators, we have seen unexpected positive changes in school climate; student and teacher absenteeism has decreased; discipline referrals have decreased by approximately 50% (See chart Carmen Arace Middle School Suspension Days) initial projections show that grade level retention will be down as well. There is more involvement of the community and families in the schools with increased attendance at school events. Likewise, more students are involved in after-school activities and clubs with approximately one quarter of the student population staying after school on any given day.

Unexpected Benefits for Teachers - Teacher’s roles have changed as well and their efforts have been recognized. Teachers serve more as facilitators in the learning process and feel more valued as professionals. They feel empowered and energized by these dramatic changes and this has propelled them toward achieving exceptional results. Teachers from our school now regularly present workshops at state, regional and national conferences. Staff recognition has included two Presidential Awards for Excellence in Math and Science Teaching 1998/99 & 2000/2001, Connecticut Arts Teacher of the Year 2000, a National Christian Educator Association Teacher of the Year Award 1999 and recognition of our principal as the Connecticut Outstanding New Principal of the Year 1998-99. Finally, we are proud to report that our school was chosen by the Connecticut Association of Schools as Outstanding Connecticut Middle School of the Year for 2000 - 2001.

National Recognition – Most recently, Carmen Arace Middle School has been featured in an article in the May 1, 2000 edition of TIME newsmagazine, an extensive feature article on the Associated Press wire service and a report on Cyber-ethics on the Cable News Network (CNN). Also, the National Association of Secondary School Principals, Lucent Technologies and Technology Higher Edge Journal rewarded our school’s technology initiatives and achievements through selection as one of the eight National Technology Excellence Awards winners. The Technology Excellence Awards program recognizes schools that enact far-reaching technology initiatives. The Technology Excellence Awards are designed to award true commitment, even when faced with limited resources.

If you are interested in finding out more information about Carmen Arace Middle School and the technology initiatives occurring here please contact Mr. Jerry Crystal, Director of Technology Integration at jcrystal@blm1ld.org or call 860-286-2622 x380

Generating Creative Vital Orientations in Cyberspace

Agata Cudowska
Department of Pedagogics and Psychology
Bialystok University
Poland
agat@noc.uwb.edu.pl

Abstract
In my article I would like to focus on the subject of generating creative vital orientations in cyberspace, discussing it within the following topics:

- applying the subject of creativity to the contexts of the present day and development of societies of knowledge;
- indicating the fundamental importance of the new media for the development of an individual's creative potential;
- presenting several examples of applying computers, the internet, and hybrid products as realisation of an individual's creative potential;
- constructing meanings of the author's idea of "creative vital orientations" within the possibilities of their development by the modern means of communication;
- attempt to indicate the connection between the chance of development of an individual's creative potential and utilising the influence of modern electronic devices based on neuro-transmitters as carriers of electromagnetic waves.

Conclusions of this article indicate the possibilities and opportunities created by virtual reality for the realisation of an individual's potential of development, increasing his or her creativity and its realisation and expansion to numerous fields of activity. Many of the discussed topics are hypothetical, however there is a number of premises that indicate the association of the two spheres is legitimate, and in the near future it can become more realistic than we are currently inclined to believe.

Creative vital orientation from transgression to trascendence

Category of vital orientations is particularly interesting to me not only because I proposed its definition and conception but also because it substantially reflects the dynamism and complexity of life of a contemporary person in the world of constant changes and unclear choices. In post-modern (informational and technological) societies it is especially important to develop a vital orientation that will enable self-creation to an individual. I perceive it as an evolutionary process and I place it on continuum from transgression to transcendency. Transgression means going beyond the limitations of human fate, which is evolution "from", and transcendency means pursuing and aiming "at". Self-updating and realisation of one's potential of development are quintessence of transcendency. Therefore, I proposed conception of "creative vital orientations" where creativity is perceived as an intersubjective value, i.e. one rooted in the axiologic conscience of a person, is a basic value. (A.Cudowska 2000b) I drew from the perception of creativity proposed by humanistic psychology (A.H.Maslow, C.R.Rogers) and definition of creative attitude by E.Fromm, as well as the philosophical concept of creativity being an indication of positive misadaptation to reality and realisation of an inner human need. (M.Szyszewska 1998) I further determine the conception of creative vital orientations on three datum planes: ontologic, psychologic and pedagogic ones. (A.Cudowska 2000)

The subject of this article is an attempt of reflection on possible application of virtual reality to generating creative vital orientations of an individual. It is not unlikely, on contrary it is highly probable that such reality will have stronger and stronger influence on creation of new activated society of jointly responsible and governing citizens in modern humanistic democracies. (E.Fromm 2000) Thus creative attitude of an individual toward himself/herself and toward the natural, cultural, and social world has special meaning. Only an individual who is creative in everyday life appears able to build new "ecohumanistic" society consciously. (L.Michnowski) 21st century is to see the development of information society (Naisbitt 1997) in which knowledge would be a strategic resource (Pachociński 1999) and source of well-being. Human knowledge resources double every six years and there is clear tendency for the time span to narrow. Capacity of computers for data storage and processing and their availability over the internet double every 18/12 months. (K.Denek 2000) In “Revolution of hope” E.Fromm anticipates possibilities of hypermedia for development of humanistic democratic society in which every individual would perceive himself or herself as an active participant of the governing process and have substantial influence on functioning of the whole organisation through activity in small groups.

New media and creative potential of an individual

Notion of creativity is present in all dissertations about future. It should be understood not as mere ornament but as response to the needs and demands of the present day. In today's societies, where post-figurative culture gradually becomes dominant (M.Mead), former illusions come true. Quantum computer was but a vision of Richard Feynman
recently, and nowadays it has been made and used for the first time. The machine uses the phenomenon of magnetic nuclear resonance: in the outer magnetic field there is some liquid in which atoms are placed. The nuclei of the atoms behave like small magnets as they arrange themselves parallel or anti-parallel to the lines of the magnetic field forces, which corresponds to zeros and ones of the binary code. We can alter location of the atom "magnets" to stimulate various physical arrangements (Wiedza i Życie 1999, 10). Perhaps next informatory revolution and the beginning of quantum calculations are not too distant. Consequences of such facts for an average computer user are difficult to predict nowadays, however they are probably impossible to overlook. This, however, does not change the fact that with all our knowledge, accumulated in the 20th century in bigger amount than during the entire history of mankind, we still cannot actually prove that it is our intelligence which makes us dominate other creatures (op.cit). There are many different theories nowadays as to how human body developed intelligence through its biological evolution. Even A. Russel Wallace as the co-originator (with K. Darwin) of the theory of creation of species had doubts whether human brain is not too complicated an organ to have its development explained only by the necessity of survival of species. After 120 years, this question of Wallace is still the central problem of brain evolution theory (K. Szymborski 1999). Creativity is strongly connected with intelligence which may explain how the nature of creation process has not yet been defined and it is so difficult to determine the predictors of development of creative attitudes in an individual which are desirable in the light of contemporaryness. The human being is born helpless and vulnerable and then spends most of his or her life learning things. They commit their time and energy to competition with other people and use their intelligence to solve problems they have mostly created themselves (op.cit). Even though we spend considerable parts of our lives educating ourselves, the traditional school system has minute achievements in the field of moulding creative orientations and creative attitude to life. There is a common opinion supported also by research (see A. Gurycka 1989), that in the process of education the natural and creative expressiveness of a child, their cognitive curiosity and commitment are successfully destroyed until there is little of them left for life of an adult. An adult person, as E. Fromm puts it (1989), mainly wants to know things while many scientific discoveries were made thanks to surprise with and interest in something that had been looked at without astonishment by others.

The Internet and civic society

It seems very appropriate to search for possibilities of stimulation of creativity and moulding of creative vital orientations through technologies offered by computer and the Internet. Not without a reason was the latter called the biggest garbage heap in the world, however we cannot ignore the fact that it is also a treasure chest with the newest information which will be available at schools perhaps in ten years, or never at all. We can already read newspapers and magazines on-line, there are information services and some publications are available only in the electronic version. It is estimated that in Poland there are approx. 2 millions of the internet users, which is still not much if compared with other highly developed countries. The technological revolution started in Poland in 1990 by connection with the international computer network EARN, via junction in Kopenhaga, certainly has some social repercussions, too, also in the field of education. Register of the most common keywords submitted to the popular search engine of Netoskop indicates that the number of people who look for specific information in the Internet is growing. Research shows that an average 'online' Polish person is young and well-educated (students and academic degree holders are more than 80% of all users). Online contacts create specific subculture whose members create virtual societies that use a special language code. During the flood of 1998 Polish Internet users showed great commitment and civic responsibility as their quick exchange of information enabled providing better aid to the victims. Thus we can speak about creation of small groups as proposed by E. Fromm in his conception of humanistic management (2000). Within those groups there is the process of exchanging information, discussions, and making decisions. There is active participation of an individual in the problems of his country or of specific communities. The hypermedia seem to comply with all conditions mentioned by E. Fromm, which are essential for creation of a civic society. The conditions are: small number of participants in discussion so that it is free from demagogy or manipulation and so that there is access to objective information. In this context we can also mention the "Virtual Commune" project realised in Raszyn near Warsaw. Within three years all the residents will obtain access to the Internet with the modern line of AOSL and the local online services are being created. Settlement of office matters, contact with the doctor, shopping, bank account management, borrowing from libraries with online videos and books, reading electricity and gas bills, discussion with local administrators, it all will be possible online. It is not difficult to imagine what consequences such situation will have for the local community, and then also to the whole society. This can influence the moulding of vital orientation of individual, because it profoundly changes the way and quality of experiencing our everyday reality. Nevertheless, it would be naive to expect that such changes may take place automatically. Certainly it is necessary to prepare the people so that they can adapt to the cyberspace as active subjects participating in creation of the social reality. Most probably, without proper education this cannot be realised. Especially as the Internet can be a medium for broadening the user's social contacts. American sociologic analyses seem to prove it by showing eg. that the electronic media users, the Internet users among them, are almost standard "electronic citizens," community of young people (between 20 and 40 years old) 48% of whom are females. People who use the net particularly often, so-called "super-connected" ones, believe in democracy and free market much more than the "non-connected" ones. In the light of the creative vital orientation category I am interested in, it is important that such people make changes willingly, that they perceive the idea of variation as the motor of development, they are more tolerant than average and they know more about the social and cultural life. They spend more time...
considerable amount of neurotransmitters that are responsible for learning, pleasure, and creativity. Aryeh Routtenberg, science. The concept seems even more realistic if we notice that electric stimulation of certain areas of brain produces a human emotions and changes of different states of conscience emit different kinds of energy (which was discovered by). The idea of applying electrostimulation to moulding of creative vital orientations does not have to be completely unreal. If puncture points it stimulates the electric field of body and has deep influence on the mind, reactions, and behaviour. The Hampton). Electrostimulation can also cause setting of bones and regeneration of organs. When delivered through acupunctures it stimulates the electric field of body and has deep influence on the mind, reactions, and behaviour. The evolution of the planet (S.Ostrander, L.Schroeder, 1997). Music, and especially Baroque music, is a famous and modern "superlearning" techniques may provide particular inspiration for the process of self-development and realisation of one's creative potential. There are many indications that such techniques offer possibilities of a more creative life. R.A.Wilson believes that the new generation of appliances that stimulate the mind will become the turning point in the evolution of the planet (S.Ostrander, L.Schroeder, 1997). Music, and especially Baroque music, is a famous and long-applied (though not on large scale) means of expanding creative potential of the mind. Such music synchronises waves of both hemispheres of brain, it increases the ability to acquire knowledge, speed of this process and duration of remembering. This fact can be very important also for the process of generating and developing creative vital orientations, changing old thinking patterns and most of all stimulating the will to change it.

Hypermedia as supportive for education

Possibilities offered by cyberspace in terms of moulding attitudes, adding new meanings and establishing more contact with the individual are seemingly still underestimated by the educators. The better prepared for the use of informationary media the individual will be, the more profound their ability of realising their creative potential. Virtual reality seems to create opportunities for overcoming the limitations of information access and division into the better and worse informed ones. Proper education and development of hypermedia and Internet skills may be a successfully eliminate the phenomena of social exclusion and marginalisation. Cyberspace may then offer chances for human development, however it can also create some dangers for them. Itself it is neither of the two and it is subject to what people make it. Although nowadays the assumption of virtual reality as a place for successful development of creative potential of individuals may seem unreal, as the task had not been realised for such a long time by the traditional education system. We cannot exclude it completely either, though, because by overcoming the shortages and limitations of traditional education it creates new forms and areas for dialogues. Online meeting creates a chance for educators to get beyond the economical client-institution paradigm in favour of a more democratic and partner-like relationship. The teacher is given a chance to build his real authority on his knowledge, skills and personal qualities instead of the illusory authority he has because of occupying a specific place in an institution. I believe that it is important to notice these opportunities already, even if their realisation requires more time, because reflections on this problem should go before the educational practice.

In my opinion, creative vital orientations of individuals can be formed only within areas of variety and possibility of making choices where the role of the teacher (master, guide) regardless of technical possibilities of the media is constituent for the process of "maturing" of individuals and of creating their own vital orientations. It appears also that modern "superlearning" techniques may provide particular inspiration for the process of self-development and realisation of one's creative potential. There are many indications that such techniques offer possibilities of a more creative life. R.A.Wilson believes that the new generation of appliances that stimulate the mind will become the turning point in the evolution of the planet (S.Ostrander, L.Schroeder, 1997). Music, and especially Baroque music, is a famous and long-applied (though not on large scale) means of expanding creative potential of the mind. Such music synchronises waves of both hemispheres of brain, it increases the ability to acquire knowledge, speed of this process and duration of remembering. This fact can be very important also for the process of generating and developing creative vital orientations, changing old thinking patterns and most of all stimulating the will to change it.

Electrostimulation vs development of creative potential of an individual

Some of those mind-stimulating appliances are a positive "dividend" from the "cold war" period (eg.). (eg. using electromagnetic fields on people). The Russian were the first to draw a map of frequencies that affect emotions, memory, mental strength, or conscience. So called "toxic frequencies" were developed that enabled electronic destruction of memory. Many positive phenomena like means of expanding memory (op. cit) were discovered at the same time. There is scientific evidence for those phenomena, although they may resemble science fiction stories. Western scientists confirmed eg. excellent results of brain electrostimulation method in treatment of memory disorders caused by alcoholism or drug addiction (recovery time 3-5 days). Electrostimulation causes production of new cells in brain and regenerates its functions (eg. research in University of Wisconsin, University of Luisiana, in Molecular Biology Lab, or in Hampton). Electrostimulation can also cause setting of bones and regeneration of organs. When delivered through acupuncture points it stimulates the electric field of body and has deep influence on the mind, reactions, and behaviour. The idea of applying electrostimulation to moulding of creative vital orientations does not have to be completely unreal. If human emotions and changes of different states of conscience emit different kinds of energy (which was discovered by Dr Leonard Ravitz from Yale), then also energy used as the media can produce specific emotions and states of conscience. The concept seems even more realistic if we notice that electric stimulation of certain areas of brain produces a considerable amount of neurotransmitters that are responsible for learning, pleasure, and creativity. Aryeh Routtenberg,
neurologist from Northwestern University, was one of the first scientists who made that discovery (op.cit), which led to invention of Brain Tuner 5+ by physicist Bob Beck (magnetic field expert). The tuner emits frequencies of three ranges of neurotransmitters that are essential for a human being: enkephalin, catecholamine and betaendorphin. B.Beck arranged those frequencies in beams and collected together 256 frequencies like a resonating musical chord. The tuner is smaller than a walkman and it is operated by a 9-volt battery. It is equipped with electrodes with stethoscope-like endings adjusted to the hollows behind ears where the acupuncture points transfer electrostimulation. Research conducted eg. in University of Wisconsin proved efficiency of BT5+ in treatment of drug addicts, increasing intelligence quotient and improving performance of nervous system. The tuner – harmless to human body – needs to be worn only 20 min. a day and people who use it claim that it strengthens memory, enhances learning process, boosts energy, helps to concentrate and reduces pain, anxiety and depression. Thus, nowadays there are possibilities of developing the creative potential of an individual (Ostrander, Schroeder 1997).

Recognition of opportunities and dangers

Application of the subject of creative vital orientations to this topic seems therefore justified, however the possibility of moulding such orientations with appliances emitting electromagnetic waves positive for human beings may seem rather unrealistic. Nevertheless, in the light of huge expansion of human knowledge and development of its branches it is not unlikely to become more realistic in the near future. This demands for realisation of possible dangers.

One of serious dangers involved in application of cyberspace to development of creative potential of an individual is certainly limitation of the individual’s “vital space”. Closing it within limits of virtual reality, channelled thinking process within infohighway limited by the capacity of a specific net search engine. Also the use of electromagnetic fields on a human being may certainly raise many doubts of ethical nature. We do not have absolute knowledge of what effects neurotransmitter stimulation of specific areas of brain may result in. Such non-researched areas imply the necessity of very careful and deliberate attitudes to currently observed effects of treatment by such appliances as BT5+ mentioned above. Cyberspace, electromagnetic waves and even sounds undoubtedly offer us many new possibilities of supporting creative potential of an individual. And although I believe that we should remain considerably skeptic and careful about them, we also ought to realise the opportunities and hope that they create for adaptation. Of new values in the life of an individual. Perhaps many current barriers against application of the hypermedia no longer lie in technological limitations but in our thinking patterns, dominated by left hemispheres of our brains and affected by our one-sided rationalism (D.Goleman 1999). This article is an attempt to inspire overcoming such barriers within our perception of creativity, opening to new and intriguing spheres, and anticipation of possible scenarios of development of creative potential of an individual.

The Rhetoric and Reality of Change: A Model for Supporting Higher Education Faculty Adoption of Web-Based Instruction

Dr. Michael Cunningham
Dr. Teresa Eagle
Dr. Beverly Farrow

Marshall University
100 Angus E. Peyton Drive
South Charleston, West Virginia U.S.A. 25303
mcunningham@marshall.edu t.eagle@marshall.edu bfarrow@marshall.edu

Abstract: The faculty at Marshall University historically have used a model of distance education for non-traditional graduate students that involved driving 1-3 hours to teach in remote sites. This strategy is changing as web-based instruction is rapidly becoming an important tool in meeting students’ needs. The faculty have developed a unique strategy for dealing with the issues related to this significant change in delivery strategies.

History
Marshall University is a regional university located in southern West Virginia, USA, serving 16,000 undergraduate and 4,000+ graduate students. Within the university, the Graduate School of Education and Professional Development (GSEPD) has as its mission the delivery of graduate education to a rural and widely dispersed population. The GSEPD offers MA, EdS, and EdD degrees in Leadership Studies, Counseling, School Psychology, Elementary and Secondary Education, Special Education, Reading Education, and Humanities. On-line course delivery at GSEPD began with one course which was developed in the Fall of 1997 by two faculty members. From this early effort, the participation in this method of delivery has grown to 35 full-time faculty members and a cadre of part-time faculty involved in teaching over 400 web-based courses, greatly enhancing the outreach effort of the school.

Challenges and Opportunities
The evolution from the two initial faculty members to the current extended team of web-based instructors has presented a melange of both challenges and opportunities. The challenges have included (a) the labor intensive nature of developing and maintaining web-based courses, (b) the need to provide system support, (c) the complexity of staffing and workload issues, (d) faculty and student training needs, (e) class size, (f) academic integrity and quality assurance, (g) fee structure, (h) course ownership and intellectual property rights, (i) the availability and access to library services, (j) the provision of student support and training , and (k) the environment of constant change. The collaborative and informal environment already in existence
among the faculty in the GSEPD was critical in addressing these challenges. This informal peer-support network presented the opportunity for faculty mentoring. One important element of the support system was a monthly group meeting of faculty members using web-based instruction. This activity allowed faculty members to share pedagogical ideas, explore technical issues and solutions, and brainstorm strategies for new course development. Other issues addressed were student training, demonstration of "best practices", and evaluation of web-based instructional strategies. This users' group welcomed faculty members who were new to web-based course delivery and offered support and encouragement.

In recognition of the need for additional support for inexperienced users of web-based instruction experienced faculty members designed and implemented hands-on computer sessions, provided one-to-one mentoring and conducted workshops for part-time faculty. Part of the mentoring process involved assisting new faculty users in training new student users. The faculty support process was also aided by a strong, informal relationship with the university instructional technologists and with computer services personnel.

Moving the academy from the rhetoric of change to the reality of change required incentives and support for faculty involvement and development. The Marshall University Graduate School of Education and Professional Development has provided encouragement, recognition, and financial support to attend regional, national, and international meetings, course development funds, purchase of hardware and software including laptop computers, ISP access and support, and the support to host regional WebCT conferences.

Outcomes and Lessons Learned

Inherent with new endeavors is the anticipation of outcomes and new information. One expected outcome of incorporating technology into a delivery system that has already experienced success in distance education was the compatibility with the historical mission of the GSEPD. Other expected outcomes were improved access to courses and programs, a more effective use of school operating funds, and a more efficient use of faculty resources.

Unanticipated outcomes resulting from the move to web-based course delivery included (a) increased faculty attention to course planning and development, (b) increased cross-disciplinary interaction, (c) a change in the role of full-time faculty, (d) an evolving role for part-time faculty, (e) the emergence of a differentiated staffing model, (f) the use of a broader array of instructional strategies, (g) a renewed sense of collegiality and sharing, (h) an expansion of resources available to support courses, and (i) the emergence of new strategies for student assessment.

The acquisition of new directions and strategies resulting from implementing change is often well worth the reality of change. As a result of adopting and incorporating web-based instruction we learned that (a) the age of the faculty member did not appear to be a variable in determining receptivity to web-based instruction, (b) web-based instruction is appropriate for most types of courses, (c) not all courses lend themselves to asynchronous delivery, (d) web-based instructional delivery expands the
range of instructional strategies, (e) web-based instruction is most appropriate for non-
traditional students, (f) opportunities for student-teacher interaction are increased, (g)
web-based instruction is effective in achieving student outcomes, (h) web-based
instruction costs as much or more than traditional instruction, (i) web-based instruction
requires more, not less, faculty resources, (j) web-based instruction requires more
faculty preparation time and is labor intensive, (k) the need for articulating the purpose
for using web-based instruction is crucial, and finally (l) faculty support systems for
delivery of web-based course delivery must be more informal than formal, available on
demand, and include one-to-one faculty mentoring.

Summary

In conclusion, the GSEPD faculty continue to be challenged and encouraged by
technology-based course delivery. The informal, peer support network adopted by the
faculty, the student support and training component, and the recognition and incentive
system offered by the administration has contributed to a model that supports a regional
mission of graduate course delivery to a rural, widely dispersed population. The rhetoric
of change is good, the reality of change is hard, and the results of change are
rewarding.
The Canadian TeleLearning Network of Centres of Excellence: A National Multidisciplinary, Multisectoral Approach to Catalyzing Innovative Research and Effective Online Learning Practice

Joanne Curry
Tele Learning Network of Centres of Excellence
Time Centre, Simon Fraser University at Harbour Centre
Vancouver, BC Canada
V3B 5K3
joanne@telelearn.ca

Abstract: The presentation will present a state-of-the-art strategy developed by the TeleLearning Network of Centres of Excellence to spearhead research in online learning applications, train students, transfer knowledge and technology, and inform practice and policy development in schools, post-secondary institutions, and workplaces. In particular, opportunities for international collaborations will be identified.

The TeleLearning Network of Centres of Excellence (TL•NCE) was selected by the Canadian government in 1995 to be Canada’s Network of Centres of Excellence for online learning research, development, and commercialization. CE has become a key repository for evidence and research results as well as solutions and strategies for the effective use of network technology in schools, post-secondary institutions, workplaces, and for continuing education. The TL•NCE is one of the few organizations in the world that integrates research, practice, and private and public sector interests into an ambitious interdisciplinary program. Since 1995 it has been transitioning from a national to a global program involving 45,000 individuals in over 200 organizations from 44 countries.

The TL•NCE is led by Dr. Linda Harasim, who is recognized internationally as a pioneer in designing and delivering online education and training and demonstrating the effectiveness of new collaborative learning models supported by computer networks. Dr. Harasim is joined by 80 leading researchers in education, computer science, and engineering science from 24 Canadian universities. Research teams work in partnership with client organizations such as the Bank of Montreal, Bell Canada, CANARIE Inc., C2T2 (the college and institute system in British Columbia), IBM Canada, Industry Canada, Nortel Networks, Silicon Graphics, and Cisco Systems.

The TeleLearning NCE Research Program

TL•NCE researchers are developing and testing leading telelearning approaches based on collaborative learning and knowledge-building. The research conducted within the program is broad and includes study of learning models, socioeconomic factors, and technologies. Research themes include Kindergarten to Grade 12 Education, Post-secondary Education, Workplace Training, and Educating the Educator.

By applying and developing innovative new approaches based on solid pedagogy developed and tested for delivery using networked learning technologies, TL•NCE researchers have made significant advances towards improved student learning. Research results have been reported in more than one thousand publications. In the post-secondary Virtual-U field trials, over 15,000 students and 500 instructors have participated in courses delivered via Virtual-U. The data includes data on instructional designs, impact on instructor and student workload, user satisfaction and practice, quality of learning, assessment issues, and student completion rates. Research showed that 100% of 100 courses studied in depth used collaborative learning approaches with high levels of completion.
The TL•NCE Knowledge and Technology Transfer Program

In addition to its research program, the TL•NCE is mandated to disseminate its research evidence to educators and trainers and provide advice to policy makers and decision-makers in the public and private sectors. A few examples that show the range of research and dissemination initiatives that have positioned the TL•NCE as a knowledge repository and advisor of choice are listed below.

Research Reports and Workshops: The TL•NCE serves as a lightning rod for issues and opportunities in online learning or eLearning. Public organizations and private companies approach the TL•NCE for information on the latest market developments and research results. Quarterly workshops are organized such as "21st Century Business Models for Online Education Markets" which brings leading experts and organizations together to explore strategies for success and pitfalls to avoid when deploying new business models in this emerging market. The TL•NCE research report series has proven to be a valuable resource for those seeking to stay abreast of topics and included a competitive analysis on online post-secondary education (www.telelearn.ca/g_access/news/comp_analysis.pdf) and the costs and benefits of Web-based training (www.telelearn.ca/g_access/news/costbenefit.pdf).

Creating New Companies: The TL•NCE is contributing to the growth of the supply sector in Canada. Researchers are developing and enhancing a variety of software tools and systems based on collaborative learning and knowledge building and 9 new spin-off companies were created to provide access to leading products and services. Recently, an eLearning virtual incubator, InVentures Incubator Inc. (www.inventuresinc.com), was launched to support the creation and success of new online education companies.

Transferring Knowledge: The TL•NCE serves as a primary channel to a network of online learning experts, providing consulting, training, and assessment services in all sectors of education and training. Research results are communicated through workshops, a research report series, monthly e-mail bulletins, and a Web site. A new company, TeleLearning Solutions Inc., was created to provide a premier access point to the knowledge of TL•NCE researchers and members, as well as other organizations across Canada and internationally. The TL•NCE has a goal to increase the capacity of the industry in Canada by attracting and training hundreds of young Canadians to the field. Over 300 graduate students have or are currently participating in the TL•NCE research program. The 150 graduating students have been quickly recruited by universities and private and public sector organizations interested in the student’s specialized knowledge and multidisciplinary, multisectoral experience.

How You Can Become Involved

On April 1, 2002, the TL•NCE begins a second phase of its program that will expand successful pilots and create large-scale testbeds that are part of organization- and institution-wide strategies. In addition to a continued focus on learning processes and outcomes, research teams will study advanced technologies and intelligent networks, business and organizational change models, and global and cultural issues. TL•NCE researchers are seeking new international research collaborators in addition to learning from related research conducted around the world. The following are several other ways an international organization can link with the efforts of the TL•NCE:

- Attend TeleLearning'2001 in Vancouver, November 10th to 13th with the theme, “The Future of the (e)Learning”. Last year's conference drew over 500 delegates from countries such as South Korea, Mexico, Denmark, Taiwan, the United Kingdom, and Finland. See www.telelearn.ca/conference.

- Participate in the Global Educators' Network, www.vu.vlei.com/GEN/welcome/welcome.html, an international online forum that brings together communities of educators to discuss the latest issues and lessons learned in online education. Currently, more than 500 participants from 40 countries are collaborating online.

- Contribute to the Open Source Initiative, TL•NCE’s model of choice for evolution and distribution of software tools. Join a cadre of international research organizations in China, Finland, and the U.K. that have already committed to participating in this initiative.

For Further Information: See www.telelearn.ca
The flexible learning model at LITU

Ethel Dahlgren, University of Umeå, Sweden; Camilla Hälgren, University of Umeå, Sweden; Per Andersson, University of Umeå, Sweden; Siv Johansson-Långström, University of Umeå, Sweden; Svante Häggström, University of Umeå, Sweden

The poster will present and demonstrate the model of learning that has been developed for courses in the field of Information and Communication Technology in Learning Environments. The learning model is constructed in the same way for all courses, irrespective of content or target group. Students on campus and on distance courses meet a learning environment and learning resources consisting of four main parts; a course manual, an electronic conference and mail system, a CD-ROM, and web-based information. Regarding the role of the instructor, he or she is more of a coach than a transmitter of knowledge. The students are, in turn, responsible for taking the opportunity to study in a flexible problem-based learning environment and devoting great care to plan for and carry out their learning process. Our experience is that the students take on their learning and assignments in a more independent way.
THE 'REDI' PROJECT. On-line educational resources for the development of professional multimedia skills

Ricardo Dal Farra, National Ministry of Education, Argentina

The National Institute of Technology Education, part of the National Ministry of Education in Argentina, began a few years ago to work on new educational profiles trying to integrate the complex necessities of the work world of today with the basic concepts (in all senses) that the school should transmit to students. From those profiles were developed a group of modular curriculum structures for the secondary level, being one of them the Technical Vocational Pathway in Multimedia Communication, based on a competences learning process proposal.
Reinventing the TV and the Video in School: Report of an Workshop for Training Teachers

Luciana Rocha de Luca Dalla Valle
TV Escola – Brazil
Education Institute of Parana – Brazil
lucdalla@onda.com.br

Dulce Márcia Cruz
Federal University of Santa Catarina – Brazil
dulce@eps.ufsc.br

Abstract:
The present paper is a report on the workshop "The Use of TV in School", which brought teachers from the public educational system of Paraná state into contact with the Brazilian educational television channel called TV Escola (School TV), and which made possible the discovery of new uses of the television and VCR in the classroom. Faced with the challenge of creating a class with pedagogical material and a VHS tape for a group of people who had just met, the teachers developed works of quality related to each one's creativity in order to allow oneself to dare, transform, alter, to touch and to give movement to the event. With candies, colored papers, box of different shapes and sizes, magazines, scissors, discussions, smiles, tears and testimonies, the teachers accepted the challenge and recreated the TV Escola, allowing for a new path for a higher quality education in our country.

Introduction

TV Escola is a program developed by the Distance Education State Bureau, of the Brazilian Education Ministry, and consists in a TV channel which airs its shows via parabolic antenna to the elementary schools and high schools. The necessary kit for the reception and use of that channel (consisting in a parabolic antenna, a television set, a VCR and 10 tapes to start the recordings) is distributed for free to all the Brazilian public schools with over 100 students. Inaugurated in 1996, that channel airs 14 hours of programs every day, being that 4 hours are always new. Due to its great variety of titles, it constitutes an option of technical and pedagogical quality for the perfection of the education in our country. Its main purpose is that the shows it airs be recorded in VCR tapes for later use by the teacher in the classroom or in his/her own professional training and updating. In addition to its shows TV Escola also offers printed material, which is sent to the affiliated institutions as educational tools for the use by the teachers. Examples of such printed material are the Revista da TV Escola (School TV Magazine), the Cadernos da TV Escola (School TV note books), and the books of the Série de Estudos de Educação à Distância (Series of Studies on Distance Education). In spite of all that effort, however, a significant number of teachers do not use the videos from TV Escola in the classroom.

In order to increase the number of technological tools available the government of Parana state gathered 400 teachers from a number of cities in that state at the CETEpar (Parana Center of Excellence in Technology) in an event called “Tecnologia educacional: uma janela para o futuro” (Educational technology: a window to the future), which took place in December, 4 to 8, 2000. During that event, which aimed at offering to the teachers an opportunity to make contact with different technologies and varying ways of using them in their pedagogical practice, we offered the workshop “A utilização da TV na escola” (The use of TV in school), which will be described bellow.

Methodology
The workshop was developed with eight different groups of teachers, totaling 40 work hours and 240 participants. Each team of 30 teachers worked for three hours in the afternoon and two more hours in the next morning. Such a division in two work stages made it easier for the teachers to think about the issues which were developed earlier, allowing them to sustain their opinions with a greater confidence.

The beginning of the first stage was directed to stimulate the integration of the group. Thus, as they arrived at the mini auditorium, the teachers received candies wrapped up in colored paper. Their look of surprise was difficult to conceal. When all were seated, we asked them to gather according to the color of the candy paper they had received. Once more the movement and imbalance in the room indicated that the work groups were beginning to organize. With the teams already formed, we allowed some minutes for each one to introduce himself/herself, and what we could see was a series of timid and embarrassed speeches. We did not interfere with that tense mood. Following that moment, each team was asked to answer a question related to general issues about the TV Escola, and eventually a real cooperation among the members of each group occurred. When all teams had their answers ready, we called their attention to their own reaction to what had been asked from them: when they gathered around a common idea (to answer the question), they began to behave like a team and, consequently, got better results. Once again there were smiles and positive comments from the teachers. It was easy, then, to relate such a practice to the kind of work we were suggesting. That was how they should fathom their work with the TV Escola: different, creative, daring, but above all, a team work. Little by little their resistance was being conquered. The teams commented on the surprises they were experiencing in the workshop.

Now feeling more comfortable, each team received a box (there were four boxes of different size, shape and color, which represented different kinds of schools). Inside them, in addition to the answer to the specific question made to each team, they found scissors, newspapers, paper, colored pens, glue, magazines and a tape with a show of the TV Escola. Except for the tape, the rest of the materials were the same in every box; the choice of such materials was not random and they were selected because they were objects easy to be found in any school of the public system, where they worked. After they received their boxes, each group had 60 minutes to plan a class resorting, necessarily, to the VCR tape of TV Escola, together with the other contents in the box which they found appropriate. At the end of that work hour, they had to present their classes to the rest of the group. The challenge was to be creative in order to elaborate a different class.

We noticed that each team found great difficulty to plan a class. As we observed, their main problem was that they could only approach the tape under the light of their own field of knowledge. They asked that we changed the tapes, not understanding that they were the ones who had to change. Following some additional minutes of imbalance, and finding support in our interventions, the teams began to shape their ideas and to break with their own paradigms. Classes began to be presented which emphasized new interpretations of art pieces, new approaches to literary texts, dramatizations of the life cycle, parodies, drama and plays to be sung. All that based on the tape by TV Escola. Teachers once afraid of using the VCR were finding in such a technology the possibilities for pedagogical innovation. Such a finding could be witnessed in the over 200 evaluations received, among which one deserves to be quoted: "I've never imagined that one day I would use a VCR to give a class on physical education. Now I understand that video tapes can be used in any discipline, we have only to look at it with attentive eyes." Our own attentive eyes noticed that at the end of the second stage, after following the presentation of a number of classes, many teachers were taking note of the strategies which were used there in order to apply them to their own future classes. Some of them, whose background had been built over 30 years of teaching practice, talked to us about their fear that technology would eventually take their place. There were many smiles and some tears from those who were experiencing a stage of professional growth and needed to leave behind many fears and insecurity.

**Conclusion**

The answers which appeared during the workshop just described suggest one path to be followed in order to allow technology to take part in the educational reality of efficient work: to train the teachers. The answers obtained by our workshop did reaffirm the idea that for an effective use of technology in the school an efficient teacher is necessary. Sometimes the teacher must be rescued, hidden as he/she might be behind his/her fear of the new and the fear of daring. We can proudly claim that in our workshop we have rescued many, but that is just the first step in the process of legitimating the School TV Project in Paraná state. There is still a lot to research on the ways to integrate more and more the professionals in education into the TV Escola in order to create significant and lasting realities in the partnership between technology and education.
Participant Interaction Models and Roles in a Computer Supported Collaborative Learning (CSCL) Environment: A Malaysian Case Study

Esther Gnanamalar Sarojini Daniel
Department of Mathematics and Science Education, Faculty of Education
University of Malaya, 50603, Kuala Lumpur, Malaysia
esther@fp.um.edu.my

Abstract: Three models of participant interactions in a web based instruction course were identified among a diverse group of seven adult learners in this paper. The three models were named the cyclical model, the hierarchical model, and the parallel model. The cyclical model depicts the interactions of the computer, instructor and the learner as in a cycle, the hierarchical model views the instructor and the computer as the participants in a level higher than the learner, whereas the parallel model sees the learner and the instructor progressing parallel to one another mediated by the computer. The roles of the participants in the CSCL class as perceived by the learners are also discussed.

Introduction

Since Lev Vygotsky's introduction of the “Zone of Proximal Development” (ZPD) (1962) continuum, it has been advocated that social interactions can act as scaffolding in the construction of knowledge. Based upon this Vygotskian view of learning as social phenomena and experience, Ryder (1994) states that new knowledge is constructed by learners as they engage in dialogue. In the late eighties, there was an effort to individualize learning processes and hence the solo learner model was prevalent in the CSCL studies (Lehtinen, Hakkarainen, Lipponen, Rahikainen & Munkkonen, 1999). However this gave rise to the concern that social interaction in the CSCL environment was being omitted. The present trend in ICT is far removed from this original situation. Current theories on knowledge building emphasize the socially distributed nature of cognition especially in the CSCL environment. Distributed cognition is believed to be a process in which individual cognition is extended and stretched to accomplish and achieve something that an individual would be unable to achieve alone. According to Norman (1993), cognitive processes can also be distributed between humans and machines. Distributed cognition as stated by Salomon (1993) can form systems consisting of the individual learner, peers, instructors and cognitive tools. Cognitive tools apparently reduce cognitive processing load (Pea, 1994). Salomon (1995) envisions the computer as a trigger for a chain reaction and therefore the computer must be allowed to serve in the way it serves best that is enhancing learning from mere recitation to exploration, manipulation and creation. Crook (1994) made a distinction between interacting around and through computers. Interacting “around” computers means that computers can be considered as tools that encourage face to face communication between participants in a CSCL environment. Interacting “through” computers according to Crook (1994) means the use of networks such as the Local Area Network, the Wide Area Network, and the Internet, which has various mediating tools such as the e-mail. The e-mail for example can be used as an asynchronous or a synchronous communication tool. Koschmann, Feltovich, Myers and Barrows (1995), say that interactions in the ordinary classrooms are synchronous and sequential. According to Agostinho (1997), an example of “flexible interactivity” in a CSCL environment is, “...how one group is able to review and participate in the dialogue of the other group. Also a member of one group can join the discussion of another group or send a message to a member in another group without disturbing the flow of discourse. The facilitators meanwhile can monitor the entire process... (p.6)” The scenario described would be a hard act to follow in the traditional classroom. Brna (1998) highlighted four different collaborative models in the CSCL environment that have different goals. They are (i) whether collaboration involves synchronous effort of a task or whether is the task divided into various parts and each handled by different collaborators, (ii) whether collaboration is a state or the process, (iii) whether collaboration is seen as a means to achieve some learning goal or whether the collaboration is in itself the end goal, and (iv) whether the participants in the collaboration state or process are aware of the existence of the formal contractual relationship (p.1). Laurillard (1993) in her conversational framework model put forward eight primary workflow actions that occur between the instructor, the learner and the interactive medium (the computer), which are, (i) instructor describes conception to be learned, (ii)
learner describes the conception, (iii) instructor rediscovers the conception, (iv) learner redescribes conception, (v)
instructor sets up micro-world activities, (vi) learner interacts with the micro-world activities, system provides feedback, and (viii) learner modifies actions based on feedback. Lehtinen et al. (1999) reiterate that social interaction between participants makes certain that each other’s viewpoints are considered. This in turn develops the participants’ metacognitive skills, as they become aware of their own knowledge.

Another important factor to consider is that, in an ever-dynamic CSCL environment, the interactions among participants and their roles are beginning to take on new and unique patterns. Lerner (1997) concludes that because of the introduction of technology, the learner’s role has shifted from “being taught” to “learning” and the instructor’s role from that of an “expert” to one of “collaborator” and “guide”. Javid (2000) calls teachers as “coaches” and “facilitators”. Strommen and Lincoln (1992) say that the teacher assumes roles such as “project manager” and “tutor” and becomes part of the team and not the heart of the classroom. In spite of an enormous amount of research on the interactions and roles of participants in a CSCL environment, Sims (1997) cautions us by saying that the dynamics of communication between the learner, instructor and the cognitive tool are as yet not fully understood. However it is clear from research that interactions between humans and machines take place at a physical as well as a cognitive level in a CSCL environment. Also the roles that participants assume are much more varied and complex in these learning environments. Cerratto and Belisle (1995) say, “With the functionalities afforded by new networked technologies, there is now the potential for students to share their learning experiences with each other and also interact more dynamically with their tutors.” (p.1). Just who is the tutor and who is the learner in a CSCL environment? This paper explores models of participant interactions that surfaced and the roles of each participant in a Course-On-Line, Masters of Instructional Technology Programme in the University of Malaya.

The KOL Course, Sample and Data

The Course-On-Line or Kursus-On-Line (KOL) ran for 14 weeks, that is one Semester. The course content focus was the integration of information technology in instruction. The instructor (also the author), used the University of Malaya’s template (http://mdc.um.edu.my:88/mdc/mainmenu.nsf) for all KOL courses which can be classified as the Content and Support Model if based upon Mason’s (1998) models of existing on-line courses. The instructor was directed to teach basic skills of word processing, presentation graphics, databases and how to use these skills in their training sessions. The problem that faced the instructor was that the seven adult learners were from professions that were profoundly different and transfer of knowledge efficiently in a direct manner to such a diverse audience was difficult. Hence, although the course content was planned and executed as wanted by the administration, the issues of learning theories and human-computer interaction was introduced by the instructor to provide a more wholesome view. The KOL was a class based upon synchronous as well as asynchronous interactions and deep cognitive engagement. Assessment was authentic. Class participation was emphasized and presentations were essential and assessed. In addition, the learners were asked to prepare a Glossary of terms learnt throughout the course as well as to keep a personal journal, which was assessed. The author wanted to identify and describe how adult learners perceived the dynamic interactions that were occurring during the 14 weeks of class and how these interactions affected participant roles. The discussion in this paper emerged from data acquired from the instructor’s observations and conversations with the learners, which was kept as a personal journal. Data was also taken from the learners’ journals.

Models of Participant Interactions: Perceptions of Learners

The prevalent interactions in the KOL class were perceived in different ways by the 7 adult learners. These ideas were revealed during one of the conversations with the learners in week 11, when they were requested to draw how they visualized the interactions that were going on between the various participants in the room. Each learner had constructed his or her own conceptions and will be discussed in turn.

Case 1: Han

Han, from the Ministry of Education drew an interesting general cycle of interaction model (Figure 1). The interaction between the learner and the computer and between the learner and the instructor was intense. This interaction was mainly in verbal form in the classes and also via e-mail at other times. In his Week 1 journal entry
Han states, "... I guess most of us including the lecturer have somehow benefited from the discussions". In Han's view, the interaction between the instructor and the computer apparently is not as intense and involved mainly input of course materials on the web.

**Figure 1: Han’s Model**

**Case 2: Sham**

Sham’s (from the electronics field) perception is shown in Figure 2. Although her general idea was generally cyclical, the learners had various phases (1 to 4) of interaction with the computer. Phase 1 was interacting with the computer, to read, explore and understand the content provided. This was followed by phase 2 where she interacted with the computer in writing, thinking and rewriting the presentation that she had to prepare each week. At this phase she is also interacting with other members of her group via the email. Phase 3 she says was the most enjoyable as she and the computer added graphics and colour to make her presentations interesting. The last phase (phase 4) was during the weekly class discussions. Here she drew a sub cycle to show intensive interaction, between her, her peers, the instructor and the cognitive tool (the computer).

**Figure 2: Sham’s Model**

**Cases 3, 4 and 5: Dura, Afie and Una**

These three learners’ models although interviewed separately, were exactly the same as shown in Figure 3. Una was involved in human resource development and Dura and Afie were involved in the preparation of courseware for instruction with no prior experience with learning theories or human-computer interaction. According to them there was very straightforward intense interactivity between all three participants in a cyclical manner. Once again the vehicle of communication was verbal (one-to-one and group discussions) and via the e-mail.

**Figure 3: Dura’s, Afie’s and Una’s Model**
Case 6: Yang

Yang was involved in IT training such as word processing, presentation graphics and such, with no background in learning and instructional processes. Her model is shown in Figure 4.

![Diagram of Yang's Model]

Yang’s idea was that there were two levels. Level one saw the instructor and the computer as equals. The learner was in level two. The interaction between the computer and the learner was one of receiving information and preparing presentations. Whereas the learner interacted through conversations and e-mail with the instructor and learnt through the feedback received. Strangely, according to Yang the interaction between the instructor and the computer was not apparent.

Case 7: Nas

Nas was from the Malaysian national automobile industry. His idea of a parallel model was unique (Figure 5).

![Diagram of Nas's Model]

Nas felt that the instructor and learner interaction progressed on parallel roads in the teaching-learning process. The computer was the mediating factor in this instructor-learner interaction.

The interaction models described above can be grouped into three main classes, namely cyclical, hierarchical and parallel. The Cyclical Model (Cases 1, 2, 3, 4, and 5) has four important characteristics namely (i) there exists a general cyclical interactivity between the three main participants in a CSCL environment as shown in Cases 1, 2, 3, 4 and 5, (ii) generally there seems to be more intense interactivity between the learner and the instructor, between the learner and the computer when compared with the instructor and the computer (Case 1), (iii) the interactivity between learner and computer seems to take place in phases (Case 2), and (iv) during class discussions and presentations, there occurs intense interactivity (high cognitive engagement) between learner and instructor, between learner and computer, between instructor and computer, between learner and peers, between peers and instructor and between instructor and peers (Case 2). The Hierarchical Model (Case 6) portrayed a more traditional setting. Yang gave equal importance to the computer and the instructor and both were placed at a higher level than the learner. When questioned as to why she perceived the participant interactions as such she said, “The computer to me presented the content. You gave the human communication necessary. Without the instructor, the learner cannot be motivated”. Hence the hierarchy in her eyes. The interactivity between the instructor and learner and between the learner and computer is evident. Interactivity between the instructor and the computer was apparently not perceived at all, perhaps because the instructor puts up the learning materials on the web before the start of the class to be accessed later by the students. The Parallel Model (Case 7) portrays the instructor and the learner being partners on the same path of constructing knowledge. It was a total opposite of the Hierarchical Model by Yang. Nas in his journal entry wrote, “The inputs derived from the students would help the facilitator to enhance her knowledge and understand the student needs and expectation. The instructor is there, but did not make herself prominent. Learning was dynamic. Learners learnt from the instructor and vice versa. It has been an enriching experience for both.” Heath’s (1997), stated that Computer Mediated Communication calls for a collaborative and group-oriented approach which encourages discussion, opinion sharing, reflection and debate. This kind of human-human communication is prominent in all three models perceived by the learners in this study.
Instructor, Learner and Computer roles in the KOL, CSCL Environment: Perceptions of learners.

Although conventional labels for the instructor such as "facilitator" and "guide" were given, several novel labels also emerged. Han described the instructor's role as one of "provider of opportunities and democracy". He felt that the opportunities provided gave him freedom (sometimes too much he says) and control over his own learning. He also states that another role of the instructor was one of an "authentic assessor". He says in his Week 2 entry, "...in class tonight everyone took turns playing roles of recaller and listener." When asked why "recaller", he explained that as presentations and discussions were taking place he had to recall what he had read and understood. Sham labeled the instructor as a "disseminator of information", "a model for constructivism", besides being a "stimulator". Her perception was that the instructor placed large amounts of information via the net every week. Then by example lead them to how they can construct knowledge from the vast amount of information given. The encouragement given in class stimulated her to construct as deep a knowledge as possible. She writes in her journal, "...she (the instructor) listened intently to our discussions and wrote down all the key points picked up from the presentations on the board. This later was constructed into the gist of the debate that went on." Nas's labels were "provider of guidance", "a mediator", and "social negotiator". When probed further apparently these roles assumed by the instructor made Nas feel comfortable and free, which triggered his intrinsic motivation. Yang also called the instructor "a motivator". Dura's journal entries reflect a colourful picture of a journey. She wrote, "...is the navigator, the others and I are sailors and we are going to cruise the tide together". Afie felt that the instructor was a "key". When asked to explain he said, "As a key to unleash creativity and communication". Una who was nearby agreed and said, "My fear to try has been unlocked". Una in his journal also stated, "Instead of telling us about the subject matter, we were given a situation and asked to reflect and discuss the pros and cons". Afie also felt that the instructor at times was like a "host of a show". This was because the instructor had to facilitate and direct questions to the "panel of experts" (the learners) in the class. All the labels given to the instructor reflected similar thoughts found in Lerner (1997) and Javid (2000). The current ideas predominant about distributed and shared cognition between the instructor and learners also seemed to be implied here. The learners also felt that they were given a lot of control over their own learning. The instructor apparently stayed in the background, while stepping in at crucial times to steer the class.

Han described the computer as his "late night companion" who helped him to finish his presentations and assignments. Dura called her computer "a friend" with whom she interacts constantly. Sham labeled the computer as her "assistant". It helps me to remember better". Afie said, "the computer helps me to simplify things". Yang said, "the computer presented content". She went on to say the computer "made things flexible". All the learners called themselves "readers", "analysts", "creators", "shareers", "critics", sailors, and "collaborators". Clearly the above ideas discloses once again that the computer is a cognitive tool that essentially helps to intensify human-human interaction, as the presentation and direct transfer of information from the instructor to the learner becomes secondary and the construction and creation of knowledge utmost.

Conclusion

As the CSCL environment continues to evolve, the actors are as chameleons that adapt to roles to gain the utmost from the environment. Riel (1994) has rightly said that the role of the teacher would shift from being the prime source of knowledge to that of expertise in learning. He said, "A good teacher should be an expert learner, who can facilitate students' learning and information seeking". Bannon (1989) stated that the computer besides being a tool, could also be a medium, which mediates collaboration with individuals. As a conclusion it can be said that this case study has uncovered some insights into how a diverse group of adult learners perceived interactions between participants in a CSCL environment and how they utilized this dynamic interaction to construct and create knowledge out of a colossal amount of information.

Gender and Online Discussions: Similarities or Differences?

Abstract: The study examined how female and male graduate students (n = 13) participated in the discussions in a web-based course by analyzing the interactions of a mixed gender group in both online chats and threaded discussions. The discussions were drawn from 4 different weeks over the semester. The purpose was to discover whether differences by gender in terms of types of substantive (that is, directly related to the topic) and non-substantive (not directly related to the content) messages existed. In addition, students were surveyed about their computer and Internet skills and their attitudes toward the course. Results indicated that overall students’ discussions included the 2 main categories of substantive and non-substantive. Both males and females had the greatest amounts in the responding and reacting (2 of the substantive types) overall. Results were mixed in terms of any differences between gender in terms of the 2 main categories over the four weeks. In terms, of the non-substantive types, females tended to make slightly greater numbers of chatting and supportive comments than males. Comparing male and female discussion leaders, the female showed greater amounts in those same 2 non-substantive types than did the male leader. It appears that any differences in male and female messages are diminished when looking at substantive remarks in online discussions.

Introduction

A number of universities and colleges are adding or converting traditional courses and programs to online learning environments. These WBI courses require not only a different design and delivery of the instruction, but also a different form of engagement on the part of students with the course materials, other students, and the instructor. These learning environments require not only active, but interactive participation through the interchange of ideas with all participants (Davidson-Shivers, Muilenburg, & Tanner, In press, 2000; Davidson-Shivers & Rasmussen, 1999).

This interchange of ideas occurs mainly through online chats or threaded discussions. The computer-mediated communication (CMC) literature documents the dynamics of online discussions by various forms of communication patterns, processes, and purposes (Walther, Anderson, & Park, 1994; William & Merideth, 1996; Piburn & Middleton, 1998; Wojahn; 1994; Jeong, 1996; McCormick & McCormick, 1992; McConnell, 1997; Sherry, 1999; Hara, Bonk, & Angel, in press; Davidson-Shivers, Muilenburg & Tanner, 2000). Wojahn’s (1994) and McConnell’s (1997) studies focused on gender differences in communication patterns in online discussions. For instance, Wojhan (1994) compared the adult communication patterns by gender using a bulletin-board communication format; she found that the length of communication patterns of men and women was very similar. McConnell (1997) when comparing patterns of men and women in mixed gender groups found that men tended to talk more and longest in computer conferencing, but that women may be less disadvantaged in conversations in online than in face-to-face. Davidson-Shivers, et al. (2000) observed contrary findings in that men in a majority-
male group made dramatically less statements in online discussions in a web-based instructional course when compared to the women in a majority-female group.

The original study of Davidson-Shivers et al. examined the interactions in chats as compared to threaded discussions in a web-based course. Students were randomly assigned to small group for comparison over a two-week period resulting in a majority male and a majority female group. The results indicated that the majority male group, tended to have fewer comments in the substantive categories of reacting and responding in both the chat and the threaded discussion in comparison to the majority female group. In addition, the majority male group also had a lesser amount of chatting and supportive comments compared to the majority female group. These findings are similar to face-to-face conversations within same gender groups (Tannen, 1990; Wojahn, 1994; McConnell, 1997). Were these findings unique to the situation and particular members of the groups? This unanticipated finding lead to further investigation as to whether there remained these differences in the online discussions when students were in a mixed gender group setting within the same course.

Purpose of the Study

The purpose of the study was to ascertain whether the mixed group sessions would substantiate the initial findings of the Davidson-Shivers, et. al. study. To gain a better understanding of the dynamics of gender in both online chats and threaded discussions in mixed group, 4 different weeks (fifth, seventh, tenth and fifteenth) from throughout the semester time frame were analyzed. The coding scheme that was used relates more to classroom activities than to communication types (as in Wojahn’s and McConnell’s coding schemes). The specific question was there a difference in the types of and amounts of comments made by males and females in mixed gender group discussion?

Methods

Participants

Participants in the study were graduate students (n = 13) in a required course for their degree programs of study from a southeastern regional university in the USA. Approximately two-thirds of the students were female. Based on the survey results, the majority of students reported that they had computer experience with some having less experience with the Internet and WWW. Participation in the discussions was a course requirement. Confidentiality of information was maintained by having surveys collected and coded by someone other than the instructor and the analysis of the discussions occurred after final grades were posted.

Course content, organization, and requirements

The course was an introductory course on trends and issues in instructional design. The course was organized by weekly topics with assignments and questions being posted to its website. Two or three questions were given with directions on how to post (either chat or threaded discussion) answers and replies. Students had a week to respond to any listserv question(s) and were also required to reply at least twice to other students’ responses during the week. Typically one additional question was scheduled for an hour and a half chat during the week. Chats were large group (whole class) in which most students were able to attend. Students were also assigned particular readings as preparation for discussing the weekly topic. They were also encouraged to draw on their own experiences, knowledge and skills. Both threaded discussion and chat could be copied and all of the chats were distributed to all members of the class. After the fifth week of the term, students were assigned as discussion leaders to facilitate the weekly discussions in both chats and threaded discussions with guidance from the instructor. The instructor participated directly in the online chats; however, less so when another student was the discussion leader. With the threaded discussions, she added her comments to a summary at the end of the week rather than commenting during the week.

Procedures

The following procedures occurred for gathering the data.

- Transcripts of the discussions for 4 different weeks were then coded using a coding scheme developed by the Davidson-Shivers et al (1999) based on the work of Piburn and Middleton (1998) and Williams and Meredith (1996). See Table 1 for the coding scheme. There were two threaded discussion questions and
Once chat for each of the four weeks; all of these discussions were whole class rather than students being divided into small groups.

- The researchers were trained to use the coding scheme and then coded each discussion transcript independently. The transcripts were coded by each completed statement/thought made rather than using a line-by-line method. The coding and analyses of the discussions did not occur until after the final course grades were posted. Complete sentences, incomplete sentences, and short phrases were considered as a statement if a new or different thought was presented within them. Incomplete sentences or short phrases were often used within the chat due to the speed and interactive nature of this format.

- Discrepancies encountered in the coding were resolved by review and discussion of the statement and the researchers coming to consensus.

Table 1
Types of Discussion Participation Coding Scheme

related to the topic directly. getting email back from the listserv... OR "How do I copy and paste the chat?"

7 Chatting Personal statements, jokes, introductions, greetings to one, etc. to individuals or the group

“How was your weekend?” OR “What is the matter with my typing tonight!”

8 Uncodable Statements that consist of too little information or unreadable to be coded meaningfully.

Typographical errors were the majority of the uncodable responses

9 Supportive Statements that although similar to chatting, there is an underlying positive reinforcement to the comment! Note: This category was added when researchers met about their coded transcripts.

“You always give such a well written answer! I enjoy reading your ideas and thoughts.” or “lol... cool idea!”

Data Sources

Survey

Data were gathered by a questionnaire distributed three times to the group. The survey asked students to report their capabilities using technology, web-based technology in particular, experience with the discipline, and other demographic data. They were also asked to critique the course as it progressed through the term in terms of technical difficulties, interest in topics, preferences to types of activities, instructional strategies used, and amount of work that this course in this format involved.

Coded Transcripts

The weekly units included two threaded discussions and one chat. The coding scheme used two main categories of substantive, messages that related directly to the content or topic at hand and non-substantive, messages that did not relate to the discussion topic. Every statement or sentence was coded using one of these 9 subcategories. (See above Table 1.) Both types of online discussions were coded for the types of statements per week and then averaged due to the disproportionate number of females to males in the course. The results are discussed are as follows.

Discussion of Results

The analysis showed that participants’ comments were made in all substantive and non-substantive categories in the chats and the threaded discussion, except that there were no uncodable statements in the threaded discussions and a few in the chat transcripts. (Note: Due to lack of space, the tables of results that will be provided in the paper presentation were omitted in this proposal.) Students overall provided more substantive statements either by responding to a question or reacting to another’s statements or comments than any of the other seven types. Since part of the course grade was based on their substantive participation, it is not surprising that reacting and responding would be high in frequency. In terms of the non-substantive category, chatting and supportive comments were greater than any of the other types for the total group.

When reviewing the substantive comments by gender, the findings are mixed in terms of amount of statements by week. In terms of the responding and reacting types of statements, the average number is greater for male students than females in the threaded discussions in week 5, but it was reversed in week 15. For Week 7 and 10, the average number of responding and reacting statements by gender was equivalent. The average frequency of responding and reacting statements during the weekly chats were fairly even with the exception of week 7 in which the females...
showed a greater number of those two types of statements. In comparing these results with the previous study by Davidson-Shivers et al., it appears that online discussions of either types may be equalizers in communication patterns by genders as Wojahn (1994) findings suggest when groups are made up of mixed gender.

With the non-substantive category of chatting, the statements in the was relatively low by comparison to and fairly even between genders for all 4 weeks in the threaded discussions. However, for the weekly chats, the chatting was low and even in amounts during the first 2 weeks, but increased as the semester progressed with it nearly tripling during week 15 of class for all students. During the last two weeks, the female students provided on average more chatting remarks than males in the online chats.

The average amount of supportive comments in the threaded discussions across weeks was even in number by gender with the exception of week 7 with a greater amount of supportive comments being made on average by the female students. In terms of the supportive comments made during the weekly chats, the average amount was even during weeks the first 3 weeks and the last week again showed the males providing greater amounts. For the online chat student discussion leaders, statements within these two non-substantive categories varied by gender. Both female discussion leaders (weeks 7 and 15) provided both chatting and supportive statements during the online chat whereas the male discussion leader (week 10) only provided chatting statements. The increase in non-substantive comments by students may be due to their becoming comfortable with web-based formats and with each other. However, it should be noted that some, but not all, of these students had on-campus courses (face-to-face) with each other that may have also helped them to become acquainted. The increase in amount of supportive statements by the female students may be indicative of a tendency for this gender to provide supportive comments to each other (Tannen, 1990) or acknowledge points made by each other (Wojahn, 1994). McConnell (1997) also suggests that men tend to support conversations at the end whereas women tend support conversations throughout the dialogue. This phenomenon may have held true for these students in online discussions as well.

Summary

Use of online discussions provides a direct and interactive environment in which students communicate with each other. Examining factors that influence these discussions are critical to effective participation in web-based instruction. Although the observations in the study by Davidson-Shivers et al., suggest that there may be differences between genders in online chats and threaded discussions, those difference might be explained by the type of group (same gender) that was used. In this investigation, examining the discussion statements of the same participants but in a mixed gender group, the differences appeared to be diminished in the four weeks that were examined. These graduate students reacted and responded to the topic at hand, chitchatted, and made supportive comments to each other were, for the most part, equivalent in type and amount of statements. As suggested by McConnell and Wojahn, perhaps females are less disadvantaged in online discussions than in face-to-face meetings after all. However, further study in the exploration of communication patterns in online dialogue is needed. The type of group—mixed- or same- gender—may make a difference in the types and amounts of communications between and within gender. In addition, further investigations of the discussion patterns with use of whole class and small groups need to occur as well. Finally, examination of communication patterns of children and adolescents by gender also need to be examined. All of these factors can affect the interactions of students in online discussions and ultimately, the success of web-based instruction.

Abstract: This paper describes the experience of conducting postgraduate students in an online seminar as part of an experiential, reflective course in interpersonal communication. It identifies some of the opportunities and challenges that online learning offer. Among these are the impact of technology, issues of participation, and patterns of communication. We conclude that critical reflection on experience is a difficult skill to acquire, even for people used to being taught in an interactive, participatory environment.

For the past 14 years part of an M.Ed. programme in “Communications, Education and Technology” has been taught experientially, with an emphasis on students’ experiences and their reflections on them. Tutorless reflection groups are a central element of each session and students are required to maintain a reflective learning journal. As far as possible the focus has been real world – exploring the patterns of communications within the group, rather than on sterile exercises. Recently, students requested that we provide opportunities for online discussion in line with changes in practice. This paper describes some of that experience. Like many postgraduate students returning to study after a number of years, they come with expectations of a passive student role and expectations of having to meet well structured, tutor-imposed deadlines. Accordingly, the first semester can be a culture-shock as students struggle to move from dependence on the tutor to interdependence on one another. Among the demands on them is they have to learn how to learn from each others’ experiences and knowledge. They also have to appreciate different patterns of communication arising from different cultures. There was little or no experience of using computers and none had taken part in an online conference previously.

Findings
There was not a great deal of activity in the conference as a whole, and none at all in two key areas which we hoped students would take advantage of: bibliographical data and reflections on the experience. There are a number of measures of engagement in cyberspace, from hits on the server to the number of words written. Clearly there are more qualitative measures, but these (for example discourse analysis) are beyond the scope of this short paper. Of the six non-participants, four were men and two were women. The activists – as measured by the number of contributions – were nearly all women, Rupert was the exception. He contributed the 3rd highest number of words through only two contributions. His statements, however, were well-formed and at a high end of the “spectrum of seriousness” (Davis & Holt, 1998: 321), perhaps influenced by his work as a journalist for a national newspaper. There are three themes we would like to analyse further: the impact of technology; issues of participation; and patterns of communication among those who did take an active part.

The impact of technology
The students were introduced to the software during the induction week of their programme. Students were therefore considered to be familiar with access and other features of the platform. Despite our beliefs, some still were not confident about how to gain access to the conference site. Nevertheless, in the post course evaluation session, Charles, whose only contribution was to ask for help, commented that the use of online conferencing should be included in the course and it might be useful to conduct the reflection groups online. This is, in our experience, not untypical. The nature of the course unit, and the learning that arises from it, develops insight and autonomy and moves students towards higher levels of interdependence. Charles’s recognition of the value of online discussion was a product of more mature thinking arising from his reflections on his and others’ learning.

A part time student was unable to access the conference as she did not have a computer at home or work and felt excluded from the experience. Part-time students can suffer from not having quite the same face to face (F2F) access to tutorial support or technology during the working day. In Nigel’s case, this meant that he did not attend the initial training session and he did not find the written instructions to be adequate. He did, however, persevere as he was keen to experiment in anticipation of setting similar conferences with his own students. He seemed to be very concerned with the fact that having missed the training session, he needed more skills or a “better” handout. We cannot clearly identify whether this was an accurate self-assessment, or a mask to cover a lack of confidence that he was unaware of.
Participation
In the face to face classroom, lack of participation can be put down to shyness, apathy, personality or cultural style. Online there may be other issues that cannot be resolved by checking other cues or asking directly for a contribution. Students can simply choose not to participate and their absence can absolve them of any responsibility to the community. They are not physically present to witness others’ frustration or irritation. One student commented in the evaluation that she was frustrated because people ignored her online. Interestingly, in the face to face classroom, she was quiet: online she was extremely “noisy”.

Patterns of communication
The first thread, initiated by Sue (tutor), was an invitation/exhortation to participate. Through deliberate choice, this was to be Sue’s only contribution to the discussion – leaving the space clear for the students to develop their own lines of research, discussion and reflection. Similarly, Mike (tutor), was not intending to take an active part, but did make more interventions by responding to direct questions. Thread two (Carole), who had found Nigel’s misdirected contributions on two occasions inside other topic areas. Despite Nigel’s earlier misgivings, he actually found help. Thread three (Mike) shared the view that quiet members of class – possibly more reflective students – could become more active online. Thread four was misplaced during Nigel’s efforts to gain access to the site. Thread five (Carole) explored some of her difficulties of accessing the material and then went on to invite contributions from her fellow students. This generated a lively discussion among three of the group, all of whom shared feelings of empowerment online in contrast to the f2f classroom environment. Jackie, a late entrant into the discussion, initiated thread six and she clearly felt the need to make a strong statement: a manifesto, rather than an opening in a dialogue. While accepting that the scope for cyber learning was great, for example people can talk to one another across distance and time, that they can learn at their own pace, that written text can be translated, that responses can be thoughtful and, “that the expertise of a few can reach a huge number of people” she also pointed to some of the disadvantages: access to technology; social isolation; lack of social interaction; the potential for undetected misunderstanding. Thread seven (Margaret) became a dialogue between her and Mike. That other students did not join in is of interest but difficult to explain. There were indications from the evaluation and from the number of hits on the server that there was more silent activity than writing. This is not untypical nor unexpected, but written contributions here were considerably lower than other evidence has led us to expect. One reason for this may be the emphasis on the use of emails in all the other course units in the degree. “Because we meet every day we don’t feel the need to communicate through facilitate.com we use emails, it’s easier” (Jackie). Thread eight gave the address of the paper site, ten was a discussion about problems associated with getting to it and nine involved Carole asking questions of the process and Mike’s response to them.

Conclusion
Critical reflection on experience is a difficult skill to acquire, even for people used to an interactive, participatory environment. In an online environment, we expected similar difficulties and barriers to effective participation and reflective thought. Not all students participated and it is difficult, in the absence of other evidence, to understand the nature of their experience of this part of the course unit. Among the confirmatory evidence was the strong suggestion that students who, in the f2f environment, would be quiet observers, became active participants and intense followers of the argument and unfolding debate. For example Helen made the most contributions, the most hits on the server and wrote more words than anyone else. There was evidence to highlight the responsibility that students took for one another’s learning, illustrated by Nigel’s success despite his self-proclaimed lack of skills in using the conference platform. In the end, he found the help he needed to start to use the medium and in doing so, made a contribution to others. There were difficulties for part time students and their access to training and technology; time constraints, levels of active participation, the potential threatening nature of the mode of communication and varying levels of understanding of the task.

This course unit intends to provide every one with the opportunity to communicate in a variety of different ways, some of which they may find uncomfortable and threatening. Computer conferencing is almost certainly an example of one of these. Although we would not wish students to feel excessively uncomfortable, we would want the course to represent real life interactions with all its complexity.

Abstract: The functional and didactical design of a virtual learning environment depends on the underlying learning theory. We discuss a virtual biotech lab as a special kind of virtual learning environment from an instructionist and a constructionist viewpoint. The virtual biotech lab introduced in this paper is an application of CoopLab, an object-oriented framework for the development of cooperative virtual labs. The virtual lab supports instructionist as well as constructionist learning and allows a combination of both approaches.

1. Introduction

Laboratory education in natural sciences is time consuming and expensive. Equipment and educational staff of a laboratory is limited and in a lot of cases not sufficient for the number of students that demand a lab course. Unexperienced students have to repeat parts of an experiment. Each mistake and a new trial produces more costs and often toxical waste. The costs for lab courses in natural sciences represent a great expense factor for universities and research institutes.

Not only material restrictions obstruct the offering of real world labs but also restrictions in the number of available tutors who have to assist the students in doing the practical experiments. Some of the students need more assistance than others, but individual assistance is nearly impossible during a practical lab course with a number of students of ten or more.

With virtual laboratories some of these restrictions can be addressed: A virtual laboratory is a graphic environment that gives the user the impression of a workbench, which is similar to a real one. Applets enable the user to perform typical biotech experiments in an analog way to a real world lab.

The background of this paper is an internal research project at GMD-IPSI dealing with software engineering, computer-supported cooperative learning (CSCL) and practical biotech knowledge. The project goal is to develop a software framework in order to simplify the implementation of such virtual laboratories. The framework is called CoopLab because an important aspect of the framework is to enable cooperative learning in the virtual laboratory environment. However, this functionality is still under development in the current state of the project.

The target group of the biotech applications built on the framework (i.e. the virtual labs) are students in molecular biology and trainees in genetic engineering, who want to prepare themselves for the practical work in real world labs. We want to stress that the virtual labs, which can be created using the framework do not intend to replace real world labs. A virtual lab created by using the CoopLab framework represents an additional workbench with the aim to improve the practical and theoretical preparation of the users and to reduce some of the restrictions of real world lab courses, which are mentioned above.

CoopLab is implemented in Java (based on JDK 1.1), but we are currently moving to Java 2. Java is becoming a prominent programming environment for the design and implementation of nearly all kinds of frameworks.
2. Application Domains

CoopLab applications are supposed to simulate real world lab experiences. So far the application domain has proven its power for the development of biotech labs, although it could also be used for other domains. The work in such a biotech lab is comparable to the work in a common chemical laboratory. To simplify it, you can say that the student in a real world biotech lab handles chemical fluids and organic material (like living cells, bacteria or plant cells) to fulfill a number of proposed tasks like DNA analysis, cloning or production of proteins etcetera.

A common practical experiment is the restriction analysis of bacteria DNA: Doing this, the user must prepare the DNA for an analysis by applying various chemicals in combination with special enzymes to the cell DNA, which has to be analyzed (see next paragraph).

Normally you cannot recognize any results with your own eyes, but instead you must use detection tools and machines, which are applied to the DNA or the containing tubes.

2.1. A Sample Biotech Experiment

As a prototypical application the biotech experiment Plasmid Restriction Analysis is chosen. A step-by-step overview of the experiment Plasmid Restriction Analysis is given here with an emphasis on common elements, which are found in many biotech experiments. For more information about genetic engineering see (Watson et al. 1992).

During this sample experiment the DNA of bacterial plasmids is treated with special enzymes (called restriction enzymes). This treatment leads to a splitting of the plasmid-DNA into different fragments. With the so-called gel electrophoresis the fragments are compared with an already known standard DNA-fingerprint (mostly the so-called λ-standard). That makes it possible to find out the length of the newly generated plasmid fragments.

The following tasks are summarized in order to provide a clue of the typical working steps in a biotech experiment:
1. Pipet plasmid-DNA into the micro tube with the enzymes and the puffer and shake it shortly with a vortexer.
2. Spread the mixtures of enzymes and DNA together with the λ-standard on a prepared agarose gel.
3. Put the gel into the electrophoresis chamber and start the electrophoresis by switching on the voltage generator.
4. When the electrophoresis is finished, switch it off and put the gel onto an UV-light screen.
5. Take a photo of the observable DNA bands and interpret the results.

The user of the CoopLab application, which is built for doing this experiment, can execute the five steps in a customized way: With the help of mouse events like clicking or dragging, the user can touch, move and combine tools, devices and tubes on the screen, which are similar in appearance, behaviour and usage to the corresponding elements of a real world lab.

The tasks that the user has to fulfill, can be presented in form of a step-by-step protocol list. This protocol can be integrated into the software e.g., as a checkbox-list or alternatively appended as a printed handbook. A typical task would be "Pipet 0.7 μl of the enzyme SacII into the micro tube with the plasmid-DNA." or "Put the gel onto the UV-light.". Each single operation can be performed with help of the computer mouse and, in cases of alphanumeric inputs, the keyboard. After a successful experiment the user gets an adequate feedback: This can be a text output like "The experiment Plasmid Restriction Analysis is finished." in combination with a visual illustration of the experiment goal.

3. Instructionism and Constructionism in a Virtual Lab

In theories on the use of computers in education two main approaches can be differentiated: The 'instructivist' and the 'constructivist' approach (Greeno 1991, p.3).

A focus of instructionism is to increase the efficiency of learning. All actions of the computer aim at transmitting knowledge to the student. By applying this approach the learner is regarded as "the passive recipient of instruction" (Reeves 1993).

In contrast, constructionism regards learning as a process in which the learner actively constructs his or her knowledge by interacting with the subject-matter. The role of the computer is to support such kind of active learning by providing an appropriate learning environment.

What do these approaches mean for the design of virtual labs? From an instructionist viewpoint virtual labs have to support the execution of a linear sequence of steps, which lead to the learning goal. Students are prompted to press the right button, to perform the right interactions or to enter the correct value in order to proceed to the next step. A virtual lab based on this approach would control the student's actions and gives feedback on their correctness. There is little space for the student to deviate from the correct way.

An implementation of the constructionist approach can be found in situated learning (Brown et al. 1989), (Lave & Wengler 1991). According to (Herrington & Standen 2000) an environment for situated learning should fulfill the following criteria:

- authentic context: The context in which the knowledge is learned should resemble the context in which it is normally used.
- authentic activities: The activities performed in the learning environment should resemble real-life activities with respect to the complexity and structure.
- access to expert performances: The student should be able to learn from expert solutions.
- multiple roles and perspectives: The environment should enable students to look at a problem from different viewpoints in order to get a more realistic model of the subject-matter.
- reflection: Reflection on the learning should be supported by providing authentic contexts and non-linear navigation through the whole virtual environment.
- collaborative construction of knowledge: The environment should support collaboration between students.
- articulation: The students should be supported in learning to speak the special language of the discipline.
- coaching and scaffolding: The teacher should be able to provide support for the students, e.g., provide hints and structure the learning activities.
- authentic assessment: The assessment should be seamlessly integrated with the activity.

Remember that in our didactic approach virtual biotech labs serve the purpose of helping students to prepare for real world labs. In the virtual biotech lab students learn about:

- the functionality and behaviour each tool in the real world lab provides,
the experimental setup for the real world lab, and
the procedures they will need to follow the tutor’s instructions in the real world lab.

In order to meet the criteria for situated learning environments our virtual lab environment provides graphical
representations of the tools and objects used in a real world lab. These representations can directly be manipulated
by the student using mouse and keyboard devices. By arranging these representations the user is allowed to con-
struct arbitrary experimental setups. A workbench is provided in the virtual lab, which serves as a common frame
for a set of tools. All objects can interact with each other on such a workbench, while each object has a certain
state and can change its state according to user input resp. interactions with other objects. Thus procedures con-
sisting of multiple steps can be performed in the virtual lab. With these features a virtual lab can provide the
authentic context, authentic activities, and articulation. Furthermore reflection on the learning process is stimu-
lated through the authentic context as well as the free navigation through the lab environment.

As stated in the introduction the cooperative learning support will become a central aspect of the CoopLab
framework, so that collaborative construction of knowledge and reflection, coaching and scaffolding can be sup-
ported in the virtual lab. These criteria fall into the category of the so-called distributed constructionism, which
extends constructionism by focusing specifically on situations in which more than one person is involved (see
Resnick 1996).

The provision of multiple roles and perspectives on the subject-matter as well as expert performances can be
achieved through external material and data or - in the collaborative usage - by co-learners and tutors. Due to its
solely preparative nature the assessment is of less importance in our virtual biotech lab.

4. Related Work

There are several web-based software systems for the training of natural science lab courses available as
described in (Hampel et al. 1998) or in available web courses like in (Physics 2000 lab). But both systems miss
the power of offering complete virtual environments that are functionally equivalent to real world experiences.
Moreover, they provide only a restricted degree of freedom with respect to the user interactions.

Two ongoing projects are more comparable to CoopLab: GenLab (Boles et al. 1998), a project conducted by
the OFFIS research institute in Oldenburg and ViSel (Giegerich & Lorenz 1998), a project conducted by the Uni-
versity of Bielefeld. They also use multimedia technologies to build up a virtual learning environment, but do not
aim at integrating any CSCL-features. ViSel is implemented as a Toolbook application, whereas GenLab is imple-
mented with Macromedia Director.

Similar virtual labs are also developed as part of the Biology Labs On-Line (Bell 2000) project, which is con-
ducted by the California State University in Chico (USA). These virtual labs provide simulations covering the
subjects of evolution, genetics, protein translation, demography and some more topics. They provide Java-based
applets, which help to understand and learn the different topics more easily. But in contrast to CoopLab applica-
tions, they do not offer a virtual lab environment, which gives the user the impression of workbenches analog to a
real world lab. They provide a fixed experimental setup whereas in our virtual labs the experimental setup can be
constructed and/or modified by the user.

5. Conclusions and Future Work

In this paper we described a constructionist approach as an enhancement of instructionism in virtual labora-
tory environments. We discussed learning in virtual laboratories from an instructionist and a constructionist view-
point and related them to virtual biotech laboratories developed as an application of the CoopLab framework.
Virtual labs based on the CoopLab framework have the capabilities to meet the requirements of constructionist
learning environments. A comparison to related work unveiled the specific potential of CoopLab applications to
support constructionist learning.

As already mentioned above, it is a future goal to support collaborative learning in a virtual lab. This could be
realized by combining the CoopLab framework with DyCE, a Java framework for the development of modular
groupware (Tietze & Steinmetz 2000). In a collaborative virtual lab its state can be made persistent on a server.
Different users can log into a collaborative virtual lab and share the same data ("lab-sharing"). If they log into a
lab at the same time, they can additionally communicate, work and learn simultaneously. The virtual lab provides
awareness of the other students’ presence and activities in the lab.
Using this technology, a tutor can enter the virtual lab and provide support, e.g., by answering questions, explaining tools, demonstrating experimental setups, or performing lab procedures. Similar to this, many more CSCL scenarios are possible. Such scenarios are even closer to the experience of a real world lab than a single user application.

Abstract: The use of Web-based systems in education is emerging rapidly. It seems that the web offers a large potential for (higher) education, although not many positive effects can be found yet. What is the potential of a Web-based system? In this article gives an overview of what Web-based systems are, how they are being used and what potential they have. The possibilities of Web-based systems, used as an integrated tool for courses, are discussed making use of the experiences of the TeleTOP project at the University of Twente in the Netherlands. The TeleTOP Web-based system enables instructors to add more flexibility, efficiency and enrichment into their courses, which will be demonstrated with some interesting examples.

The potential of WWW based systems

For some time now the use of WWW-based system is increasing rapidly in (higher) education institutions. (Collis & V/d Wende, 1999; Veen et al, 1999). It seems that the use of these systems has an enormous allurement, many projects have been set-up to build and/or implement Web-based course support systems. But what are Web-based course support systems? There are many sorts of learning systems which can be used through the WWW and many classifications have been made. For example Berge (1995) and Collins (1995) indicate a set of instructional modes comprising the overall complex of computer-mediated communication (CMC) technology: mentoring, project-based instruction, lecturing, information retrieval, chat, peer reviewing, tutorials, simulations and drills. Collis (1999) refers to five main purposes of using teleware (the whole set of tools, resources, and instruments that support learning-related communication-based processes): (1) publication and dissemination of information; (2) structured communications; (3) collaboration; (4) information and resources handling and (5) support for course delivery. Robson (1999) devides 5 sorts of tools: Computer-mediated communication; Navigational tools; Course management; Assessment and Authoring tools. Teles (1993) analyzed Web-based support of cognitive apprenticeship by features that embody a variety of methods (e.g., sequencing, scaffolding, exploration, reflection) in online-apprenticeship or tele-apprenticeship activities.

A lot of Web-based systems have been built to make all kinds of learning (-organisation, -communication, -materials, -support, etc.) possible. Landon (1999) has made an impressive, but rather technical, overview of over 60 available systems. But how are Web-based learning systems used? Mioduser (2000) looked at 500 cases to search for what the web was really used for. He found that most educational WWW-sites support cognitive processes such as retrieving information or rote learning and higher learning skills as inference processes, problem-solving and decision-making were much less present. Within the 500 cases less than 3% supported any real form of collaborative learning. "Only a few sites included feedback, either automatic (16.3%) or human (5.5%)" (pp 19). The researchers conclude that the potential of the new pedagogical forms are emerging out of unique features of the technology but are still far from being implemented in most educational Web sites. The same conclusions are found in a smaller research of case studies. Van der Veen et al (2000) reported that the reasons mentioned for using the Web environments within the cases that have been evaluated are mostly not didactical but are aiming at flexibility for students. The students however report limited added value. Veen et al (1999) found in a national research that most institutions in the Netherland initiated ICT in their organisations with motives relating to educational innovation in a broad sense rather than attempting to raise levels of effectiveness and efficiency.

It seems that much is being done, but the results are still minor. The research of Russell (1999) subscribes this. In his meta-research "The No Significant Difference Phenomenon" he found that less than 10% of all papers
reported any significant positive results of using ICT in education. Is there a potential, but we have not yet put our hand on it? In the next section the experiences of the TeleTOP project at the University of Twente demonstrate that it takes time to accomplish something, but that the promise of Web-based systems can be fulfilled.

A Web-based course support system; TeleTOP

At our University of Twente in the Netherlands we have national and international reputation in the field of Information and Communication technology (ICT) and learning. In stead of the term ICT we rather use the term Telematics, which stands for the branch of computer science involving the combination of information and communication technologies in particular, related to the Internet and the World Wide Web (WWW). Also the application of telematics applications to the teaching and learning process, what we call "Tele-learning" (Collis, 1998), has a high priority. Tele-learning, in our definition, does not necessarily imply distance education, but instead emphasises the increased flexibility, efficiency and enrichment that can come to the teaching and learning process through the combination of the new possibilities offered by the WWW and new ways of teaching and learning.

In 1997 the Faculty of Educational Science and Technology initiated the TeleTOP Project. The overall goal of the TeleTOP initiative was to stimulate the innovative and appropriate use of the WWW for learning purposes within the faculty in order to make the educational delivery more efficient, more enriched, and more flexible (Collis, 1996). The TeleTOP system was build upon a powerful database (Lotus Notes) and to be used by everybody in the Faculty of Educational Science and Technology; it was made to be WWW-based (for both students as well as instructors) and it was made accessible through an ordinary Web-browser everywhere in the world. The TeleTOP system became a very easy to use system and it allowed to a certain extent fit with the instructional practices of an on-campus University and extent these to distance students as well. It also did engage change to new didactics. The starting-point was that WWW-based learning environments should not replace existing teaching and learning, but should add to them.

The main question within the TeleTOP project was and still is: what (added) value can there be? In the beginning of the project we focussed on three main points: flexibility, efficiency and enrichment (Collis, 1996). With regards to flexibility in telematics we distinguished: flexibility in location, in programme, in types of interactions and in forms of communication. Flexibility was a main issue, as a new group of students should be able to follow all courses within the curriculum. A partly distance variant was made available for these new students. The distance students within the program visited the university every other Friday, and were able to take courses in the same pace as the on-campus students. Also on-campus students are now able to choose this variant of courses, so the offer became more flexible.

Now that a lot of study material is available in course environments it became much easier for instructors to set-up a new course environment for a specific group. This "flexibility in programme" was being realised at our faculty within the Masters programme. The Masters programme has its core set of courses, but already two new programmes (the HRD programme and Telematics Applications in Education and Training) have been set-up with less effort compared to the situation that a system as TeleTOP was not available. Figure 1 shows how earlier used course material easily can be re-used in new course environments.
Figure 1. Course materials can easily be re-used in new course environments.

This interface is for the instructor, no technical support is necessary, and it is fully Web-based. The re-use of materials is also a good example of efficiency.

Another type of efficiency is the way instructors are dealing with the different students within one course environment. As mentioned, on-campus as well as distance students can take a course. All students start at the same point (date) and preferably will finish their course at a set date. This gives the instructor two advantages; he can focus on his teaching in the time that has been allocated for teaching, (it takes instructors a lot of time and effort to help students who want attention after a course is done), and the instructor is able to set-up one environment in which he can teach several groups of students, so he can re-use course materials. See for example figure 2, a screen dump of the roster in a course for 2 groups.

Figure 2: The roster in a course, set-up for 2 students groups.

Most of the flexibility and efficiency aspects are implemented in the past two years. Interesting is to see were we are at with regards to the enrichment which has been identified as another powerful added value of
Telematics in education. First, what sort of enrichment can be distinguished? Enrichment can occur in “educational materials (i.e. Web-links to papers, multi-media, actualities, etc), in pedagogy and/or learning styles and in better insights of relations and links between courses.

The use of possible enrichment in educational materials and pedagogy and/or learning styles proceeds not as fast as the efficiency and flexibility possibilities. Fullan (1991) notes that a major change in an institute takes 5 years, so it seems natural that new ways of teaching and learning with the use of additional resources and new media takes time. To encourage this it is important to show instructors possibilities and options so that these can be integrated within the courses.

For the second year a survey was set up to look at how “rich” the telematics were used, in particular with regards to assignments and feedback. Table 1 is derived from Peters and de Boer (2000) and shows what sort of assignments and feedback were used within 27 courses.

Table 1: Variety in assignments in 27 TeleTOP courses (4 courses had more than one sort of assignment)

A map with this overview and an interesting collection of “good practices” examples of the use of telematics within our faculty was created (De Boer & Manuhuwah, 2000). There is variety of assignments through the courses, but much more is possible. The types of feedback do seem very alike; most instructors only gave personal feedback to the assignments. We organised workshops where instructors were invited to listen and discuss about the other and new possibilities. All of the support-materials (i.e. the good practice examples) were also made available through the web, and instructors were able to look at the examples at their own place, in their own time. It would be interesting to see whether the courses would contain more variety in assignments and feedback next year.

Another type of enrichment that can be supported by telematics would be enrichment of learning materials. An important philosophy within our education programme is the active learning strategy (Simons, 1999). As a consequence, students in the courses are invited not only to study passively, but also to find and/or create new learning materials. These can be resources that are located on the web, but can also be the writing of articles about certain topics that can be used by the instructor in the courses, as well as in other courses. An example of how telematics can support this is shown in figure 3.
Conclusion and Discussion

Russell (1999) states that less than 10% of all papers reported any significant positive results of using ICT in education. So should we stop? Isn’t there a potential?

We believe, and think we are proving, there is a large potential, but it certainly takes time to effectuate this. Good tools and good strategies with customised support should be effective and all cohorts could benefit form this. Students have several options to take a course: i.e. students have flexibility in time, place, but also in learning style (i.e. teacher guided, or self-regulated). Instructors are able to communicate more targeted and directly with all their students. Instructors have a way to see each other’s materials en can easily share resources. More interaction is possible. Also new ways of learning are possible, instructors could use the active and participating student involvement approach, where not only the instructor contributes to the learning environments with new related and actual materials, but students contribute as well. Students should also be able to be reflective and look at their own and each other’s work.

The main success indicators could well be the quality of the Web-based learning support system, as well as the (educational) support related to this. This support could be human, via support systems, or a combination. Further research should be done to answer these questions more specifically.

ESCUELA: A Platform Which Assists the Work of the Teacher and Supports the Learning of the Student

Gisela de Clunie, Universidad Tecnológica de Panamá, Panamá; Ana Regina da Rocha, Universidade Federal do Rio de Janeiro, Brazil; Gilda Campos, Universidade Santa Úrsula, Brazil

This article presents the prototype of a working platform, which incorporates technological innovations to be used in schools interested in promoting a modification of the pedagogical-didactic paradigm, integrating environments of work suitable to different necessities and situations of learning.
Distance education is emerging in many aspects of university education. Lecture broadcasts, delivery of course material and on-line tutor support are becoming standard applications of ICT in education. But especially in technical studies another important capacity of such technology in education is also to enable remote classroom and laboratory work.

We present a part of our results and experiences from technology supported distance education, especially when using video communication as an add-on. We first outline our implementation of the video supported web lecturing. It consists of indexed video stream, presentation slides and text subtitles. Then the remote laboratory examples with real-time video support is described. This distance experiment includes remote student work via WWW, handling of the laboratory process in real time and monitoring of the whole activity using a video camera.

The common denominator of the two examples is video streaming over Internet. It is not an absolute necessity in any case, but it is our finding that the learning outcome and acceptance by students is greatly enhanced in both applications when video is part of the user interface to the lecture or experiment.
A REVIEW OF WEB-BASED LEARNING SYSTEMS FOR PROGRAMMING

Fadi P. Deek, Ki-Wang Ho, and Haider Ramadhan
Computer and Information Science Department, New Jersey Institute of Technology
Computer Science Department, Sultan Qaboos University, Muscat, Sultanate of Oman

Abstract

We provide a review of web-based interactive programming environments which facilitate learning programming concepts. The main focus is to categorize web-based programming systems into classes according to their pedagogical approaches and provide a brief review of individual systems. The paper is intended to give a survey of available systems and a discussion of the differences and the commonality of the tools.

Introduction

Traditionally, computer-based learning systems have been built and deployed using static media, such as disks and CD-ROMs. Currently, client-server systems can be deployed with increased access and availability. With the web, it has become much easier to distribute educational material widely. Also, with such implementation of learning environments, enhancing contents is simple, and users' needs are quickly addressed. There is a wealth of learning resources available on the web. However, not much is available to guide the user and assist in determining the appropriateness of a particular system for a certain situation or need. This paper is the result of an extensive search for available web-based instructional systems that can be used for learning programming. The goal is to organize these systems with respect to their functionality and usefulness for the learner and to provide a concise evaluation of their suitability for their learning objectives.

There is a need to organize and classify the systems into different groups based upon a set of identifiable and distinguishable characteristics. The intent in providing this categorization of these instructional systems is to offer web users - ranging from those who are just learning programming to those who are already experienced programmers - a 'guidebook' to available systems that will most likely match their educational needs. The classification of the systems fell into the educational software categories of drill and practice systems, tutorial systems, and simulations (Pienaar, 1997). Of the systems reviewed, each one is distinctly aligned with one of the three categories, allowing for slight overlap in common capabilities. A classification of the systems into the three categories of drill and practice systems, tutorial systems, and simulation systems is provided, along with a review of each system; in addition to URLs, references to published papers are included, were appropriate. A discussion on the distinguishing patterns and the commonality of systems reviewed is then given.

Classifications and Review

We have arrived at a classification for instructional systems that fall into the following three categories: drill and practice systems, tutorial systems, and simulation systems.

Drill and Practice Systems

Within the broad family of instructional learning systems, a subset categorized as drill and practice systems constitute the category of systems designed to provide users with practice for already defined skills. Drill and practice systems serve to reinforce learning that has taken place external to the system. In most cases, they can be used to supplement external instruction, or to refresh the learner's knowledge. Drill and practice systems include capabilities to provide immediate feedback, and usually some form of corrective action. Skills taught
elsewhere are reinforced. Next, we discuss the drill and practice systems we reviewed, along with a brief description and the web URL where the systems can be accessed.

LISPTUTOR (Villamil, 1995) is a web-based tool that teaches the basics of the LISP programming language. It was developed as a student project at Tulane University, Louisiana. The LISPTUTOR provides a free-format interface for the user through the use of its ‘teacher board’, which is a picture of a blackboard with the various LISP concepts that, when clicked, bring the user to a page where the subtopics/feature concepts are presented. The interface provided by the teacher’s board presents all the various concepts that are being taught, and the student has the option of deciding what to learn. The concepts covered range from data structures, input and output, control structures, recursion, basic arithmetic operations, and sets, with a comprehensive graded test that covers all the concepts and provides feedback. The LISPTUTOR can be found at the URL: http://www.cs.tulane.edu/www/Villamil/lisp/lispl.html#text

This C Programming tool (Brown, 1984-1999) is an online introduction to the C programming language. It consists of a collection of web documents that are organized into chapters and subchapters. The concepts covered begin with variable declaration, arithmetic and relation operators, programming constructs, and end with dynamic memory allocation, pointers to functions, and compile options. Interspersed between chapters are optional interactive multiple-choice tests, which provide immediate feedback to each selection made by the user during his test. The feedback given takes the form of a one or two sentence response to the user’s selection in a popup window. The C Programming Course can be accessed at the URL: http://www.cit.ac.nz/smae/cprogram/default.htm.

The RIT CS Course Exercises (RIT, 1999) consist of two online exams developed by the computer science department at Rochester Institute of Technology in New York. The exams were created to supplement the course lectures for its CS1 course and C++ courses. There are two exams: one covering the aspects of the Eiffel programming language, the other the C++ programming language. The organizational structure for both exams is similar. Each is broken into several high-level exercise areas, with each exercise area containing a collection of sub-lessons. Depending on the exercise area chosen, sub-lessons may be tackled in any order, or must be done in a sequential fashion. Both these exams can be accessed at the URL: http://www.cs.rit.edu/exercises.html.

The TTT (Topic, Task and Test) Online Learning System (Chopping, 1996) is an online course covering the fundamentals of structured programming using the C++ programming language. It presents an introduction to the basics of C++ program structure, syntax, control structures, and functions. The TTT learning system’s course is organized into several sections, each of which contains a group of topics covering a particular C++ programming concept. Each topic is a web document containing three sections (the three T’s). The TTT Online Learning System can be accessed at the following URL: http://clio.mit.csu.edu.au/TTT/

Lovelace (Wheeler, 1996) is an online interactive course on the Ada programming language. Lovelace’s instructional material is broken into a set of lessons, which are further broken down into sections. Each section presents some instructional content along with sample code. The sections end with a single-question quiz to reinforce the user’s remembrance of the material. Lovelace also contains a separate Java section describing to the user how to create Java programs using the Ada 95 programming language. Sample programs and reference links are provided. The Lovelace tutorial can be accessed at the URL: http://www.adahome.com/Tutorials/Lovelace/lovelace.htm

**Tutorial Systems**

Tutorial systems comprise the largest category of instructional learning systems. Unlike drill and practice systems which supplement learning that has already taken place externally, tutorial systems are concerned with the teaching of new concepts, and providing capabilities to aid the learner in retaining what has been learned. Good tutorials attempt to deepen the level of processing of the instruction by providing different strategies to recall prior knowledge, making the instruction as relevant and meaningful as possible, and including aids for incorporating old with new information. Next, we discuss the tutorial systems we reviewed, along with a brief description and web URL where the systems can be accessed.

ELM-ART (ELM research group, 1997) is a web-based LISP tutoring system that integrates the features of electronic textbooks, learning environments, and intelligent tutoring systems. It was developed at the University of Trier in Germany. ELM-ART (Episodic Learner Model – Adaptive Remote Tutor) is based on ELM-PE (Weber & Specht, 1997), which is an on-site, platform-dependent intelligent learning environment featuring example-
formed programming, intelligent analysis of students' problem solutions, and advanced testing and debugging facilities. ELM-ART can be accessed at the following URL: http://www.psychologie.uni-trier.de:8000/elmart

ADIS (Warendorf & Tan, 1997) was developed at the Nanyang Technological University in Singapore as a teaching aid for a beginning course in Data Structures. ADIS is integrated with a graphical user interface that can display data structures pictorially on the web browser, as well as allow the student to graphically manipulate the data structures created. Through interacting with ADIS, students learn basic algorithms (insertion, deletion, etc.) of data structures visually. ADIS can be configured either as a standalone application, or, as discussed here, a client server/application with the parent canvas residing on a central server, and students access the ADIS Intelligent Tutoring System as clients. ADIS can be accessed at the URL: http://www.jime.open.ac.uk/98/adis/adis.html

Opsis (Michail, 1999) is a Java applet designed to teach binary search tree algorithms. By visually manipulating abstract tree fragments and/or single nodes, the learner is able to actually implement various binary tree algorithms such as binary tree search, binary tree insertion, binary tree deletion, and AVL balanced binary trees. Opsis adopts a state-based model for representing a program. By specifying the possible transitions from one state to another via manipulation of abstract objects in a visual manner, the user creates the algorithm. All states in Opsis are abstract states - which is an abstract visual diagram that represents a set of possible concrete states. In Opsis, abstract states are identical only if their respective visual diagrams match identically in appearance. The Opsis Homepage is located at the following URL: http://www.cs.washington.edu/homes/amir/Opsis.html/

The IBM Java Software Group offers a family of free online courses covering different aspects of the Java programming language and development environment. The courses make extensive use of IBM's Bamba, Macromedia Shockwave, and IBM's Hot Audio multimedia products to stream audio and video content as complements to its text lessons. Each course is presented in a slideshow format with an accompanied audio soundtrack. The courses begin with an audio/video clip introduction by the instructor, who outlines to the user the purpose and goal of the course, and the knowledge the user should expect to acquire after taking the course. The courseware are accessible from the URL: http://www.software.ibm.com/developer/education/java/online-courses.html

The SQL Tutorial is a web-based tutoring environment for the Structured Query Language, and incorporates with lessons the use of its online SQL interpreter and database where tables can be created and modified the user. This tutorial is meant to be an introductory course in SQL. It covers the concepts of the Select Statement, Table Creation, Row Updates and Deletion, and Table Deletion, in that particular order. The tutorial is arranged in a linear fashion, with the user being presented with the concept of the Select statement, and moving forward. Concepts are presented in the following format on each HTML concept page. The system can be accessed at the URL: http://torresoft.netmegs.com/

The Webmonkey HTML Teaching Tool teaches the user the basic concepts of using the HTML language to develop a webpage. It covers the basic html tags in a series of non-sequential lessons. The user is presented with a page listing all the available concepts available to be learned. Each concept corresponds to a lesson on one of the basic html tags taught by Webmonkey and can be accessed by clicking on its hypertext link. The Webmonkey HTML Teaching Tool can be accessed at the URL: http://www.hotwired.com/webmonkey/teachingtool/index.html

SOLVEIT (Deek, 1998) is an integrated environment designed for users to learn problem solving and program development while operating within a software engineering framework. Developed at the New Jersey Institute of Technology, SOLVEIT (an acronym for Specification Oriented Language in Visual Environment for Instruction Translation) is based on Deek's Dual Common Model for Problem Solving and Program Development. This dual common model represents the integration of a cognitive model for problem solving with the tasks involved in program development, and is the foundation of SOLVEIT. Consistent with the model, the SOLVEIT environment involves six stages: problem formulation, solution planning, solution design, solution translation, solution testing, and solution delivery. The SOLVEIT environment is available from the URL: http://www.cis.njit.edu/~fadi/research/solveit/solveit.htm

The Java Tutorial (Camione & Walrath, 1996) is an online guide to writing programs in the Java language. The tutorial is organized into a series of "trails" - programming lessons grouped together based on topic. Trails can intersect where they share the same lesson. The Java Tutorial assumes the user already has some programming experience, and does not cover the syntax of the Java programming language; rather, it's trail lessons cover topics such as techniques and concepts useful for developing standalone Java programs or applets, tools required for creating graphical user interfaces, information about the Java development environment, and
differences between Java and C/C++. The Java Tutorial can be accessed at the URL:
http://sunsite.utk.edu/java/docs/tutorial/

The ACT-R Tutorial (ACT Group, 1998), developed at the Carnegie Mellon University, is an interactive
web-based tutorial to teach the user about the ACT-R environment. The ACT group (1998) is concerned with the
theory and architecture of cognition. The goal of this research is to understand how people acquire and organize
knowledge and produce intelligent behavior. ACT-R is a theory that attempts to explain human cognition by
developing a model of the knowledge structures that underlie that cognition. This model takes the form of a
computer simulation that is capable of performing and learning from the same tasks worked on by human subjects
in laboratories. Users programming in the ACT-R programming environment use declarative and procedural
knowledge structures and production rules as building blocks towards the development of complex ACT-R models.
The ACT-R Tutorial can be accessed at the URL: http://128.2.248.58/inter/Welcome.html.

The LOGO Tutor and Programming Environment (Golze, Chau, Hirsche, 1997/1998) is a tutorial on the
LOGO graphics programming language and an introduction to computer programming. Through the use of simple
commands, the user can manipulate a little turtle on the graphics screen in order to draw and paint shapes, and
event provide animation. The LOGO tutorial is presented as ten lessons that cover all the important aspects of
programming in the LOGO language. The lessons are based upon the previous ones, and the user is encouraged to
tackle them in that order. The LOGO Tutorial website can be accessed at the URL:
http://library.advanced.org/18446/eindex.shtml

Simulations

Simulations cover the family of instructional systems that approximate, replicate, or emulate the features of
some task, setting, or context. The majority of CAI simulations relating to the teaching of programming
concepts or programming languages employ software visualization techniques such as graphics and animation to
describe a program or its underlying algorithm. The level of user interactivity during the simulation varies from
system to system. Next, we discuss the simulation systems we reviewed, along with a brief description and web
URL where the systems can be accessed.

The Interactive Data Structures Visualizations System (Arc & Feldman, 1997) was developed at the
George Washington University School of Engineering and Applied Science and designed for use by CS2 students
to further their understanding of data structures. The system covers CS2 level data structures and algorithms for
graphs, trees, and sorting. The system is organized into three main sections: Graphs, Trees, and Sorting, with each
section broken into subtopics. Navigation through the system is unguided and open. The user clicks on the sidebar
for the hyperlinked subtopic interested in learning. The Interactive Data Structures Visualizations can be accessed
at the URL: http://tangle.seas.gwu.edu/~jarc/idsv/

Jeliot (AAPS, University of Helsinki, 1997) is an interactive algorithm animation environment for
animating user algorithms. It was produced by the AAPS (Animation Aided Problem Solving) research group and
was developed jointly by AAPS members along with CS students in the Department of Computer Science at the
University of Helsinki. The name Jeliot is shorthand for Java-Eliot, where Eliot is the non-web-based predecessor
of Jeliot. Using Jeliot, the user can produce animations for algorithms written in EJava, a programming language
nearly identical to the Java language, but with new animation data types along with some restrictions. The Jeliot
Interactive Algorithm Animation Environment can be accessed at the URL:
http://www.cs.helsinki.fi/research/aaps/Jeliot/

The Java Sorting Algorithm Page (Mitra & SUNY Brockport, 1997) was developed at the Computer
Science Department of SUNY Brockport, and consists of a collection of applets for illustrating the operation of
various commonly studied sorting algorithms. The Java Sorting Algorithm Page can be accessed at the URL:
http://www.cs.brockport.edu/cs/javasort.html

JAWAA (Pierson & Rodger, 1996; 1998) is a command language for creating animations of data
structures and algorithms and displaying them with a Java-enabled web browser. JAWAA was developed Duke
University and implemented in Java. The JAWAA applet provides an interface for reading animation scripts
developed by users to display their animations over the web. The JAWAA home page includes a collection of
algorithm and data structure animations such as those illustrating depth first search, LR(1) parsing, and circular
graphs. The JAWAA home page can be accessed at the URL: http://www.cs.duke.edu/~wcp/JAWAA.html

The Java Algorithm Library (JAL) Animator (Silicon Graphics Inc., 1996) consists of a suite of algorithm
animations that operate on elements in an array. The algorithm animations are broken into four classes: Inspection,
Modification, Sorting, and Numeric algorithms, each which apply some action to a range of elements in the array. The JAL Animator interface is a Java applet which offers the user some control for setting up the animation. The JAL Animator can be accessed at the URL: http://reality.sgi.com/austern/java/demo/demo.html

The Generalized Algorithm Illustration through Graphical Software (GAIGS) Home Page (Naps, et. al., 1999) is maintained by the Computer Science Department at Lawrence University, and contains a collection of viewable algorithm animations. The GAIGS Home Page is currently still under development with new algorithm visualizations to be added. It can be accessed at the following URL: http://gaigs.cmse.lawrence.edu/cmsc34/AVCAlient.html

JSamba (Duskis, Dey, Lambada Project, Hartley, Wagner, 1999) is a Java version of the Samba algorithm animation system developed by the Graphics, Visualization and Usability (GVU, 1998) Center at Georgia Tech. JSamba runs as an applet on the web and is, in essence, an interactive animation interpreter that reads ASCII commands entered in by the user and performs the corresponding animation actions. JSamba can be accessed at the URL: http://www.cc.gatech.edu/gvu/softviz/algoanim/jsamba/.

Analysis

All the drill and practice systems examined exhibited strong competency in informing users about the goals and learning objectives of their respective systems, as well as providing methods to elicit user performance. The capabilities relating to the presentation of instructional material were also strong, which is worthy noting, as most traditional drill and practice systems focus on the reinforcement of existing knowledge, and not instruction of new knowledge. Feedback capabilities amongst all the systems in the drill and practice category were notably weak, which can be attributed to the fact that most of the exercises used to elicit user performance take the form of multiple-choice questions. Questions in such a format, in practice, offer the system little opportunity to truly providing evaluative feedback on the user’s entry. It is interesting to note also that the drill and practice systems provided the least focus, of all the three system categories, toward incorporating the use of devices to gain user attention.

The majority of the tutorial systems employed successful techniques to gain user attention. Their success in informing the user of the system’s goals and learning objectives was varied, however, with some systems faring better than others. Almost all exhibited strong capability in presenting the instructional content to the user, as should be expected in tutorial systems. However, the majority of the tutorial systems performed poorly in their ability to stimulate the user’s recall of prior knowledge, although a significant amount did provide good learning guidance to users for new instructional material.

The simulation systems, like the tutorial systems, also successfully incorporated techniques to motivate users and engage their attention. The majority of the simulator systems offered adequate support in informing the users of the system’s rules and objectives, as well as presenting users with the stimulus instructional material. However, only approximately half of the simulator systems provided any form of learning guidance to supplement its instruction content.

It is interesting to note that all the reviewed systems from all three categories shared a lack of any definitive support in the area of assessing user performance. In order to provide for some worthwhile assessment, systems need to include facilities to record the users’ activities throughout the training session, take note of where much of the users’ time is spent, record their performance on lesson exams and tasks, and ultimately examining all this data and being able to construct an informative user model or profile. All the reviewed systems were deficient in this regard, with some systems only providing partial support for the stated facilities.

In general, almost all the systems were successful at informing the users about their goals and objectives, and presenting them with stimulus instructional material. Facilities to stimulate recall of prior knowledge prior to reception of new instruction was poor in all systems, with drill and practice systems providing a surprisingly stronger showing of support than the other two types of systems.

Use of Video Mediated Instruction in Teaching American Heart Association
Emergency Cardiac Care Training Courses

Darrell James DeMartino
Department of Curriculum and Instruction
University of Houston
Houston, Texas, USA
darrell@bayou.uh.edu

Abstract: This paper provides a historical look at American Heart Association training regimens
associated with previous training methods are identified. Following this is rational for movement
to a standardized training program facilitated through video training with instructors as facilitators
rather than lecturers.

History

In the past 35 years, since the introduction of modern techniques in cardiopulmonary resuscitation (CPR),
there have been dramatic advances in emergency cardiac care (ECC) of victims in profound circulatory collapse
and/or cardiac arrest (American Heart Association, 1992). The 1966 National Academy of Sciences- National
Research Council (NAS-NRC) conference on CPR made recommendations for the training of medical, allied health,
and other professionals in the use of external chest compression technique according to standards set forth by the
American Heart Association (AHA) (National Academy of Sciences, 1966). During the mid 1960 and throughout
the early 1970’s strides were made to implement these recommendations via training materials and programs
designed by the American Heart Association. In the 1973, the second national conference on CPR and ECC was
held. Among the recommendations of this conference was the: (1) extension of CPR programs to the general public;
(2) training in CPR and ECC in accordance with the AHA standards; (3) certification of competence at various
levels of life support based upon a nationally standardized curricula that included written and performance tests
(American Heart Association, 1992). Since 1973, five other national conferences have been held updating
guidelines and recommendations for emergency cardiac care (1979, 1983, 1985, 1992, 2000). In each of these
conferences, there was further support for educational efforts in training health care professionals and the lay public
about cardiac symptoms and treatment.

Role of AHA in Education

The American Heart Association (AHA) has been involved in educating the public and health care
professionals in emergency cardiac care for over 30 years. The development of training programs has involved the
effort of national and international organizations in reviewing scientific data, developing guidelines, and translating
guidelines into training programs for the lay public and health care professionals. In these efforts, it has been the
role of the AHA to provide strictly educational programs and not to be a certifying body attesting to competency of
health care professionals (American Heart Association, 1992).

Educational Training Programs

In training individuals about ECC, programs must be designed to motivated adults to learn CPR and to use
these skills in situations as warranted by their training (American Heart Association, 1992). It has also been noted
that retraining is an important issue for retention (Kaye, 1991; Mandel, 1982). Within 1 year of completing
advanced ECC courses, health care providers have difficulty in recalling knowledge and performance skills (Kaye,
The reason skill deterioration has been difficult to determine is because it is unclear as to whether the problems stem from problems with the training course or whether it is a retention issue (Kaye, 1989; Lownestein, 1981). Some of the factors identified with educational failure include, insufficient practice time and complexity/large amount of information covered (American Heart Association, 2000).

The traditional format of training has relied on lecture, skills demonstration, skills practice, and evaluation using skills checklists. In courses prior to 2000, with the exception of one particular training program (Heartsaver AED), the instructor was free to organize the course, timing, teaching method, and evaluation in a way that s/he preferred. This format was in essence “instructor-led.” There were no criteria on how much time should be spend on specific topics and was highly individualized. Various studies evaluated these programs on instructor performance (Kaye, et al., 1991), post-course skill performance (Brennan & Braslow, 1995), and retention (Liberman, et al., 1999; Kaye & Mancini, 1986; Wilson, Brooks, & Tweed, 1983; Mancini & Kaye, 1985; Mandel & Cobb, 1982). In most of the studies, post-course skills performance and knowledge retention were low. Kaye, et al. (1991) showed that instructors tend to spend too much time lecturing and allow for little time in skills practice. They identified a poor feedback mechanism portrayed by the instructors, with little assistance in providing correction of skills performance.

Reliable between instructors in evaluation of skills are also low (Mancini & Kaye, 1985; Brennan, Braslow, Batcheller, & Kaye, 1996).

Numerous instructional methods have been introduced to try to improve student performance, including:
1. Over-training (Tweed, Wilson, & Isfeld, 1980),
2. Simplification of content,
3. Videotaped instruction for initial training and reinforcement (Mandel & Cobb, 1987; Eisenberg, et al., 1995; Schluger, et al., 1987)
5. Use of “practice-after-watching” videotapes with instructor support (Aufderheide, Stapleton, Hazinski, & Cummings, 1998), and

Retention

Resuscitation skills deteriorate at variable rates (Weaver, 1979). Various methods of training have been attempted to minimize this loss of knowledge. The American Heart Association (1992) believes to improve retention, (1) multiple step procedures must be simplified for easy recall, and (2) key factors that determine successful performance must be highlighted throughout the training course. In dealing with issues of training and retention, flexible models of education have been encouraged. One example is the American Heart Association’s advocating the use of public service announcements and videotaped training.

To increase retention, attempts have been made to simplify the content. Braslow, et al. (1997) study showed that a student focusing on a single task (1- rescuer adult CPR) after watching a 34- minute video retained more information and skills that a student who learned multiple topics in a 4-hour training course. Additional studies with audio prompts (Doherty, Damon, Hein, & Cummins, 1998; Strarr, 1997) have also been useful in simplifying CPR training. Similar techniques to simplify content have been used successfully in Advanced Cardiac Life Support (ACLS) training (Kaye, Dubin, & Rallis, 1988).

Video Training

In efforts to maintaining a truly national training program, the AHA, in its 2000 conference update, has moved to using video-mediated instruction in all their training programs. The used of video instruction is not new, as the use of this method of instruction has been implemented in training the lay public in CPR since 1995. The training of health care providers has been primarily lecture based, moving to a more interaction case-based system in the mid-1990’s. The variations in instructional skills of trainers across the nation, and the concerns about provider skill retention have prompted the AHA to develop small video segments to be played by the instructor throughout the training course. This would ensure that all providers learn the skills and techniques in a similar manner, as well as ensure that the important factors associated with techniques are outlined. In addition, the use of video-mediated instruction provides visualizations that are difficult to depict in a classroom environment. Recent research (Kaye,
1995) has shown that video-based instruction is effective for teaching the lay public CPR and has better retention rates than standard instructor-led training programs.

However, the use of video without an instructor has not been found to be as beneficial as programs with instructor involvement. Video self-instruction is an effective method, as are other techniques, to teach initial cognitive and psychomotor skills, however most these people tend not to retain their skills for long (American Heart Association, 2000). The only exception is Darup, Doering, Moser, and Evangelista (1998) study, were they found respectable retention rates in highly motivated individuals who review and practiced their skills. However, for those who do not practice or review, low retention rates are inevitable. Studies have also found retention rates lower in the less educated, elderly, and male population when using self-instruction. Moser, Dracup, Guzy, Taylor, and Breu (1990) found that instructor-led sessions were more effective.

Result of these studies yielded varying formats of video-based instruction including: (1) passive watching, (2) learn/practice while watching, and (3) learn/practice after watching.

Passive Watching

The passive watching technique is useful for conveying information but does not involve any psychomotor training. This method may be motivational and students report “feeling more comfortable” after the video viewing (American Heart Association, 2000). This method has resulted in poor initial and long-term outcomes (Schluger, Hayes, Turino, Fishman, & Fox, 1987).

Learn/Practice while Watching Technique

The learn/practice while watching technique is a self-lead video sessions including a manikin for psychomotor performance. This method has been heavily studied with positive outcomes, but lacks and instructor to provide feedback or answer student questions.

Learn/Practice after Watching Technique

The learn/practice after watching technique is where the student watches a video segment, the instructor demonstrates critical actions, and student performs skills as demonstrated on the video. This method requires a trained/certified instructor to provide feedback and ensures students correctly perform the skills before moving forward. The video sessions provide for standardized training, thereby ensuring consistent training throughout the country. These videos are tightly scripted thereby limiting instructor variation, which has been a problem in ensuring that the same message is sent to all students throughout the United States. The goals of the videotapes are to improve consistency of information while maximizing skills practice time (American Heart Association, 2000).

Conclusion

According to the American Heart Association, video-based instruction offers many benefits including: (1) consistency of content, (2) less time needed for instruction demonstration, (3) more time for skills practice, and (4) a shift from a teacher-centered to a student-centered learning environment. The videos are beneficial in showing various angles when demonstrating skills and provide a focus on the most important aspects of the training. Video mediated instruction has a potential to motivate students by presenting real-life case scenarios or reenactments. As well, video serves as a visually stimulating educational tool.

The new courseware for these training programs were to be released during December 2000, however was delayed in production. Do to this delay; an impact study was not completed at time of this writing. Long-term data analysis evaluating students’ perceptions of this training medium as well as retention studies will be started this summer.

TOETS : development of a computer assisted assessment system

Eddy Demeersseman, KULAK, Belgium; Bert Wylin, KULAK, Belgium; Jos Panen, KULAK, Belgium

In this session we will present the results of a project to develop a comprehensive and flexible computer assisted assessment system. This system, called TOETS, delivers an item bank, an item editor, an test editor, a management tool and of course a student assessment tool. All these tools are internet based and are using the TCP-IP protocol to connect to a database on a TOETS-server. The re-use of items and complete assessments within new items or assessments and cooperation between instructors on items and assessments are very important characteristics of this software. Central issues during the development were also the ease of use, an intuitive graphical interface and flexibility. All kinds of multimedia (sound, pictures, video, animations) can be integrated in the items and in the feedback.

Abstract: TOETS is a comprehensive and flexible computer assisted assessment system that delivers an item bank, an item editor, an test editor, a management tool and of course a student assessment tool. All these tools are internet based and are using the TCP-IP protocol to connect to a database on a TOETS-server. The re-use of items and complete assessments within new items or assessments and cooperation between instructors on items and assessments are very important characteristics of this software. Central issues during the development were also the ease of use, an intuitive graphical interface and flexibility. All kinds of multimedia (sound, pictures, video, animations) can be integrated in the items and in the feedback.

Development and implementation?

TOETS had its origin in an institution-wide questionnaire on the needs of the innovation of our education. Within the whole group of teachers and instructors assessment was found to be the hottest item. Instructors of both our institutions were asking for training, support and tools to improve quality of assessment. That was in 1998.

Today, three years later, three projects have already been worked on. The original goals and project options have been profoundly changed. The first project aimed at making ‘assessment’-templates within existing programs like MS Word and Authorware. Now TOETS is an independent program written in C++ with an extensive and internet-based open source database. Ready for implementation...

Recently the University of Louvain decided to implement a campus-wide computer assisted assessment system. An advisory committee decided to attain a product of a private company. This decision to 'outsource' CAA had noting to do with the quality of our or other products. The development and support of a CAA-system within the university itself was too risky...

A comprehensive and flexible CAA-system

TOETS is a comprehensive and flexible computer assisted assessment system. TOETS is Internet based. However it does not make use of a browser like Internet Explorer or Netscape. TOETS has its own interface allow users (students, instructors and system administrators) to interact with the TOETS database.
on a server on the Internet. TOETS uses the TCP-IP protocol that is the Internet protocol. The choice for building a
TOETS interface that did not work in a browser was made for reasons of flexibility (a broader variation of
interactions is possible) and security.
TOETS contains a big and highly structured open source database.
TOETS has a modular architecture. Within each of the three modules all functions and features of importance for a
specific user group are integrated. The three modules of TOETS are: instructor, student and management..

The management module

TOETS is installed on a server on the Internet. It can be used by one institution by a co-operation of several
institutions. In both cases TOETS needs a system administrator. His function is to manage users, groups,
organisational units, educational units, and courses.

The instructors module

If one wants to make tests available to students on the Internet, the first thing one needs are items, a lot of good
items. An item has many multimedia components and properties: question, answer, distracters, scores, pictures,
sounds, video, comments and feedback, hints, links to external resources, etc. At this moment only multiple choice
is available. Instructors can insert one or more multimedia components (picture, sound, video) on all levels: on the
question level, on the answer and distracter level, on the general or answer specific feedback level. It also possible to
add meta-information on items… (difficulty, course, description, author, date of last modification,…).

A group of items form a test. Instructors can add and modify tests. They are able to change lay-out, preferences and
options of tests (the colour, background, feedback on/off, timeline on/off, free or fixed navigation through the test,
etcetera). Each test consists out of one or more blocks of items, their preferences and options (see above). TOETS
has the possibility to build user defined or system defined item blocks (a selection of items in a certain order). In a
user defined item block the instructor selects the items and chooses the order of the items in the block, using the
search and browse tool. In a system defined item block the instructor selects a combination of criteria and rules. The
system (TOETS) then picks out, at random, items based on the rules and criteria. It is possible to do this only once in
advance at the instance of the instructor (resulting in an identical test for all users). But it is also possible that the
selection of items from the item bank is made (based on the instructor-defined criteria) at the very moment that a
particular student wants to do his or her test (resulting in a different test for all students).

Very powerful tools of TOETS are the block rules and block navigations. At the end of each block instructors can
set rules and connect them with navigations. TOETS holds a score for the test as a whole but also for each block or
group of blocks that were defined in an test. In one or more rules (e.g. "if the score on block 1 is less than 50 %")
instructors can directly navigate students to another block or to the end of the test (navigation). This system of
blocks (and groups of blocks) gives the instructors a very flexible way to build student centred tests.

When a test is ready instructors can decide for which students (or group of students (see management-module)) a
test was published. It is also possible to specify a period in which the test is available. We call this a session.
Tools to analyse and report results are under construction. We are working on tools to analyse items (difficulty,
mean score, number of times the test was run,…), to analyse tests and sessions (difficulty, scores, mean score,
highest score, lowest score, standard deviation,…), to report the results of individual students (and groups of
students) on an test or a session (difficulty, scores, mean, highest score, lowest score, standard deviation,…), to
calculate item-test correlation (discrimination), A-values (attractiveness of distracters), etc...

The student module

The function of the student module is quite straightforward. To let students choose a test that was made available for
them (see management module) for this period (a session). To let students do a test. To give students feedback. To
create the possibility to interact with (send email to) the instructor if there are problems while doing a test.
Teaching OOT Using a Framework and Both Direct and Net-based Tutoring

Abstract: We report on experience from teaching OO project courses to undergraduate students. Before they can successfully tackle projects they have to climb a rather steep qualification ladder: pick up a working knowledge of some OO language, learn and practice OOA and OOD, and get used to advanced ideas like patterns and frameworks. In order to relieve this heavy burden somewhat, we provide an object-oriented application framework as a common base for the projects. That way, the students are given an architecture, which they have to adapt to their specific task instead of doing all the design on their own. We also believe that this policy closely resembles the way beginners are integrated into on-going projects in practice. We briefly describe the Java framework we use and then concentrate on the organizational issues involved.

Introduction

Education in object-oriented (OO) technologies has become a core part of any modern education in software engineering. A well-known problem with education in this field is the relatively long period of time that is required to get accustomed to "OO thinking":

- First, learn to solve problems by building small communities of interacting objects. People with a strong background in classical structured-procedural programming may first have to unlearn their previous algorithm-centered approach.
- Second, adopt the habit of reusing existing classes instead of inventing new ones. This requires you to know where to look for reusable components.
- Third, start to think flexibly about the organization of the software development process. Beginners have to be taught the importance of a formal software life cycle and of a proper requirements analysis (see e.g. Wilkinson 1995, Wirfs-Brock, Wilkerson & Wiener 1990 and Rumbaugh, Booch & Jacobson 1997).
- The most advanced concepts we teach to our novices are patterns and frameworks (see Gamma, Helm, Johnson & Vlissides 1994, Froehlich, Hoover, Liu & Sorensen 1998). Patterns describe concepts of proven solutions for recurring problems: when, where and how to apply them. Frameworks are application skeletons that can be turned into complete applications by providing parameters and/or subclasses of the framework's generic classes.

Here, we describe our current approach, which we have found very useful and which might be applied similarly by other organizations as well. This approach was developed jointly between Dresden University of Technology and the University of the Federal Armed Forces in Munich, and is applied at both universities. The central idea of our approach is to first provide a rapid and dense education covering all topics mentioned above in an introductory course, which immediately precedes the project course. The project course where student teams are assigned indi-
vidual tasks requires extensive practical work based on a given object-oriented application framework. This provides valuable experience for programming assignments and advanced courses in the postgraduate phase of their studies.

A strong motivation for putting so much emphasis on using a framework stems from the following observation: In academic as well as industrial settings beginners will often join projects that are already well in progress. Finding out enough about the project's structure to be able to do your job is similar to learning how to apply a framework. Experience with this activity is likely to be reusable to some extent also in a non-object-oriented context. A practical course based on one common framework even offers some more advantages:

- For the organizers it is easy to define a number of similar projects and to scale the projects' complexity from moderate to reasonably hard. Since they are based on the same framework, all the different tasks are still comparable.
- For the students it is simpler to extend the application architecture predefined by the framework than to design it for each application from scratch. Also, the framework provides many domain-specific components that can be used "off the shelf".
- Beginners get a chance to learn good design by example: Frameworks by definition are designed for change. Therefore, they typically exhibit patterns that increase flexibility.

The rest of this paper is organized as follows. First we briefly describe the domain, components, adaptation interface and documentation of our SalesPoint framework. The next section outlines the project organization: our aims, the persons involved, the timetable and, most important, our tutoring concept. The final section gives some statistics and recent experience.

The Framework

Our SalesPoint framework supports the development of point of sale simulations ranging from simple vending machines to big department stores. Typical applications include an exchange office where you can obtain foreign currency as well as a post office offering stamps and a well-defined set of services. The simulations comprise both business with customers (selling, buying, or renting goods) and administrative tasks (like accounting, refilling the stores, removing slow-moving articles, and putting new kinds of items on sale). All applications from the SalesPoint domain share the following characteristics: There is one single shop where customers are served at a number of counters (or SalesPoints, in our terminology). At each counter there is a queue of customers. Every counter offers articles from some fixed catalog. For each article, the catalog has an entry giving its name, price, and other relevant properties. A stock is a bag of articles from the catalog. Examples of stocks are: the goods on an order form, the articles contained in a vending machine, in the shelves of a store, or in a customer's shopping basket. Money fits into this terminology as a special case: Here the catalog is called a currency. It describes the set of valid bank notes and coins and their values. The contents of a personal purse or those of a cash register are called money bags. SalesPoint customers have data baskets, which may contain a number of goods chosen by the customer. Thus data baskets closely resemble the shopping baskets carried around by real customers in real shops. The contents of a data basket represent the state of a customer's current shopping transaction. Like other transactions, data baskets can be committed (e.g. when the goods are paid for and taken out of the shop) or rolled back (i.e. the goods are restored to the shelves they came from).

All SalesPoint applications have similar organizational and GUI requirements. Accordingly, the SalesPoint framework supports the development of point of sale simulations by providing (among other things) similar GUIs built from the same components including generic form and menu classes for user interaction. A shop is represented by a main window, which contains a set of subwindows, one for each customer at the currently visible counter. Tabular form components are available for presenting catalogs and stocks. The common organizational part comprises base classes for catalogs, stocks, currencies, and money bags, persistency management (on request the state of the simulation can be stored in a file to be restored again later), user management (allowing users with possibly different capabilities to be created), time management (for controlling the simulation time), transaction support including rollback, and a logging mechanism.

On a more technical level, framework users expect their framework's software to be robust and flexible. Among the robustness features of the SalesPoint Java implementation that require no activity on the part of the application developers (and thus might even go unnoticed by them) are: SalesPoint data structures are thread safe, i.e.
they can be accessed concurrently from different threads. SalesPoint guarantees the referential integrity of catalogs and stocks, i.e. you cannot add an item to a stock if there is no matching catalog item in the corresponding catalog. And you cannot simply remove a catalog item without first removing all corresponding items from all stocks based on this catalog. These properties are implemented using suitable Java Event and Listener objects. In order to make the SalesPoint framework flexible suitable design patterns were applied, e.g. the Factory Method pattern for creating stocks and the Bridge pattern for choosing between different time management implementations.

Like other frameworks, SalesPoint is adapted to its users' needs in several ways: first, by supplying specialized subclasses; e.g. menu sheets are easily adapted using Java's inner classes; second, by providing hook methods; e.g. the presentation of tables is adapted with hook methods: redefining the method compare(x,y) that compares table rows one can impose any sorting order one wishes; third, by providing parameters; e.g. when creating a new stock object one of the constructor's parameters describes which catalog to use, another chooses one of the algorithms for building stocks with a given value.

The SalesPoint on-line documentation consists of three complementary descriptions: a top-down introduction to the purpose, architecture and components of the framework, a javadoc-generated detailed documentation of all the framework's classes and methods including all the predefined adaptation interfaces, and a tutorial describing in a line-by-line fashion how the framework can be used for building a typical application: the simulation of a Fast Food Restaurant.

For more details on the introductory course and the framework see (Demuth, Hussmann, Schmitz, Zschaler 1998) and (Demuth, Hussmann, Schmitz, Zschaler 2000a). On the (English) SalesPoint homepage (Demuth, Hussmann, Schmitz, Zschaler 2000b) all the material for using the framework (code and on-line documentation) is accessible.

Organization

The project course organization, which we describe in the following, is very similar at both universities. A few differences come from varying conditions: the large number of students that participate in the project course every year in Dresden; two semesters (Dresden) versus three terms (Munich) per year; and students living on campus in Munich.

Aims

For the majority of students, the project course is the first hands-on experience in software engineering. Prior to that, they were taught (among other things) structured programming and verification techniques, sorting algorithms and data structures including hash tables and AVL trees. Programming tasks were defined precisely, small to moderate in size and typically could be solved by one person in a few days. In order to succeed with their projects students now have to develop a number of new ("soft" and auxiliary) skills:

- They have to learn to work in teams: assume different roles (team leader, developer, etc), communicate in a professional way within the team and with customers, and work systematically for a period of three months following some given method and a plan made by themselves.
- They have to find out what their task is: In contrast to the programming tasks they were given before the project definition is rather sketchy. It is the students' job to find out what to do and to negotiate with their "customers".
- They have to present their work: Both oral and WWW presentations are required. The presentations are aimed at either customers or consultants and thus differ very much in the level of abstraction and amount of technical detail.
- They have to acquire a working knowledge of the tools they need: In addition to some Java IDE they need a CASE tool and some HTML and FTP background as required to set up their own small WWW site.

During the project course a written process outline, guidance by the tutors and feedback from the presentations are available. With this background, the students are expected to develop the soft skills mainly by themselves.
Persons Involved

The students are asked to form teams of five or six persons each and to adopt a chief programmer team organization, i.e. to assign chief, assistant, secretary and developers' roles to the team members. The resulting teams are coached by senior students who in turn are supervised by the project course leader. The senior students work as tutors: They are both consultants for the younger students and clients for the software project. Technical questions and requests for framework correction or extension are handled by senior students who have participated in the framework development.

The situation resembles that of a start-up software company specialized in some domain (as represented by the framework). The company's technical staff consists of a technical director, four or five experienced developers (one of whom is responsible for the framework) and a bunch of 50 to 150 beginners who are to be "trained on the job". To avoid disaster, some strict discipline and a lot of communication is required:

- Teams have to adhere to a predefined timetable (see below). Otherwise, management cannot guarantee that projects will be completed in time.
- Development has to be founded on the framework. Beginners tend to do everything from scratch and "reinvent the wheel" many times. Only by using the framework they will contribute to the company's know-how and produce solutions that can be maintained easily.
- Guidance by management (i.e. the tutors) is impossible unless progress is documented extensively all the time. The company’s work process description therefore lists what kind of documents have to be produced in which phase.

Teams that will not stick to these rules are excluded from the project course.

Timetable

A rather rigid timetable is prescribed for project work. Once or twice during each phase, results (documents, programs) have to be presented to the tutors. Final delivery includes a formal oral presentation per team where the main results including the working program have to be shown and questions to be answered. The timetable is as follows (The number of weeks per phase is given for Dresden/Munich. A Dresden semester has approximately 13 weeks, a Munich term only 11 weeks.):

<table>
<thead>
<tr>
<th>Phase</th>
<th>Weeks</th>
</tr>

<tr>
<td>Implementation and Test</td>
<td>3/2</td>
</tr>
<tr>
<td>Maintenance</td>
<td>3/2</td>
</tr>
</tbody>
</table>

Table 1: Project timetables

Alternatively, incremental development with several development cycles is allowed. This approach is adopted by most teams. In the Start phase students establish their teamwork organization, obtain and install the development and documentation tool sets as well as the SalesPoint framework software and documentation. During this phase the students also have to study the framework and its tutorial. We experiment with different approaches to learning the framework. For example, each Munich student has to implement the same and rather simple SalesPoint application at the beginning of the project course. This takes time (3 weeks), but it helps the students to develop their main application much faster than when learning the framework in parallel with the software development. In the Analysis phase, students first identify the use cases of the system to be built. CRC card sessions are then used to elaborate corresponding scenarios in order to better understand the dynamic behavior and the classes of the target system with their responsibilities. OO modeling has to be documented in UML notation (Rumbaugh, Booch & Jacobson 1997) using static, use case, state and sequence diagrams. In the Design phase, suitable framework components are identified for implementing this model. The model is adapted accordingly and a first prototype can be built. The Implementation and Test phase is devoted to growing and testing the prototype. The Maintenance phase includes the removal of bugs and satisfying some minor clients' wishes. The latter serves as a test whether the design is clean enough to allow for easy modification.
Net-Based and Direct Tutoring

All information is distributed via WWW: the framework, its documentation, the tutorial, and the project specifications. Using email help can be obtained all the time from the tutors, the frameworks specialists, from system administrators, and from the course manager. Framework bugs and requests for new framework features can be entered into a web-based list. A public electronic calendar is kept for booking presentation dates and rooms. Some teams even install their own private electronic chat-rooms and bulletin boards for communication within teams. All these communication channels are used rather heavily indicating that without net technology this kind of course might not be possible - or at least take much more time for all persons involved.

The students are required to present their solutions on HTML pages. For this purpose, each team is given an account on one of the institute's web servers. Student team web sites are the most important prerequisite for net-based tutoring: therefore, the students are required to publish their results as early as possible and to update them on a daily basis. That way, the tutors and the course manager can asynchronously observe student progress all the time. This allows for instant (email) feedback and thus helps to avoid mistakes and too much time spent taking wrong turns. For beginners this kind of continuous guidance is very important.

However, net-based tutoring alone does not suffice: In difficult situations, inexperienced developers cannot be expected to even state their problems precisely. Some find it difficult to overcome the psychological barrier of asking an anonymous consultant for help. To get them started, tools and ways to work with the documentation have to be shown them directly. Although student web sites are really helpful, not all mistakes show up there. And sometimes it is easier to give feedback when meeting in person.

At the end of every phase (Dresden) or every week (Munich) students have to present their progress orally. In a short presentation of 15-30 minutes at most the teams demonstrate the latest version of their prototypes; each developer explains his or her contribution showing documentation and code fragments, and answering questions from the tutors or course managers, respectively. This is a way of ensuring that all team members actively take part in the development. Also, frequent presentations result in a more regular style of working. In the final presentation, we also collect student feedback for improving the course organization.

Evolution the Framework-Based Project Course

Since winter 1997/98 when we first taught the framework-based project course we have improved both the used framework and the project organization every year (Demuth, Hussmann, Schmitz & Zschaler 1998). A major step was taken in winter 1999 (Munich) and summer 2000 (Dresden), when we upgraded successfully to version 2.0 of the framework.

The overall results of the previous project courses are very encouraging. In Munich, there were no dropouts so far. This is probably due to the fact that in Munich almost the same number of tutors are employed as in Dresden while the student numbers are much smaller. Another advantage is that Munich students are paid by the armed forces and live on campus. The table below specifies the number of teams and the total number of students for each project course up to now.

<table>
<thead>

<td>115</td>
<td>54</td>
<td></td>
</tr>
</tbody>
</table>

Table 2: Project success rates

During the whole process we had a lot of feedback: from the tutors, some students' questions, many intermediate documents, final presentations with discussions and the detailed questionnaires we requested from the students. We learned that:
studying the framework took more time than we had expected (about 25% of the whole effort); in retrospect we feel this justified since it covers a good deal of what would otherwise have been part of the design phase; students rated the tutorial and the on-line support rather high;

- the time table was realistic, given the students' tendency to postpone work towards the end; on an average, the students spent about 10 to 12 hours per week on their projects; some additional time was needed to catch up on missing OO and Java knowledge from the introductory course;

- students generally liked the tasks they were given; some teams even tried to find out real clients' requirements by doing field studies; a growing number of students, however, would prefer to develop real applications instead of just simulations; students rated their own achievements rather high; for them, team work experience was novel and important;

- in the tutors' opinion, most students performed rather well, but there still seemed to be some who had hacked their way without a true appreciation of OO technology; on the positive side, the framework proved practicable and accommodated all kinds of students' approaches: everyone felt they had learnt a lot.

In the summer 2000 (Dresden) project course another 20 students were sent to a software company to do "real" projects there. Typically, more successful students applied for the external projects. The four teams were coached by a former university colleague. On an average, they spent as much time on their projects as the framework-based teams, but produced twice as much code. Also, they liked their projects very much.

So why not send all the students to industry instead of doing in-house projects? There are several problems: First of all it is difficult to find enough software companies where beginners are systematically trained as opposed to being misused as cheap code hackers. Today, short-term profit appears to rank higher than long-sighted investments in education. Because of the diversity of projects and companies it is difficult to offer equal opportunities to students; also, the organization and necessary quality control would probably bind at least as many university resources as the framework-based course.

On the other hand, our approach should carry over easily to frameworks in other domains and there provide the same advantages for beginners: realistic professional activity is simulated and guidance in the form of a framework is offered.

Abstract In spite of the growing interest in interaction design, there remains a large user population that needs special interest; users with special needs. These users can dramatically benefit from software that better responds to their interaction needs, not mentioning the fact that designing software that takes into account the special needs of such users makes software more easy to use for everybody. In this paper we present PERIGRAMMA, a system designed to offer an integrated environment for the support of people with movement or cognitive impairments who offer secretarial support in a modern office environment. The system is currently in its final stage of implementation and offers an easily accessible environment of four applications: a word processor, an e-mail client, a calendar and a web publisher.

Introduction

Arguments typically leveling against designing for user with disabilities include the claims that costs are too high, and the benefits serve too small a market. (Glinert & York 1992). The traditional view of people “having a disability” or “not having a disability” is overly simplistic. All users have a range of capabilities that vary across many dimensions depending on the user and his or her life stage, task and environment. People may experience sudden temporary or permanent changes in capabilities at any time in their lives. If a computer user falls and breaks a wrist, he will spend several weeks or more with much the same keyboard capabilities as many people with spinal cord injuries or missing limbs. In fact, a significant number of user requirements for people with disabilities apply to almost any user, given the right circumstance or task context. (Newell & Cairns 1993).

The system addresses primarily people with movement impairments and people with light cognitive impairments offering secretarial support in the environment of a modern office. Word processor, E-Mail Client and Calendar ranked first as the applications used most often in a survey on fully capable people offering analogous services. In addition, we decided to implement the web publishing application in an effort to offer such people the opportunity to easily circulate their documents and diminish in this way the factor of social isolation they face in their everyday life.

By the term “movement impairment” we are referring to disabilities that affect the ability to move, manipulate objects and interact with the physical world (e.g. spinal cord injuries, degenerative nerve diseases, stroke, missing limbs and repetitive stress injuries). Cognitive impairments on the other hand range from dyslexia to difficulties remembering, solving problems, or perceiving sensory information to problems comprehending and using language.

Several applications have been developed for the disabled at a commercial or research level. Applications such as Writing with Symbols' address people with cognitive impairments. The teacher or parent builds an on-

screen selection window(s) and places the vocabulary in it. The student then writes by clicking on items in the selection window(s). As items are chosen, each selection puts text, or text and pictures, into a writing area above. Multiple on-screen selection windows can be linked together to provide a large vocabulary of pictures. Set ups and writing files may then be saved for later use.

Figure 1. Writing with Symbols

Special Learning Food for Thought introduces the vocabulary of Food and engages learners in activities that challenge and stimulate them at their own level of thinking. It helps them learn and develop skills in language, counting, choice making, matching, identification, vocabulary and visual and auditory discrimination (Figure 2).

Figure 2. Learning Food for Thought

GRAFIS (Stephanidis 1999) supports the typical word processing functionality, through a simple interface, accessible through conventional as well as alternative input-output devices. The basic characteristics of the interface are: (a) a clear separation between the ‘text-input’ and ‘function’ areas, and (b) elimination of overlapping objects on the screen through the grouping of functions in alternative functional areas. In addition to text input (in Greek and English), manipulation and formatting, GRAFIS features a simplified interface for

storing, retrieving and otherwise managing document files. The user is supported by an extensive on-line help system, which describes the interface and guides the user in the completion of common word processing tasks. GRAFIS also supports saving and loading documents in Rich-Text Format (RTF), thus allowing users to share and exchange documents with their able-bodied counterparts employing mainstream word processors. Several other software applications are available for disabled, focusing on case-specific specialities (Sirmakessis 2000).

**Design Considerations**

In our effort to address as big a percentage of population as possible, we distinguish two main levels of difficulty (novice and expert) in a total of three distinct user profiles, summing up to 6 instances of the system. Each instance is differentiated by the kind and the degree of special needs to be covered and the assistive technologies to be integrated. More specifically, we designed two versions of the system for people with movement impairments and one additional version for people with light cognitive disabilities (see Table 1). Each one of these versions required a different approach as we had to deal with different interaction scenarios (input devices) and screen layout.

**Table 1. Supported profiles based on the user needs (two levels of movement impairments and one level of light cognitive impairment)**

*People with heavy movement impairments that cannot have control neither over the mouse nor the keyboard,* but can use some kind of switch have access to the system via a combined use of an on-screen keyboard and the scanning technique. The system supports three different layouts of the keyboard (QWERTY, horizontal grouping and vertical grouping layout). The scanning technique is based on two actions: NEXT and SELECT. Action NEXT moves the user to a dialog’s next step (steps vary depending on the interaction control encountered by the scanner). Action SELECT is interpreted as the user’s wish to actually interact with the control currently activated (optically highlighted) by the scanner. For instance, if the currently highlighted object is a button, NEXT will move on and highlight the object next to this button, while SELECT will activate the button and result in executing the button’s operation. This user profile has posed some very interesting questions on the subject of screen layout, as it is of crucial importance to insure that all buttons and interactive objects are placed and grouped in an ergonomic way, limiting the time required to select and activate any given control (on a most commonly used basis). *People that can use the custom mouse device but not the keyboard,* can fully interact with the system via the mouse and an on-screen keyboard activated by the mouse. In this case, no scanning is required. This profile was the easiest—in comparison—to handle, as it was closer to our notion of a usable and ergonomic interaction. *People with cognitive impairments* raised serious issues to consider on the design of the user interface, the exact captioning of buttons, the metaphors adapted in the design of the graphics, the presentation of error messages and system messages in general, the learnability and memorability of controls and tasks, as well as the overall design and implementation of the help system.
Architecture and Functionalities

The Word Processor offers the custom set of text editing, formatting and management of text files. The format of the created documents is .rtf so that they are compatible and recognizable by all commercial software. The user is also offered the capability to import a picture, find/replace a word, print-preview the current document and also save it in html format so that it can be published on the web using the web publishing application of the system.

The E-mail Client supports both POP 3 and IMAP and offers the capability to send/receive, forward and reply to messages, manage mail attachments and interact with the Address Book in order to locate the e-mail address of a recipient or update the Address Book with the e-mail address of the sender in the message currently selected.

The Calendar provides a view of the current month so that the user can locate the day of interest and a daily view of the recorded events. For each event a reminder can be set with the option of an accompanying sound. With every new event entry a check is performed that informs the user of a potential overlapping with a prior entry. A set of secondary calendar applications is also under development, which shall be supported in the expert version of the system: Tasks, Notes, and Address Book (in fact it is the entity mentioned in the E-mail Client, which is updated and accessed by both applications). All the system’s individual applications can communicate with one another via the clipboard. A high level representation of the system is depicted in Figure 3.

One fundamental feature of the applications that comprise the system is that they have basic functionality, which is common to all of them. This raised the necessity to adopt an architectural model, which takes advantage of this fact not only in the development phase of the system but also during its operation as far as performance is concerned. The model, which is adopted and best fits the above-mentioned system is called component oriented.
According to the component oriented model the applications of the system are broken down to their structural components. The structural components are responsible for the fulfillment of the operational specifications of the system. It is obvious that each structural component implements a set of operabilities. Each structural component must provide access to its operabilities, so as they can be used by the application. This access is obtained through interfaces. Each structural component may provide one or more interfaces. Each interface provides access to a group of operational or conceptual interrelated operabilities. The access is performed either through method invocations relevant to the requested operability or by accessing publicly known properties. It is not necessary to use all the interfaces that a structural component exposes. Each application may use only those interfaces, which provide the needed operability.

The following figure depicts the relations between the applications and the interfaces of the structural components.

![System's component model](image)

**Figure 4. System's component model**

The system comprises four main applications. Each one offers a complete set of functionalities that overbalances those identified as typical secretarial needs. As refers to the functionalities that should be left out from the novice version of all applications, the help and guidance from scientists that work with people with
special needs and particularly people with cognitive problems was necessary. Certain options from the word processor and the e-mail client were left out, while in the case of the Calendar, the secondary applications were considered too complex for comprehending and using in the novice version of the system. At the point of installation, there will be two options regarding the kind of the user's special needs (whether there are cognitive or movement impairments) and in the case that movement impairments are selected, there will be an extra dialog about whether or not the user needs to interact through some kind of switch (in which case the scanner must be activated). In addition, either "Novice" or "Expert" must be set according to the level of user's prior experience with the system and with computers. An option "settings" available at all times will allow the user to change the system's level of difficulty (novice or expert), fill in and alter data required by the e-mail client and the web publishing application (FTP server, login, password, directory, mail server, etc.) as well as the size of buttons and the size and type of fonts, the number of days a message stays in the trash before being permanently deleted, sound activation/deactivation, etc.

Figure 5. The main screen of Calendar with daily entries presented in the white frame. The system interface is in Greek but the user can enter English as well.

Conclusions and Future Work

PERIGRAMMA is an integrated office environment for people with movement and light cognitive impairments. This environment offers significant potential for increasing their social inclusion. It can be used to fully support teleworking, since through a common environment; one can prepare a document, send it to someone else by e-mail or publish it for generalized access on the web. Moreover, since the interface is designed in a simplified manner and tasks in the profile version are easy and straightforward to execute, the system could be used by inexperienced fully capable users and children. We have already planned a series of evaluation sessions for the two target groups using a "think aloud" procedure and lab observation. We intend to continue evaluation and system redesign, as feedback from the actual target group in this case is irreplaceable. Our future directions include the further extension of the system so as to expand and foster the needs of more categories of special needs (e.g. low vision problems is our next working hypothesis). In addition, our efforts will focus on extending the degree of system customization to a user's specific preferences, as well as an English version of the system.

Improving Motivation by Flexible Course Organization: Case Study on Telecommunications Education

J.B. Destro-Filho and J.P. Breda-Destro
DECOM - FEEC - UNICAMP
State University of Campinas

destro@decom.fee.unicamp.

Abstract: This paper proposes a simple method for improving student motivation, which is based on the following principle: the pedagogical strategy to be followed by the teacher must be flexible and fit to a specific student profile. The fundamental role of multimedia and Internet are discussed. We report the application of the new methodology to an undergraduate course at the Faculty of Electrical and Computer Engineering (FEEC) of Campinas State University (UNICAMP)-Brazil.

Introduction

Motivation of students in classroom plays a key role for any academic course. In our local context, State University of Campinas (UNICAMP) has organized in 1998 an internal meeting in order to develop undergraduate teaching. However, to our knowledge, it seems that few works of the engineering education literature are devoted to the crucial problem of student motivation. For example, according to the proceedings of the last international engineering education meeting (ICECE 99), only 10% of the articles have made explicit reference to the issue.

In this paper, we introduce a new strategy for motivating students. Our proposition is simple: professor must change his/her traditional behaviour towards the course organization. As a consequence, undergraduate courses pedagogy should be based on the following three-step procedure: pointing out problems, looking for problem causes, proposing effective solutions.

New Strategy and Case Study

Firstly, it is necessary to realize the problems of the course to be taught by means of extensive discussions with previous lecturers, students and also the administrative staff. After getting a complete picture of the problems from several viewpoints, it is then possible to propose preliminary solutions. Then, based on these solutions and on the characteristics of the current students, it is possible to propose a coherent pedagogical strategy to overcome previous problems, as well as to match the course goals to the current students needs and expectations.

Of course, there are several problems to be tackled, however in this article we are convinced that two issues deserve special attention: the order of the topics to be studied and use of several different pedagogical tools. In fact, based on the principle that each student has a personal learning process (Pintrich 95), current pedagogical research strongly motivates the use of different tools: transparencies, informatics, practical experimentation, visits outside the classroom, group work, etc. According to a recent research, computers and INTERNET represent an important element in the daily life of UNICAMP students, before their arrival at the university. As a consequence, multimedia and WEB-based resources should be used in courses, so that students will feel “at home”.

In the following, we discuss the application of the new strategy to the undergraduate course on waveguides of FEEC/UNICAMP. This course, which will be abbreviated by EE753, comprise 64 hours (4 hours per week), and it has been taught during the period March-July/2000. Firstly, the following problems have been pointed out after discussions with the academic community.

(P1) It is difficult to understand and to work with Maxwell’s equations.
(P2) Links between theory and practical situations or applications should be provided.
(P3) The subject is lengthy and there are few relationships with courses of other fields (electronics, control).
Based on the previous discussions and on the profile of the students, the following guidelines have been set up.
- Emphasis on microwave circuit design for telecommunications applications.
- Review on Maxwell’s equations and soft transition from circuit to wave theory.
- Illustration of transmission line concepts and exercises based on software tools provided in the website of the University of Utah, as well as by the well-known microwave package PUFF.
- Analysis and visualization of 3-D electromagnetic fields, as well as microwave devices design, by means of 3-D-plot software and by multivariable function packages.

Results

In (Destro et al. 2000), we discussed the evaluation of student motivation and a new method for assessing it has been proposed. This method is based on taking note of all interactions (doubts, remarks, discussions) between students and the lecturer, classifying them according to some criteria and estimating some motivation indexes, which characterize the motivation level of the class. The first three columns of (Tab. 1) present experimental bounds of these motivation indexes. For further details, see (Destro et al. 2000). The last column of (Tab. 1) (in the right side) present results achieved by means of the new pedagogical proposition. Clearly, (Tab. 1) points out that all motivation indices of EE753 are much more closer to the well-motivated class, which characterizes the good performance of the proposed strategy, as well as the great improvement associated with the use of information-technology resources.

Table 1: Theoretical bounds for student motivation indexes and current results

VII. CONCLUSION

In this paper, a new pedagogical method for improving student motivation has been proposed. A case study on telecommunications education has been presented, attesting good results of the proposed strategy. Concerning multimedia and INTERNET resources, experimentation pointed out that they represent fundamental tools for concept visualization and simple circuit designs, specially in the context of complex tridimensional electric and magnetic fields. Current work involves the search for other INTERNET/multimedia resources, as well as new pedagogical tools based on a multidisciplinary approach.

Crossing Boundaries: An Integrative Architecture for Campus-Wide Digital Libraries in Research Universities

Barbara I. Dewey
University of Tennessee
Knoxville, Tennessee, USA
bdewey@utk.edu

Abstract: This paper examines the creation of robust digital libraries and information systems using a campus-wide architectural model through two means: 1) an analysis of selected Digital Library Federation members and 2) an examination of the University of Tennessee as a case study for developing a model which crosses boundaries of departments, colleges, museums, libraries, and research centers. The goal of such a model is to advance the integration of digital scholarly resources and services for teaching and research.

Introduction

Although many universities have developed so-called “digital libraries” few have truly integrated digital resources campus-wide. Barriers to such development rest more with campus organizational, political or boundary crossing issues than with technical issues. Using an analysis of selected research libraries, and the University of Tennessee as an emerging example, the paper reviews strategies for overcoming barriers and establishing powerful systems of deploying digital content and service. The paper also examines potential issues and next steps for federating multiple “digital libraries” on a national and international level.

The Current Context of Digital Libraries and Universities

Digital libraries of one form or another exist in nearly every modern research university today. However, the content of the so-called “digital library” is as diverse as each institution. In almost every case the term “digital libraries” refers to both “born digital,” commercially available digital resources, and re-formatted digital content administered or controlled by the university library. Digital services such as electronic reserves, virtual reference, and web-based tutorials are sometimes included in research libraries’ articulation of their digital library. The emergence of an identifiable digital library by name is a relatively recent phenomena with leadership coming from associations like the Digital Library Federation (DLF). The DLF is a consortium of libraries and related agencies that are pioneering in the use of electronic-information technologies to extend their collections and services. Through its members, the DLF provides leadership for libraries broadly by identifying standards and “best practices” for digital collections and network access, coordinating leading-edge research-and-development in libraries’ use of electronic-information technology, and helping start projects and services that libraries need but cannot develop individually (http://www.clir.org/diglib/).

Common Characteristics of Digital Libraries in the DLF

DLF members share some common attributes related to their digital library efforts:

- A name or identity has been established for an institution’s digital library initiative.
- The “content” of most institutions’ digital libraries is administered by the library rather than integrating resources found elsewhere on campus.
- Most institutions do not appear to have a robust search engine designed specifically for cross campus searching of digital (including multimedia) scholarly resources.
Organization and staffing models of digital library initiatives vary tremendously ranging from establishing a department, using a committee model, and/or deploying existing staff from across the library system to population digital library initiatives in an integrative way.

University of Tennessee: A Case Study of Emerging Initiatives

The University of Tennessee is a comprehensive public “Carnegie I” research institution with land grant status. The UT Libraries is also a founding member of the Digital Libraries Federation and is active, both in the Libraries and elsewhere on campus, in developing digital library capability along with the underlying infrastructure needed to deploy scholarly resources in the digital environment. A unique aspect of the University is the rapidly emerging boundary-crossing activities between the Libraries, the Office of Research and Information Resources, the School of Information Sciences, and and a number of Colleges/academic departments. The UT Libraries has been at the forefront of several digital initiatives noted below:

Content

- **Unique digital collections.** The UT Libraries (led by the University of Georgia) were awarded a second IMLS grant to scan 1,000 original documents and visual images relating to the Native American population of the Southeastern United States (http://aztec.lib.utk.edu/~di/). Other digital collection projects include digitized photographs related to the Great Smokies region.
- **Commercial e-resources.** UT is expanding its suite of full-text journals, e-books, and electronic databases.
- The UT Libraries play an active role in the campus ETD (electronic thesis and dissertations) project.
- The UT Libraries are playing a leadership role in implementing the Tennessee Electronic Library (TEL), a state-wide digital library collection.

Services

- **Digital Media Services (DMS) department.** The primary objective of DMS is to serve as a production facility for faculty to digitize a wide range of materials for courses. It will also be used to help the Libraries explore scholarly publishing with faculty, departments, and research centers.
- **A next generation media services department** (formerly audio-visual) with electronic text and imaging capabilities is being implemented for image archiving as well as multimedia image creation. Electronic reserves and Web-based tutorials have been implemented.
- A **research data services department** is being implemented.
- A working group has been established to develop a virtual reference services capability.

Infrastructure

- UT is a founding member of the Digital Library Federation and is now part of the initial testing for the Open Archives Initiative metadata harvesting project supported by the Mellon Foundation.
- **Wireless technology** has been installed in the UT Hodges Library as part of a campus-wiring upgrade project called Volnet.
- Interlibrary Services implemented the ILLIAD system providing electronic access to patrons to track their requests. Additionally, material is sent electronically whenever possible to the user’s desktop.
- ASERL (Association of Southeastern Research Libraries) is moving forward with the virtual electronic library catalog, Kudzu, which will provide access to the rich resources of the large research libraries in the Southeast including digital library collections.

Next Steps for Integrative Digital Architecture

The ability to identify and link to existing campus-based digital archives, collections, databases, and other kinds of research materials is an important next step in the Tennessee digital initiative work. On a broader basis more work needs to be done at the DLF and other consortial levels to allow for identification and access of digital scholarly resources across institutions and disciplines.

Barbara I. Dewey
University of Tennessee
Knoxville, Tennessee, USA
bdewey@utk.edu

Abstract: This paper examines the creation of production and “studio” models for digital image deployment for teaching, learning, and creation of multimedia scholarship. Two new services being developed at the University of Tennessee will be examined including the Digital Media Service, a production facility for course material preparation, and a “new AV center” embracing a studio concept for multimedia access and production.

Introduction

The deployment of multimedia digital materials, including images to support teaching and learning, is an important need at research universities. The ability to integrate discipline-appropriate and robust digital content for course WebPages and scale production of such content at large campus such as the University of Tennessee was a major driver for the Digital Media Service (DMS). The need to provide a space for a wide variety of digital creation activities for course assignments and research was the motivating force in overhauling the UT Libraries’ Audio Visual Department. These collaborative digital initiatives provide service to the entire campus.

Digital Media Service: A Production Model

The Digital Media Service (DMS) came out of an interdisciplinary working group appointed by the UT Office of Research and Information Technology and the Libraries. Its primary goal is to digitize and store instructional materials for faculty from all Colleges with the ability to convert all formats into digital media. Faculty will be referred to appropriate staff for copy permission, instructional technology needs (Web page development and training), and identification of course-appropriate resource materials from the library and elsewhere. In the future it is hoped that the service would be able to provide digitization for grants and contracts, for department needs that are not course-related, and for electronic scholarly publishing production.

The DMS is a true partnership between the Libraries and the Office of Research and Information Technology (ORIT) reporting jointly to the respective heads of both entities. It will be funded and staffed by ORIT with a library point person and a jointly populated steering committee providing day-to-day operational guidance. A larger interdisciplinary advisory committee with faculty users will commence after the service is underway to provide strategic direction (including representatives from the School of Information Sciences, College of Communication, the School of Broadcasting, early faculty adopters, and the various IT groups on campus). Staffing consists of a DMS coordinator, a digitization specialist, and student assistants. The permanent staff are supervised by the university’s Customer Technology Support group. The facility is located in a high traffic area of the UT Hodges Library.

It is hoped that the DMS will be seen as THE central campus facility for course-related digital production, therefore alleviating the need for individual colleges and departments to maintain their own production facilities. It will also provide faculty with much needed support to integrate the use of digital resources into their courses through course Websites. Scaling production at a large campus (26,000 students) is now possible with a central facility.

The “Studio” Approach to Image Deployment: UT’s New AV Services Unit
At about the same time the DMS was being created a new initiative began to modernize the University Libraries’ Audio Visual Department. When Hodges Library opened in 1988 the AV Department was a state-of-the-art facility deploying film and video to individual carrels as well as to a number of viewing rooms located throughout the library. This capability enabled faculty from all over campus to show films and videos to classes as well as have students individually study materials in viewing carrels. Audio carrels were also built in the unit. While the group viewing rooms and traditional services of centralized AV deployment will still be continued there is a growing unmet need for digital multimedia collections, deployment, and application to teaching and research. Audio carrels could be eliminated to make room for new services in the facility originally built in 1987.

A “New AV Task Force” worked to define new services. Members also met with faculty from disciplines who currently use AV or would most likely use the multimedia services to support teaching and research. The group developed a plan for the implementation of new services:

- Add multimedia computers and high-end software for use by students or faculty
- Provide access to multimedia instructional programs
- Enable student production of multimedia assignments using text, images, video, audio, and/or a combination of these formats
- Provide group areas for multimedia production
- Provide group and individual instruction for users
- Provide technical support

New Services

Two major new services are also planned including collecting and archiving images for use in academic departments such as art, classics, anthropology, history, agriculture, etc. A number of commercial digital archives are being considered for purchase and digitizing locally held images is planned. An enhanced electronic text capability is also planned where e-text literary collections will be increased, and encoding capability and training will be added for students and faculty wishing to do text analysis.

The implementation of these capabilities will truly enable students and faculty to use the facility as a multimedia studio to, not only view and manipulate digital multimedia resources, but also to create multimedia “products,” scholarly resources, and assignments. The facility is seen as a central studio supplementing specialized computer labs located in the Colleges. These labs are only open limited hours and are restricted in their use and do not always feature on-site assistance. As with the DMS the “New AV Department” will be a collaborative effort drawing on expertise found from throughout the campus to help build the collections, conduct training, and identify priority services. Staffing will come through reallocation of existing staff resources in the current AV Department and from other sources.

Summary

Implementation of the Digital Media Service and the “New AV Department” will provide the University of Tennessee with a much greater capacity to deploy resources based on images and other digital multimedia. Students and faculty will be able to integrate these resources into their teaching, learning, and research. Redundant and expensive services scattered throughout the campus will not be necessary. Issues remain including effective marketing of the new services, staff training, and relationship building to continue the collaborations at a high level.
Designing a Virtual Laboratory for an Online Course in Microelectronics

Gabriel Dima, Razvan Matei, Ciprian Cudalbu, Marcel Profirescu
EDIL R&D Centre
University "Politehnica" of Bucharest
Romania
gdima@edil.pub.ro, rmatei@edil.pub.ro, ccudalbu@edil.pub.ro, profires@edil.pub.ro

Abstract: The paper presents the design, development and implementation of a virtual laboratory associated to an online course in Microelectronics within the EDIT Distance Learning Network (EDIT DLN). This way students from different Romanian universities have access to expensive computer hardware and software resources that are not available in their own universities by means of web-based interfaces of the needed simulation tools as well as to the expertise of the best experts in the field.

General Presentation of EDIT DLN

The EDIT DLN was setup within a project financed by the Romanian National Higher Education Funding Council for a period of three years and run by a consortium of four Romanian technical universities (University "Politehnica" of Bucharest, Technical University of Cluj, Technical University "Gh. Asachi" of Iasi and University of Craiova) and IBM Global Services, Education&Training, La Hulpe, Belgium (see Drondoe et al. 1998 and Voinea et al. 2000). The project main objectives were to assist the implementation of the distance learning methodologies and to setup an academic open and distance education network in the field of Microelectronics and Information Technology.

Course implementation

The pilot course entitled Numerical Modeling of Carrier Transport in Semiconductor Devices was derived from a "classic" postgraduate course given at University "Politehnica" of Bucharest and was implemented in LOTUS Learning Space 4.01 environment. The text-based course material was reorganized in a larger number of chapters in order to better keep trace of the students' assessment. The students must pass a preliminary test from the course prerequisite topics in order to be admitted. Furthermore, the access to a given chapter is granted only if the student passed the tests from the previous chapters. A maximum number of attempts to pass a test may be imposed by the tutor.

Laboratory implementation

Some chapters have laboratory work that in the first implementation stage was "classically" perform in our center in a face-to-face approach. The reason for doing this way was that the needed software run only on powerful RISC workstations that are not commonly found in Romania. In order to have a full online course we decided to design web-based interfaces for all the simulation tools used within the lab that will allow a student to launch remotely a job using a low cost Pentium based computer. As the jobs might run for periods of time between half hour to several hours depending the simulation tool and the computer load, we choose an asynchronous way of working, the results arriving as attachments to e-mail messages in the student mail box.

It is important to point out that these interfaces offer limited access to the simulation tools features as they are topic-oriented designed (Drondoe et al. 1999). This way the student can easy cope with the complexity of the simulators (keywords, physical models, numerical methods, etc.) and spend most of the time for the real
work. Through the integrated communication system the student is encouraged to discuss the results together with others and can contact any other student or a tutor. In the same time each simulator has an extended help that offer on-line guidance when needed. For research purposes the students may have full online access to a specific simulation tool through special interfaces.

Figure 1: Screen snapshot of the WWW interface for a device simulation tool

Conclusions

A pilot implementation of virtual laboratory associated to a course in Microelectronics within the EDIT DLN has been presented. This way students from different Romanian universities have access to expensive computer hardware and software resources that are not available in their own universities by means of web-based interfaces of the needed simulation tools as well as to the expertise of the best experts in the field.

Study of Thermal Phenomena in Junior High School
A New Technology - Based Learning Environment.

P. Dimitriadis, L. Papatsimpa, G. Kalkanis
University of Athens, Pedagogical Dept. P.E, Navarinou 13A, Athens, GREECE.

Abstract: The use of the New Information Technologies in the laboratory of Natural Sciences leads to a satisfactory approach, by the students, to the scientific views in thermodynamics, when compared both to their original ideas, voiced during the labs, as well as the situation described in the international bibliography. Taking into account the current developments in the teaching of Physics, we designed and applied a program that studies thermal phenomena in the laboratory, through the use of MBL

Introduction.
The rapid scientific and technical developments, a defining characteristic of our time, call for a radical change in the content, as well as the method, of the teaching of Physics throughout all stages of education.

Even though there is almost a consensus among the teaching researchers, concerning the need to change the content and method of teaching Physics, there has been considerable argument about the direction of such change. However, most of them agree that the following goals have to be attained(1):

- That the students understand the basic concepts of Physics and their relation to the natural world, the activities of everyday life, as well as high-tech devices, so that the subject of Physics be widely accepted, rather than considered to be meant for future specialists.
- That there be a more active participation of the students in the process of learning.

Without a doubt, the attainment of the above goals can be simplified by incorporating the use of new technologies in the process of education, which can lead to the design of new educational tools, which, in turn, can allow students to collect, analyze, visualize, model and announce data, so as to understand Physics through their active participation(2).

Subject/problem.
Long-term studies in various countries have shown the lack of functional distinction of the concepts of heat and temperature (3) by the junior-high students, as well as the inability to understand the concept of thermal equilibrium (4) and the procedure of heat transfer by conduction (4,5). In general terms, most students believe that the temperature of objects depends on the material (6), and as a result, they do not acknowledge that the same object can have different temperatures. They do not acknowledge that different objects that come into thermal contact will eventually reach the same temperature. They cannot percept the concept of heat, as a form of transferred energy (4,5) and they confuse thermal conduction and temperature of materials (6).

The laboratory practice, which is supported by the New Technologies, can play an important role in the improvement of the teaching results, regarding the concepts of thermodynamics and thermal phenomena. In particular, the use of sensors for the taking of measurements (e.g. temperature) and their simultaneous display on the computer screen, in the form of a diagram, gives the possibility:

- To observe the change of temperature in more than one systems simultaneously.
- To focus the students' attention on the phenomenon, and relieve them of the "dull" process (as they perceive it) of taking measurements and creating the relevant diagrams.
- To detect the students' preconceptions as well as to develop Socratic dialogues between the teacher and the students during the experiment.

Design and procedure.
Taking into account the current developments in the teaching of Physics, we designed and applied a program that studies thermal phenomena in the laboratory, through the use of a computer, connected with sensors to the laboratory equipment. The program included 5 labs that referred to calorimetry, linear dilation, propagation of heat through conduction, thermal equilibrium and energy conservation. Three grammar schools in Athens were selected to be school units of application, so that the sample would represent the average Greek student. There was a total of about 250 participating students of ages 14-15, that created 10 groups, divided into experimental group and control group (5 groups each). The teams of the groups were selected in such a way that they were almost equally matched, the criterion being the average mark of the students last year in the subject of Physics.

The experimental application classes used various simple means – hotbeds, isolating containers etc., and worked in MBL environment, which disposed a computer, proper software, a printer, a projection screen, a video projector, sensors of force and temperature, as well as an interface for the sensors and the computers. In the experimental group, two additional teaching hours took place, so as to help the students become familiar with the software and the use of sensors. The current textbook was used, as well as a laboratory guide, with proper work-
sheets, and suitably configured labs. The students worked in groups, but the answers to the questions of the worksheets were given in individually.

At the original stage of the execution of the labs by use of multiple choice questions, the students were asked to predict the development of the variables displayed on the computer screen.

After the conclusion of the experiment, they had the possibility to compare directly some of their original predictions with the actual experiment data. The worksheets included both a quantitative processing of the data, as well as questions regarding the concepts and the laws under study by the students, which were helpful in many cases for the development of a Socratic dialogue with the professor.

The experiment's design for the control classes was based on the traditional lab equipment. All the activities provided in the textbook were realized, as well as the relevant labs from the experimental group. The students created and studied relevant diagrams in the lab, and they were also given filled-out diagrams, which were talked about in class.

The experimental and control classes operated equally in every school unit, on every aspect. The teachers were the same for both classes. Students in both classes worked under the supervision of two teachers and they filled in worksheets. The efficiency of each teaching intervention was evaluated through a questionnaire, common for both classes. (The filling in of the questionnaires was conducted a week after every laboratory experiment).

Results

Ten days after the completion of those labs, a test was given to the students, which consisted of multiple-choice question of an open type (where they were also asked to justify their answers) as well as the construction of a diagram. The results, which are presented suggestively, concern the dependence of the rate of heat transfer to the nature of the material, the concept of thermal equilibrium, the use of the relevant law to calculate the amount of heat transferred, and the application of the principle of conservation of energy during the heat transfer.

According to the results: a) Although an equally big percentage of students (80% for the C.G. and 90% for the E.G.) acknowledges that heat transfer causes a rise of temperature, the experimental group surpasses the control group by 40% in correctly recognizing the diagrams that display the development of the phenomenon in two different materials; b) the experimental group surpasses the control group by 40% in constructing graphs that show the development of temperature by exchanging heat between two materials of different temperature, and by 30% in understanding the approach of the state of thermal equilibrium; c) the percentages of correct application of the relationship of heat calculation were 50% for the E.G and 35% for the C.G. The percentage of students connecting heat transfer with the conservation of energy, with correct justification, were low in both groups, but the E.G. was still leading by 12%.

Conclusions.

It comes forward, by the results of the above study, that the use of New Information Technologies in the laboratory of Natural Sciences leads to a satisfactory approach, by the students, to the scientific views in thermodynamics, when compared both to their original ideas, voiced during the experiment, as well as the situation described in the international bibliography. Furthermore, the use of the Environment of New Technology bolsters the ability of the students to describe, understand and predict the development of natural phenomena through diagrams. Similar conclusions can be drawn by the application of the ENT in another field of knowledge, on students of the same age (9). Generalized use of the ENT in various cognitive fields and educational stages may become a substantial contribution to the confrontation of the problem of drawing the interest of students, as well as improving the effectiveness of the provided education in Natural Sciences.

Abstract: A number of approaches for expert-based evaluation of Instructional Multimedia have been proposed during the past few years. However, there is little evidence in the literature regarding how effective they are, especially in identifying real learner problems. In this paper we report an empirical study which assesses whether experts can predict the problems experienced by students. The evidence suggests that expert evaluators, although successful in predicting usability problems, still have difficulties identifying certain types of learner problems, such as comprehension and learning support. We conclude that expert evaluations do not eliminate the need for tests with actual learners, and suggest ways of improving their effectiveness.

Introduction
The usability of Instructional Multimedia (IMM) applications is vital for their success and for the satisfaction of their users, as the confusion resulting from using poorly designed programs can be particularly detrimental to learning performance. To avoid this, the evaluation of such software should assess how successful learners are at achieving learning tasks, and not just how effective and efficient they are while interacting with the application (Squires and McDougall, 1996). To measure the former, ‘before’ and ‘after’ knowledge tests are typically performed with learners (Draper et al, 1996). However, learner tests have been found to be expensive in terms of the time and effort required, and recruiting users can also be problematic (Dimitrova and Sutcliffe, 1999). Due to these problems, involving learners may not be feasible in many projects, and alternative evaluation methods need to be explored.

A number of expert-based methods for the evaluation of IMM have been proposed in the past few years, such as Interactive Multimedia Checklist (Barker and King, 1993) and Multimedia Taxonomy (Heller and Martin, 1999). However, there is little evidence in the literature regarding their effectiveness, especially in terms of identifying real learner problems. In a review of expert- and learner-based evaluations, Reiser and Kegelmann (1994) criticise the expert-based approaches for having poor reliability as the majority of them required evaluators to make subjective judgements. The authors also acknowledge that teachers and students rate software differently, however they do not explain the nature of these differences. Tergan (1998) also criticises checklist-based approaches for their inability to assess the instructional efficacy of the software. Although these reviews are useful, they do not provide empirical data to support the conclusions reached. The reviews also do not give details about the differences between expert and learner evaluations.

In this paper we report an empirical study which assesses the effectiveness of expert predictions using three different evaluation methods by asking the question whether experts can predict real learner problems. To address this, we compare the results produced by two types of expert - subject matter specialists and multimedia designers - to those from learner tests and discuss their similarities and differences in terms of the number and the type of problems predicted.
Study Design

The IMM Application

One section of a multimedia environment for learning Mathematics at university level was evaluated. The selected topic covers the principles of exponential functions and the three types of transformation of these functions – Scaling, Reflection and Translation. A series of 23 screens presents the Maths content in textual, graphical and animation formats. Interactive quiz-like tests are also provided, which enable the users to plot exponential graphs and test their knowledge of transforming them.

Learner Tests

Four students undertaking a course in Mathematics at City University London were involved in the learner tests. Before the experiment, pre-exposure knowledge tests were administered to establish students' prior knowledge of the material. Each student was then given four tasks to perform, which consisted of learning about the principles of exponential graphs and exploring the three different types of transformation. During the usability tests, the students were asked to think aloud while performing each task. After the students had completed the tasks, they were interviewed by the experimenter to determine their attitude towards different aspects of the application. The student sessions and the interviews were recorded on video. At the end, comprehension tests were administered to reveal the knowledge students gained while working with the software. The material covered by the students was divided into 20 knowledge propositions, of which the students were expected to have a reasonable level of comprehension after working with the application. Each proposition was tested in the post-exposure comprehension tests.

Expert Evaluations

Ten experts took part in the expert evaluations, including six multimedia designers (MMDs) with varying degree of design experience and four subject matter experts (SMEs), all of whom had significant knowledge in this area of Mathematics and experience in teaching it to students.

Each expert was asked to use one of three usability evaluation methods. The first method was Multimedia Taxonomy (MMT) (Heller & Martin, 1999), which represents a three-dimensional categorisation framework of multimedia issues, such as media types, their expression and contextual aspects like the target audience and the content. The taxonomy contains 120 cells, in each of which evaluators can ask questions regarding specific issues of media design. The second approach was Multimedia Cognitive Walkthrough (MMCW) (Faraday & Sutcliffe, 1997), which concentrates on cognitive aspects of multimedia presentations. It involves three steps of evaluation of the media design, the media combination and the media selection. Each step contains a set of guidelines against which the relevant presentation segments can be evaluated. Finally, the Interactive Multimedia Checklist (IMMC) (Barker and King, 1993) comprises twelve categories, such as engagement and interactivity, which embody essential principles of good design. The authors suggest 90 questions distributed amongst all categories, and experts are expected to answer the ones relevant to the application being evaluated. The MMT and the IMMC were used by two multimedia designers and two subject matter experts, whereas the MMCW was used by two multimedia designers, as recommended by the authors of the techniques. No subject matter experts used the MMCW because it concentrates on low-level multimedia design issues, and it would not be appropriate for such experts to use.

Results

Learner Tests Results

The video footage containing the student interactions, their verbal protocols and the post-exposure interviews was analysed to identify usability problems. Problems were identified using a set of nine criteria, such as 'the learner articulated a goal but cannot succeed in achieving it without external help from the experimenter' and 'the student expresses confusion while trying to achieve a task'. A total of 51 unique usability problems were found to match the criteria. The comprehension test results showed that students understood the concepts of Reflection and most of
those of Translation. However, they had particular problems understanding the principles of Scaling, as well as some principles of Translation. In particular we found that the students had difficulties comprehending 13 of the 20 knowledge propositions. We defined comprehension difficulties as cases where at least two students did not grasp the essence of the knowledge proposition. Thus, as a result of all learner tests we found that the students encountered 64 problems in total, i.e. 51 usability and 13 comprehension problems.

**Expert Evaluations Results**

A total of 191 unique problems were identified by the experts. The total number of problems identified by each expert group is shown in Table 1. 27 problems were identified by both types of experts using the IMMC, and this number has been included in both totals given in columns 4 and 5.

**Analysis of the Evaluation Results**

The main question to be answered was whether the experts were able to predict the problems experienced by the learners. Therefore, we compared the experts’ predictions with the results from the learner tests. To be able to match the two problem sets, six matching rules were established. For instance, problems were matched if both problem statements described the same learner behaviour or if both described the same fault with the same design feature, although it may have been observed in a different page of the application. The results of the problem matching are depicted in Figure 1. As can be seen from the figure, only 28 of the 64 learner problems were predicted. It was found that in total 60 statements identified by the expert evaluators mapped onto 28 of the learner problems. In the following sections we discuss these results.

**Number of Correctly Predicted, Unidentified and Unobserved Problems**

We first analyse the number of correctly predicted versus the number of unidentified learner problems. We then discuss the number of problems the experts predicted, which the students did not encounter in their interaction with the application.

**Correctly Predicted Problems**

From Figure 1 it can be seen that the experts predicted 28 of the 64 learner problems, or 44%. In particular, we found that 24 out of the 51 usability problems were identified by the experts, or 47%. However, the experts could predict problems with only 4 out of the 13 knowledge propositions which caused comprehension difficulties to the students, which is less than a third. The multimedia designers predicted more of the usability problems, whereas the subject matter experts identified more of the comprehension problems.

**Unidentified Problems**

The expert evaluations failed to predict certain problems that the students did encounter. We found that in total 36 of the 64 learner problems were not predicted by the experts, or 56%. In particular two thirds of the comprehension
difficulties and nearly half of the usability problems the students encountered were not predicted by the experts. The above results show that the experts had difficulty identifying potential comprehension problems, but they were more successful at predicting usability problems which the learners experienced.

Unobserved Problems
Apart from the 60 problems which were matched with the learner ones, the experts also found 131 other problems. We divided these into two categories – specialist problems and false alarms.

The specialist problems category includes 81 problems, which students cannot be expected to identify. These problems concern a variety of issues, such as the accuracy of the Maths equations and the notation used. We found that a significant proportion of the problems identified by the SMEs fell into this category (in total 60% of their predictions), whereas only 25% of all issues predicted by the MMDs were specialist ones.

False alarms are issues which experts identified as problematic but which did not cause problems to the learners either while interacting with the software or during the knowledge tests. We found 50 false alarms in total, which amounts to 26% of all expert predictions. Most of them were raised by the multimedia designers. One reason for this could be that the MMDs were more critical about the design of the application, pointing out minor issues which did not cause problems to the learners.

The analysis so far only provides information on the proportion of the learner problems predicted or not by the expert evaluators. The next part of the analysis aims to provide a more detailed review of the types of problems which the learners and the experts focused on during the evaluation of the IMM application.

Types of Problems Identified

From the analysis we found that although there are some similarities between the problems identified in the learner tests and the expert evaluations, each group paid attention to different aspects of the IMM application.

Types of learner problems the experts could predict
One area where the experts predicted all learner problems is affordance, which encompasses difficulties relating to students not being able to identify which part of the presentation affords certain actions or what action a particular button affords. An example of such problem is shown in Figure 2 (a), which illustrates that after reading the instruction circled the students had difficulty identifying where to click for the graph of 10^x. Both expert groups also detected some issues of learner engagement, i.e. how interesting and challenging (or not) the application was to the students.

The multimedia designers also focused on problems with the design and appearance of the media resources used, such as the design of the graphics, graph lines, quality of the icons and the pop-up message boxes. This kind were also identified by the students. The experts further spotted some problems with synchronising time-varying media resources, such as animated text which changes too quickly for the students to read. The MMDs also identified some problems with the navigation within the application. Finally, mostly the SMEs, but also two of the MMDs, pointed out some areas in the presentation which they believed were not sufficiently clear, and the students actually had difficulties understanding these sections.

Types of learner problems the experts could not predict
On the other hand, a number of learner problems eluded the attention of the experts. These fall into three categories: learning support, comprehension and missed interaction.

Learning support problems deal with how much explanation of the material the students required. This greatly depends on the students' prior knowledge. Most students requested more help with Scaling and Translation, especially Scaling, since they had no previous knowledge of these concepts. Although before the evaluation sessions the experts were told to assume none or little prior knowledge of the subject matter, none of them could envisage where students may need further explanation of the material. Furthermore, none of the evaluation methods explicitly asked the evaluators to consider students' prior knowledge in order to identify such issues.
The comprehension problem category describes which parts of the material the students had problems understanding. Although the experts identified some areas of the material which could potentially cause such difficulties to students, they missed out a significant number of them. One factor found to influence the comprehension was the varying complexity of the Maths material. The higher the complexity of the material the greater the cognitive task requirements were on the students. Reflection was found to be the simplest concept, the principles of Translation were slightly more complex, and those of Scaling were the most complex of the three. The comprehension test results showed that all students grasped the concepts of Reflection, the majority of them got the Translation right as well, however most of them experienced difficulties with understanding Scaling. None of the evaluation methods suggests that the complexity of the material or the cognitive task requirements should be considered, and none of them correlates these aspects to how media resources could be used and designed to represent complex concepts in order to enable students to comprehend them easier.

Finally, missed interactions are situations where the students did not perform an interaction which is considered important for achieving their learning tasks. One such situation arose on the Horizontal Reflection screen, illustrated in Figure 2 (b), where a student skipped the test regarding Reflection, which would have helped them reflect on what they had learned about it. Such situations occurred predominantly because the learner’s attention was not explicitly drawn to the important parts of the presentation. As can be seen from Figure 2 (b) the icon to start the test is placed at the bottom right-hand corner of the main presentation screen where the learner is not likely to look very often.

Types of problems the experts predicted but the students did not encounter
As mentioned earlier, the experts predicted a number of problems which the students did not experience, which we categorised as specialist problems and false alarms.

Specialist problems include pedagogical and instructional design issues, which fall into four categories. Firstly, many predicted problems concerned the accuracy and completeness of the Maths content and the notation used. Such problems were identified by the subject matter experts. For instance, two SMEs identified a mistake in one of the equations of Vertical Scaling. Secondly, issues regarding the adequacy of different monitoring and assessment techniques were identified. A third set of issues questioned whether different expert system facilities are required to support learners. Finally, the experts also made suggestions as to how the design of the application could be improved. Some of these specialist issues can potentially point to usability and learning problems. However, they were specified in a way that only revealed design faults, without identifying the likely effect of the faults on the learner’s behaviour or performance.

In the false alarms category we include issues which experts identified as problematic but did not cause problems to the learners. Most false alarms were due to experts making wrong assumptions about students' sense of orientation within the application and the information presented, their control over the application and preferences regarding
customisation of program settings. For example, one expert thought that students could lose a concept of where they are in the application, however when asked during the interviews none of the students reported experiencing such confusion. Such comments were made predominantly by the MMDs. The multimedia designers also commented on design faults which did not seem to bother the students. Perhaps because the students were so engaged in grasping the Maths material, they did not seem to notice presentation imperfections, such as some of the letters in the titles not being properly drawn. Such issues, however, are valid design considerations and can be useful for redesigning the application. Finally, the SMEs presupposed that learners’ attention and concentration could not be maintained consistently, which was not the case with the students. However, the experimental nature of the evaluation could have caused the students to be more focused.

Conclusions

The results of the study presented in this paper show that the experts were successful at predicting a number of usability problems the students encountered. However, despite using formal usability evaluation methods, the evaluators did have difficulty predicting certain types of learner problems, particularly comprehension, learning support and attention to important information. One explanation of this is that the experts and the learners showed differences in focus. The subject matter experts emphasised matters of the content, the multimedia designers paid particular attention to the media and presentation design, media synchronisation and navigation, while the students were more concerned with how understandable the material was. Another critical issue that emerged from the study is that expert evaluators tend to uncover design and content faults, but rarely try to infer what consequences such faults may have on learners’ behaviour and performance. Even when they did try to predict the effects on the learner, they often made wrong assumptions. The evaluation methods also did not support experts in making such predictions. The evidence presented above suggests that expert evaluations, although effective, do not eliminate the need for actual tests with learners.

The prediction rates of expert evaluations could be improved by training the experts in how to use learner data more effectively, so that they can make better assumptions about students’ interaction with the IMM, and their behaviour and performance. Furthermore, more research is required into how the design of IMM should take into account relevant learner characteristics, such as their prior knowledge, metacognitive skills and personal motivations, and incorporate the findings into evaluation methods for use by experts. The existing usability evaluation methods also need to be enhanced to consider how the major factors contributing to effective IMM design - the learner, the subject matter content, the instructional approach adopted and the context of use – all relate to each other. This will provide a more integrated approach for evaluating the effectiveness of IMM.

Abstract

In this paper, the author looks at how the Internet can help Africa develop educationally. The research also highlights the problems, which have caused the slow growth of Internet access in education in Africa. The author then suggests solutions to these problems in an effort to bring full Internet access to Africa as quickly as possible.

Keywords

Internet, Africa

1. Introduction

Before the Internet was introduced in Africa, (Osburn, 1999) observes that there was no other method capable of transmitting the same information and at the same time to both industrialised and developing countries. With the Internet, the people of Africa have, for the first time the opportunity to have access to the same information, and at the same time, as people in industrialised countries.

Other than giving Africans the same development opportunities as the industrialised world, the Internet is the fastest growing communication technology. According to (Molosi, 1999) it took 38 years for the radio to have 50 million listeners, 13 years for the television to reach the same mark and only 4 years for the Internet to cross the same line. By the end of 1998, more than 100 million people were Internet users. With the ability to grow so rapidly, one wonders why more people in Africa have not been able to gain access to the Internet, and have not been able to use it as an educational tool.

As the use of the Internet continues to grow, this will have profound implications for African countries. According to (Africa on the Internet, 2000), there are fears that if Africa does not 'connect fast enough' the growth of the Internet will only accelerate marginalisation of the African continent. As the pace of growth accelerates even more, the gap between those who are linked up and those who are not grows larger. These
dangers and fears are real and should not be underestimated. Lamenting them will not stop the growth of information technology. Instead, Africa's civil society, governments and entrepreneurs need to be challenged to take advantage of the information technology revolution now gripping the rest of the world and bring the Internet to Africa.

2. Problems Causing Africa's slow Growth in Internet access

Internet access in Africa has slowly improved over the years, but many people in the continent are still unaware of the Internet and those who may be aware of its existence don't know how it may be of benefit to them. There are several reasons why Africa's Internet infrastructure has remained so fragile, therefore slowing down the rate at which people are able to access the Internet.

2.1 Interference of state-owned PTCs

According to (Adam, 1993), the state-owned Posts and Telecommunications Corporations (PTCs) involvement and approval is usually required to proceed with networking plans in the area of telecommunications in most African countries. Because, in most cases, the PTCs have rigid policies and poor management and computing capabilities, the need for approval by the PTC to proceed with any networking plans frequently hinders the progress of networking in Africa.

(Adam, 1993) further observes that in most cases these PTCs claim to be the national networking institutions. This creates confusion because these PTCs now “go beyond service provision to becoming regulators of all communication equipment.” Other main bottlenecks to networking are that there are no clear communication policies to support data communication in general. Also, there is usually a lack of co-operation between the private or academic sectors and these government-run PTCs. This has slowed down the implementation of intensive networking in Africa.

Because of their rigid policies where telecommunications are concerned, the PTCs have actually slowed down the implementation of the Internet to Africa. In most African countries, these PTCs have the monopoly over all telecommunications infrastructure and no competitors are allowed to try and improve the services provided by the PTCs. The existence of several players in the telecommunications field greatly improves the services of the companies as each tries to outmanoeuvre the other.

If the state monopolises telecommunications, there are no controls to the prices that they will charge for accessing the Internet. The problem is even compounded in Africa because of the few telephone lines, which exist. (Cohen, 1999) puts it this way: “A few statistics illustrate why the basic requirements of access-a-telephone-line presents problems for less industrialized countries. Globally, 49 countries, 35 of which are in Africa, have less than one telephone per 100 people”. The lack of telephone lines in some areas makes it difficult to cultivate an Internet culture, as there is need for a telephone line and a computer in order to be able to gain access to the Internet.

Besides not having reliable telephone lines which are necessary for usage of the Internet, cost is also inhibitor to Internet access. (Guinness, 1999) states that access is:

...typically at around US$3 for half an hour...Equipment prices are [also] high once you move north of South Africa. Add up to a third once you hit Namibia or Botswana, more as you reach Zimbabwe and northwards. In one very typical African country, even a modest secondhand PC can cost at least $1,000- the price of a new machine in America. And signing up to an ISP [Internet Service Provider] could cost $130 a month.

Some governments at times tries to regulate the content of the information accessed over the Internet. According to (Cohen, 1999), this happens in countries where telecommunications are monopolized by the state. Governments can also restrict access for political purposes and economic gain. (Cohen, 1999) further observes: "Globally, some governments have chosen to control the liberalising effect of the Internet by..."
denying access to entire segments of their populations, either through exorbitant charges or by confining access to select groups”.

2.2 Computing Equipment in Short Supply

(Adam, 1993) highlights the fact that both hardware and software are difficult to source in Africa in terms of cost. Therefore, equipment is usually in short supply. If it is available, it is either obsolete or under utilised. In an institution, one may find mainly old mini-computers and low-end personal computers with limited application software.

One is convinced that if the policy makers appreciate the importance of computer literacy, the resources would be made available to purchase computers for schools. The policy makers would also see it that computer education is included in the school curriculum.

2.3 Low Investment in Research and Development

Statistics indicate that African universities and governments invest only a small percentage of their budgets in research and development. The policies implemented by the governments may only be short-term and do not take into account any long-term research options. As (Adam, 1993) put it, "the research staff work under extremely difficult conditions. Salaries and incentives are limited and not sufficient to promote the use of modern technology for research".

Usually an individual researcher or a research department in an organisation or an institution is not able to afford the costs of using computing technologies in research and development. A lack of understanding of the impact of electronic communications on the telecommunications infrastructure and the impact on research and development is one of the persistent challenges to network development.

2.4 Extreme Dependence on External Technological Sources

There is an extreme dependence on external donors in the area of information technology. This dependence could be in the form of finance for purchasing equipment or computer hardware and software donated to an institution. According to (Adam, 1993), this has a few disadvantages such as:

1. The use of information technology is mainly limited to themes selected by donors, consultants, etc. If the donors have donated equipment which they want to be used in the engineering department of the school, then even if there is a greater need for the equipment in the computer science department of that school, the equipment cannot be shifted there.

2. There is an overall dependence on the importance of information technology equipment and accessories, often at high cost. Such dependence limits the type of scope of use of the equipment and is often controlled by consultants. These consultants may be preaching their own approaches which usually lack concern for the growth of national networks (Adam, 1993).

Despite these disadvantages, external sources are very important in bringing the Internet to Africa. They have the financial resources, which are needed in order to purchase equipment and train the system operators and users. Without them it is not feasible to try and implement a network plan in Africa which will benefit a greater part of the population. So there actually has to be a trade-off between the resources which have been donated by these external sources and the control that they have over the use of equipment.

2.5 Lack of formal training in the area of networking

There is an observable slack in the area of formal training in computer networking. (Adam, 1993) observes:
There is a lack of formal training in the area of networking in Africa to give a broad view of electronic communications, including telecommunications policies and intermediate and advanced networking technologies. Network administration is a new field, even in developed countries, and it is often difficult to find skilled resources for it.

Because of the lack of training in network design and management, and the fact that those who are skilled in the networking area move to places that offer better salaries which is usually in foreign countries, there is, therefore, a shortage of human resources in the field in Africa. In order to curb the brain drain, industries should be challenged to give salaries and conditions of service, which are comparable to those in countries, where the experts in computer networking are moving to. To curb the brain drain, industries should be challenged to give salaries and conditions of service which are comparable to those in the countries where the experts in computer networking are moving to.

2.6 Lack of culture for sharing information

In academic institutions and industry there is the problem of lack of a culture of sharing information, which should exist mainly in these circles. There is an unwillingness to share information and resources, maybe because of the competition for foreign resources.

With companies which are competing, this is understandable. Each of the companies wants to get ahead of the rest of the competitors by improving services and, therefore, increasing their customer base. In academic institutions, this problem sharply limits progress in the area of computer networking. If one has an idea or information that they have been able to source, then sharing it with others will also improve their understanding and maybe bring in new insights that they had not realized before.

3. Suggested Solutions

The problems, which have been listed in the previous section, have seriously affected the connectivity of African countries to the Internet. Although the Internet is essential, building intensive Internet connections require a thoughtful plan, long-term commitment, financial support for sophisticated Internet technology, sufficient human resources to run sophisticated networks, and in-depth knowledge of networking.

3.1 Sensitisation and Teaching

Sensitisation and teaching are important activities in networking. Continuous sensitising and teaching theory of networking costs system operator’s time, but is most useful during the first stages of building a national network. There are several ways in which people can be sensitised on the use of the Internet. One method is to introduce electronic mail (email) through easy and understandable means.

Email is an Internet facility, which can be used by anyone needing to send a message to someone else who is connected to the Internet. This facility should be automated and user friendly in order to catch the attention of researchers in different fields who have no interest in the Internet.

3.2 Frequent Updating and Change

Communication resources are usually used up to the extent they become available. Networking is a dynamic area that needs frequent updating and change. Realising the fact that there is a continuous change in computer technology, there is a grave need for frequent upgrading of the equipment that an organisation has, and an improvement in the skills of the people in the computer field.
3.3 Collaborate with PTCs

Government-owned Posts and Telecommunications Corporations (PTCs) have been one of the major stumbling blocks to networking in Africa. PTCs actually claim to know much about networking than they do. If policy makers and key industry players collaborated with PTCs, they would be able to encourage each other in networking technology.

PTCs should also acknowledge that electronic networking would not threaten their networks or reduce annual telephone bills but would rather improve their capacity and generate demands for newer services. In essence, this would be an advantage for the PTCs. If they have improved services, they are better able to compete with new players who come into the telecommunications market. Thus, long-term collaboration schemes should be established between community and government PTCs.

3.4 International Cooperation

The networking map indicates that Africa lags behind all other continents in the use of data communications technology. While the global Internet is growing at a phenomenal rate, its potential changes to society are becoming immense, and the creation of a truly global internetworked research village is becoming evident. Isolation from this global movement is still very much in evidence in Africa. African network enthusiasts can only become self-sufficient through learning from the experience of the international community.

3.5 Institutional Support

Institutions play a major role in promoting networks. Lack of institutional support and political will to promote a network initiative are, according to (Pimienta, 1993), major stumbling blocks to networks in the region. To quote him directly, “Building of network user groups, supporting official structures for academic institutions such as science and technology commissions, and involving active researchers to obtain political backing from their institutions," are ways of improving institutional support.

3.6 Financial Resources

Technical plans and network architectures should be based on available financial resources. (Pimienta, 1993) lists the following as major costs of a network: the coordination of a network from conceptualization to implementation, the installation and configuration of a network, network support, including training (user support), the maintenance both at user level and at nation level and communication costs. Dependence on foreign assistance to cover all of the above costs makes national network overly dependent. When such donors withdraw, national networks may be jeopardised. (Pimienta, 1993) suggests methods of building cost recovery tools into the national network to help to support it. Some of these tools include institutional subscription fees, additional fees for conferences or other Internet services and training and support fees.

3.7 Technical Plan

A sound technical plan is also a critical element in sustaining a network. Networks should match national infrastructure and user requirements. (Pimienta, 1993) suggests an affordable yet advanced entry solution such as UUCP, a migration strategy to Internet, and the development of Fido-based networks wherever and whenever appropriate. (Pimienta, 1993) further suggests that concentrating efforts toward building large national hosts (rather than numerous smaller nodes) allows for better transmission media and continuous support for the improvement of bandwidth.
Wireless technologies are actually being seen as one of the most important ways of addressing the needs of a continent with the least developed telecommunication systems in the world. (Jensen, 1996) though argues that “although wireless systems can offer far more rapid roll out times, greater reliability, lower maintenance costs and better security, wireless Internet connections are also not inherently more viable than wired networks – they are more appropriate in applications where traditional solutions for some reason are not feasible or cost-effective. These traditional solutions would include access to the Internet via a telephone line and a modem.

Apart from the additional equipment that makes wireless systems more costly, they often require skilled technicians to install. The TCP/IP protocol was designed for a relatively error-free environment and, according to (Jensen, 1996), many wireless technologies are inherently prone to errors.

Conclusion

Although Africa is lagging behind the rest of the world in Internet connectivity, it is rapidly trying to catch up. Africa has realised what a cost-saving measure it can be, and how it can address the big problem that Africa is facing, which is isolation. The past three years have seen an explosion of Internet sites, by Africans for Africans. The Internet is also becoming increasingly sophisticated in the dissemination of news and information and dozens of African newspapers are now producing editions that can be read on a computer screen.

The Internet is a communication tool that should not be confined to industrialised nations and begs to be utilised now to address Africa's chronic need for communications and development of education. The ushering of Africa into the new information age will be realised through a partnership of African governments, private business and donor agencies. The desirable outcome is a sound telecommunications infrastructure, decrease in access costs and equipment costs, proliferation of telecentres in rural areas, heightened computer awareness and improved communication.

Abstract

Current workflow systems largely assume a closed network where all the software is available on a homogeneous platform and all participants are locally linked together at the same time. The field of Electronic Distance Education (EDE) on the other hand requires the next-generation workflow that will integrate workflows from a distributed heterogeneous environment in order to support students who are not only dispersed over a wide geographic area but are working at different times. The notion of agents, particularly mobile agents provides an elegant way of executing workflow processes across geographic borders. This paper looks at integrating agents into the current workflow systems that support distance education in order to create a theory for the design of intelligent workflow systems. This will enable an active collaborative work among participants who subscribe to EDE.

Introduction

The Internet has accelerated the development of electronic distance education (EDE) as a medium for providing efficient global communication. At present numerous virtual universities have sprung up. However, none of these sites is totally automated as human intervention is required for routines such as exchange and assessment of course work. The teacher makes no provision for the student to initiate submission of course material. Almost equally passive is the teacher's action. Here the teacher sends the student course material and waits for the student to reply via e-mail. There is no automatic notification of the tutor once the coursework arrives on his machine. A push strategy is required to speed up submission of course work by the student and quick response on evaluation from the tutor.

Neither EDE nor the Internet respect artificial boundaries and the teacher and student may be situated at many different locations spread across the world. A worldwide audience of students is able to benefit from one specialist in a particular field through subscribing to EDE. The quest for higher education will see a lot of movement towards EDE. Therefore methods have to be used to ensure efficient student–lecturer interaction in an EDE environment. The other reason why there is need for efficient EDE implementations stems from the poor data communication infrastructure installed in most developing countries. This infrastructure was meant to support voice traffic rather than data. The bandwidth is generally limited leading to reduced performance. The result has been increased timeouts as students try to download their courseware. In most cases the bandwidth is limited to 64k putting a strain on the system and in some cases resulting in congestion. The use of automated systems will result in reduction of congestion in the network. Data can be cleared pretty fast due to the use of agents which are employed in the routing process. The longer the data stays in the system the higher the loading of the system.
It is inevitable that EDE systems will use different software and hardware platforms. To support such a heterogeneous environment, EDE software must be able to execute uniformly, unaffected by the platform on which it is executing. Automated mechanisms are needed to cut across the different virtual environments.

In education, just like in many business applications decision-time is a crucial factor that provides a cutting edge over competitors. Reduction in interaction time through automation in education requires close coordination between the tutor and student. But more EDE applications still involve a substantial human element, which in turn limits the speed at which interaction occurs. Consequently a major objective of EDE research is a reduction in human involvement in the intermediate stages of course delivery. An EDE system should therefore support the ability to embed intelligence in the system, to automate strategic decision-making that was traditionally performed by humans. Moreover the decision-making capability provided should be dynamic, reacting to user needs and the current environment.

Typical course offerings over the Internet require many interactions, each of which must be communicated over the Internet, which is much faster than prior human-to-human communication but relatively slow compared with the computers that the Internet interconnects. An EDE system that can perform interactions locally without repeated Internet communication will achieve significant performance over prior approaches. To satisfy these requirements for an EDE system, mobile agent technology emerges as an appropriate technology. This technology allows an agent in the form of program code, data and execution state to be packaged into a message and sent across the Internet to remote computers. The mobile agent can execute on remote computer, and only bring back the results to.

In the educational marketplace, many suppliers adopt a push strategy to announce their coursework and conduct surveys of student response to the quality of the coursework. Traditionally this has been done by humans, who visit the student on behalf of the tutor. With appropriate automation, mobile software agents can be sent to many student sites, quickly and with low cost, obviating human involvement in the educational process. Mobile agents can be used as student assessors to determine the quality of education. In the past this would have been achieved by querying many students individually in a student survey, analysing the response, and determining the optimum quality of teaching and to maximise the student. With mobile agents these calculations can be done dynamically at student sites, to determine the student response and quality of courseware and to adjust the courseware accordingly. The objective of the mobile agent technology is to maximise the returns of the courseware.

Workflow automation is emerging as the most rapid, cost-effective enabler of change even in EDE. It allows organisations to become more adaptable by continuously customising their work processes. Workflow automation achieves this through intelligent applications of codified business rules, processes and best practices, and by automatically providing the right individual with timely access to relevant information. It allows employees to perform their jobs more efficiently and cost-effectively. Workflow automation in conjunction with agent technology will improve the efficiency of EDE-related workflows.

2. What is workflow automation?

Workflow automation is the automation of business processes, in whole or in part, during which information of any type is passed to the right participant at the right time according to a set of intelligent business rules [White, 2000]. This allows computers to perform most of the work while humans have only to deal with the exceptions. At its most basic level, workflow is the passing of documents, information or tasks from one participant to another, or from one application to another. Workflow automation has the potential to deliver the following benefits:

- Improved productivity
- Reduced operating and labour costs
- Improved customer service
- Increased sales
- Reduced waste and duplication
• Improved access to timely information
• Minimal IT and job-specific training

Routing, rule enforcement, role/relationship definition and tracking/auditing are essential characteristics of workflow systems. Routing involves transferring information from one defined person or automated process to another. For example, data from the fixed format part of a Web questionnaire might be routed to another program for analysis, while data from a "comments" section on the same questionnaire might be routed to a human being for review. Rule enforcement is a defined procedure that determines the action taken when a particular information task is received. A rule might state, for example, "If a sale decreases inventory to a certain level, then launch a new work task to restock that item."

Role/relationship definition is a group of one or more people in a workflow environment who share common responsibilities [Workflow, 2000]. For example, "authorized virtual university student" could refer to any one of several individuals who might fulfill that role. Data in a workflow system is often routed to an individual by virtue of their authority to serve in a specific role. The assignment of a specific person to take on the role is based on who is available when and where a particular task needs to be done. Tracking/Auditing is the ability to readily find out where a particular task is and where it has been already. This capability is often missing from the processes that automated workflow systems are intended to replace, i.e. the old "it must be lost in somebody's inbox" problem. Questions such as "has the course material been delivered to the authorised student", and "has the right course material been delivered" are answered by this.

Workflow systems can be classified as image-based, form-based and co-ordination-based [Workflow,2000]. Image-based workflow systems are designed to automate the flow of paper through an organisation, by transferring paper to digital images. These are used in EDE to transfer documents between the student and the lecturer. These were the first workflow systems that gained wide acceptance. Form-based workflow systems are designed to intelligently route forms throughout an organisation. These forms, unlike images, are text-based and consist of editable fields. Forms are automatically routed according to the information entered on the form. In addition these form-based systems can automatically remind people when action is due. They can be used by the tutor to alert students when the coursework is due. This can provide a high-level of capability than image-based workflow systems. Form-routing systems vary from traditional vertical market workflow systems, like those used for insurance claims processing, to the recent crop of products that handle general administrative tasks like travel expense reimbursements across many types of businesses. Coordination-based workflow systems are designed to facilitate the completion of work by providing a framework for coordination of action. The framework is aimed to address the domain of human concerns (business processes), rather than the optimisation of information or material processes. Such systems have the potential to improve organisational productivity by addressing the issues necessary for customer satisfaction, rather than automating procedures that are not closely related to customer satisfaction. They are useful in defining the sequence of course modules in EDE.

Workflow systems can also be classified as queue-centred systems, ad-hoc systems and collaborative systems. Perhaps the most familiar queue-centred system comes in the form of telephone interactive menu systems, where you wait till a person is available to handle your request. In distance education the student sends in their assignment and wait for the teacher to reply. These systems can be more complex when they provide, for example, elaborate workflow handling for exceptions, or serve as a front end feeding into other workflow systems. Ad hoc systems mimic what was once done in face-to-face meetings and phone calls. They typically exploit the ability of "GroupWare" software and modern email systems to handle routing slips, voting, etc. Circulating resumes or getting approval of minutes are two examples of how such systems are used. This form of workflow is also finding application in distance learning where it can be used to simulate traditional classroom interaction. Collaborative routing systems are appropriate workflow tool in a regulatory approval process, for example, where circulating drafts are to be reviewed and revised until they are rejected or approved for handoff to the next system. These systems may handle both highly structured data typical of "forms routing" systems as well as less formal data characteristic of ad hoc systems.

Agents in conjunction with workflow automation offers a chance to improve the efficiency of EDE-related workflows.
3. What is an agent?

An agent is a simple heterogeneous autonomous communicating software component. Autonomous agents are able to work on behalf of the user without the need for any interaction or input from the user. They act without human intervention, tirelessly performing tasks. Some of these systems scour the world's databases, usually via the WWW or other generic access methods returning interesting and relevant information such as the literature recommended by the tutor.

Intelligent agents are software entities that carry out some set of operations on behalf of a user or another program with some degree of independence or autonomy, and in so doing employ some knowledge or representation of the user's goal or desires. A typical example might be an information-gathering agents. Agents operate without the direct intervention of humans or others and have some kind of control over their actions and internal states. Many agents are meant to be used as intelligent electronic gophers - automated errand boys. Tell them what you want them to do - search the Internet for information on a topic, or assemble and order course material according to your desired specification - and they will do it and let you know when they are finished.

The typical client/server architecture communicates via requests and responses, which require a round trip trek across the network. Often the client and server pieces are on separate machines and they communicate over the network. When the client needs data or access to resources that the server provides, the client sends a request to the server over the network. The server in turn sends a response to the request. This "handshake" occurs again and again in a traditional client/server architecture.

In mobile agent architecture, the client actually migrates to the server to make a request directly rather than over the network. When the client in the mobile agent architecture needs data access to a resource that the server provides, the client does not talk to the server over the network. Instead the client actually migrates to the server's machine. Once on the server's machine, the client makes its request to the server directly. When the transaction is complete, the mobile agent returns home with the results.

Mobile agents solve the client/server network bandwidth problem such as that arising in EDE as a result of the poor communications infrastructure versus efficient student-tutor interaction. Network bandwidth in a distributed application is a valuable and sometimes scarce resource. A transaction or query between a client and a server may require many round trips over the wire to complete. Each trip creates a network traffic and consumes bandwidth. In a system with many clients and/or many transactions, the total bandwidth requirements may exceed available bandwidth, resulting in poor performance for the application as a whole. Mobile agent architectures also solve the problems created by the intermittent or unreliable network connections. Agents can be built quite easily that work "off-line" and communicate their results back when the application is "online".

A mobile agent is an entity composed of two different pieces. One piece is the code itself, which consists of the instructions that define the behaviour of the agent. The second piece is the current state of execution of the agent. Often these pieces are separate. For example, in a typical computer program, the code sits on the disk while the executing state sits in RAM. A mobile agent however, brings the two together. When an agent migrates to a new host, both its code and its state are transferred.

If the state monopolises telecommunications, there are no controls to the prices that they will charge for accessing the Internet. The problem is even compound in Africa because of the few telephone lines, which exist. (Cohen, 1999) puts it this way: "A few statistics illustrate why the basic requirements of access-a-phone-line presents problems for less industrialized countries. Globally, 49 countries, 35 of which are in Africa, have less than one telephone per 100 people". The lack of telephone lines in some areas makes it difficult to cultivate an Internet culture, as there is need for a telephone line and a computer in order to be able to gain access to the Internet.

Besides not having reliable telephone lines which are necessary for usage of the Internet, cost is also inhibitor to Internet access. (Guinness, 1999) states that access is:
...typically at around US$3 for half an hour...Equipment prices are [also] high once you move north of South Africa. Add up to a third once you hit Namibia or Botswana, more as you reach Zimbabwe and northwards. In one very typical African country, even a modest secondhand PC can cost at least $1,000- the price of a new machine in America. And signing up to an ISP [Internet Service Provider] could cost $130 a month.

Some governments at times tries to regulate the content of the information accessed over the Internet. According to (Cohen, 1999), this happens in countries where telecommunications are monopolized by the state. Governments can also restrict access for political purposes and economic gain. (Cohen, 1999) further observes: "Globally, some governments have chosen to control the liberalising effect of the Internet by denying access to entire segments of their populations, either through exorbitant charges or by confining access to select groups".

4. The link between agents and workflow in EDE

The concept of an agent, in particular that of a mobile agent which travels around the network on behalf of its owner has gained significant interest in various areas of computation such as Artificial Intelligence, distributed computing and communications [Chang, 2000].

Workflow processes are associated with these agents. For example, a typical organisation usually has its own workflow process defining business activities and overall control flow of work. It seems reasonable to assume that mobile agents in a collaborative environment should have process information embedded within them in order to find a target destination once an activity has been initiated. Additionally a mobile agent must know the various characteristics of the actual roles involved with workflow processes. For example, a mobile agent at a project leader's machine may have all the access privileges to a deliverable schedule, while a mobile agent at a programmer's may not. Obviously, this difference is not bound to an actual machine but by the roles participants play. Infact, if a programmer is allowed to act as a project leader, (perhaps because the project leader is sick), a mobile agent must change its characteristics dynamically in order to avoid any disruptions in the workflow process.

Virtual universities are a natural application area for image-based workflow systems, since they still process enormous amounts of paper work. Virtual universities can adopt workflow for the routing and control of documents in the form of images between tutor and student. It is almost impossible to make use of imaged documents without implementing workflow software at the same time. Workflow is viewed as primarily a means for tracking and controlling documents. The five benefits for adopting workflow systems are the following. There is faster processing of work, since the total transaction time is generally much greater than the time to complete the work steps. Workflow systems are usually based on the client-server architecture, as opposed to mainframes. The information processes of the "work flows" are made explicit and are more easily changed. The amount of paper used is reduced. eliminated. Financial losses from misprocessed paper are also eliminated.

Workflows in EDE involve the following procedures:

- Rapid information dissemination of coursework from the tutor to the student
- Submission of assignments to the tutor by the students in the shortest possible time
- Efficient feedback mechanism on submitted assignment from the tutor to the student.
- Evaluation of the quality of coursework by student for the tutor
- Authentication of access to resources by students who subscribes to a particular university
- Collaboration with other virtual institutions on exchange of course material
- Connecting students who subscribe from other virtual institutions
- Search for literature across the Internet/Intranet /Extranet as advised by the tutor.
- Scheduling of courses
- Computer conferencing hours between the tutor and student.
- Scheduling of examinations
- Tutoring
4.1 Student assignments

In traditional paper-based distance education, course material follows a sequential route through the tutor, post office and student. In contrast, companies employing workflow utilise imaging systems to manage information. The course material is entered into a computer system. With a few strokes, information is routed, tracked, stored and managed by mobile agents. Students in different geographic regions can simultaneously access the material, perform their assignment, and send it back to the tutor. No multiple copies of a document are needed in order for the different students to work on it. At the stroke of a button, the coursework is sent back to the tutor.

4.2 Authentication of students

Depending on the structure of the virtual university, if the courses are available over the Internet, then there is free access for all to the course material. But where an Intranet/Extranet exists, access to courseware is controlled. For example, where an Extranet exists, the virtual organisation mails the password to the subscriber, and where an Intranet is concerned, only the staff and students can have access to the password that allows them to access the resources. Agents can come in at several points. There can be an agent to direct a student with a particular password to the appropriate resources. Another agent to trace a product, i.e., that student X has not been sent the same assignment twice.

The agent should incorporate features that ensure minimum delay in transfers. The agent should monitor the routing options and select the most optimum route. The agent can enforce security by preventing unauthorized access to the data itself by other users of the system other than the recipients. This agent should be able to determine multiple retransmissions and therefore block retransmission of the same data. Systems without agents suffer service degrading due to too much traffic load.

4.3 Search for literature across the Internet/Intranet/Extranet as advised by the tutor

The sheer quantity of information accessible through the Internet poses the question of where to start searching for prescribed literature and where to go next. Another problem is that the networkable capabilities of many current systems mean that the data to be examined may exist on many different machines in a variety of forms. This means that a variety of access protocols have to be used in order to obtain the data in the first place, and then it has to be converted into a suitable format for integration with other data sets currently under investigation. The problem of searching for data is suited to an agent-based approach. Setting the agents off and allowing them to integrate data sets from different databases across the world requires autonomy and asynchrony [Beale, 1994].

4.4 Scheduling courses and exams

Having a desktop agent that can manage your time and scheduling of multiple courses is an example of a local application that is suited to agent-based interaction. This task is inherently difficult due to the problem of trying to satisfy multiple sets of time constraints, and due to the asynchronous nature of the information transfer between geographically separate users. Each user has to have an agent that is able to communicate with other agents.

4.5 Tutoring

The heart of tutoring is an intelligent agent. This agent imbeds sufficient knowledge of a particular topic area to provide "ideal" answers to questions. The Intelligent Tutoring System [McAuthur] can monitor the student as he/she solves algebraic problems and can determine every step in the right direction. Tutoring agents are entities whose ultimate purpose is to communicate with the student in order to efficiently fulfill their respective tutoring function, as part of the pedagogical mission of the system [Mitsuru, 1997]. So, educational applications, in general, are based on Tutor and Mentor agents.

4.6 Assessment of student work and quality of courseware
Pedagogical agents have a set of normative teaching goals and plans for achieving these goals (e.g., teaching strategies), and associated resources in the learning environment [Thalmannn, 1997]. The utility driven agents (e.g. Web agents) are used by pedagogical purpose like reminding the deadline of homework.

Conclusion

Workflow systems for EDE need to combine flexibility with optimisation. Agent technology offers mechanisms for such. They support not only local but decentralised, distributed and flexible workflow through asynchronous communication. This research looked at the integration of agents into EDE workflow systems, and how this integration improves the efficiency of these workflow systems.

Conceptions & Tensions, Theories of Action, for Embedding Learning Technologies in Higher Education

m.dobson@lancaster.ac.uk

Abstract: An evaluation studied the perceptions and structure of awareness in program designers involved in a consortium of programs for supporting embedding of learning technologies in higher education. Technology embedding was idealized in terms of alignment of use with learning objectives, alignment of different technologies and practices, penetration within the university, and alignment with cultural perspectives in organizations. Frameworks for developing skills in technology integration were discussed in terms of integration with course production, through training programs, through evaluation activity, through research activity and by creation of new institutional structures. The study concludes by outlining possible tensions in the EFFECTS theory of action, 1) between academic's operational needs, demands and the potential for those interests to develop into scholarly reflective practice; and 2) between accreditation as a motivator to participate and the disincentive of evidence reporting and 3) between the often technical skills offered and the scholarly goals intended, and 4) between the widespread operational need for skill development and the mostly teaching staff target audience for the program.

Introduction

The limitations and costs of poorly integrated technologies often obscure their benefits and, as a result, the technologies and their use do not receive wide-spread understanding or achieve effective use. This gap between affordance and understanding signals a need for professional development. The EFFECTS project is a multi institutional initiative in English Higher Education funded by HEFCE and DfENI as part of TLTP (the Teaching and Learning Technology Program). The project objectives are given by Oliver and colleagues (1998) as, “to draw up a professional development program (for academics) so they may receive accreditation by developing a set of generic learning outcomes for staff development in the use of C&IT that will enable existing courses to be accredited at a national level.” This paper studies the program designers’ perceptions and beliefs about actions required to achieve the program goals. The EFFECTS project is part of a strategic approach (represented by the broader goals of TLTP) to achieve long term high quality teaching and learning with technology. The evaluation study is scoped to include useful data that will inform this overall goal.

The Study

There are five institutions involved; as results are presented below the reference to each institution has been omitted to protect confidentiality. A co-constructive interview approach began with a series of questions developed in conversation. The approach implies the continuous development of understanding in the target area. New issues and questions are introduced at each data collection event depending on the researcher’s sense of progress and opportunity. This process is not specifically designed to enable inter-institutional comparison but rather for developing a coherent and progressively deepening sense of the perceptions held by program developer group. The first set of questions addressed program designers notions of embedding and of frameworks. This progressed to discuss the target audience for the programs, strategic role and alignment with organizational practice, implications for organizing practice and chances of substantive scholarly results, the role of institutional independence and centralization on success.

Findings

The question, “What is embedding?” was dealt with mostly in our first interview and we were able to provide three aspects of embedding that capture the perceptions in the project. The first, technical integration, describes the extent to which systems work together in this case how well technical systems work with the human systems in place in the university. The second is described as cultural integration which describes the normacy of use. The third aspect of embedding is the alignment of learning outcomes with the affordance of the technology. This aspect can be ascertained though first understanding the teacher’s learning goals for the instruction and then having them reflect on the value of the technology in achieving these goals. This dialog continued after discussing definitions of the concepts to elaborate short case-studies which illuminated each of the three conceptions. The discussion continued to elaborate on another three possible conceptions for the idea of a framework. A second series of questions considered the impact of the EFFECTS programs in each of the sites. This topic helped illuminate differences among the institutions involved. One group stood out from the rest in the by showing no interest in developing an accredited course in the area. They preferred to see their role as understanding ‘the integration problem’. However each of the other sites have had significant difficulties and become progressively indifferent to the idea of the accredited course in learning technology integration until at the time of writing the evaluator’s impression is that only one group is strongly in favor of the approach.

What's in a Course?

_The EFFECTS program is specifically about courses for professional development to be accredited at a national level. For a student a course may be a hurdle to qualification or a focus for interesting activity, for a university administrator it is a unit of production in the workflow, and for peer quality control it is a suitably targeted, contained, consistent and financially sustainable activity. For staff developers, courses do not normally follow the same pattern as for academics. For most of the partners the content and syllabus of the academic staff development programs are determined partly by the emergent needs of the participants. Such a “syllabus” might eventually include everything the course participants..._
need: principles of instructional design, practical media development expertise, a reflective practice approach and an understanding of the available tools and techniques. But syllabus is generated by the nature of program participants not necessarily by the needs of the institution for development and attainment of high-quality teaching and learning with technology. Neither is the content specifically determined by any notion of discipline integrity (what the learner's ought to know). In two of the interviews the informants demonstrated reservations about the course model, instead one identified a "research" approach where there was no use of accredited professional development or evidence-based assessment.

"Philosophically I don't believe a course is the right way with this, this is a research program about coming up with a framework which is a different entity in my mind/my way of thinking. So I thought right we can use this money to bring a person in who will actually have one leg in learning resources and one leg here, they had to have higher education teaching experience and experiences as a techy in some way shape or form, actually doing stuff as a techy so they talk in both languages not an easy combination to get hold of, [ ] he's done a tremendous job and he's bridged that gap."

Another concern with an accredited program delivery method is one highlighted by commentaries on agencies of change (e.g., Balogun & Hope-Hailey, 1999). This is a concern which applies to change agencies rather than to professional development programs per se. The pertinence of the concern therefore depends on the goals and evaluation stakeholder interests, which for the EFFECTS project, remains unclear. Balogun and Hope Hailey tell us that in an educational model for change that participants can very easily voice support and then walk away and do nothing. These symptoms were found in several places and appear a major reason for flagging enthusiasm among tutors. In one site it was the intention to keep an on-going cohort of staff who could share development experiences which would be gained by reflection on action. This group found, on their pre-accredited pilot course, while interest in the targeted support was strong, the motivation for the accredited certificate was not high and participants were not interested in completing aspects of the course that would eventually lead to certification. Participants may walk away either because they don't support the goals of the program or because the method of achieving those goals is not consistent with their work goals and practices, or because there are other pressures on their time which reduce the priority of the activity. Program developer views were based on time constraints.

"I mean a lot of them said they appreciated the course and they would like to have spend more time going through the materials but once they were out of our room they just didn't touch it, didn't have time to go near it. [ ] perhaps there is a degree of naivety in thinking that accrediting a program like this would have been a reasonable carrot for most academics and maybe this sort of gets to the heart of the institutional differences [ ]. You don't stop teaching the students, you don't stop doing the other administration because other people place pressures on you, so the one thing that goes is the thing that I have control over — my own staff development. It is short sighted from the individuals point of view, it's short sighted from the University's point of view but it happens all the time."

However it is a particular view of staff development that places new skills acquisition in the peripheral role that a course approach suggests. That the individual can walk away from the program without affecting their short term goals may suggest a problem with the program design. The reflection-in-action (Schön, 1983; Schön, 1987) and activity research approaches to professional development favor the realism of practice as context for development which in this case would be the teaching which the informant claimed was impossible to interrupt. The problem appears to lie in the design of a reflective action model within the framework of a course. The course model seemed to cause difficulties with the organizational culture of validating academic effort. At least two of programs experienced frustrations in their course validation process. While in each case these have been overcome, the difficulties still attest to the unfamiliar and unusual pedagogy of the program. One participant declared their motivation for the course was not in-line with what is expected by the standard course validation process.

"The validation panel said "look when you validate an academic program we're only interested in the outcomes for the individuals, we don't care what the institution needs we only care about the outcomes for individuals" so we went away and rewrote our course proposal to say "individuals really need to have these skills to cope in the current climate" and so on. We had done that work of translation well enough to pull the wool over their eyes [ ] they explicitly did not have that perspective that we had as developers."

From the academic staff development perspective the program would provide skills for the functioning of the university which were needed for successful progress. However the validation committee is more used to accepting courses on the basis of student demand and discipline integrity. In one site we found the course was not accepted at the first validation stage. In this case the problem was lack of academically qualified teaching staff and was solved by bringing in external professorial teaching and research resources from academic units outside the support group. In this way aligning the teaching function of the initiative with the teaching organizational units in the university. At two sites it was demonstrated that without the willing support and active participation of others involved in the information infrastructure in the university, these skills would not amount to successful integration. The successful achievement of improved teaching and learning with educational technologies is unlikely while treated as if it were the sole responsibility of the teaching academic or even the academic in partnership with the staff developer. Teaching in this sense involves other important roles in the university, librarians for example, technical support systems, general information infrastructures, policy commitments and champions in positions of influence. The lessons of other programs and projects of enhancement also suggest that focusing on academics' competencies is insufficient to achieve quality delivery (Bates, 2000). The EFFECTS project was not directly concerned with non academic staff (which is clearly stated in the project objectives) and to this extent may be misguided but program developers demonstrated their experience of attempts to address the issue.

"I think in this institution we have been very successful in accreditation schemes for academics, so we have the Learning and Teaching in Higher Education course we've been able to put together Embedding Learning Technologies and lots of other modules. But an attempt by people in the support area to put together qualifications for support staff has been met with great resistance."

The program emphasizes scholarly practice to support reflection on operational activity which represents a departure from traditional approaches and deserves attention. The tensions between need for technical support and the desire for scholarly practice combined with limited time signal a concern which we explored with the informants. At one site after beginning with a cohort approach a more personal approach soon became the normal mode of interaction. It appears that much of the support (particularly when provided one-on-one) took on a technical flavor and was generated from the immediate problems, interests and concerns of the participants. One reason for this was that the skills available from the support person serving the EFFECTS participants were often technical and so the support was almost inevitably technical but those with a
learning agenda appeared to experience similar reactions.

"I have an education background and I find they tend not to like having the educational input and they get very uppity about it, so you have to couch that in the technology part, in a way you have to be technology led and then feed in the other part, back to front, because they see someone as coming and teaching them what they already know. Even though of course they don't and its different with the technology in any case."

The interviews suggested that support of a pedagogic nature was less welcomed by the participants and for that reason was hidden within suggestions about the technology (technology as cover story) rather than made explicit. Technical support may well be what the clients of a project like EFFECTS would want and our informants often believed this.

"There's a study done by the TALISMAN project [...] which revealed that the number one thing that people want or need in order to get started with learning technologies is technical support. Number two is training, skills development in particular and sort of knowledge about how to use learning technologies and the education side I'm afraid comes like third or fourth quite often."

Both of these explanations alert us to the possibility that demand or needs-led approaches may, without additional interventions, inherently tend toward solution-oriented knowledge acquisition and a particular set of materials and experiences rather than acquisition for understanding (Ohlsson, 1997). In as far as the EFFECTS programs have been demand-led in their interactions with participants this would affect the nature of any scholarly work done and would seem to affect the potential for development and change. The benefit and particular use of different technologies was under-stated in the interviews. The technology referred to most was the centralized computer-based testing system that was referred to extensively in two places. The value of this was introduced each time as a solution to a teaching and learning problem.

"[the problem was] particularly assessment, you know they have cohorts of up to a couple of hundred and they had to do assessments for all of them and it was just taking too much time, they were looking for some method of automating it."

This technology plays a learning management support function rather than a teaching and learning one. It is more integral to administration of learning than to learning itself. If the balance of technologies referred to in the interviews were reflected in actual implementation this would also be a cause for concern and one intuitively consistent with a demand-led approach.

Institutional Independence.

In considering the direction that the EFFECTS project takes in relation to national initiatives it is worth recalling what the Dearing report had to say about the centralization of information and communication integration plans.

"We believe that the creation of C&IT strategies will create a focus for debate within institutions and throughout the sector. Central initiatives can help, but they alone cannot deliver our vision of higher education for the next century. Institutions themselves must do that through ownership of their C&IT strategies. Dearing report (CIHE, 1997) 13.19.

Others have noticed the trend which is counter to those commercial organizations for the public sector to develop what Blackler critically calls the new machine bureaucracies (Blackler, 1995). So should teaching and learning strategies be any less in the control and ownership of the individual institutions? Does centralized accreditation and framework alignment make individual creative design any more difficult? From our interviews it seems that the EFFECTS project compliance with SEDA, is viewed positively because their framework is designed for professional development in mind. The framework regards reflective practice and support as key to development and while maintaining or proposing a resource-based academic investigation has tried to avoid occupational standards and competency oriented outcomes approaches.

"I mean we have a really large team delivering that course, we do it in a way which is based very much around the SEDA model, very much about values and support, supporting people in the first year of their experience of being a lecturer and they have this real cohort to really support one another it's like their first experience of being in a cohort sort of thing. That's not true for all but I think there's lots of things about that course which are very motivational which are nothing to do with the fact that there is accreditation at the end of it. [ ] It's about the SEDA values and reflective practice more than it's about accreditation."

It is hard to see that a set of very general and apparently well-designed professional training guidelines could detract from the success of initiatives to develop the goals of the EFFECTS project. However it is also hard to infer from the SEDA guidelines the kinds of strategies or alternative frameworoks suggested above. What's at stake here is whether approaches other than those of staff development, for example, central management of projects, doctoral programs in teaching disciplines in each faculty, and others, are likely to arise from staff development workshops. In the author's tentative opinion such are the theories of action from other communities of practice and would be unexpected. Exactly what could be expected from the design of a project like EFFECTS in terms of relation to national policy is not clear. We cant read the hypothetical basis for action taken by HECFE in supporting this project. However the intention of the project to provide a framework for national accreditation would suggest alignment with the centralizing agenda and would certainly signal the concerns raised several times by Dearing.

Institutional independence from national initiatives could allow other approaches to take hold and yield a better chance of at least some institutions achieving successful integration. Even after this evaluation the nature of EFFECTS in terms of strategic approach remains unanswered largely because of access difficulties with stakeholders. The important issue for programs like EFFECTS is that if it really is a strategic approach then it can be evaluated as such by the normal criteria associated with agencies for change. Is it the result of sensitive analysis of roles and needs? Is there a well-defined transition state to which the project is directed? Is the program a collaborative, participative, coercive or educational initiative for change and is the selection of method appropriate for the cultural and social context of the organization(s) involved? The project does not make explicit these choices within the bigger picture of change in higher education and because of this may leave itself open to the critique that the project has no clear idea who it serves.

"The points of difficulty are around things like areas of responsibility for the computing services training team as against educational development as against staff development where traditionally staff development is for non academic staff or is sort of for everybody who is non academic, whereas education development is traditionally academic development and computing services traditionally train people to use computers. [ ] in practice organizations are not just individuals as learners they are also
empires and power structures and people wanting to hold onto their bit of security, that's the big thing you that you come up against.”

In fact the weakest point in the evaluation comes from our inability to identify and access the evaluation stakeholders. The project has argued (EFFECTS, 2001) this issue need not be addressed because its only objectives are processes for the positive and constructive growth of professional and personal development. However, with the deliberate selection of resource-based learning, the provision for evidence based assessment and the proposal for centralized brokerage of credit, its hard to take this claim at face value.

New Institutional Directions

Here we look at some of the developing initiatives in the institutions affected by the EFFECTS project. While program developers were often understandably frustrated by difficult working relationships with support groups in the rest of the university several constructive solutions were suggested. One approach would be to introduce EFFECTS programs (or similar) for operational staff within the university. In fact one site involved the broadest cross-section of university staff in their workshops and consulting activities.

“We've got lecturers on the course and we've got some support staff on the course and that's because it needs to move across the entire University, I'm not here for the lecturers I'm here for the University and OK they're the people who are teaching but they don't teach in isolation.”

It is possible such an approach might not only address the immediate difficulties for teaching academics but would be more in-line, and consistent with the changing and converging roles of all staff in the university. Non-academic librarians may for example participate in such a program and choose to focus on development in information literacy; computing staff focus on on-line support for users and so on. The partners recognized this difficulty and (probably for other reasons as well) are moving elements of their staff development units much closer to academic faculties.

“We're merging in a way which we don't know the full details of with [an academic department concerned with research in education] to produce some sort of unit [ ] that focuses on higher education research. The primary reason for that move in fact has been in relation to the development of our certificate of academic practice [ ] is in that in order to run an accredited unit we really needed or it was thought that we really needed to be part of an academic group rather than a central support group.”

From this it would appear the institutional approaches to addressing the EFFECTS goals have been modified by the institutions.

Conclusions

The EFFECTS project has been an ambitious initiative involving participative, communicative, and developmental activities in a wide spread of Higher Educational sector in the UK. This study has looked at some of the perceptions of program developers and has provided some reflection on those perceptions. The EFFECTS framework has been a coherent and important spur to action in all these related developments. It is the framework that must be concluded on and not the interpretations created by the individual institutions.

The core aspects of EFFECTS are widely thought to be what are known as the learning outcomes. These key process points which are partly derived from the SEDA key values are recognized as playing a vital role in guiding successful reflective action research in teaching and learning. Other aspects of the project which were valued included the cooperative sharing approach taken by institutions which led to stimulating development activity for all the project participants including the program developers. These two aspects of the project were favored most highly. The main aspect to attract less support and more concern was the exploitation of accreditation to achieve the overall strategic aims of the project. However the core aspect which we think is most important here is what (Agyris & Schon, 1978) would simply call the project theory of action; the hypothetical basis for action taken to achieve the project goal. The EFFECTS theory of action is that action-research staff development in learning technologies will achieve high quality teaching and learning with technologies. For policy makers the important transfer question is whether the EFFECTS theory of action is useful. In fact the EFFECTS approach involves a series of claims that can be summarized as:

- Scholarly professional accredited research activity at a masters degree level will support reflective practice and achieve long-term high quality teaching and learning with technology.
- Participant effort led by demands and needs will lead to enthusiastic engagement.
- National program accreditation is an opportunity to enhance the status of teaching and learning with technology as a scholarly activity rather than an end in its self.

This study has raised several concerns with this theory of action which can be summarized as:

- Demand-led (just-in-time) support tends to lead to technical and solution-oriented knowledge acquisition rather than learning for understanding. It leads to solving problems rather than finding niches.
- Technical support for small projects may motivate more than accreditation of programmatic effort.
- The course model serves the leverage of resources to integrate the technology but may be out of synchrony with the needs of learners and jars with the validation process.
- Accreditation has led to weighty evidence reporting that was unattractive to program participants.
- There may be other alternatives which could work better (although they are not the subject of this study).

Perhaps the main outcome of a this study of the project lies in things that are learned, new hypothesis that are held by the designers and will drive the design of programs designed to achieve similar aims in the future. In this regard we see that among those we interviewed there was a strong sense that these matters were often outside their control. In its various forms the EFFECTS project has made it a central commitment to achieve scholarly reflection in consort with developing new skills and technical knowledge. There were considerable doubts expressed about the design of the program, the value of a course, the potential of a course to keep academics interested in spite of their other work commitments, difficulties fitting the course into the standard delivery program, demand for scholarly support and the potential for contributing to quality while led by
participants operational demands. In short there may be an uneasy fit for an academic staff development program, taught with the involvement of traditional staff development centers, providing masters degree credit normally only available directly from academic units, for the purpose of satisfying a nationally conceived goal.

Reflective Learning with Agent Simulations in Emergency Team Training

Mike Dobson, Michael Pengelly, Walter Odnio & Julie-Ann Sime
Center for Studies in Advanced Learning Systems

m.dobson@lancaster.ac.uk

Abstract: Learning in high fidelity virtual reality simulation environments presents great advantages to emergency training where real practice is impossible and drills are costly and ineffective in preparing for non-recurrent incidents. Simulations of group communications require de-briefing with team members and representations for reflective coaching. We present a tool used to reify the communication acts of team members that demonstrates support for reflective practice in action. The representations of emergencies in Nuclear Power generation and in Underground Railway emergencies are both shown and the reflective tools illustrate the different cultures of practice in team interaction.

Introduction

We claim that simulations provide an ideal environment for learning through situated practice, especially when support for reflection is also available. We also claim the case is reinforced in those areas where the cost of the alternative realistic preparations for situations are prohibitive. It is also true that learning with simulations can be a very frustrating experience and that practice at least in certain stages of competency can lead to poor outcomes. However the approach here modifies the traditional simulation in two important ways. In the first place ours are team interactions and when skills are limited, an expert collaborator or an expert agent can provide direct guidance. The second form of guidance is given by the careful design of representations to help reflect on team interactions.

There is no doubt that reflective thinking plays an important role in the development of self-regulatory cognitive skills. Reflection enables planning which often leads to the regulation or revision of a prospective course of activity, sometimes even before the activity has begun. We usually think of reflection as a tool for assessing outcomes after the event, often when activities have failed to lead to the desired outcome. These ideas have been in currency since Dewey (1933) and have been applied in more recent years particularly to attempts to develop informed and self monitoring approaches to scientific reasoning. Schaubel's and his colleagues including Robert Glaser (Schaubel, Raghavan, & Glaser, 1993) developed a graphical framework and representational language for reflection in scientific reasoning. The language reifies goal and sub-goal hierarchies in an attempt to help users remain aware of reasons for their actions. It also focuses problem solvers on the relation between goals to which particular activities are directed to help users concentrate on hypothesis driven activities and not simply data driven search. Their DARN (Discovery And Reflection Notation) tool was achieved through an activity trace that was then recast into a graphical format for viewing by the user.

In a similar way we have developed a graphical trace that begins to address some of the key learning requirements for emergency executives, and indeed for all kinds of team-work, by capturing the historical events of communication acts that occur during execution of the group simulation. These acts are the key forms of interaction between collaborating agents. Our tools provide reification of the important communicative processes, compensatory speech acts, anticipation of needs and so on, that are found to be important in the current emphasis on participation. Just as Glaser's tools helped learners to reflect on strategies used to achieve problem solving goals by reifying aspects of the problem solving process, so our tools provide representations of the communication acts which occur among our problem solving teams.

The reflective tool currently provides three representations, 1) a histogram of communication acts to and from each actor, 2) a control-monitor or baton passing representation showing the passing of floor control between actors, and 3) a sociogram which shows a view of the complete set of communications after the
training event is over.

Training Objectives

The team behaviors that we are trying to encourage are derived from a number of past taxonomies (Cannon-Bowers, Tannenbaum, Salas, & Volpe, 1995; Fleishman & Saccaro, 1992; McIntyre & Salas, 1995; Nieva, Fleishman, & Reick, 1978; Swezey & Salas, 1992). We use the term ‘team competencies’ when talking about the behaviour of individuals which directly contributes to team performance. Those that we have chosen to implement within the intelligent agents and which are emphasized in the training are those perceived to have priority for the end users. They are applicable to communications intensive environments that require shared understanding of team and individual goals, and the plans, procedures, and roles of individuals to achieve those goals.

- mutual performance monitoring,
- giving and receiving performance feedback,
- loop closing communications, e.g., checking that information is received,
- backing-up actions of other team members with informative compensatory and anticipatory speech acts,
- adapting to resource scheduling conditions by actively balancing task-loads,
- co-ordinating action with compensatory and anticipatory communications,
- modeling team players to understand roles.

The emergency management teams we are interested in are the control room team of the underground Metro Bilbao in Spain, responding to a fire on a train in an underground section of the metro; and the emergency response teams of the Spanish Electrical Power generating company, Iberdrola, who advise and co-ordinate external resources during a nuclear accident at a nuclear power plant (NPP). In both cases any training exercise they undertake requires the commitment of considerable public resources since they both employ various public emergency services, ambulances and fire brigades, in resolving the incidents. Any exercise also causes disruption to the normal public service, which is unacceptable on any frequent basis. The Metro Bilbao team work in shifts and although the team normally work together they must all be recalled simultaneously for training. Training also requires that they use the same space and resources that the operational shift are using. In the case of the emergency management team for handling nuclear incidents they are experienced personnel who do not normally work together and have commitments that make it difficult for them to assemble simultaneously in the same place.

The ETOILE project sets out to solve these problems. The re-creation of suitable environments is being addressed through the development of networked simulation based learning systems using desktop virtual reality to create a sense of presence. The problem of assembling a complete team at the same time is being overcome by incorporating ‘intelligent agents’ as substitutes for absent team members. These features increase the frequency of opportunities for training and the opportunity to learn is designed around the reflective practice that will help learners to adapt current practice through a review of past performance and importantly, through basing the training, and necessarily the activities of the computer based agents, on the explicit recognition of the role that shared mental models play in the development of team competencies (Cannon-Bowers, Salas, & Converse, 1993; Cannon-Bowers et al., 1995).

In summary, the perspective is a fusion of the need for situated practice with realistic interactive shared representations of work place practice, a focus on develop communicative competencies in teams, the goal to development flexible competencies in response to new and complex emergencies through the study of exemplary error mitigating behavior, and the need to focus in situ on representations which form both a part of practice and can be used to describe and reflect on it.

The Reflective Tools

The sociograms shown in Figure 2 allow the overall quantity of communication between each
participant to be estimated. The size of the arrows on the lines joining participants gives a qualitative estimate of the number and hence load, and possibly by implication stress, on any individual. The representation also allows patterns to emerge in the dialogue which relate to beneficial and undesirable communication clusters. This circular representation works by placing all those agents (passive and intelligent) and human learners involved in a scenario in an equidistant ring arrangement. Messages collected during the scenario are filtered and shown as lines between participants. The density of communication between any two players is shown by the size of the arrow head going in any direction. From this we can see the distribution of messages relative to particular individuals in the group; a feature that can yield useful reflections on the work-load balance within a scenario. The sociogram representation is most effective in showing the densities of communication between roles (lots of lines joining to one agent). Where the team members are in the same room it also provides an easy method of assessing whether they are physically talking across one another. Each of the circles representing a participant in the communications can be presented on screen into the physical locations of the team members; hence rearrangements of seating plans could be made that reduced, cross conversations.

The baton passing representations (see examples in Figure 2) show the control of communication among agents in the dialog. When an individual speaks, their contribution is logged against a time record. The next agent to talk has her contribution logged similarly, and the two coordinates are joined, in this way generating a continuous line of communication control through time. These representations show the same data in different ways and therefore make best advantage of the representational affordances of each representation. Several vital instructional benefits are available from these tools for the learner to support reflective insight. The most important of these are,

- time and resource distribution in communication behaviors,
- relative significance and roles of passive and intelligent players in the construction and storage of shared mental models, and
- the occurrence and progress of specially typed speech acts in team communication.

The relative affordances of each representation means they can be used to address certain conjectures and working hypotheses about team behavior. Such conjectures also point to aspects of behavior to look for in the analysis of interaction within a particular team. In our on-going work we are experimenting with several example sets of data from team interactions (mostly under stressful circumstances) and we are beginning to notice useful correspondences among variables that are all made clear from the representations. For example, hierarchically organized teams tend to exhibit concentrations (densities) of communication around particular team members usually the leader. In drill situations and even emergent circumstances where skill demands on the team remain close to recurrent this appears to have no effect on performance. However, when emergency situations present complex novel problems to solve these teams do not perform so well as other teams with more devolved decision making and consequently more balanced communication patterns.

**The Study**

The scenario provided from our underground railway emergency demonstrator shows the traffic operator (TF) being trained with the emergency center supervisor and with a trainer also present. The scenario is an enhancement of the one provided by (Maseda, Arenillas, Garzon, Arcos, & Castano, 1999) describing requirements and roles of participants but with a few other selected events and errors which take place. The scenario includes only a small number of people and roles which could have been involved. Indeed of the more than twenty roles identified in the requirements document this scenario includes only nine roles and an agent for managing events called the scenario agent. What we see from using the log analysis tool.

The distribution of communication events around the team involved in dealing with the Metro Bilbao underground railway scenario is broad. From the sociogram representation (Figure 1, left) we see there are no overly sized arrows between any of the communicators. This illustrates that no two participants have to take an unbalanced weight of communication during the unfolding of the emergency. The sociogram reveals its own limitation here however, in that while no two participants are responsible for an over heavy set of communications, the traffic operator (shown as TFOperator) communicates with other agents than any other. This we can see quantitatively from a histogram that is also available to the users but cannot be shown here.
because of space limits. The accumulation of communications from several individuals, which can be seen by the addition of the smaller arrows leading to his role, mean that the traffic operator’s role in the emergency is actually quite onerous compared with others in the scenario although overall the pattern remains balanced.

Figure 1:

simulated emergency (right).

The diagrams also provide a very quick and simple method to check that all the proper communications back against the emergency protocol in (Maseda, Arenillas, Garzon, Arcos where we find that the train driver is supposed at one time to communicate with the station supervisor agent. This error checking with a team in post hoc analysis.

differences between those that appear on the sociogram and those which appear on the floor control diagrams. The reasons for any one role players’ experience of a scenario some players do not need to be implemented to demonstrate that role. In our demonstrator many of the ‘peripheral’ roles are not implemented. For example, the communication between the SOS agent and the police, the ambulances, the hospitals the red-cross and the government mediation services, even the communication between the driver and the public who are the first to alert the driver to the emergency, are just not shown on the graphic, because they are not functional to the individual needs of the target individual in the training scenario. We think this reveals a need to improve the simulations so they may provide a broader picture of the relatively peripheral roles for any given agent.

In the floor control representation (Figure 2), communications which do not generate immediate responses from anyone do not show up either. A lot of the communications in teams is informative, broadcast for information to all, and therefore unlikely to generate immediate responses, and will not appear on the floor control diagram in its current implementation. There is also currently a limitation in the algorithm for presenting the data. At present the each time an agent speaks the time is noted and a line drawn back to the intersection of time and identity of the previous speaker. In this way the continuity of speaker contribution is maintained through the team dialog. This representation is based on use within a closed group of speakers, often in the context of face-to-face management meetings, or board meetings. The representation is used as a tool for analysis of power relationships in groups. However in our simulations agents often talk to other agents who do not speak to other agents within scenario. For example, when the SOS agent receives a message from the emergency center supervisor in the underground railway simulation, this is likely to precipitate a message to the ambulance or the government mediation service. But since they are not shown on our demonstrator, the message from the SOS agent will not be shown, and the relative importance of his role will not be seen. The
baton passing representation is therefore contextual to the scenario and for the people for whom the scenario was developed to train.

![Figure 2: Control passing representations of Underground railway (top) and Nuclear Power Generator simulated emergencies (lower).](image)

In comparing the nuclear demonstrator with the underground railway demonstrator we can see immediately from the sociograms (Figure 1) that the role of the emergency director is one principally of informing others around him and with relatively little feedback from those other role players. Compared with other role players he receives a similar amount of information but his role in sending this information to others is perhaps six fold that of any other agent. From looking at the baton passing representation from the nuclear demonstrator shown in figure 2 (lower) we can see the extent to which the baton remains in the hand of the emergency director. The flat lines drawn along the DE axis of this graph show situations when the emergency director (DE) communicates and then the next communication to follow was also from the director. The role did not have to wait for further information to continue. The spikes on this diagram show that the director mostly generates the questions for new information from his team mates and is quickly provided with it (shown as a quick return spike) whereupon control and stability returns to the director.

The two scenarios display very different communications patterns aspects of which can be seen through each of the three representations shown in the log analysis tool.

Conclusions

The log-analysis tool studies showed that communication patterns varied widely between the two simulators illustrating differences both in practice, culture and process in the two scenarios. Organizational factors in communication during unfolding of emergencies that may not be obvious without these carefully constructed representations. The tools have potential to help users understand the entire sequence of an emergency, not just their own role, and this should promote the development of shared mental models and
better performance in teams. The representations are likely to take some time to master: even when they are improved in those ways suggested, but the study provides encouraging evidence this effort will be worthwhile.

We believe the development of these demonstrators has been a significant contribution to the application of innovative pedagogy and new communications and information technologies in two fascinating, complex and pressingly important domains.

The ETOILE project was originally conceived by Peter Goodyear in C-SALT at Lancaster University.
Competitiveness in today’s knowledge and technology-based economy requires constant professional updating to meet the demand for new skills in an increasingly global market. Skills acquisition and development, coupled with the concept of lifelong learning requires a framework or tool to support skills audit, profiling, planning of learning and development, integration of teaching, learning and assessment processes, evidencing of progression, recording of achievement and ‘value added’ for Quality Assurance purposes and also for accrediting competences and capabilities. The paper-based resource most currently in use is bulky, not easy or cost effective to update, and can easily be lost or destroyed, suggesting a need for a flexible, electronic tool for individual or organisational use. This project is involved with the development of a web-based Professional Development Planning (PDP) tool prototype that offers more cost-effective integration of a number of educational, training and development and organisational processes.
Quo vadis, School: Looking Back and Ahead
or: How Can Schools Be Supported by Meaningful Online Services?

Michael Drabe
Verein Schulen ans Netz e.V.
Max Habermann Str. 3
D - 53123 Bonn
E-Mail: mdrabe@san-ev.de

Abstract
Due to the german initiative "Schulen ans Netz" (schools online) a lot more schools were enabled to work with computers and networks than with any other experiment or pilot project so far. In particular schools where neither teachers or pupils had any experience with computers or networks were invited to take part. Of course this meant above all to show them how teaching and learning can be supported by these new media and which possibilities were opened by working with computers and world-wide networks. This supplement tries to give answers to the following question: How Can Schools Be Supported by Meaningful Online Services?
Schulen ans Netz e. V. (Schools online), a joint initiative of the Federal German Ministry of Education and Research (BMBF) and of Deutsche Telekom, set itself when starting in mid-1996 the initial aim of connecting 10,000 schools to the Internet within 3 years. This aim was largely surpassed by the association: more than 13,000 schools providing general or vocational education have been connected with the help of suitable supportive measures. And a certain number of schools were able to connect by supplementary initiatives of Federal States and in cooperation with regional sponsors. By end 2001 all German schools will have access to the Internet thanks to Deutsche Telekom.

Why Should Schools Be Online?

Due to this initiative a lot more schools were enabled to work with computers and networks than with any other experiment or pilot project so far. In particular schools where neither teachers or pupils had any experience with computers or networks were invited to take part. Of course this meant above all to show them how teaching and learning can be supported by these new media and which possibilities were opened by working with computers and world-wide networks.

Due to initiatives such as eEurope, eRate (USA) and similar activities on other continents an extensive discussion about the pro and cons of suitable media use has been launched. The currently most heatedly discussed opposing position on the use of the new media in class is represented by the Alliance for Childhood under the header „Fools Gold: A critical look at computers in childhood“. Unfortunately the positions are presented in a diction that can be summerized in phrases like: "S/he who uses technology in class hates children". Or "technology use in class is industry-driven". It is certainly not helpful to discuss sensible IT use in such 1-0 or black and white scenarios. The numerous scientific studies published by now show that how the use of media in class has to be looked at differentially. The musician Dizzy Gillespie once said it took him ten years to master his instrument and another ten years to know which pieces he should better not play. Transferred to our discussion it means we should allow us minimum five years of exchange of experience before coming to first conclusions. It will certainly need more than these five years in order to know at which point it would have been better to abstain from technology.

We, that are the assets at Schools Online, started out with the conviction that media accompanied teaching can sensibly support the new forms of teaching and learning. In particular in the field of communication we saw for schools a substantial potential for development:

- opening schools by communicating and co-operating with other schools in Germany, in Europe as well as world-wide,
- competent and responsible use of networks as well as the creation of a specific culture of information and learning in the framework of a contemporary media education,
- the support of interdisciplinary partnerships between schools, training centres, education facilities and universities

The Working Platforms of Schools Online (Schulen ans Netz e.V.)

To support the work with the new media in day-to-day teaching, Schools online, a registered association, provides various online platforms:

- The Homepage of Schools online (http://www.san-ev.de) is the initiative's communication and information medium. This is the place where all interested find topical news items about and around schools, latest news on current activities as well as background information on all working areas of Schools online. A monthly newsletter to the subscribers at home gives the latest news of the Schools online web pages. This newsletter is also available in an offline version which could be pinned to the school's pinboard.

- Lehrer-Online (http://www.lehrer-online.de) (Teachers-Online) is the up-to-date online service to all teaching. Schools online offers here an extensive subject and school related portal with individually adapted service offers for preparing classes and teaching practice. In the centre of Teachers-Online are of course the new media and the indication of strategies for their meaningful use and implementation into classroom teach-
ing. lo-net (http://www.lo-net.de) is the interactive communication and working platform of Lehrer-online which provides teachers with a multitude of possibilities: they can manage their files online, they can design their own homepage with a few mouseclicks, but they can also work together with colleagues in group rooms on specific projects or deal with their own students in their classroom on lesson projects which they can present online via lo-net, if wanted. This service is supplemented by LeaNet (http://www.leanet.de) a site which addresses exclusively female teachers in the Internet. Apart from numerous information offers this service has a "Ladies only" discussion, learning, and working platform. By registering all LeaNet members get automatically a free e-mail account and access to all offers and working areas.

- Business@school" (http://www.business-at-school.org) is a co-operation project together with The Boston Consulting Group. The aim of the project is to improve the insufficient knowledge on economy at school by making this topic come alive. To reach this goal, teachers and students explore with the help of the Boston Consulting Group experts the topic economy by studying real business situations and finally develop as a team new business ideas. In detail, the aim is

- to develop a feeling for economical questions,
- to come to know about the reality of corporations, medium size and small size companies,
- to develop an entrepreneurial way of thinking,
- to improve presentation and public speaking faculties,
- to train result-oriented teamwork,
- and finally: to relay the fun that is also in this topic.

- Naturdetektive 2000" (http://www.naturdetektive.de) Nature Detectives is a environment related activity in co-operation of Schule ans Netz e. V., and the German "Clearing-House Mechanismus" (CHM) and further partners. The action is supported by the Federal Ministry of Environment (BMU).

  Students and classes as well as individuals and nature conservation groups all over the republic have here the possibility to gain information on environmental and nature conservation by the help of the Internet. They can transmit their own observations and take part in a direct information and knowledge exchange on environmental activities. The aim is to increase and strengthen the awareness of students of all ages on environmental and nature issues by immediate experience and personal action.

- The project "Exil-Club" – the establishment of an online-magazine on persecuted intellectuals was initiated by Schule ans Netz e. V. in cooperation with the "Else Lasker-Schüler – centre for burnt and banned poets/artists" foundation. In project groups students do research on the biographies of exiled intellectuals in the past and present. At the same time they grasp the historical, sociological, and political backgrounds which led to emigration. The Federal President wore in a letter to the persons responsible: "(...) Your decision to use the new means of communication and put the Exil club into the Internet with a homepage of its own distinguishes this project from others. (...) I do welcome it very much, that you don't only ask teacher and pupil to get active and to take over guardianships for applicants for political asylum but also offer to publish papers and projects online. Your engagement is an important contribution to the active concern of young people with the situation of foreigners in this country. To be sensitive to the problems and needs of foreigners is the basis for tolerance and defiance against rightwing violence." The results are presented on the "Exil Club" website (http://www.exil-club.de).

- LizzyNet – Female Students in the Internet (http://www.lizzynet.de) is the online project which Schools online started in April 2000 with girls and young women as specific target group. Here they find offers to how to communicate and play in cyberworld. Apart from that they find information and education platforms that look at the world of computers, jobs and life in general from the particular angle of girls and young women's view. The project targets its proposals at beginners as well as at the "Internet pros" and offers innovative possibilities for a self-determined and active use of the Internet.

  In autumn 2000 a CD learning programme called "Surfcheck" was published. Its aim: to enable the student to gain access into the Internet by him/herself; but experienced surfers too can find many information around the network of networks. With this programme we wanted to show that the Internet does not have to be a closed book and that the use of this new medium is accessible even with little technological know-how. Voluntary tests at the end of each chapter check whether the subject has been grasped correctly. After having
Co-operation Projects: What is Meant by That?

Schools online has launched a number of initiatives respectively accompanied them in partnerships where the aim was not only to learn co-operation but also to experience it as an active process. In general such projects were initiated in form of competitions, such as the following examples:

**EnterPreis:**

The above mentioned discussion contribution „Fools Gold“ by the Alliance for Childhood questioned in particular the use of technology in primary schools. We wanted to have more certainty: Under the header “EnterPreis – we board the Internet” we started on 1 October 1999 the first Internet competition for primary schools. The patronship was held by Maus from “Sendung mit der Maus” (a popular pre-school plus programme with a mouse as main character), and head of the jury was the well known science journalist Ranga Yogeshwar.

We were looking for thrilling websites, which the pupils created themselves in teams of maximum six participants and which were put out into the Internet. There was no restriction to the children’s imagination: paintings, drawings, texts and even photos were permitted – providing they were scanned and attainable from the Internet. The competition was open to all primary pupils in the following groupings: grade 1 and 2, grade 3 and 4, and grade 4 to 6. One or two teachers looked after the teams whose participants could also be from different classes or even different schools. For German schools abroad as well as foreign schools that offer German as foreign language in this age group there was an „International EnterPreis“.

The results can be admired at by entering http://enterpreis.san-ev.de. They show in an impressive way how the respective experience worlds of children can be represented in online presentations and how much pleasure the children gained from their results. In the stipulated documentation are listed a number of experiences which can be a source for everybody’s own work. However the teams had to overcome considerable problems with regard to copyrights which impaired their work significantly.

**uni@schule (university@school)**

"Classroom teaching in the middle of a forest – an utopia? What is usually constricted to the rare outings and excursions became the starting point to an very unusual expedition of an under-16 biology class. Tables, chairs and blackboards – the complete classroom equipment was transferred into the forest by students and teachers of the Ernst Moritz Arndt-Gymnasiums in Bonn helped by two biology students of Bonn University.

The team did not need furniture transport. And those who were interested to follow the call of science into the thicket did not have to get the wellies out: this expedition consists uniquely of bits and bytes. And it is so thrilling that even those who normally just shrug when asked the meaning of "photosynthesis" can become real flora and fauna experts. That at least is the hope of Barbara Scherer, team leader and biology and chemistry teacher at the Ernst Moritz Arndt-Gymnasium."

These are the opening lines of a report which we recently published for the above mentioned competition. The scientific studies confirmed in their interim reports how successful developing processes in schools could be assured above all by the participation of university establishments. "Tomorrows teaching, a team effort" was thus the motto for the competition „Uni@Schule“ (http://www.san-ev.de/uni-schule) which Schools online started on 10 March 1999. „University@school" called upon all those teaching and studying at German universities and schools. Requested were practical lesson projects which include new media realistically while being creative and innovative. With the new competition we wanted to stimulate the creation of didactic and me-
thanical lesson models on the net. 48,000 Marks in all as well as attractive prizes donated by the competition sponsors awaited the winners.

106 teams took part – and in the end the jury had to evaluate more than 50 contributions. The results can be examined at the above mentioned address. We would also recommend to look at the participant's documentation which give a good insight to the difficulties which had to be overcome.

Further, mainly internationally important co-operation projects are:

Thinkquest

The ThinkQuest Internet Challenge is a competition for young students which is held annually by Advanced Network & Services (USA). The objective of the competition is the promotion of the "Internet way of learning" – an interactive variety of learning which trains the student to use the Internet as a continually growing source of information as well as an important tool. To this aim a team, consisting of two to three students and one to three coaches, designs a website. The winning teams will split scholarships and prize money of more than one million Dollars between them. For further information see http://www.thinkquest.org or http://www.thinkquest.de.

Netdays

Each year thousands of projects in Europe, initiated by schools, vocational training centres, youth clubs and cultural institutions, make use of the internet and the new media, adding up to a colourful array of events. The overall name for these activities is Netd@ys Europe. This broad initiative wants to demonstrate how much the new media can facilitate learning, teaching, and discovering in an information society. The idea of Netd@ys came up in the USA in 1996 and contributed decisively to the fact that over 50% schools there are connected to the Internet. In contrast to America the main focus of Netd@ys Europe is not just on improved technical computers and Internet equipment. The objectives of Netd@ys Europe are:

- the promotion of the use of the new media and of the Internets for teaching, learning and discovery purposes;
- the exchange of experiences and developments of new pedagogical contents;
- the support of interactive projects in education and culture.

In the year 2000 this event will take place for the fourth time running. Netd@ys Europe's influence is increasing with every year. It helps to form new partnerships, to inform more and more organisations and to increase the number of participating countries. By now Netd@ys Europe has become a unique event: it has become the biggest event in the world which aims at raising awareness for the use of the Internet and the new media in the fields of education and culture in all places and for all ages. These aims can only be attained if new partnerships between the public and the private sector are established and if organisations of all kinds and sizes are brought together. To this end Netd@ys Europe is engaging itself.

Outlook: Working in Networks

Currently the public discussion turns around the so-called "digital splitting" (cf. http://i-d21.de/news/disp.pdf) and the consequences of IT applications in schools (s. a.). On the spot, however, a number of problems have to be solved first. The most important tasks for school governments is the practical putting into action of school development plans. With regard to a responsible costs-benefit relation the desired planning measures should find their way into them by giving practical examples of how to use the school's infrastructure effectively. Additionally it is important to show more pointedly the utilization potential of further online services (s. a.) as well as to demonstrate suitable embedding of IT into lesson teaching. It should also be assured that an exchange of ideas on the benefit of IT use in class takes off by providing suitable platforms.

Based on scientific evaluation it can surely be said that there is a positive attitude towards the use of new media in schools. It could be considerably improved by providing proper technical access solutions. Research groups pointed out a number of action options of how schools could be supported at this. There is enough proof to dem-
onstrate how the initially euphoric and then successfully used implementation of IT infrastructures came to a standstill or even stopped altogether due to organisational alteration processes. This point has to be more closely watched in future.

Another very important point is the need for a suitable teacher's training to assure a successful introduction of new media in schools. A non-representative survey among its networking schools led the Bertelsmann Foundation to point out a possible strategy which is based on a decentralized training course for teachers (cf. http://www.netzwerk-medienschulen.de/dyn/1006.asp). A German research team was able to show that we are only at the beginning of e-learning activities. Therefore it is not possible to give conclusive answers on the possibilities of meaningful online learning. More time and experiments are needed.
Computer Based Video Production

Bogdan Dugonik
Faculty of EE&CS Maribor, Slovenia
bogdan.dugonik@uni-mb.si

Abstract: This article contains video production procedures for distance education systems. Important criteria for efficient preparation and production of video materials for distance education are the used technical tools and procedures for video production. These include videotaping procedure, digitalization or transmission of the video to the computer, digital non-linear editing and video conversion into a suitable format for computer presentation and efficient transmission via WWW. The article introduces the procedure of non-linear editing and the procedure and conversion of the video for fast and efficient transmission via the Internet, as done at the Center for Distance Education Development (CDED). The center is involved in several international projects, which include video at a high level of integration as a study media. Some results are already presented on the Center's web pages.

Introduction

Nowadays, the most useful and popular learning aid is the computer. Learning by means of moving pictures is a well-known, efficient and popular way of studying. Because of its efficiency and capacities it is not only used for studying but also for the production of study materials in video form. This article contains video production procedures for distance education systems. The following paragraph presents the Basic video Equipment needs and the procedure of video production. The third paragraph contains the rules for the correct lecture recording and description of non-linear video editing and transmission procedure from a camera to a computer and opposite. Its popularity and interactive design make the WWW currently one of the most interesting media, whose advantages can be well used for distance education. Below given is an example of how viewing of a longer video can be provided for the users with somewhat slower transmission connections.

Basic Video Equipment

Professional digital video cameras of the DVCPRO format are lately substituting efficient Beta analog video cameras. Some less demanding recordings, e.g. lectures, may be taped by the cameras of the Mini DV (Mini Digital Video) format. An important criteria for a satisfactory video recording is sufficient light: not too dim, too bright or contrasting. The camera requires a stable support, provided by a well-grounded tripod. Emphasis lies also on the sound quality. Its loss may result from the size of the room, distance of the microphone from the speaking person and additional surrounding noises.

Transmission, Digitalization, Digital mounting, Coding systems

Video is transmitted to the media directly (e.g. videoconference) or edited by computer video mounting (postproduction). Recorded by a digital camera, the video can be transmitted to the computer in a compressed (MPEG-1, MPEG-2 formats) or uncompressed form via a fast Firewire (IEEE 1394 standard). Data storage onto a disc depends on the available hardware. More expensive equipment allows work with non-compressed data but demands extremely high capacity of storage discs. The advantage with such mounting is in the preservation of the original video quality. When individual clips are stored on a hard disc, digital mounting begins. The procedure is composed of: cutting the video to shorter clips, sound adding, adding of
sound and visual effects, film production or tape rendering, video coding and transmission to other media. Suitable hardware and software equipment for the production of learning videos is of middle price range (e.g. Speed Razor 4.7.), which costs approximately 7000$. There are many cheaper systems available, suitable for production of shorter videos, but are characteristically unstable. After viewing, the video is cut to individual clips and only those are preserved, which are later used for the final video. They are stored with sound and visual effects in the project folder. Video tracks are arranged according to the planned scenario in the time window and supplied with transitions. Sound tracks are supplied with additional sound or / and sound effects. The results of editing are simultaneously viewed on the video monitor. When the modifications are satisfactory, the video is rendered in a single file. Rendering is a time-consuming procedure, which can take up to a few hours. The final product is stored on an outer media - CD, DVD or over the Firewire on videotape. Coding is a mathematically extremely complicated procedure, therefore such process can last for hours. Each second of non-compressed video takes up to 20 MB of disc storage space. The Mini DV format is based on 5:1 code ratio. Video material quality depends on the system and level of encoding. A CD can store up to 65 minutes of an MPEG-1 coded video. The MPEG-2 format allows an outstanding picture quality and can even be stored on an ordinary CD, yet its capacity allows only 10 of these video minutes. The MPEG-4 format is very popular because it allows good quality as well as large data quantities.

**Video lectures on the Center for Distance Education Development server**

Software equipment (browsers) allows video broadcasting in various formats with the addition of video players (Real Media, Windows Media Player, Quick Time). Broadcasters allow two ways of transmission or broadcasting. Video via the network (*.avi,*.rm,*.mov) video is transmitted to our computer's storage unit and is viewed, when the transmission is finished. The other allows simultaneous viewing from the moment of data transmission (Advanced Streaming Format). ASF allows transmission of various combined data (video, audio, URL addresses etc.) in a single data stream via the Internet. The ASF format allows the production of different video qualities. Several files are made, of which the user chooses the quality that allows undisturbed viewing of the multimedia presentation according to the transmission bandwidth.

The CDED at the University of Maribor organized and formed the first on-line presentation of dissertation in Slovenia. The presentation was given as a web lecture, supported by a video and transparencies. The ultimate sound and picture quality were provided by two types of files to allow undisturbed transmission of files via the 56 Kb/s and 128 Kb/s modems. The data can be compressed for higher transmission speeds, which results in better video and sound quality. The latter is rarely used, primarily in the local environment with cable modems. Both variations focus on the quality of sound rather than picture. At compression, the picture size and its quality are adjusted according to the required data speed at transmission via the Internet. After video mounting and editing the video file is equipped with orders for synchronization and connection to additional materials (electronic transparencies, web pages, subtitles, index and other materials). All suitably formed materials are combined into one web page. Video supported lecture in the duration of 43 minutes is available at [http://www.cded.uni-mb.si/predavanja/dr/potocnik/index.html](http://www.cded.uni-mb.si/predavanja/dr/potocnik/index.html).

**Conclusion**

Modern computer technology and development of telecommunication systems allow efficient transmission of streaming video via the Internet. The systems for digital mounting, storage and transmission are in full swing and are becoming price wise accessible. In Slovenia, the first introduction of ASF video supported Web lectures was given as a doctorate dissertation by the group, active at the CDED at the University of Maribor.
Standardized Metadata for Education: a Status Report

Erik Duval
Departement Computerwetenschappen, Katholieke Universiteit Leuven
Celestijnenlaan 200 A, B-3001 Leuven, Belgium
Erik.Duval@cs.kuleuven.ac.be

Abstract

This paper starts with a brief background to worldwide standardization activities in the field of educational technologies. It then focuses on the specific area of metadata, and introduces the two most relevant approaches there: IEEE LTSC LOM and DC-Education. We review how different communities adopt and support educational metadata for their constituencies. This paper can be considered as a follow-up to [20].

1. Introduction: the role of Standardization

The main aim of standardization is to achieve interoperability between systems or components from diverse origins. Interoperability in this context can be understood as ‘enabling information which originates in one context to be used in another in ways that are as highly automated as possible’ [1]. In an educational context, this should enable reuse of tools and content across functions (cataloguing, discovery, etc.), levels (simple to complex), semantic and linguistic barriers, and, of course, technology platforms. Standardization is a requirement for large-scale deployment of learning technologies, as it prevents users from being locked into proprietary systems. Moreover, standards are needed to develop an open base infrastructure that components can be plugged into. This is especially important in an educational context, because of the wide diversity, and the lack of consensus on a universal best solution.

It is important to realize that a standard does not impose a particular implementation. Rather, as a common specification, it establishes an opportunity for competition or collaboration by diverse groups.

Very important in the domain of education and training, is that standards can help to establish a base technology infrastructure with permanency. This is a high priority need in our field: many impressive results of R&D projects from the last 15 years (and more!) are gathering dust on shelves, because the tools and the equipment that they rely upon no longer exists, or are no longer maintained. Without such permanency of technology, we will not be able to build upon the results of our predecessors, and we will never achieve real impact.

Finally, it is important to note that ‘real’ standards are produced by ‘accredited’ organizations, that guarantee an open, fair, transparent and inclusive process, and that take care of the maintenance of the standards. Rather different from these ‘de jure’ standards, ‘de facto’ standards are based on specifications made by a consortium or company. The proper process (see also figure 1) relies on the development of specifications in consortia, where experience can be gathered on their practical use. When specifications have matured, they can be fed into accredited organizations that can use this input as the basis for ‘real’ standards.

2. Standardization of Learning Technologies

There are three important accredited standardization organizations in the domain of education and training.

2.1 IEEE LTSC

The aim of the IEEE Learning Technology Standardization Committee (LTSC) is to develop technical standards, recommended practices, and guides for software components, tools, technologies and design methods that facilitate the development, deployment, maintenance and interoperation of computer implementations of education and training components and systems [2]. The LTSC includes a number of working groups, which deal with:

- general issues: architecture, glossary;
- learner issues: learner model, student identifiers, quality, competency;
- content issues: interchange, sequencing, packaging;
- (meta)data: Learning Object Metadata (see section 3.1), localisation, bindings, protocols;
- learning management issues: Computer Managed Instruction, tool-agent communication, platform and media profiles.
The LTSC scope explicitly excludes issues that the organization believes ought not to be standardized (evaluation methods, delivery systems, etc.), and issues that it believes ought to be standardized elsewhere (multimedia, education standards, cultural adaptation). The overall strategy is to standardize the smallest, useful, doable specification that has technically feasibility, commercial viability, and widespread adoption. The group started in 1996, and holds quarterly meetings.

2.2 CEN ISSS LTWS

The CEN ISSS Learning Technologies Workshop (LTWS) has developed a report that identifies requirements for standards on learning technologies [3]. The main requirements are to improve support for reusability and interoperability, collaboration, metadata, quality, legal issues, multilinguality and multiculturality and accessibility. The report includes recommendations on:

- promotion activities on standards in the educational arena in general, and on accessibility guidelines in particular;
- the development of taxonomies and vocabularies, as these can increase ‘semantic interoperability’ and enable translations and mappings of (meta)data;
- the elaboration of an ‘educational copyright license’.

More generally speaking, the report emphasizes the need to support multilinguality and cultural wealth. It is explicitly recommended to avoid English as a lingua franca. The workshop has also been working on localisation issues of the IEEE LTSC metadata standard (see section 3.1), in order to ensure that European requirements for cultural diversity and multilingualism are properly met. A French, German, Catalan, Spanish and Italian version of LOM have been developed.

2.3 ISO/IEC JTC1 SC36

Recently, a new subcommittee on ‘Information Technology for Learning, Education, and Training’ has been set up under the umbrella of the ISO/IEC JTC1 Joint Technical Committee. Its scope is ‘standardization in the field of information technologies for learning, education, and training to support individuals, groups, or organizations, and to enable interoperability and reusability of resources and tools’ [4]. Working groups are currently being set up on issues such as vocabulary, architecture, learner-related activities, learning object metadata, learning management systems and collaboration technologies. Both LTSC and LTWS have liaison status with ISO/IEC JTC1.

3. Standardized Metadata for Education

In order to promote (re)use of learning content, identification of appropriate learning material needs to be accommodated. This requires searchable descriptions of the material, called metadata, if we want to go beyond simple keyword searches and support queries like ‘simulations of a nuclear power plant, that run on the Linux operating system, take students of undergraduate university level 45 minutes to work through and learn about the influence of cooling water temperature on nuclear reaction speed’. As interoperability is key to collecting a critical mass of metadata, standardization efforts in this field are especially relevant. In the remainder of this section, we present and compare briefly the two main initiatives in this area.

3.1 IEEE LTSC LOM

The purpose of LTSC Learning Object Metadata (LOM) is to facilitate search, evaluation, acquisition, and use of learning objects by learners or instructors [5]. The purpose is also to facilitate the sharing and exchange of learning objects, by enabling the development of catalogs and inventories, so that users can create and publish educational material. This three-year-old initiative has developed an elaborate metadata scheme with a hierarchical structure. Data elements are regrouped under categories (general, lifecycle, metadatadepend, technical, educational, rights, relation, annotation and classification). Especially relevant is the educational category that includes elements such as

- interactivity type (active versus expositive),
- learning resource type (exercise, simulation, questionnaire, etc.),
- interactivity level (from very low to very high),
- semantic density (idem),
- intended end user role (teacher, author, learner, manager),
context (primary education to vocational training),
typical age range,
difficulty (from very low to very high),
typical learning time,
description,
and language of the typical intended user.

Besides these data elements that are specifically geared towards the domain of education, LOM also includes a rich set of data elements in the other categories. The core specification is now in version 5.0, which will be submitted to a formal ballot. The schema specification seems to be quite mature and stable. The main reluctance from the user community concerns the restricted nature of the vocabularies for certain LOM elements. That is why it was recently decided to change the status of these vocabularies to suggested good practice.

Fig. 1: The main organizations involved in standardization for education and training

3.2 Dublin Core – Education

The Dublin Core (DC) is a set of 15 metadata elements intended to facilitate discovery of electronic resources in a general sense. The objective of the Working Group on Education in the Dublin Core Metadata Initiative is to develop a proposal for the use of Dublin Core metadata in the description of educational resources [6]. At this moment, the Education group recommends to add the following data elements to DC:

- audience (both intermediate, like teacher or author, and end users, mostly learners);
- organizational, professional, province/state, national, and international educational standards;
- interactivity type, interactivity level and typical learning time: for these, the DC-Education group recommends adopting the corresponding LOM data elements.

3.3 Comparing LOM and DC-Education

LOM was originally developed specifically for the domain of education and training, and is becoming gradually more and more deployed outside of this specific domain. It is rather the other way around with DC-Education, as the Dublin Core metadata element set was originally developed for general resources, and is now being adapted for the specific field of education and training.

It is clear that LOM provides a far richer structure with more detail for ‘semantically interoperable’ metadata on learning objects. The use of namespaces to achieve semantic and syntactic interoperability between DC-Education and LOM is being discussed in a working group with representatives from both organizations.
Awareness in the sector of education and training on the issue of learning technology standardization in general and on metadata specifically, is definitely growing fast. On the other hand, with awareness of the importance of these issues also seems to grow the confusion and misunderstandings. For many interested parties, the difference in status between for instance consortia and accredited standards organizations is not at all clear (see above). And, as has happened so often before with educational technologies, there is a definite danger that expectations are being raised unrealistically high.

4. Adoption in Practice of Educational Metadata

4.1 Adoption in Consortia
There is considerable overlap in the work of the different consortia (ADL, AICC, ARIADNE, IMS, etc. – see figure 1 and below) that work on actual implementations of metadata and other standards. This is quite natural, as many of these consortia contribute to the development of the standards, and then adapt them to the needs of their constituencies, a process referred to as 'profiling' in the standards world. In fact, having several independent implementations of the metadata standards increases the probability that problems or shortcomings will be identified early on. In this section, we briefly review some recent developments in a number of the more relevant such consortia.

- The ARIADNE project (1995-2000) recently transformed into a permanent self-sustainable Foundation [7]. One of the most important aims of the Foundation is to organize the further development and exploitation of the Knowledge Pool System, a distributed database of reusable learning components, with associated metadata that describe them. ARIADNE and IMS (see below) jointly submitted their metadata specification to the IEEE LTSC and continue to collaborate on this issue. Within the ARIADNE community, the so-called metadata recommendation makes 23 of the LOM elements mandatory. ARIADNE has developed a taxonomy of science types, disciplines and subdisciplines. These are used to indicate the semantics of the learning object, using the facilities that LOM provides for this purpose. The technological basis for the ARIADNE tool development is XML and databases.

- The IMS 'global learning consortium' released version 1.1 of its metadata specification in May 2000. This was a minor update to the previous version, based on LOM version 3.5 [8]. The IMS specification includes suggestions of controlled vocabularies for 12 elements. Often, it lists multiple suggestions, with their origin and suggested applicability. A binding to XML, in the form of a DTD, is also defined.

- The US Department of Defense launched the Advanced Distributed Learning initiative in 1997 [9]. In January, ADL released version 1.0 of the 'Sharable Course Object Reference Model (SCORM)'. This reference model applies LOM to raw media (7 mandatory elements), content (15 mandatory elements) and courses (15 mandatory elements). Since January 2000, developers have started to implement the model, which culminated in the so-called plug-fest in May. In parallel, a test suite for SCORM is being developed. The main technology binding is XML.

- EDNA [10] relies on DC with additional elements for when the metadata were entered, who approved them, when the learning object is to be reassessed, the user level, categories, conditions, indexing, review, version. EDNA includes its own lists for types of learning objects, user levels and coverage, for the Australian context. The main technology relied upon are HTML META tags.

- The EUN SchoonNet initiative regroups most of the ministeries of education in Europe [11]. For its metadata applications, it relies on the Dublin Core metadata element set, with additional elements for rights, approver, release, user level and version.

- The Gateway to Educational Materials (GEM) [12] relies also on the Dublin Core element set, with additional elements for DC with additional elements for audience (distinguishing who uses a tool from who benefits from its use), cataloging, duration, essential resources, grade, pedagogy, quality and standards. GEM has also defined controlled vocabulary for audience, format, grade, language, pedagogy (divided in teaching methods, grouping and assessment), relation, resource type and subject (a two level classification system).

- NEEDS [13] and SMETE [14] are build defines its own metadata element set for searching, with title, contributor, publisher, subject heading, affiliates keywords, platform and MIME type.

- The European Joint Research Center has developed a 'Global Education Multimedia server' (called GEM, but not related to the Gateway of Educational Materials mentioned above), which should act as a clearinghouse of information, products and services [26,27]. Similar to for instance ARIADNE, a
relational database is used to store the metadata on the server. Access in four languages takes place through a web interface. The GEM system can import from or export to LOM.

4.2 Adoption in Projects and Use in Research

Many smaller scale projects, typically confined to one organisation, are including metadata in their development efforts. Sometimes, the basic idea is to provide a useful service within the own organisation, and sometimes, the main focus is on further research that requires metadata support as basic functionality. Below, we review some of the more noteworthy activities in this domain.

- Work at Carnegie-Mellon investigates how metadata can be used to develop tools that automatically evaluate the consistency of a course [22]. The core idea is that the course is composed of learning objects whose metadata describe the prerequisites and learning objectives. Thus, it is possible to verify automatically that no learning object is presented before the necessary prerequisites have been covered (as learning objectives of preceding material).

- The GESTALT project implemented an extended version of LOM [23]. Tools were developed to match metadata against user profiles, so as to implement personalized educational programs. A CORBA based architecture was developed to access an ‘asset metadata server’ and user profiles from an LDAP server.

- LOM was adopted as the metadata set for a database of resources for schools in Hawaii [24]. These resources include Ph.D. students, software, weather stations and remotely controlled cameras, courses in computer science and mathematics, telescopes accessible through the web, etc. For this context, the LOM structure was extended (as anticipated in the specification) with more detail on audience, community involvement, discipline, educational objectives and pedagogy. In this process, much earlier work by GEM (see section 4.1) was integrated in the LOM context. These experiences influenced some final developments and fine tuning to the LOM specification.

- At the Darmstadt University of Technology, a LOM editor has been developed in the context of a project on adaptive hypermedia [25]. Learning strategies based on different kinds of relations (is_a, proceeds, part_of, etc.) are supported by dynamically matching metadata of so-called ‘media bricks’ with a ‘concept space’ that describes the structure of the application domain.

- At Acadia University, one theme of LOM related work is the use of XML tags and Xlink to connect metadata and the learning objects they describe [15]. Another theme relates to the description of the potential role of the learning object: for that purpose, the concept covered by the object, its context (including prerequisites), ways it can be used in instruction and possible student activities are described [16].

- At the University of Paderborn, granularity of learning objects has been researched, distinguishing between media elements, learning elements, content modules and thematic metastructures [17].

- The Essen Learner Model includes an extension of LOM to provide more detail on didactical methods used with a learning object [18]. Learning sequences are represented as processes that cover the main activities, interactions, information systems and persons involved.

- At the University of New South Wales, the role of learning objects, with associated LOM metadata, in administration, content authoring, learning resource catalogues and delivery has been studied [19]. Basically, the authors argue that these different components should be more tightly integrated.

- Commercial systems are beginning to support LOM, even though, as noted above, the standard is not completely finalized yet. An example of such a commercial systems is imc’s CLIX [21], which has been used to build learning sites for companies like Lufthansa, Chrysler-Daimler, and others.

Conclusion

It is striking to note that, at present, there is little activity on interoperability between independently developed systems for metadata management. Some demonstrator work has been done between the ARIADNE and GESTALT consortia (see section 4.1), but larger scale developments are rare at this moment. We believe that it is now time to start this interoperability development, as the specifications and implementations are maturing. Only then will we be able to amass a critical quantity of learning material, and will the standard indeed serve its ultimate goal.

Abstract: We present a case study in requirements modeling for a medical multimedia Lecture on Demand (LoD) system. Our focus is to produce a requirements model reflecting the functional and the Quality of Service (QoS) requirements for LoD instruction on medical procedures, and to also consider requirements from other telemedicine multimedia applications in order to create a general requirements model for medical LoD systems. We discuss the medical LoD application, characterize requirements for other telemedicine applications, and represent the resulting requirements model as a UML use case model.

Introduction

The OMODIS project focuses on developing infrastructure to support Quality of Service (QoS)-aware distributed multimedia and LoD systems. The effort reported here is to develop the requirements model for the medical LoD prototype (Wang 2001), capturing both functional and QoS requirements. For this we focus on the Multimedia-Supported Learning of Practical Procedures Project (Bach-Gansmo 1998) at the Medical School of the University of Oslo. A project goal is to deliver lessons of actual procedures, recorded in the hospitals, over the internet. We have also drawn requirements from other telemedicine projects (e.g., http://www.telemed.rito.no).
QoS is critical for these medical procedures. For example, from audio, it must be possible for a student to learn to differentiate between stridor, caused by an obstruction of the large airways, and asthmatic breath sounds. In a remote controlled medical procedure, the delay (for both the video and the controlled instrument) between the remote operator and the procedure site must be well less than human response delay. Thus, some individual use cases may be subject to QoS constraints, and there may also be QoS constraints between pairs of use cases.

We present our requirements model as a UML use case model, see (Fig. 1). The core LoD model developed seems to be relatively well structured and flexible. We were able to easily extend the model with a Teleconferencing area that supports both consultations and Remote Procedures. We also show adding QoS constraints to a use case model. As examples, data sequence and time delay constraints are shown on the Remote Procedure use case, and an event-response delay constraint is shown between the Ask Question and Notify of Event use cases.

The OMODIS Project (Object-Oriented Modeling and Database Support for Distributed Multimedia Systems) is funded by the Norwegian Research Council (NFR), Distributed IT Systems (DITS) program. Information about the OMODIS Project is available on the internet at http://www.ifi.uio.no/~plageman/omodis.html.
Technology has much to offer in refining and improving conference design and management as well as raising delegate satisfaction. Based on experiences from the Southern Cross University AusWeb conference series (http://ausweb.scu.edu.au), this poster presentation discusses the advantages of end-to-end electronic submission, refereeing and publication to the Web, CD-ROM and paper. Pre-delivery of papers (via the Web and/or print via mail) to delegates ensures that delegates are fully briefed on the content to be discussed at the conference. The option to link Web-based multimedia presentations to the formally refereed papers provides authors with the opportunity to expand upon, present updates and in general invite delegates to explore in greater detail the ideas and concept they are presenting. In this way conference sessions can be designed to reduce the time for the delegates presentations and to increase interaction between authors, moderators and delegates. Conclusions are drawn for the design of educational delivery systems.
Accreditation of Prior Learning through Internet Technology

Abstract: This paper describes the CREDIT-system, an Internet-system that helps people with the assessment and accreditation of prior knowledge (APL). Users can have their knowledge assessed through the Internet, with the help of an advisor. For a full accreditation, the user will have to provide the system with evidence for already acquired knowledge, which will be judged by a human assessor. Otherwise, the user can opt for a self-assessment, to get a clearer view of personal knowledge and skills.

The usefulness of this system is evident: People do not have to go through cumbersome paper and pencil exercises, but can use the system to organize their evidences. Another use of the system is competence management: companies can easily chart their employees' knowledge and skills. The CREDIT-system makes it possible to do assessment in a time and place independent way.

Introduction
A consortium of training companies, software companies and a university joined in the CREDIT-project, that develops the CREDIT-system (www.eurocredit.org). The general goal of the CREDIT-system is to support the assessment and accreditation of skills and knowledge combined with the offering of advice in further learning and training. The system gives insight into the competencies of people, by building an electronic portfolio through collecting evidence (Groothuismink & Oprins, 1999).

Many people acquire knowledge and skills through self-study, volunteer work or other means, for which they cannot show official diplomas. The CREDIT-system supports two routes: formal assessment through evidence collection, potentially leading to an official accreditation, and informal assessment, allowing users to self-assess their knowledge and skills in a particular area. For companies it is useful to have insight into the skills and knowledge of their personnel for the arrangement of training, for the allocation of staff, for the selection of personnel, or other Human Resource Management related tasks (Groothuismink & Oprins, 1999). The CREDIT-system makes it possible to do the processes of assessment and accreditation in a time and place independent way. At present, the CREDIT-system is available in the languages English, German, Spanish, Portuguese and Dutch. The domains for which the CREDIT-system is available are Childcare, First Level Management, and Software Engineering, but it is easy to incorporate new domains (Sandberg et.al., 2000).

Description of the CREDIT tool
The CREDIT system consists of four different tools (see figure 1.). The Skills Matching Tool is used to investigate the skillsets that are available within the CREDIT system. It gives insight into what domains are available, and what skills are required for the various qualifications and accreditations. Users can also perform a quick self-scan/self-assessment to get an idea of their own performance in a certain domain.

For the Evidence Tool, which works off-line, it is necessary to download a set of skills to be assessed against. With the Evidence tool, the user can collect evidence to prove he has acquired the skills and knowledge for a specific
domain, or skillset within a domain. This evidence can be of any type (photo's, video's, references, certificates, descriptions, etc.). Since the matching process can be time-consuming, this is done off-line. When the participant is ready, he can send the entire file (skills and evidences) to his advisor to get advice or to an assessor to be evaluated. The Advisory Tool is used by the advisor for feedback on the user's evidence. It typically will mark which skills are acknowledged, which skills need more evidence, and what skills need further training, in order to be acknowledged. Learning routes to fill the training needs will be offered to each individual.

The last tool, the Knowledge Tool helps the participant searching for possible learning materials. (For a full description of the system, please refer to the User Guide by Matt Street, 2000).

Evaluation results

The first version of the CREDIT-system has been evaluated with user-trials. The goal of these trials was to gain information from users, and be able to improve the system. 115 users from different countries and different domains were involved in these user-trials. Three methods of evaluation were used during the trials. A web-evaluation (on-line), that was available for the general public, and where people could try the system and give comments. A workshop evaluation, in which the system was demonstrated to a group of users. And an individual evaluation, in which users had to work with the system while being observed by a researcher. Afterwards the users had to fill in a questionnaire and were interviewed.

The main result of the first user trials is that users judge the system as useful. They can easily imagine to use a tool like this in the future. Most users did not have difficulties to understand the functionalities of the system, and they approved the idea of the different tools. However, many remarks concerned the User Interface Design. The Interface was generally judged as too complex, more help and guidance should be available, especially for the more complex procedures (Oprins, 2000).

Discussion

The CREDIT-system is based on user requirements, gathered with a survey amongst the potential users of the system. It is a valuable tool in the in the area of lifelong learning. Users can get insight into their own level of knowledge, they can get diplomas and certificates without having to go though courses and exams again, and thus save much time. For example, this possibility is expected to be very useful for people that are moving from one country to another within Europe, and that want to have their diploma's acknowledged across the two countries. Another example is represented by women re-turners who often acquire knowledge and skills in an informal way during their non-working period and who will through CREDIT find a way to demonstrate their knowledge and skills. For companies the system offers an easy possibility to have their personnel gain official certificates (for example when these are obligatory due to official regulations). Furthermore, companies have a strong tool to find the right man for the right job. User trials indicated that the CREDIT-system is on the right track, but that it needs improvements. Currently, a new version is released and new user trials are in progress.

Current work

At this moment, the second version of the CREDIT-system, having implemented a completely new interface, is ready, and the system is evaluated through a second set of user trials. This time the evaluation set-up is different. More users are involved (appr. 300 participants), and they will have to perform certain scenarios with the system. Training companies within the different countries have created these scenarios specific to their country and their situation. About 20 different scenarios are created this way, covering all the aspects of the new version of the system. Thus during the second user trials a full evaluation of the entire CREDIT-system will be performed. During the presentation, not only the CREDIT-system will be demonstrated, but also the results of the second user trials will be discussed. Furthermore attention is given to the user friendliness and usefulness from the viewpoint of organisations and companies, that want to use the system and want to be able to swiftly add new skill domains, job descriptions etc.

References

Abstract: A typical Web-based training development team consists of a project manager, an instructional designer, a subject-matter expert, a graphic artist, and a Web programmer. The typical scenario involves team members working together in the same setting during the entire design and development process. What happens when the team is distributed, that is when the instructional designers and the developers are not in the same setting? How can a geographically dispersed team work together meaningfully? What are the challenges they will face and how can they be overcome? Because it is becoming more common for instructional technologists to be brought in from several locations long-distance team building presents an important challenge to the process. This paper addresses several issues that instructional designers face when working in such distributed environments based on our experiences during a collaborative project between Syracuse University and a multi-national corporation. Toward this end, we propose using Web-based CSCW systems to support distributed group design process.

Introduction

The distributed group instructional design project was the outcome of an initial understanding between a multi-national Corporation and the department of Instructional Design, Development and Evaluation (IDD&E) at Syracuse University. It called for a collaborative engagement between a higher education institution and the industry. The task as set out by the multi-national Corporation was the design of a Web-based instructional product to train its clients on how to read financial reports. Although a print-based product existed, the development of a version effective for web-based delivery was in line with the client’s goal of using the World Wide Web (WWW) as an emerging and competitive tool for training. For the purposes of this task, an instructional design team was formed in Syracuse. The development team and the user group were at another location together with the project manager provided by the client.

Since the design and development teams were distributed among several locations, the challenges and issues faced by such a group were vastly different compared to those of a conventional design process of Web-based training (WBT) where the team members are located in the same setting. We quickly realized that two factors were critical to the process: group-model building and computer-support for communication. Besides being interested in the design process we had some specific questions we wanted to explore:

1. How can communication and collaboration be achieved at a distance?
2. What works and does not work for a team working from different geographical locations?
3. How to create an effective, cohesive team when the team is geographically dispersed?
4. What are the best and effective modes of communication using the WWW?
5. What are the critical processes involved in a distributed instructional design group using a technology-mediated environment?
6. What are the group dynamics that support a distributed design process?

Reflecting on our experiences, this paper discusses a number of important issues concerning work practices, especially communication and cooperation among people, group facilitation and the group-model building process between the instructional design team and the development team. Finally, we propose using Web-based computer supported collaborative work (CSCW) systems as a working environment for distributed group design process. The paper concludes with important elements that such systems should incorporate in their design in order to support and enhance distributed group design process.

Distributed Group Design Process

Group design refers to the design approach in which different stakeholders, such as users, designers, and graphic artists take active part throughout the design process. We adopted Gould and Lewis’s (1985) three principles: (i) early focus on typical users and tasks, (ii) empirical measurement that focuses on intended users, and (iii) an iterative design process. In the area of software design and artificial intelligence strong emphasis has been placed on group design (Bannon, 1990; Greenbaum, & Kyng, 1995). Bodker, Grønbæk, and Kyng (1991) also advocate participatory design in the area of software design: “computer applications that are created for the workplace need to be developed with full participation from the users-both from a democratic point of view and to insure that competencies central to design process are represented in the design group” (p.215). However, they point out that users may require help to take on the new role of participant, and designers may need help in their new roles as facilitators: “Full participation requires training and active cooperation…designers should know how to set up the process and need to make sure that everyone gets something out of the interaction” (Bødker, Grønbæk, & Kyng, 1991, p.215-216).

These comments of Bodker et al. highlight an important need for group design that our experiences have also confirmed: group-model building and team facilitation. Our collaborative design process can also be distinguished from similar work with one very important factor: the instructional design team was not in the same location as the development team and user group. Therefore, a very important challenge was that of team building at a distance. Designing training at a distance with a distributed design-development was a unique experience. Besides, neither of us had prior experience with designing training where more than one instructional designer was involved. Since, our experiences with designing WBT also showed a great diversity it was necessary to find a solid base for our efforts.

Group-model building refers to a dynamic model building process in which all the stakeholders are deeply involved in the process of model construction (Vennix, 1999). For instance, the system dynamics community has made considerable progress in developing tools and techniques to support a group-model building process and knowledge elicitation (Morecraft and Sterman, 1994; Richardson & Andersen, 1995; Richardson et al., 1989). Vennix (1996) has connected these efforts of system dynamics model builders to the realms of decision-making, small-group dynamics, and group facilitation. Empirical studies show ultimate gains from group-model building activities in these contexts. Although these domains are different from those of instructional design, the group model building process may likewise enhance instructional planning and analysis. The added advantage is that participants in group planning processes fit well with the notion of participatory design.

Our process can be likened to the reference group approach (Randers, 1977) used by the system dynamics community. Characteristics of a reference group approach are: (a) the product is a process of learning rather than a statement of fact, hence the model becomes a tool to improve discussion; and (b) the group becomes tangible hence providing a continuous interaction between its members. The reference group approach consist of a number of stages (Sternberg, 1980):

1. initiation of study;
2. establishment of reference groups;
3. initial meetings with reference group to define problem;
4. construction of the initial (simple) model based on discussions with the reference group;
5. model improvement through scenario discussions with the reference group;
6. reporting;
Our initial group meetings started with a series of audio conferences and e-mail exchanges with the client for the purposes of project planning, and we agreed upon tasks, timeliness, responsibilities, and deliverables. Then, the instructional design team began the process with task analysis, negotiating the conceptual framework and content outlines of web-based training module. Our deliverables included detailed storyboards created on Microsoft Word™ that the developers could then use to create the actual training Web site. A preliminary initial model was made by the instructional design team. Microsoft Word™ was used as the primary software tool for creating the storyboards as a special request from the development team. In order to maintain consistency, a template with the color scheme and the overall layout was developed to help us replicate the user interface. The team members divided the tasks and began to create sections of the product in his/her own student directory.

As the creation of the storyboards progressed, we began to engage in an iterative, nearly simultaneous process of design and revision. The rapid revision process that followed was a direct result of our use of a mediated environment consisting of e-mail messaging and a shared design and common file sharing area on the Web. As one member of the design team designed a piece of the product, other team members would comment on it and provide feedback; making changes, when appropriate. Thus, the team’s multiple perspectives resulted in a product that was emergent. Records of all e-mail, face-to-face and audio communications were also maintained.

As we came together to work on the project, we agreed on having open communication with each other. This proved as an effective group work leading to improved productivity. The team members worked collaboratively sharing or linking related elements. Our group members each wore many hats. Where skills were lacking, team members with greater expertise coached the others. We followed a collaborative design process by asking questions, requesting technical information, and seeking opinions about dealing with problems. Often, alternative views resulted in major differences of opinion. We acknowledged opposing viewpoints, questioned alternatives, and negotiated differences of opinion. In order to move the design process forward without drifting away, we found that it was important for team members to establish a shared understanding and vision of the final product. Our team organized itself in a way that made the most of individual strengths.

After the design team completed the first prototype, it was sent to the development team and the user group to provide feedback. These efforts were facilitated by the project manager. First tests were conducted on the paper versions before the actual prototype development took place. This iterative process of design and testing took place until all the members were completely satisfied with the overall interface design and the presentation of the content leading to prototype development.

**WWW as an Enabling Technology for CSCW Systems**

Although our experiences with electronic mail has proved to be successful confirming the past research (Bullen & Bennett, 1990; Grudin, 1991) using a sophisticated, seamless, shared, electronic workspace as described by Ishii, Kobayashi, and Arita (1994) would have proven to be more efficient. Our team members relied heavily on e-mail accounts on different systems and were also using the student accounts on the university's network server. Later on we set up a group account on a web-based shared file storage drive that all the team could access. It facilitated our work affording file sharing and version control. At the beginning of the project, our problem was in gathering and compiling all the materials and information with the necessary tools for design and communication. Our design process was guided by our own input as users, learners, and designers, and was facilitated by the types of communication exchanges that the e-mail system supported. However, we felt a great need to have a Web-based CSCW system that could have made the communication and collaboration more efficient and effective with the other members of the team. Such a system would make organization, communication, and revision of materials easier.

For widely dispersed working groups, where members may be in different organizations and different countries, issues of integration and inter-operability often make it difficult to deploy existing groupware applications. Although non computer-based solutions such as telephone and video conferencing technologies provide some support for collaboration, empirical evidence suggests that computer systems providing access to shared information, at any time and place and using minimal technical infrastructure, are the main requirement of groups collaboration in decentralized working environments (Gorton et al. 1996; Rao, 1995). By offering an extensible centralized
architecture and cross-platform browser implementations, increasingly deployed and integrated with user environments, the Web may provide a means of introducing CSCW systems which offer much richer support for collaboration than e-mail and FTP, and thus serve as an 'enabling technology' for CSCW. Bentley et al. (1997) explain why the Web offers a potential platform for enabling the CSCW technology very well:

- "Web client programs (browsers) are available on all popular computing platforms and operating systems, providing access to information in a platform independent manner,
- browsers offer a simple user interface and consistent information presentation across these platforms, and are themselves extensible through association of external 'helper applications',
- browsers are already part of the computing environment in an increasing number of organizations, requiring no additional installation or maintenance of software for users to cooperate using the Web,
- many organizations have also installed their own Web servers as part of an Internet presence or a corporate Intranet and have familiarity with server maintenance and, in many cases, server extension through programming the server API" (p.3).

As a basis for deployment of CSCW applications in real work domains, the level of acceptance and penetration of Web technology in commercial and academic environments is grounds alone for suggesting that CSCW should pay serious attention to the World Wide Web for supporting distributed group design process.

Conclusion

Given the context, our instructional design process can be characterized by two very distinguished factors: (a) group design, and (b) distributed design teams. Although the team as a whole was primarily interested in the design and development of Web-based training we were also concerned with studying the process and the learning that supported it. We believe such distributed group design projects will soon be a reality in the field of instructional technology.

While the above case presented the distributed group instructional design process, experiences were specific to our own group; we believe our skills as collaborative designers have been enhanced. The strength of the group-model building model for distributed design process is in making designers aware of process that is often covert.

As team members began to develop expertise in the process their initial roles began to evolve. No one member possessed the expertise of the entire group. All team members contribute their expertise and full participation took place. In turn, our individual team building skills and content specific skills were enhanced. The group became a self-organizing system.

We believe that Web-based CSCW has a lot of premise in supporting group design efforts, especially when the group is geographically dispersed. However, in designing such systems, it is important to closely consider the dynamics of collaborative design teams. The system should also allow implementation of group-model building techniques.

We also argue that the field of instructional design should start to address group design. Tennyson (1995), states that ISD has undergone four generations of evolution: first (behavioral-linear model), second (behavioral-cognitive with phases from a systems perspectives), third (primarily cognitive with strong influence from software engineering and cognitive science-waterfall design), fourth (cognitive-constructivist with strong influences from action research and activity theory). The first two generations do not adequately address the collaborative nature of design appropriately. Their focus is more on the processes, i.e., analysis, design, development, and evaluation (Gustafson & Branch, 1997). The third generation models to address the issue, affected by software engineering but the models are to generic and do not focus on the roles of people involved. We found Tennyson's (1995) ISD-4 particularly useful in that focuses on the activities of those involved in designing instruction that the process itself varies greatly depending on context and circumstances.

Abstract: ADAPT™ is a European project within the Information Society Technologies programme that is providing design methods and tools to guide training designers according to the latest cognitive science and standardization principles. An extensive needs assessment phase has been completed. The aim of this effort was to explore current practice in instructional design and associated with that, the needs of the training designers in order to improve their practice and to insure that real world needs will be addressed in the project and its products. This paper reports the needs assessment procedures and outcomes informing how they guide the efforts within the project.

Introduction

Advanced Design Approach for Personalised Training- Interactive Tools (ADAPT™) is a European project coordinated by the Dutch National Aerospace Laboratory (NLR). The aim of ADAPT™ is to create and validate an effective training design methodology, based on cognitive science and leading to the integration of advanced technologies, so that the training community can better meet the many challenges of the information society of the 21st century. The effort falls with the European Commission’s Information Society Technologies programme (IST; see http://www.cordis.lu/ist/) and includes as partners: National Aerospace Laboratory, the Open University of the Netherlands, the University of Bergen, SevenMountains Software, EuroControl, the Swedish Air Traffic Control Academy, and Piaggio Aerospace.

ADAPT™ is developing a personalised training design methodology, providing associated design tools for the efficient realisation of that methodology, and validating the methodology in different training domains. The three-year project began in February 2000, with an estimated total of 181 person-months required for completion. The effort is broken into these 9 work packages:

1. Project management  
2. Design preparation  
3. Design of the ADAPT method  
4. Development of the ADAPT tools  
5. Using ADAPT: Design process evaluation  
6. Using ADAPT: Design product evaluation  
7. ADAPT™ revisions  
8. Standardisation  
9. Integration, dissemination, exploitation

Page 474
The aviation industry is targeted for this research and development effort as it is a key industry that is faced with difficult training problems and complexity of skills for which the design method is intended. Current challenges for aviation training relate to the increasing complexity of dynamic task environments, increasing time constraints, and increasing demands for cognitive and information-managing tasks. As technology takes over or automates many basic tasks and adds functionalities to operational systems, the result is that more demand is placed on humans to perform higher level and supervisory tasks. The problems within aviation training are exemplary of highly complex and automated task environments that require flexible skills and are likely to forecast training problems in other professional domains. Two quite different training areas within the aviation industry (air traffic control and aircraft maintenance) are involved so as to insure generalisability of the methodology and the tool to other subject areas and industries (see Eseryel & Spector, 2000 for more details).

Project partners are currently collaborating on designing the ADAPT methodology and associated tools (work package 3). The early literature review and training requirements analysis indicated that the most appropriate and relevant methodology was the four-component instructional design (4C/ID) model (van Merrienboer, 1997). In developing ADAPT methodology, the 4C/ID model will be: (1) extended to become a personalised training approach; and (2) tailored to meet the needs of actual designers or design teams in a variety of training domains, economical sectors, and company sizes. In order to achieve the latter, current practice in designing training for complex cognitive skills had to be identified. The project team realised this through three different data sources. First, the literature on training designers’ needs was reviewed. Then, in order to better understand the instructional design practice of our target group, questionnaires and extensive interviews were conducted with training designers in the aviation industry and in other business and industry sectors across Europe that involved training of complex skills (work package 2). In this paper, the findings of this needs assessment phase are presented. The next section contains a review of the literature on current practice in instructional design together with the findings of the interviews and questionnaires conducted during the needs assessment phase. The paper concludes with implications of the needs assessment phase for the design and validation of ADAPT methodology and ADAPT instructional design tool.

Current Instructional Design Practice & Needs

Literature review on current instructional design (ID) practice reveals that ID practice is significantly different from what is prescribed in ID models (Holcomb, Wedman & Tessmer, 1996; Klimczak & Wedman, 1997; Loughner & Moller, 1998; Pieters & Bergman, 1995; Rowland, 1992; Seels & Glasgow, 1991; Visscher-Voerman, 1999; Wedman & Tessmer, 1993; Zemke, 1985). The most prominent activity prescribed in ID models, but rarely completely performed by practitioners, is task analysis. Other instructional design activities that are often omitted or only partially performed are assessment of entry skills or characteristics, and the pilot testing of programs prior to implementation. Studies that investigated expert instructional design performance also revealed important differences between the activities expert designers perform and what is prescribed in ID models (Maistre, 1998; Perez & Emery, 1995; Rowland, 1992).

In the literature, several reasons have been identified that might explain the lack of proper application of ID models. These reasons can be divided into reasons that are either internal or are external to ID (Gros, Elen, Kerres, van Merriënboer & Spector, 1997). Internal reasons refer to insufficiencies of current ID models that might be responsible for their limited usefulness. These are threefold: (1) the models are not sensitive to the design context; (2) the models do not match with the way designers work in practice; and, (3) there are many ID models and they are hard to differentiate. On the other hand, external reasons refer to deficiencies in the application of existing ID models. These can be attributed to the lack of professionalism in the ID field and lack of necessary design skills and knowledge. In order to improve instructional design practice, ID tools have been developed to fill this gap (Spector, Polson, & Muraida, 1993). However, what have been missing in the area of automated instructional design are sufficiently elaborated design models with associated guidance and frameworks that are appropriate for the design of training for complex cognitive skills. The ADAPT project is intended to fill this gap with the set of methods and tools available to instructional designers. For the project to be successful, it is important for the design team to know the needs of the probable users of system. Therefore, training designer’s need across Europe had to be identified as a next step of needs assessment phase in the project.

Next to the more global literature review, designers’ needs were identified by means of questionnaires and interviews (see ADAPT, 2000). The target group was training designers in Europe who are actively involved in the
design of training for complex domains. Training designer needs are defined as the requirements that have to be met in order to change and improve current design practice. These requirements refer primarily to instructional design practitioners’ perceived needs for support to use and apply instructional design theories and models.

The questionnaires were sent to respondents in different sectors: education, information and communications technology, transportation, business, and manufacturing. The response rate was low (8% of in total 150 questionnaires), which is attributed to the length of the questionnaires and the time required to fill them out. Although this may be counted a weakness, the questionnaires provided in-depth information to make informed judgments about the target group. Besides, the questionnaires were backed up with extensive interviews in order to gather more detailed information on current training design practices, the problems that are encountered and the desired support and specific needs during the training design process.

Each interview took around three hours. In total, 10 interviews were conducted involving: 1 naval college, 3 air traffic control centres, 2 aircraft maintenance organisations, 1 telecommunications organisation, 1 information technology company, 1 training consultancy organisation and 1 distance education company. Unlike the questionnaires that produced data in one format, the more in-depth interviews were intended to provide detailed and rich information about company design practices. As interviewee background and companies differ substantially, the interviews were loosely structured in the sense that questions were open and no pre-defined answer categories were supplied. This was intended to stimulate the interviewer towards more natural, personal and company-specific responses. Some structure was provided for the interviewer by a list of questions and themes to be addressed. The interviews not only yielded more detailed information, but, more importantly, they yielded an impression or feeling of current design practice, which did not emerge from the questionnaires.

The emphasis during these data gathering efforts was on the difference between current and ideal training design practice, on the problems experienced during the design process, and on the ideal characteristics of an instructional design tool. Table 1 provides an overview of the most important characteristics of current design practice that emerged from the results of the questionnaires and the interviews. The literature review, the questionnaire survey and the interviews have also resulted in training designer’s needs for ADAPTIT. The most important designer needs for ADAPTIT are summarised in table 2.

<table>
<thead>
<tr>
<th>Category</th>
<th>Current design practice</th>
</tr>
</thead>
<tbody>
<tr>
<td>Training designer background</td>
<td>• A majority of training designers have an operational background and became designers after having worked in the operational field. They are not fully occupied with designing training as it is often combined with roles as instructor or training manager.</td>
</tr>
</tbody>
</table>
| Training design process   | • Current training design practice does not follow a standard Instructional Systems Design model. Activities are carried out selectively and often partly and are often characterised by implicit and intuitive methods.  
  • The analysis phase is not carried out explicitly and in detail, mostly due to constraints involving time and resources.  
  • The design phase appears often to be combined with the development phase, and often happens implicitly as part of the development and implementation of training. Specific instructional design models or principles are rarely explicitly used by designers with an operational background. However, many basic ideas and some instructional design principles seem to be intuitively understood and used.  
  • A detailed and systematic evaluation does not occur and is for a large part based on subjective data. The distinction between formative and summative evaluation is not found. Formative evaluation seems to take place informally. Summative evaluation mainly focuses on short-term evaluation. |
| Organisational aspects    | • In general, training is not designed in formally structured design teams. The most important actors in a team are subject matter experts and instructors, who typically design the training. Collaborative design does not seem to take place explicitly. |

*Table 1: Characteristics of current design practice that emerged from the questionnaires and the interviews*
Category | Training Designer’s Needs
---|---
Training designer background | 1. Target at training designers with an operational background but do not exclude those designers with an educational background;  
2. Use non-academic instructional design language, fitting the main target group of designers with an operational background.

Training design process | 1. Support an explicit, structured and systematic design process, especially for the analysis, design and evaluation phases;  
2. Take into account that current design practice is often characterised by implicit and intuitive methods. Support the designers in the change in design process (e.g. by allowing some intermediate ways of design focusing on the vital aspects of training design);  
3. Convince the users to adapt their working practice (e.g. by explaining the added value of the different design steps and explaining the steps by means of practical worked-out examples);  
4. Provide pragmatic, practical useful methods that yield quick results and can be easily used to produce at least a minimal required training design (see also 2).

Organisational aspects | 1. Address the relational aspects during the training design process (setting up teams, involving users, methods for teamwork, collaborative design, communication etc.).

Design tool characteristics | 1. Provide practical worked-out examples;  
2. Provide support/guidance in applying instructional design principles;  
3. Link together the different training design products;  
4. Provide methods for file management and version control;  
5. Make information easily re-usable and retrievable;  
6. Allow different degrees of freedom (e.g. from structured to non-sequential design);  
7. Increased efficiency: design training more quickly;  
8. Increased effectiveness: design better training.

| Table 2: Some of the training designer’s needs identified by the questionnaire survey and the interviews |

Current instructional design practice and the training designer’s needs emerged as an outcome of needs assessment phase strongly suggests the demand for an integrated ID method-tool combination by business and industry. ADAPT project aims at bridging the gap between complex training problems and new technological possibilities by developing and validating a training design framework to guide the use of state-of-the-art cognitive approaches within advanced training systems. In order for the project to be successful, the design effort is guided by the outcomes of the needs assessment phase as design requirements (work package 3). These outcomes will also be utilized for evaluating the final outcomes of the products (work packages 5 & 6). The next section discusses the implications of the findings of needs assessment for the design and evaluation of ADAPT.

Implications for Design and Evaluation of ADAPT

The training designers’ needs that form one of the guiding principles for ADAPT is originating from the fact that respondents questioned the merit of a tool as opposed to current design practice. Respondents were justifiably concerned with regard to a tool constraining the application of their current working methods and knowledge and skills. As instructional designers vary along the dimension from novices to experts with corresponding cognitive differences in the way they approach their tasks the system should be flexible enough (i.e., weak approach to design) to handle different sequence of uses and the messages should be tailored to the designer’s level of expertise. ADAPT should therefore be set up in such a way that all designers, including designers without a specific educational background, should quickly become aware of and convinced of the additional value of ADAPT. The system should be flexible enough to allow advanced users integrate their own design practise, knowledge and skills. Inexperienced designers may require (ask for) more support in the process of structuring their
analysis and design results. For this kind of audience, the use of non-academic language is of utmost importance. In addition, a number of design supports will be integrated in the system:

1. The ADAPT methodology handbook that will describe how to analyse complex cognitive skills and how to design training for those skill along with worked-out examples.
2. The CORE software tool that will support the use of the ADAPT methodology by allowing storing and viewing analysis and design results and by producing a blueprint for training in such format that it can be further worked out with third party authoring software.
3. An online help system and manuals, describing functionality and procedures for using the ADAPT tool with implementation examples.
4. An expert design and standards advisor.
5. An evaluation software (EVAL) to support formative and summative evaluation of the training.
6. Familiarisation training for the trainers to teach to apply the ADAPT method and tool supported by a web-based online tutorial.

The ADAPT system should have an impact on training design practice. Therefore, the method-tool combination is aimed at ensuring effective training design for complex cognitive skill embodying a validated training design methodology for personalized training that is based on the latest developments in the cognitive science. The tool itself also aims at more efficient training design by integrating several technologies, such as the re-usability of intermediate design products, version control, and support for adapting training design to changes in the external constraints (e.g., training time, characteristics of the target trainee, etc.). Furthermore, the system will be customisable to user preferences and allow collaborative design and rapid prototyping.

The project recognizes evaluation for its critical role it plays throughout the lifetime of the system. Functional specifications arising from the needs assessment phase and the aims of the system forms the basis of the evaluation plan guiding the design, production and revision of the full-scale system. The evaluation and validation activities in the project are twofold: (1) evaluation of the training design process; (2) validation of effectiveness of training design products. Integrated in the former, the instructional design modelling approach will also provide the means to pinpoint problems in instructional design guidance that the system provides. In both studies, the impact of the ADAPT system will be compared with the traditional practices. The project partners from aircraft maintenance and air traffic control will be involved in these studies to insure the generalisability of the methods and the tools to other domains. The user-centred process adopted for this project insures that the real world needs will be addressed in the project and its products.

The work presented in this paper is the outcome of the collaborative efforts of ADAPT project partners (see http://fjellbekk.eist.uib.no:2008/adapt/) co-ordinated by J. van der Pal at the Dutch National Aerospace Laboratory NLR, pal@nlr.nl.
A Study of Technology Cost of Primary School in Taiwan

Rong-Jyue Fang, National Kaohsiung Normal Univ., Taiwan; Yi-Shian Jong, National Kaohsiung Normal Univ., Taiwan; Hung-Jen Yang, National Kaohsiung Normal Univ., Taiwan; Jui-Chen Yu, National Science & Technology Museum, Taiwan; Hung-Ming Jang, National Kaohsiung Normal Univ., Taiwan

The purpose of this study was to analyze the cost of technology at primary school level in Taiwan. There are four major goals of this study. Those are:

- Review the current status of using technology in primary school
- Review the goal of primary school technology plan
- Survey the current budget used for school technology
- Analyze the cost of school technology plan

According to the goal of technology plan and reality, this study will conclude unit costs for many infrastructure and network electronics components of advanced telecommunication systems now being installed in schools. A hypothetical case study of the cost of a typical new elementary school needs increased space and creates other factors raise costs.
A Study of How Technology Influences Interior Design of Primary School

Abstract: Impact of technology is always one of the major concern whenever applying technology. The purpose of this study was to analyze the technology influence on primary school interior design. Upon the investigating of 238 primary schools, statistical analysis was designed to answer the research problem. Technology used in primary school in Taiwan could be categorized into computer, networks, and audio/video three groups. Power system, light system, air-condition, and physical space were four areas of interior design influenced by technology. This study was concluded that how these four areas influenced by each category of technology.

INTRODUCTION
Technology has always been a factor influencing the process of change. Recent technological developments have presented us with opportunities to explore the farthest reaches of the solar system, personal computers, the capability of storing the equivalent of an encyclopedia on a small optical disc, and the replacement of human organs with manufactured ones (Yang, 1997). One area where this is apparent is in the planning and design of an educational facility. The integration of technology with the interiors of a building is a tremendous challenge. Telecommunication has become the fourth utility in the construction industry, along with electrical, plumbing, and HVAC (McDavitt, 1999). In Taiwan, computer with networking system is a token of technology. It is essential that this utility is planned for in educational facilities in conjunction with interior design. Interior design must suit the needs of student, instructor, and technology (Gregg & Persichitte, 1992). They pointed out that audio, lighting were both interior design consideration could not be neglected. Providing students with optimal design technology environment is the major concern of this study.

Statement of the Problem
The problem of this study was the technology influencing interior design of primary school in Taiwan.

Purpose of the Study
The purpose of this study was to identify how technology influences interior design of primary school in Taiwan. The goal of this study was to:
1. Review the technology used in primary school
2. Review the technology plan of primary school level
3. Investigate the goal and interior changing of implementing technology plan
4. Analyze how technology’s influences on primary school interior design

Need for the Study
The motivation for this study was desires to provide an understanding of how technology-influencing interior design of primary school. The challenge of preparing the children for a life which does not yet exist and whose nature can only be imagined is an awesome task for us. Therefore, it is imperative that we in education as well as all concerned laypeople recognize this challenge and begin to take the necessary steps to meet it. Educators have already been busy re-examine every facet of the teaching-learning process in an effort to obtain greater efficiency and greater productivity. The technology plan is under constant review in Taiwan, but interior design seems lack of focus. It is important to make the need of interior design clear.

Procedures of the Study
The procedures of this study consisted of the following: Identify a research problem, Review related literature, Design survey instrument, Conduct the survey procedure, Analyze the data collected by survey instrument, Make discussion, conclusion, and recommendations.

Methodology
The investigating method was used to conduct this research. In this section, population, sample, instrument, data collection, and hypothesis were described.

Description of Population and Sample
The target population for the investigation is primary school in Taiwan. There were 2,583 primary schools. A random sampling technique was used to select appropriate proportions of the sample. Total 258 objects were selected and there were 238, 92%, return questionnaires.
Development of the Instrument

The questionnaire method of data collection was used for this study. The instrument contains 44 questions. Rating scales for each item included: Strongly Not Agree = 1, Neutral = 3, and Strongly Agree = 5.

Data Collection

The questionnaire was delivered to selected primary school. A cover letter introducing the investigator and explaining the purpose of the study and assurance of confidentiality of data was enclosed. It was noted that the person who fill the questionnaire should be the one with job task of conducting technology plan or experience of implementing technology plan. The participants were asked to complete the questionnaires within one week and to return it.

Hypotheses And Statistical methods

<table>
<thead>
<tr>
<th>Hypothesis</th>
<th>Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.</td>
<td>It was hypothesized that the score of each statement was significantly different from the same for each interior power.</td>
</tr>
<tr>
<td>2.</td>
<td>It was hypothesized that the mean score on interior design statement is the same for each interior light changing.</td>
</tr>
<tr>
<td>3.</td>
<td>It was hypothesized that the mean score on computer technology is the same for each interior air-condition.</td>
</tr>
<tr>
<td>4.</td>
<td>It was hypothesized that the mean score on network technology is the same for each interior air-condition.</td>
</tr>
<tr>
<td>5.</td>
<td>It was hypothesized that the mean score on audio/video technology is the same for each interior air-condition.</td>
</tr>
<tr>
<td>6.</td>
<td>It was hypothesized that the mean score on computer technology is the same for each interior physical space.</td>
</tr>
<tr>
<td>7.</td>
<td>It was hypothesized that the mean score on network technology is the same for each interior physical space.</td>
</tr>
<tr>
<td>8.</td>
<td>It was hypothesized that the mean score on audio/video technology is the same for each interior physical space.</td>
</tr>
</tbody>
</table>

The two-tailed t-test for independent samples was used to test hypothesis 1. The one-way ANOVA was used to test hypothesis 2,3,4,5,6 and 7. The 0.05 alpha level was selected to test the statistical significance.

Conclusions

Based on literature review and survey result, the technology used in primary school could category into three groups. Those are: Computer, Networks, and Audio/video. Technology influences interior design in four areas. Those areas are: Power system, Light system, Air-Condition, Physical Space.

According to the statistical test result, it was concluded that:
1. It is not required an air-condition system for using network technology in the classroom.
2. It was not required an air-condition system for using network technology in computer lab.
3. It is not required an air-condition system for using audio/video technology in the classroom.
4. It was not required an air-condition system for using audio/video technology in computer lab.

Although computer, networks, and audio/video all significantly influence primary school interior design, computer's influence is significantly higher than both networks and audio/video. Although interior design of power system, light system, air-condition, and physical space are all influenced by primary school technology, power system had the highest degree of technology influence. Whenever primary importing technology of computer, networks, and audio/video, the power system made changes of: Capacity increasing, Outlets increasing, Ground system, UPS system, Power backup system. Whenever primary importing technology of computer and audio/video, the light system made changes of: Indirect lighting, Task lighting, Light control points. Whenever primary importing technology of computer the air-condition system made changes of: Server's room, Classroom, Computer lab.

Whenever primary importing technology of computer, and audio/video, the physical space made changes of: Window shielded, Monitor direction, Reservation space, Zone separation. Whenever primary importing technology of networks, the physical space made changes of: Wiring system, Network outlet, Space reserved for networking instruments, Space reserved for servers, Desktop area and laptop/notebook area, Sign and direction of accessing network service.

A Study of Teaching Belief of Using Technology in Taiwan Primary School

Rong-Jyue Fang, National Kaohsiung Normal Univ., Taiwan, R.O.C.; Hung-Jen Yang, National Kaohsiung Normal Univ., Taiwan, R.O.C.; Jui-Chen Yu, National Science & Technology Museum, Taiwan, R.O.C.; Sun-Der Su, National Ping-Tong Teachers' College, Taiwan, R.O.C.; Yun-Pin Chen, National Kaohsiung Normal Univ., Taiwan

The purpose of this study is to identify the primary school teacher's teaching belief of using technology. Belief is the subjective probability of a relation between the object of the belief and some other object, value, concept, or attribute. A teacher may believe that technology possesses certain attributes that a given behavior will lead to certain consequences, and that certain events occur contiguously.
The Hypermedia as Supporting Tool for the Learning Process

Adriana Claudia Fantini
University of Patagonia
Trelew, Chubut, Argentina
fanguer@infovia.com.ar

Marta Isabel Dans
University of Patagonia
Trelew, Chubut, Argentina
mdans@cpsarg.com

Abstract: The aim of this paper is to present an application of regional interest (a hypermedia on the province of Chubut –Argentina-) using the Hypermedia Model for Meaningful Learning (MHAS, its acronym in Spanish) as innovative tool which facilitates the task of designing educational hypermedia. MHAS provides the hypermedia a structured hyperspace adequate for educational purposes. Helps in construction of the conceptual –interdisciplinary– network, the design of interactive activities and evaluation.

INTRODUCTION

The teacher plans his/her work in the classroom elaborating activities for didactic units. The didactic units are made up of contents, activities (teaching-learning, synthesis and recapitulation) and evaluation. All these components must be related to each other and articulated according to an organizing axis (topic) around which the other components are constructed. The model for the design of educational hypermedia (MHAS) is based on the reappraisal of such activities as central tools for contextualizing and highlighting the information present in a hypermedia.

MHAS Guidelines for Developing the Application

Selection of subject: Definition of axes and sub-axes.
The general subject of our work is about Social Sciences area of the fourth level of the General Basic Education. Denominated: My province, Chubut. We knew beforehand that the subject would produce convocation of teachers, due to its regional significance. We organized both thematic axes and sub-axes around which the hypertext would be constructed. Contents were located in the corresponding axis/sub-axis this location of contents resulted in the linking points (through shared contents) among the axes. The teachers participating chose axes to develop activities.

Contextualization.
On learning theories: The preparation of activities taking the didactic unit as reference, the sequencing of such activities and contents, the selection of materials and their representation (text, sound, image, etc.) according to an objective, provide the structure for the hyperspace and give sense to browsing in the educational hypermedia. Therefore, the preparation of the hypermedia should begin with the elaboration of a script, that allows creating a framework for the topics and educational needs that shall be dealt with by the hypermedia.

On the characterization of hypermedia readers: It is essential to characterize different kinds of readers that may be in contact with hypertext. For the construction of this software, we have taken into account the editor style of reader which include others most passive.

Compilation of Material.
In this moment appear linking points between the concepts and the activities due to the interaction of the teachers that participate. They carrying out of joint activities, leading to a more comprehensive treatment of the concepts and enriching the resulting hypertext.
Preparation of a Script.
The script is the hypertext general structure. The hierarchical navigation is defined to relate concepts, starting from general ones and moving on to more detailed ones. The teachers while interacting find navigation alternatives, which resulted from the relation among different views of the same concept evoked in different sub-axes. Such alternative navigation will be controlled in order to avoid disorientation; the student will be able to exclusively go back to the starting point to continue with the hierarchical navigation or else, move to the newly found axis starting from a main node. Said restriction on navigation tends to strengthen the contextual visualization of each and every sub-axis as well as keep in the student's memory the main axes around which each concept develops. Nevertheless, navigation alternatives due to filtered visualizations contribute to reflect on cross relations.

Selection of Materials.
Together with the script preparation, a pre-selection of the materials compiled was carried out, trying to find in each case the most suitable presentation in order to catch the student's attention as much as possible. In this experience, preference is given to those materials that allow the gradual insertion in the real and concrete world. As these children are highly susceptible to visual and auditory stimuli, the capacity of the hypermedia to represent the same concept through different means (text, image, sound and so on) acquires great relevance. Besides, as children are initiated into inductive reasoning, they learn as they navigate in the hypermedia.

Preparation of the interactive activities and learning evaluation.
Some nodes where self-evaluation activities. The application comprises puzzles, matching activities, crosswords and activities to find words. Besides showing to the student his/her progress, these activities give the teacher some idea of the hypermedia comprehension via the statistics stored to record the performance of each student work.

Implementation.
A simple style was chosen to prepare the pages, the graphics, buttons and text being kept in a fixed position. Each page is self-contained. The text –brief and clear– is structured like a dialogue with the student. The images appear whenever they are necessary. We develop a product suitable to be used in a standard multimedia configuration, so that it could be distributed in the schools in the interior of the province of Chubut, which are not still furnished with highly sophisticated equipment. We use Neobook and Clic to implement, they are accessible and easy to use. These, together with the MHAS guidelines allowed the teachers to actively engage in the design and implementation.

Conclusions
A simple style was chosen to prepare the pages, the graphics, buttons and text being kept in a fixed position. The page size was adjusted to fit a screen. Each page is self-contained. The text –brief and clear– is structured as a dialogue with the student, encouraging him/her to go deeper into the subject, thus fostering research. The images appear whenever they are necessary. In this regard, the decision was made to design a product suitable to be used in a standard multimedia configuration, so that it could be distributed in the schools in the interior of the province of Chubut, which are not still furnished with highly sophisticated equipment. It is worth mentioning that a lot of small communities in the inland areas of our province are now supplied with electricity as the result of the introduction of computers in the schools. We believe that equipment must not be an obstacle that limits its use. Neobook and Clic were chosen as implementation tools, as they are accessible and easy to use. These, together with the MHAS guidelines allowed the teachers to actively engage in the design and implementation.

DESIGNING EFFECTIVE USER-INTERFACES FOR COMPUTER-BASED AND WEB-BASED TRAINING PROGRAMS

Peter Fenrich
Technology Centre
British Columbia Institute of Technology
Canada
Email: peter_fenrich@bcit.ca

Abstract:
This highly visual and interactive presentation on designing effective user-interfaces gives practical guidelines on what works and what doesn't work in designing and developing computer-based and web-based training materials. Topics include menus, orientation information, image location, screen design, effective use of colour, controlling animations, highlighting, displaying questions, control options, time delays, and narration. The highlighted software samples are designed from the perspective, "If you have to explain how to use it, you have done something wrong." There will be numerous specific objectives taught. Participants will be able to design more effective menus and screens, use colors more effectively, design clear and concise buttons, effectively highlight text, place orientation information, text, images, and buttons at appropriate screen locations, allow users to properly control animations, design more effective questions, explain why it is generally best to instantly display information, state when to use narration and when to avoid it, and evaluate software.

INTRODUCTION

The following points on the user-interface and screen design are generalities. There are exceptions to these generalities. Also, there is much more to user-interfaces and screen design than can be covered in these notes.

The user-interface and screen design are particularly important on your first project. Those who resist educational technology will often criticize these aspects, especially if they can't find a flaw in the content. So, on your first project, do everything right to ensure that it will be accepted. Consider working with external professionals on your first few projects.

CAUSES OF USER-INTERFACE AND SCREEN DESIGN PROBLEMS

User-interface and screen design problems often result from:
- Not knowing what should be done
One typical reason is that people often get into creating computer-based training applications without learning how to do it right. Teaching with computers is inherently different than with traditional methods.
- Not getting enough user-input
One of the best ways to evaluate the user-interface and screen design is to watch a variety of novice users use a prototype of the system. As soon as they hesitate or click on the wrong prompt ask them what was wrong. Use the philosophy: "It is impossible to make anything fool-proof because fools are so ingenious."
- Getting user-input too late
Get feedback on an initial prototype so that it is cheap to make changes. Also, evaluation and revision should be an integral part of the entire instructional development cycle.
- Presuming that users have a high level computer ability
There are always novices and new employees. Also, remember that you are familiar with the interface so what you easily understand others may not.
- Inadequate budgeting for evaluation and revision
Unrealistic or changing requirements can take money away from evaluation and revision.
- Inconsistency in screen and user-interface design
For example, inconsistent use of colours and varying screen locations for standard components.
To be successful, design from a typical user’s point of view, relate the interface and screen designs to what is done in the real world, evaluate and revise early, thoroughly, and throughout the process, be consistent in the overall screen design, use of colour, buttons ... Do not force students to search for repeated components. You should design with the philosophy: “If you have to explain how to use it, you have done something wrong.”

**MENU SCREENS**

To capture a learner’s attention, have something “lively” happen on the main menu or first screen that is viewed. This could simply be animated text. A muted image is often attractive for the menu’s background. Each menu should have a meaningful title that is easy to read over the background (e.g., with black shadows). Buttons or hot areas should be highlighted when a mouse is over it or a mouse button is pressed down. This is particularly important if buttons or hot areas are not obvious. Buttons should be centered or at least appear like their locations are deliberate. Buttons or hot areas should have meaningful labels that cannot be misinterpreted. The labels should also indicate sequencing if it is important. Menu buttons should have a check mark on them after the learner returns to the menu. These only indicate that the section was entered rather than stating that the section was completed or mastered (for logistical reasons and to not make incorrect conclusions). Menu metaphors (e.g., outdoor table and chairs for a chat location or bookshelf for a reference section) should have labels to ensure the correct interpretation. Most menus should have a prompt indicating what the student should do. The prompt should often state the correct sequence for selecting the menu items. Present the main menu selections in the sequence that they should be chosen and clearly label the buttons.

**ORIENTATION INFORMATION**

Orientation information should be at the top left of the screen so that it is the first thing a learner reads. It should have a section or module title (usually the same as the menu button), page title, and the page number out of a total page count. Stating the time required to complete a section can cause problems if the learner finishes too quickly (perception of simplicity) or too slowly (feeling of inadequacy).

**IMAGE LOCATION**

Images should be located to the left of the text because people tend to view images before reading. This allows for natural eye flow across the screen. This leads to elegant screen designs. Images should not be place in the middle of text (i.e., should not be sandwiched by text because this causes the text’s flow to be disjointed).

**ANIMATIONS**

An animation should only begin when a learner is ready to view it (e.g., by clicking an “animate” button). This ensures the learner will not miss the animation and will focus their attention on it. The “animate” button and text prompt should disappear when the animation is playing since the button is inactive. They should reappear after the animation ends to allow the animation to be played again. Do not assume that viewing the animation once is enough. What if the learner was looking the other way or was interrupted? Do not have the animation repeat endlessly after a learner clicks a button to see it. It is distracting when the learner tries to read the text.

**TEXT**

The text on each screen should have a header. Text should be in a bright colour (e.g., cyan) on a consistently-coloured dark background. The foreground and background colours should have high contrast. Bright backgrounds can cause eyestrain over time. Prompts, when needed, should be placed underneath the content’s text or at the bottom right of the screen. The bottom right can be a consistent place for instructions. This is where one’s eyes finish after reading a screen. Prompts should be in a different colour than the content’s text.
HIGHLIGHTING

Some screens need highlighting to allow pertinent information to be quickly found. Highlighting text with a bright colour (such as yellow – depending on other factors such as the background colour) is better than underlining or bold. Remember that red can be effective but some people have a colour deficiency towards red (and green). Use one highlighting method sparingly. Too many colours or highlighting methods can be distracting. Too much highlighting hides what is important.

CONTROL OPTIONS/BUTTONS

Each screen should at least have the control options of “Exit”, “Main Menu”, “Page Select”, “Previous Page”, “Previous Menu”, “Hints”, “Help”, “Glossary”, “Calculator” ...

Note that “Exit” is more positive than “Quit”. Each button should have a text label that is meaningful. For example, “Return” works but “Main menu” provides more information and gets the learner used to the name of the screen. Text labels are much better than icons since icons can easily be misinterpreted. Framing/seperator bars help separate orientation information and control options from the rest of the screen. A de-highlighted previous page button can be used on the first page of a section. This is better than leaving an empty area for the button or having a “normal” button not working. Similarly, a de-highlighted next page button (with a text prompt) can be used on the last page of a section.

QUESTIONS

Orient the learners and make questions obvious by putting in a header such as “Review Question #1”. Prompts for questions should be placed underneath the question’s text. It should be in a different colour than the text of the question. This clearly separates it and makes it easy to find. These prompts should be removed once the learner makes their choice since the prompt is no longer valid. As is appropriate, each distracter (answer choice) should be grammatically valid, be a reasonable choice, and finish the sentence. Feedback should not be in red if the student answers the question incorrectly since some viewers have a colour deficiency towards red. Consider providing detailed text feedback and even highlighted images for feedback. Only have students try again if there is educational value in the task. For example, it is pointless trying a true/false question again.

TIME DELAYS

Instantly display information. Students can get frustrated if they read faster or slower than the display speed. If there is an educational reason for not instantly showing all of the text, let the learner control when the screen should build. For example, allow this with a “More details” button.

NARRATION

Narration is great for ESL learners. Always give the learner control of whether the narration is heard. Also, have a separate audio toggle button for each paragraph to allow for quick review. Do not automatically start each page with narration. As with displaying text with time delays, narration can also frustrate many learners since the narrator is usually slower or faster than the learner’s reading speed. Remember to create the narration near the end of a project when all of the text edits are done. This ensures that the narration matches the text.

Abstract: This paper describes a collaborative drawing software developed within the "cartable-électronique"® project, in collaboration with teachers and children. It is a groupware which is intended to be used mostly in classroom settings, by children aged 5-6 years. It provides children with the means of working together to produce graphical realisations. It also includes functions allowing the teachers to regulate the drawing activity. Regulation here resides in the possibility of defining pedagogical scenarios and submitting the collaborative activity to them, thus giving the teacher the possibility of constructing various pedagogical situations. Collaborative drawing appears to be an interesting means for children to learn socialisation and develop oral expression, which are two important skills to acquire in primary education. Regulation functions are grounded on a general theoretical model (the participation model) which proposes to take into account the social aspects of collaborative work.

Introduction

Most of the time, when speaking of new technologies to be integrated in classrooms, people think of computers: just buy them, the most sophisticated possible, and use them! There is no time taken to think about what kind of hardware or software would be useful or what could be done with this hardware or software; and, if there is, teachers are most of the time not involved in the discussion. The work we present here puts the teachers and even the children at the center of the process. We present a drawing software which was developed in partnership with teachers and pupils. We have deliberately chosen to place this software in a collaborative context. We present in what follows the way children can draw together, the way the drawing activity can be regulated by the teacher, and the "participation model", the theoretical model on which the regulation functionality is grounded. We then show the challenges of such a collaborative situation. Before that, we present the overall framework within which this application has been developed: the "cartable électronique"® (electronic satchel) project.

The "cartable électronique"® Project.

In an attempt to address the issues of teaching and learning with technologies, Syscom has established the "cartable électronique"® project. It was inspired by the main object children carry every day when they go to school: the "cartable" (satchel), which contains books and pens, toys and drawing tools. Technology gives us the opportunity to reduce the weight of the "cartable" without losing its content. SysCom is working on this project in collaboration with educational organizations in France (the French Ministry of Education and local authorities representing the Ministry) and the Departement of Savoie local government (Conseil Général).

The long-term goal of the project is to provide an opportunity to develop applications and services that can be considered by teachers, children and their families when they work with the children. The "cartable électronique" has three main axes of development. The first concerns hardware: people involved in the project participate in the design of wireless computers adapted to children. The second is the creation of a support on which services and applications can be put and proposed to teachers, children and their families. An educational web portal has already been developed to play this role. The third is the services and applications one. The collaborative drawing application refers to this third dimension. We here pursue the same objectives as I3net ESE projects Nimis (Nimis website), (Hoppe et al. 2000) or Kidstory (Kidstory website): developing new technologies for educational purposes.

The Collaborative Drawing Application

The collaborative drawing software developed within the "cartable électronique" project is intended for children aged 5-6 years and for their teachers. It provides children with the means of working together to produce graphical realisations: drawings and graphics (- note that graphics has to be distinguished from drawings. It is also a drawing activity but a very constrained and directed one. It is used as a pre-writing activity, to develop fine psychomotivity. Children are told what to draw, where and how; they usually draw curves or "bridges" or "scales", like the ones drawn on the fish in (Fig. 1), because this is a way of preparing them to acquire the physical abilities for
writing -). It is intended to be used mostly in classroom settings. It also includes functions intended for the teachers allowing them to regulate the drawing activity. Regulation here resides in the possibility of defining pedagogical scenarios and submitting the collaborative activity to them. These functions, as well as the graphical tools proposed to children, have been designed in collaboration with teachers and children themselves. We describe them in what follows.

We should first mention that we have chosen to install the application not on classical hardware (like personal computers) but on pen tablets. These tablets have an interactive pressure-sensitive touchscreen replacing the traditional chalkboard. Children can draw on the tablet with a sensitive pen as if they were drawing with a real pen on a sheet of paper. Tablets are so much more usable by young pupils. Furthermore, they present the advantage of being easily carried, which is an important feature to consider, as we want children to be able to use the application in classroom settings but also at home.

The application has been developed with the JAVA language and can thus be installed on various operating systems (we have already tried successfully to make it run on heterogeneous OS machines including Linux, windows NT and windows 95). We used the SWING package for the design of the interface and the RMI mechanism for communication between the tablets.

The Graphical Tools for the Children

The drawing application is designed around a series of graphical tools that children pick up and apply using the sensitive pen. The tools are:

- crayons of different thickness,
- a palette to choose the colour of the crayon,
- an eraser to do fine erasure,
- a rag to do rough erasure,
- an album to arrange the drawings done,
- scissors to cut out parts of the drawing (a part can then be put in the album or moved around the drawing in order to be pasted on it),
- an "undo" function which makes the drawing go back one step.

These tools can be accessed via the graphical interface shown in (Fig. 1). Particular care has been taken in choosing the icons that represent the tools.

![Figure 1: The interface of the collaborative drawing application](image)
Drawing Together

Children can choose to work together or on their own. When working together, each child belongs to one group. In a given group, each child has his/her own tablet and his/her tools. The children share the same drawing space but not the tools. When one child modifies something on the current drawing (by drawing, or erasing, or pasting, or cutting, ...) on his/her pen tablet, the others immediately see what has been changed. It is a WYSIWIS approach, with strict synchronisation of the different children’s views onto a shared workspace. Note that, as tools are not shared, the views onto the tools are not synchronised. Thus there is no problem of concurrent access to one tool. One child is either working alone, or as a member of a group. As soon as he/she becomes a member of a group, the drawing of the group appears on his/her tablet: he/she becomes immediately involved in the collaborative drawing process and can contribute to it.

The Teacher, Regulator of the Collaborative Activity

The teacher can use the graphical tools as if he/she were a child. He/She can be a participant in the drawing process of a group as the children are. But he/she is the teacher: it is his/her social status. So he/she has the specific role of being in charge of the management of the groups and, in a more general way, of all the mechanisms which regulate the group activity. He/she thus has at his/her disposal, through specific interfaces (Fig. 2), functions allowing him/her:

- to create groups ("add group" button in (Fig. 2)),
- to define and describe the participants ("add child" button in (Fig. 2)),
- to define roles or hierarchical positions ("add role" and "add hierarchical position" buttons),
- to put one participant in one group or remove him from one group,
- to attribute tools and/or roles and/or hierarchical positions to one participant,
- to select, from predefined scenarios, the ones which will be put into practice in one group.

The last three functions use "drag and drop" facilities to be activated. For example, in (Fig. 2), the teacher has created the "rabbits" and "graphists" group. He/she is currently working on the "rabbits" one, which is represented physically by a square in (Fig. 2). Defining who is a member of that group is just a matter of selecting the photo representing the pupil, dragging it onto the "rabbit" square and dropping it into the square. This has been done in (Fig. 2) with "Luc", "Paul" and "Marcel". It is the same with the roles, hierarchical positions and the tools; they are dragged onto the pupil to whom the teacher wants to attribute them. Idem with the scenarios which can be selected from a list a predefined ones and dragged into one group to become active (this is done via an interface which looks like the one presented in (Fig. 2), except that scenarios take the place of roles, tools and hierarchical positions).
The roles can be created before dealing with group creation or during this process. Actually, defining a role consists in defining a set of tools which will be attributed to the participant playing this role in the group. So one role can be created dynamically because the teacher has attributed tools to one child and then has defined a role that the child wants to play (he/she may ask him the name of this role, thus contributing to enhancing the imagination and creativity of the child). For example, in (Fig. 2), the "artist", "wizard", "drawer" and "onlooker" roles have been defined. A drawer can use all the tools available in the drawing application, whereas an onlooker is just a spectator: he can't draw. Luc and Paul are "drawers"; Marcel is an "onlooker".

All these functions can be activated dynamically, even when children are involved in drawing. It is thus a good way of giving the teacher the means to influence the way the activity will proceed. It is a way of achieving flexibility in groupware. Note that the teacher plays several roles at different times: he can be a "contributor" to the drawing in a group, the "regulator" at the same time or at a different one, the "supervisor" (he/she monitors what happens in the group at a given time), etc.

The Administrator, Creator of Scenarios.

We have mentioned before that the teacher can choose scenarios to become active in a group from a set of predefined ones. Actually, scenarios are a way of describing the rules and laws, etc. which have to be respected in the group. These scenarios are therefore to be defined. This is a particular function which, at the present time, cannot be handled by the teacher, as it supposes being finely aware of the theoretical model underlying the regulation process (see section below). So it is handled by a person whose role is "administrator" (currently the designers of the software). We have developed a separate interface allowing the administrator to define scenarios (Fig. 3).

![Creating & Modifying Scenarios](image)

Figure 3: the administrator interface for defining scenarios

A scenario is a sequence of contributions (e.g.: "choose-tool", "attribute-tool") and sub-scenarios. It can have a condition for success and a condition for satisfaction. Roles are linked to contributions by means of semantic cases which determine the involvement of the participant having that role in the scenario (does he make the contribution? is it made to his/her benefit?, ...). The "drawing" scenario presented in (Fig. 3) says that "only actors (participants) having the role of drawer can draw". Moreover, as scenarios have to modify what is occurring whilst using the graphical tools during the collaborative drawing process, one more function has been provided to the administrator: it is the means of linking the contributions occurring in one scenario to the corresponding events coming from the drawing application and to the corresponding method invocation.

The Theoretical Model Underlying the Regulation Functions.

The interfaces offered to the teacher to regulate the collaborative drawing activity and to the administrator to define scenarios are just customized views of a general model of regulation that we call "the participation model"
(Ferraris & Martel 2000). This model is a proposition to take into account the social aspects of collaborative work, which most of the time are rarely supported in groupware. It proposes to consider the persons involved in a joint activity as active participants who can organise their activities, define the conditions under which they will be exercised and negotiate their commitment to these activities. It can enable compromise between the interests of the group and those of the individuals, between the dependencies that stem from relationships among individuals and their autonomy.

The objective of the participation model is to organise the shared space, the rules and agreements, the users and their actions or interactions. It is a conceptual model that describes, formalises and builds the context of the joint activity, the relationships of dependence and the structure of exchanges within the group. It proposes to describe the arenas (locations) where the activity will take place, the interactive scenarios guiding the interactions and the actions of the participants, and the participants themselves. They shall be represented in the arenas by means of computer entities which we call actors.

The arena is the common area where the activity takes place. It contains the actors, the operators and the functions which the actors will use, and the artefacts activated by the operators and functions (the artefacts are the objects that the participants can manipulate in the arena). In the example above (Fig. 2), it corresponds to the definition of groups. Two of them have been created: the "rabbits" one and the "graphists" one. The operators and functions are the graphical and regulation tools; the artefacts are the pieces of drawing which compose an entire drawing.

The interactive scenarios describe the social protocols in effect in the group. They were inspired from the dialogue models of the University of Geneva (Roulet et al. 1985) that attempt to explain the succession and the intertwining of conversational exchanges. In the same manner, the scenarios will describe the possible exchanges between participants and define the possible sequence of these exchanges. This does not entail a rigid and deterministic description of the interactions between participants (which does not seem possible to us for most joint activities) but rather the furnishing of guides to help the participants govern their exchanges, such as is proposed by (Bider et al. 2000) for workflow. From a social point of view, the interactive scenario constitutes a means of subordinating the activity to the context (educational, commercial, technical, etc) in which it occurs and explains the typical sequences for each of these contexts.

The actors are computer entities that allow one or more users to fit into a network of exchanges. Their main function is to represent the participants and identify them. They are also supposed to facilitate communication between participants and to assist them in task execution. They are characterised by their roles (thematic or casual), their places (hierarchical positions) and their positions. An actor plays a specific role during an interaction according to his/her contributions (Martel 1998). In the example of (Fig. 2), there are 3 actors in the "rabbits" arena. These actors are named Marcel, Luc, and Paul. They represent 3 children who want to draw together (in the same group). Luc and Paul have the "drawer" thematic role; Marcel the "onlooker" one.

Pedagogical Challenges

In such a context, collaborative drawing appears to be an interesting technology for children to learn socialisation and develop oral expression, which are two important skills to acquire in primary education. As is done in (Benford et al. 2000) or (Hoppe et al. 2000), the drawing software we have developed provides opportunities for children to discover the benefits of working together. They can choose with whom they want to draw and how to proceed: socialisation is thus encouraged by this means. Oral expression is encouraged by the fact that children, having to achieve a collective task, have the possibility of discussing and negotiating the way they are going to work (what are they going to draw? on which part of the screen? who does what? who is the wizard? who is the "colourist"? etc.). They can also react to what is happening during the drawing process itself: for example one child can make suggestions about something new to draw; or they can discover together the need to define "rules" in their group ("hey! you don't have the right to erase what I have drawn!", which, once again, is a way of discovering life in a group.

The teacher has at his/her disposal a software on which he/she can act. It is flexible and can be manipulated as he/she wishes. So he/she can create various pedagogical situations according to what he/she wants the children to discover or learn. He/she has the means of enhancing collaboration between children. For example, in a situation where children have to make graphics (draw curves for example), he/she can put in the same group one child having difficulties in drawing the curves and one who is quite a good "curves-drawer" so that the second one will play the role of "assistant" for the first one: he will be able to help his friend, to show him how to do the right gesture, in the right direction, etc.

The teacher also has the possibility of enhancing discussion and negotiation between the members of a group. His/her role will then evolve to an animation and observer one (he/she observes what happens in the group he/she has defined). Furthermore, as the drawings are recorded and as it is possible to know who has drawn what, he/she will be able to analyse what was done by each child and then to personalise the way each of them is followed up.
Assessment and future work

The drawing collaborative application will be tested in classrooms in two schools in the neighbourhoods of Chambery during the ongoing scolar year. We expect a lot from this experiment, in particular the validation of the regulation model through the interface proposed to the teacher. Furthermore, we have seen that regulation is teacher-centered in this application. The teacher builds situations where children play with tools and talk about simultaneously. Activity needs not only to be explained to children but also to be negotiated with them, step by step. That's why we aim at moving towards a pupil-centered regulation, which will allow children to take hand on activity and to organize the framework of cooperation. This will exploit the reflexive feature of the regulation model. It will be one of our future work. The other one will be to give the regulator, be it a child or a teacher, the possibility of defining himself/herself the scenarios by providing an intuitive interface as this has been done with the management of groups and roles.

Conclusion

The future of education will lead children, teachers and families to use many electronic devices like e-books, the e-satchel, etc. Before the use of these objects becomes a habit, it is time today to construct practical experiments to evaluate their impact in educational processes. This is what we are doing through the "cartable electronique" project and the applications developed within this project.

Situating Training for Early Childhood Educators in An Authentic Multimedia Learning Environment: The Case of Chelsea

Gail Fitzgerald, Univ. of Missouri-Columbia, USA; Louis Semrau, Arkansas State Univ., USA

Materials to assist early childhood educators in working with children with behavioral problems are currently in high demand. This poster provides a demonstration of an interactive multimedia program for use with early childhood providers. The program, "Chelsea", is designed to enhance problem-solving skills of educators by involving the user in authentic, case-based instruction with opportunities to use program resources, utilize tools and procedures needed in real job situations, and respond to reflective prompts to assess decisions. The materials include software and multimedia placed on a CD, resource materials in PDF formats, and electronic performance support tools. Implementation is supported through statewide trainers and online discussion groups. Research with the interactive case-based training materials has documented the effectiveness of learning through multimedia cases for pre-service teachers. The work is presented as a model for effective implementation of technology-enhanced training in a real-world setting. See www.coe.missouri.edu/~vrcbd for further information and availability.
Abstract: This paper reports the process and results of a qualitative study conducted in a graduate course on designing hypermedia learning environments for children. Learning to produce software using Authorware Professional, graduate students from many international countries worked with elementary-aged children in an English-as-Second-Language program to produce creative stories in a hypermedia format with tri-lingual narration. Children wrote and illustrated their stories and worked with their partners to make choices on screen design, animation, and sound effects. Multiple data sources were used to examine the impact of children-as-design partners on their hypermedia programs, features important to the children, and the change in design knowledge structures of the developers. Feasibility issues are discussed for replication.

Designing Hypermedia Products for Children

Too often, software is developed by adults from adult perspectives with evaluation only by adults; input from children is not sought and the voices of children are not heard. In designing new technologies for children, industry has discovered that children have unique likes, dislikes, and needs that are often different from those of adults. As stated by Druin “We need to establish new developmental methodologies that enable us to stop, listen, and learn to collaborate with children of all ages” (Druin, 1999, p. 53). Interestingly, when children are observed using software, researchers find that children use technology in different ways from adults. “Many times they do not have a defined task and their activities are open-ended and exploratory” (Druin, 1999, p. 53). Thus, it is critical to involve children as design partners in the development of software and explore the impact of their participation on us as developers.

Popular forms of software to promote literacy and exploration in young children are interactive books. While these books are “cute” and engaging, there is no evidence that the features of the books are important to children or that children use the books as the producers intended. See for example, Grandma and Me (The Learning Company). In fact, adult testers of interactive books frequently cite problems with navigation and ‘save’ functions of such products, yet the market demonstrates continuing popularity of these products with children.

In this study, children from an English-as-Second Language (ESL) class in an elementary school were involved in writing and illustrating their own stories. Ten children from Bosnia, Turkey, Nicaragua, Mexico, and Rwanda participated. Graduate students in educational technology served as design partners to convert the stories into interactive, tri-lingual stories: English, Chinese, and the child’s native language. The child/developer teams decided on desirable features such color, graphics, animation, and sounds. Additional features included text and narration in three languages, electronic writing pad, and an author bio. Observations of the design and development steps were made to explore the design process, usage patterns, and response to interface design.
Description of the Hypermedia Design Course

The developer were enrolled in a semester-long graduate course with dual purposes of learning to program with Authorware Professional and to produce hypermedia learning environments. This course was an advanced interface design course for students majoring in educational technology in a college of education. Instruction in Authorware was interwoven with readings and discussion focusing on hypermedia design, research in hypermedia, and designing with children-as-partners. The graduate students were primarily international students from Korea, China, Taiwan, and Turkey, with a few from the United States. The teaching team included the faculty member; a doctoral student conducting Authorware training; a doctoral student in art education focusing on screen aesthetics; a technical support person for audio, video and graphics; and a student focusing on formative evaluation procedures.

Data Sources and Analysis

Tri-lingual Story Artifacts

The hypermedia stories were examined for use of hypermedia features, balance of input from the child versus adult developer, and story themes. Logs from design meetings were used to track design decisions.

Children Talk about Hypermedia Design

The children were observed sharing their final interactive stories with peers to capture their commentary on their stories and patterns of use. Following direct observation, they were interviewed regarding the features they liked in their programs, changes they would like to make, and how they felt about being authors.

Developers Talk about Hypermedia Design

The graduate-student developers wrote reflection papers regarding their design process, interactions with the children, assessment of the stories, and suggestions for improvement of the design partnership project.

Change in Knowledge Structure of Developers

The graduate-student developers completed two semantic maps during the semester, one prior to beginning design work with children and the second at the end of the semester. Semantic maps are a powerful method for assessing change in knowledge structures, as prior knowledge becomes reorganized in semantic memory. Change reflects growth in knowledge structures as graphically depicted in the semantic maps. (Jonassen, 2000).

Importance of the Work

The results of this study have important implications for designers of hypermedia programs for children, particularly in the area of literacy, creative writing, and multiculturalism. Involving children as design partners provides a bridge between software created by adults for children and software created by children for children. Published studies on hypermedia have focused on how adults and children learn using hypermedia learning systems (Ayersman, 1996) and have not investigated the question of hypermedia from the child's design perspective. Further, results have implications for training future developers of children's hypermedia and recommendations for replication.

Abstract: Although the Web is convenient for finding information, it is not necessarily reliable. While opportunities exist for students to hear about evaluation strategies there is no data to suggest whether they are using what they hear. The purpose of this study was to investigate students' assignment of credibility to a web site to determine whether or not participants believed information found on a site and what criteria they used to make their decision. Researchers utilized verbal log analysis and transaction log analysis to observe college students' evaluation processes as they searched the Web.

The World Wide Web is a convenient resource for finding information. It is available 24 hours a day, seven days a week and doesn't require leaving the office, home or school. It is little wonder that it has become popular among students who are writing research papers. Although the Web is indeed convenient, it is not necessarily the most reliable source of information. The freedom to publish information on the Web is unrestricted and there is generally no review process. People have been known to publish professional looking sites that contain incomplete information, pranks, contradictions, out-of-date information, improperly translated data, unauthorized revisions, factual errors, biased information, and scholarly misconduct (Fitzgerald, 1997; Oppenheimer, 1997). In order to find reliable information each web site needs to be examined with a critical eye.

Librarians and media specialists have recognized the problem of inconsistent quality on the Web and have developed guidelines to assist searchers in choosing credible sites. While differences exist in the criteria for evaluation that are recommended there is also much agreement. At a minimum, web sites should be evaluated based on the authority of the site author, currency, purpose, and objectivity. Opportunities exist for students to hear about evaluation strategies through classes in online searching offered on campuses and on many library web sites; however, classes are often sparsely attended and no reliable statistics exist on how many students visit library help pages. Students may not be aware of the need to evaluate information found on the Web as more reliable than that found through other strategies (Morrison, Kim and Kydd, 1998).

The purpose of this exploratory study was to observe undergraduate college students' evaluation skills as they searched the World Wide Web. This study had, as its emphasis, student assignment of credibility to a site rather than relevance of subject matter. The study was planned to determine:

- whether or not students believed information they found in a web site
- how students decided what information to believe
- the criteria students used to make this decision

A qualitative approach was selected in this study because of its sensitivity to gaining understanding of participants' perspectives and to the process of exploring patterns of behavior within a realistic context (using a topic to conduct
searches which supported students’ coursework requirements, within a campus computer lab). Primary data collection techniques included observation of students’ behaviors, recording of their verbalized thoughts, and documentation of their computer interactions.

Participants were questioned regarding their use of the Web and familiarity with their chosen topic. A ‘think aloud’ procedure was explained to students who were then asked to think-out-loud as they searched the Web, examined the returned results, chose which sites to visit, and examined each web site visited. Participants used a computer connected to the Internet, running tracking software to record their navigation through sites chosen. Participants were asked to choose a search engine and conduct a web-search relevant to one of their courses. Post questions followed the 30-minute think-aloud procedure. These questions probed participants’ reaction to sites visited during the think-aloud process and their general attitudes toward web quality.

Transcripts were made of each session using both the videotape and audiotape. Time stamps were used on the transcripts to allow matching between the transcript and the transaction log. Both researchers collaboratively conceptualized and analyzed the data (Strauss & Corbin). Open codes were identified by analyzing whole sentences and paragraphs in the first two transcripts and identifying major themes related to the research questions. Following discussion, codes were agreed upon by each researcher. New codes were established if new information was found in the remaining transcripts that was deemed relevant by the researchers. Transcripts that had already been reviewed were re-examined to determine if any data matched the new codes. Categories and subcategories representing the phenomena of students’ evaluation of web sites were thus derived from the data.

Findings

Media Equivalence

Students frequently compared the Web with other media tools, particularly journals, magazines, and textbooks. One student negatively compared a company’s web-site with its television counterpart, stating:

I know the Discovery Channel has lots of good programs and things, but I was kind of disappointed by their lack of resources on the Internet... maybe they feel that they don’t need to have that kind of resource on the Internet, because there are other places out there that do it. So I was disappointed in the site. Adam

Evidently, Adam’s judgment of this web site was based on his experience of the company representation in another media format. His disappointment resulted in part from the advertisement of a video by this site, which although likely to be very relevant to his study, was not free. A much more emphatic rejection of the web – in general, was provided by this student:

The web just seems like it’s more garbage than anything. It’d be better if it were all books... I was thinking that I don’t want to do this. [Laugh] I’d rather just get a book. Amanda

Of the seven participants involved in the study, this student, alone, expressed a preference for the use of books above web resources. Two students expressed their belief in the equivalent value of web site and textbook/magazine resources:

On people’s personal web sites... the information there is I consider it to be on the same wave-length as if they had published a book. Anyone can publish a book and facts at least in this area, which might be conflicting or have different opinions. Adam

I don’t think that this information on websites is any less credible than like a newspaper or journal. And everybody’s opinion has points. Kristen
Both students justified their belief in the equivalence of web and book resources with the suggestion that each medium offers a forum for expression of personal opinion. Additionally, two students, Daniel and Katie cited examples of the superiority of web sites compared with other media resources. The complementary use of the Web (supporting the completion of newspaper crossword puzzles) is cited below:

...a lot of times you can’t look in dictionaries or encyclopedias because the clues are kind of vague but if you just write the clue in sometimes it [the Web] brings it right up, it will tell ya.

Daniel

The same student later discussed the advantages of web sites in compensating for course content not provided in books:

...like in the textbooks for your classes or stuff, you don’t get a lot of information. You can’t really get a newspaper in that language or something like that, or about those countries. So you can just look on the Internet and read the newspapers in that language or from that country.

Daniel

Katie also expressed her preference for the use of the Web to locate information:

I have used it [the Web] for speeches, for class information that I wouldn’t have to go to the library for, that’s easier accessed by using the computer.

Katie

This preference for web site resources, above the use of textbooks, was hinged on efficiency.

Use of Domain Knowledge

The participants often used prior knowledge to evaluate the information found on a web site. Two examples were noted: information that confirmed the participant’s prior knowledge and information that “made sense” in light of the participant’s prior knowledge. For instance, in evaluating the content of a web site Adam exhibited both behaviors:

Now this doesn’t surprise me because there was such a sudden cultural shift. He’s calling it an aesthetic and individual religion it probably had no deep roots – which makes sense because they probably, I mean, the roots of this can’t have gone very far back, cause, like I said, for nine-tenths of their history, they’re a deeply pantheonic people.

Adam

Kristen and Daniel did not engage quite as extensively with the information they found but they did match the content of the web site to information they had received in class:

Democratically inclined teachers reporting style and discussion. We definitely learned about the importance of discussion in a democratic classroom. That definitely emphasizes the child-centered aspect.

Kristen

Key terms and concepts. This is worth copying down I think. We’ve touched upon a couple of these things.

Daniel

In activating their prior knowledge these participants validated their own knowledge, searching for inconsistencies, and reasoning about the new information they found. Since each participant came to the session with a research topic in mind we were not surprised to find the participants had prior knowledge in the subject they were searching.

When asked, “If you’re not familiar with the subject that is being addressed on the site, how do you know that it is most students mentioned evaluation criteria such as those found in the literature.

I think if you’re not familiar with the topic and it’s not a web page that you’re familiar with, then you really don’t have a good indication. If it’s kind of general knowledge, you can take a look at it and if it sounds plausible or the person that
they’re talking about has some kind of accreditation if they’re a professor or a doctor, then that might be more reason to place more trust in the content. *Adam*

If you’re not familiar with it, like if I wasn’t familiar with space or anything I would go to NASA. Or like for my sexual education paper, like family services …you go to the people that you know are associated with the topic. *Amanda*

If you went up to somewhere and you looked at the URL and it was somethin’ like members at AOL or somethin’ like that, then you know this is somebody making their own little web page, so you might not want to take that information at face value. But if you know if you saw that it was on, like you know, the APA’s web site you could tell that its more credible. *Daniel*

A lot of times I try to look for, em, like big web sites, you know like government…but also, like almost anyone can put a web site out like anyone can put a page out so you have to realize that not all information can be correct and you have to go through it and screen things. *Katie*

These four participants mentioned “authority” as an important criterion for evaluating sites when their domain knowledge is low. These answers were supported during the study when they used authority to accept a page. For instance, Adam mentioned at one point that a web site was “good” because there were works cited he transferred the authority from those citations to the web site.

One participant, Eric, mentioned the use of triangulation (used in library science to verify source information by locating it in more than two resources) to verify information on a web site. “I would most likely go to another page. And see if it has similar information and if I match 3 or 4 of them together then I know that it’s probably right since they all say the same thing.”

**Currency**

Currency was not mentioned independently during the observation sessions by any participant. Although several sites viewed had “dates of last update” this was not mentioned in students’ think-alouds. Some sites visited by participants were several years old. When prompted during the interview session to think about the issue of currency, five participants mentioned knowledge of the “dates of last update” and their possible use to check currency. Only one participant added the caveat “you don’t even know if they changed anything”. Two of the participants tied the importance of currency to the topic they were researching — one stating that currency was not important when looking at archeological sites and one stating that currency was important for educational sites.

One participant, Katie, stated that she thought information on the Web was more current than information that you could find in the library.

> I think sometimes you can get like more current information on the Web, than you can like in the library because, its more updated, its easier to update than it is to like, print a book and then get it in the library and things like that. *Katie*

While several participants mentioned knowledge of this particular evaluation strategy none of them exhibited it during the search process.

**Discussion**

This study provides rudimentary evidence of the use of web-evaluation skills by undergraduate college students. Results of this study suggest that evaluation is clearly linked with user domain knowledge, apriori the Web search, understanding of web currency issues, and perceptions of web quality, as compared with other media information sources. Data gathered during the student interviews support these findings, however these findings were not always corroborated by students in their practical searches. Inconsistencies between stated knowledge and practice were
frequently noted by the researchers. For example, regarding the quality of the information found on web-sites, one student suggests looking at:

Well...logos I guess and other stuff cause some of the pages just look like a personal essay that someone threw on there.  

*Amanda*

While Amanda suggests looking at web-site appearance and “like names and like when they tell you who they are” to validate the quality of information provided on a site, she visited and revisited a number of sites which were inappropriate for her search (commercial sites, advertising goods, etc.) without seeming to recognize either the site address, name or general appearance.

Findings presented under the broad category of media equivalence, provided some insight regarding students expectations of the quality of web-sites, which in turn influenced their perceived need for evaluation of these resources. It was evident that students came to the web-search experience with certain beliefs (and mis-beliefs) about the quality of information resources found on the Web, compared with those found in other media (television, print, etc.) These expectations inevitably influenced their use of evaluation strategies. For example, despite being asked to visit new sites, two students visited familiar web sites during their search and did not demonstrate any evaluation strategies:

The nice thing about encyclopedia Brittanica is that it also searches web sites out for you. This one’s on Radon and these two only got one star each. Mmmm, although this one has a biography related to Nefertiti... so I’m going to take this link.  

*Adam*

Clearly Adam placed his trust in the merit of the Encyclopedia Brittanica’s star quality rating. He did not question the reliability of these star ratings. On the contrary, he selected sites based on these recommendations.

It must be said that while students indicated (by action or verbal response) their awareness and use of certain web evaluation strategies, the researchers could find no evidence to suggest that the participants did not believe everything they saw on the Web. Rejections were made based on relevance to the chosen assignment. Confirmations were made based on evaluation criteria.

**Implications and Recommendations**

The researchers make a number of recommendations regarding the methodology used to gather data in this study. The complementary data gathering strategies (interview and think-aloud) are considered a strength of this study. Reliability of web evaluation data is further enhanced by the use of tracking software to document student interactions with web resources.

Additional questions are recommended for inclusion in the interview instrument. Such questions should seek specific information regarding whether or not students have previously taken a class in web-site evaluation, had read any information on this topic, and whether or not students had ever come across a site that contradicted what they already know to be ‘true’. Further studies might examine the role of epistemology, in predisposing students toward certain evaluation criteria. Additionally, the role of motivation and interest in determining use of evaluation strategies, is worthy of exploration.

Student knowledge of web search strategies played a large part in the study. At the conclusion of the study, when invited to ask questions or seek assistance on their search activities, each participant asked for advice on improving his/her search strategies. Two participants in this study did not have the skills to effectively search, and therefore infrequently reached the point of web site evaluation. Their decisions to select certain web sites were based on relevance and are thus beyond the purview of this study. The researchers recommend that future studies begin with a brief web search instructional sequence for participants, thus ensuring baseline skills to support web searching and providing opportunities for observation of web site evaluation skills.

Finally, given the lack of research concerning the evaluation phase of the web-search process, the researchers recommend that additional research be conducted with varied age groups.

Abstract: A multi-modal course, Feeding Young Children in Group Settings, was developed and offered for mass audiences in the Western hemisphere. The diversity of a mass audience provides special technological considerations and challenges for professors. Instructional design for the course includes live session broadcast via satellite (now captured on videotape); a comprehensive web site with handouts, bibliography, and web links; and course activities using WebCT. The web site also includes a thorough manual for local site facilitators. A key strategy for the instruction was development of 30 video vignettes of children and their teachers eating in group settings. These diverse vignettes provide multiple points of application for our varied audiences and their local facilitators.

In the United States of America over 5 million young children are in child care and government-sponsored programs for children. Most of these children eat at least one meal per day in these settings. Issues arise in such settings for staff development and training around feeding children. Feeding children in group settings is minimally addressed in local training for child care teachers and minimally in undergraduate programs. Opportunity for training is inhibited because child care teachers are place-bound and time-bound by their jobs. Economic constraints in children’s programs result in limited resources for training.

Feeding Young Children in Group Settings is a national North American distance education course produced by the University of Idaho. The intent of this course was to provide access for training about feeding children to a mass audience. The course is offered for academic credit, continuing education units, and as a non-credit professional development activity. The targeted audiences include teachers, center and family child care providers, extension educators, nutrition educators, food service workers, and others who train staff and parents or parents on issues related to feeding children. The targeted audiences also include university and community college students majoring in child development, nutrition, and education.

We selected multiple instructional media to reach the widely diverse audience. These include live sessions broadcast via satellite (now captured on videotape); a comprehensive web site (http://www.aee.uidaho.edu/feeding) with handouts, bibliography, and web links; and course activities using WebCT. Printed curriculum and support materials for the course are convertible to Adobe Acrobat format and are distributed exclusively via the web site. Our web resources page also allows us to gather websites that would be helpful to those who feed young children in group settings. Nearly 10,000 copies of the instructional materials have been downloaded by participants. We have had particular success with the portion of our web site that provides site coordinators with support handouts and materials for their participants. More than 3,000 support documents have been downloaded by site coordinators. Our 15-page satellite coordinator’s handbook was downloaded nearly 900 times. Internet-based capabilities add a dimension to the course that brings a much higher “touch” with our students than the satellite or videotape sessions alone.

WebCT courseware is used to provide the on-line course activities. Students seeking academic credit view the satellite or videotaped sessions. Following each video session, students log in at our web page to access course materials and complete assignments. These include readings, analyses of scenes of children eating, evaluation of linked web resources, and practical application of concepts from the sessions. Students submit all assignments via the web.
The video sessions for the Feeding Young Children in Group Settings course consist of four, two-hour programs. Seven to eight field-produced, real-life video segments were developed to enhance instruction for each class session. Approximately 100 hours of videotape were shot at child care centers and Head Start programs across the western United States. The high-quality video segments are important instructional components for the course. Approximately 200 digital still photographs were shot and used to make high quality graphics for the course. Attention to diversity was important to the project team in developing visuals for the varied audiences served by the course.

The Feeding Young Children in Group Settings web site has been an asset for marketing the course, gathering information about participants, and providing instructional materials for the participants. All participant information is compiled in an Access database. The database is published to an internal web site providing all of the team members and departmental staff with immediate access to the information. This information enables the team to help prospective students locate participating sites in their region.

An obvious and essential part of developing a multi-modal course for mass circulation is teamwork. Our team included a multi-media designer, two video specialists, a data base programmer, an instructional designer, and teaching faculty. The determination of content and the production of the materials called for many decision points and much cooperation.

The team developed an understanding of the mass audiences' wide variety of technological skills and access to technology. The concept of the "digital divide" is constantly evoked by the questions and responses we receive as we market and carry out the course. We frequently receive calls and e-mails from first time users of on-line course materials. An invigorating part of the process of working with first time users is seeing the success our participants have as we talk them through learning to use the technology.

Our goal for the Feeding Young Children in Group Settings course is the same as it was when the course was initiated. That goal is to provide widely available, sustainable, cost effective instruction to a widely diverse audience of people who work with children in group settings. The mass audience certainly can be reached using multi-modal technology, and the course can be up-to-date and sustainable with awareness of the ever-changing technology available to instructors and those who support them.

New Possibility in Medical Education

Erzsebet Forczek, SZTE, Hungary

Over the last years, a lot of attention has been paid to studying the possibilities of using Multimedia on the Internet as a vehicle for open learning. The WWW system proposes a new way for merging and sharing information in workgroups for educational purposes. As the World Wide Web may ultimately become the delivery mechanism for the majority of education and training worldwide, more emphasis is needed to ground further development in strong theoretical principles related to learning. Our goal was to explore how to integrate it into the medical curriculum in order to lay the foundation of future professional development.

This paper reviews the education in medical informatics at the University of Szeged. All the topics are illustrated with practical examples. The description includes a brief outline of the curriculum, together with the hardware system configuration, software tools, some applications, samples and a description of methodology.
INTERCULTURAL FOREIGN LANGUAGE STUDIES IN THE RUSSIAN ON THE NET LEARNING ENVIRONMENT

Nina Forsblom
Hypermedia Laboratory
Tampere University of Technology/Digital Media Institute
P.O. Box 692, Fin-33101 TAMPERE, Finland
E-mail: nina.forsblom@tal.ti

Abstract

The purpose of this article is to describe the learning environment (<URL:http://matwww. ee.tut.fi/venaja>) called Russian on the Net developed to support the www-based study of Russian and also to describe how the environment supports the intercultural study of a foreign language. The article surveys situations in foreign language learning as linguistic encounters and preparation for linguistic encounters. The article falls into two parts: In the first part I describe the concept of learner-centred learning underlying the Russian on the Net learning environment, the spaces in the environment and their properties and also analyse the findings of earlier teaching experiments. The latter part of the article introduces the principles of intercultural foreign language learning and describes how this is implemented in the Russian on the Net learning environment.

1. Introduction

The development of Russian on the Net, a learning environment for elementary Russian began on the KUOMA -pilot project (concerned with new learning materials for schools) under the more extensive ETÄKAMU -Project. The further development of the environment is being continued in a project in learning environment (<URL:http://matwww. ee.tut.fi/venaja>) at the Hypermedia Laboratory of the Digital Media Institute (DMI) of the Tampere University of Technology. The article also includes an analysis of the results of earlier teaching experiments. These findings indicate that the environment's communication tools and the tools designed to enable project work were not used in the experiments. In order to make the best possible use of hypermedia-based learning environments in learning there is a need for pedagogically validated models and concrete instructions in the planning of teaching to be accomplished with the net. The aspect of intercultural foreign language learning may offer new models of thought and methods for teaching and learning taking place over the net.

Russian on the Net is a pilot and part of the Teks-financed Open Learning Environment -Project, whose objective is the development of a technically functional and pedagogically appropriate open learning environment. The underlying notion in the development of this learning environment is the learner-centred conception of learning, in which the activity of the learner is emphasised in the acquisition and processing of information.

The objective of the Russian on the Net pilot is to develop the elementary learning environment created within the KUOMA -pilot content wise, technically and pedagogically. The results of earlier teaching experiments (Hämäläinen & Muhonen 1999) show that insufficient attention was paid to pedagogical considerations, and presumably for this very reason, the properties available in the environment were not fully exploited. In the further development of the Russian on the Net learning environment the objective is to take account of the most recent trends in foreign language teaching, one of the most significant of these being intercultural language teaching. If the aim of foreign language teaching is intercultural learning, then the learning environment ought to support interaction with people from different cultures. On the net interaction, encounter can occur, for example in the form of interaction between learners and teachers and as communication between experts.

In intercultural foreign language learning the emphasis is on communicativity and co-operation that transcends the borders of one's own country. This article aims to illustrate and present ideas and alternative pedagogical hints in order to realise intercultural foreign language learning in concrete learning situations. The teaching experiments due to begin in January 2001 at polytechnics and upper secondary schools operating both in daytime and in the evenings are intended to ascertain how the perspective on intercultural foreign language learning evinced in the article and the pedagogical hints developed thereon are implemented in the various spaces of the hypermedia-based Russian on the Net learning environment. It is hoped that the perspective of intercultural learning will increase the options for utilizing the environment in the study of Russian.

2. The conception of learning underlying the Russian on the Net learning environment

The development of the Russian on the Net learning environment rests on the learner-centred conception of learning. The environment is based on seven learner-centred characteristics of meaningful learning as presented by Jonassen (1995) - constructivity, activity, co-operativity, intentionality, contextuality, transferability and reflexivity. Ruokamo & Pohjolainen (1999) have further refined Jonassen's seven characteristics of meaningful learning to be appropriate for the development of open, network-based learning environments and all the pilots within the A&O Project seek to implement the characteristics of learner-centred learning.

The ideal objective of foreign language study should be the holistic understanding of that foreign language and culture. Nowadays the curriculum is frequently perceived as contents and processes to be assimilated and which is planned by teachers and students together (Kohonen 1998:29). Greater opportunity for the learner to influence his/her own learning increases commitment and motivation to study.

According to the learner-centred conception of learning the learner participates actively in the learning process, plans, acquires and processes materials, makes a critical assessment of the outcome and develops this on the basis of the assessment. All these actions develop study skills; not only the product is considered important, the process of developing holistically as a functioning, thinking human being is also an objective. According to the learner-centred conception of learning the teacher's role is to support and direct the learning process (Lonka & Lonka 1993). The change in the role of the teacher for dispenser of information to supervisor and supporter of learning must be gradual, as research shows (e.g. Opettaja 2000) that the pedagogical counselling and support currently available are inadequate.
3. A description of the Russian on the Net learning environment

WWW-based Russian on the Net learning environment is based to support Russian language learning. It contains elementary learning material for Russian and tools that enable communications between learners, teachers and other experts. There are also tools for producing material and accomplishing projects. The Russian on the Net Learning Environment was developed for pupils at secondary and upper secondary school, but it can be used also in adult learning.

A steering group comprising teachers of Russian and experts in Russian language participated in the development work on the environment. The aim of the development work was to support the learner's own learning process. The learner can progress independently in the material at his/her own pace, or then as directed by the teacher, when the whole class progresses according to the teacher's instructions. The environment includes various communication tools enabling the learner to obtain support and feedback from other learners, teachers and experts. The environment also includes tools for project work either independently or co-operatively. (Hämäläinen & Muhonen 1999)

The metaphor for the Russian on the Net learning environment is that of a building containing six spaces in which there is a learning centre. The spaces in the building are Training Space, Studio, Staff Room, Backstage, Links and Gallery. All Internet users have access to the building, and are called visitors, and are admitted to the Training Space, Links and Gallery. A password is needed to access the Studio, Staff Room and Backstage, and the passwords are different for teachers and learners. Teachers and other experts have freedom of access to all the spaces in the environment. With the exception of the Staff Room the learners have access to all the spaces in the environment.

The Training Space contains elementary learning material. This material is divided into various themes and includes audio and video materials, tasks which can be checked by the computer and material based on links and ready made tasks and more extensive subjects for project work accompanied by directions. A vocabulary has been compiled from the utterances on the videos and it is possible to practise the most important utterances on the videos by repeating the sentences in the bubbles. An effort has been made to present grammar material constructively so that the learner can form a picture of the grammatical point to be studied and derive rules in order to learn something. For grammar the links are constructed so that familiar matters already assimilated serve as the basis for new things to be learned. For example, while studying the accusative forms of the personal pronouns it is possible to revert to the nominative forms in order to see from what forms the accusatives have been derived.

The Studio contains tools for teachers, learners and experts to maintain contact and the tools needed to accomplish various types of projects. The real-time Chat tool enables teachers and learners to communicate. The News-type discussion tool enables teachers, learners and experts to maintain contact and also the exchange of feedback and instructions. The interactive cartoon strip is a real-time discussion tool enabling learners to discuss and simultaneously create a cartoon strip of their selected characters. The projects which learners exhibit in the Gallery are done with the www-editor. The instructions for using the www-editor are to be found in the 'help' elements of the environment. Projects can be accomplished either alone or with others.

The Staff Room contains the same communication tools as the Studio, but serves as a meeting place for teachers and experts to which learners are not admitted. The Staff Room enables discussions on Russian language and culture and on matters pertaining to learning Russian. Using the www-editor teachers can make their own materials and locate it in the Backstage. The Staff Room has an archive (BSCW space) for storing completed projects in various programs (Word, PowerPoint, Excel) for the use of teachers and other experts. It is possible to delete material from the archive and to edit the messages of discussion groups. In the section for returned assignments the teacher can look at assignments completed and returned by learners. On returning their assignments learners select their teacher's name from the list, thus the teacher can find his/her own students' work under his/her name.

The Backstage is a space in which teachers, experts and learners can see the material created in the Staff Room. Preparatory material for tests can be located there, while the tests can be located in the Staff Room, to which learners do not have access.

The Gallery is a space for locating work accomplished by individual learners of groups. The teacher's or learner's assessment of the learning process and the final result of the work can be appended. All the completed work can be located in the Gallery and a vote taken as to the best project.

The Links space contains useful and up-to-date information on matters pertaining to Russian language and culture. The space is divided according to subjects, making it easier for learners to find relevant information, for example, for projects and portfolios. Learners, teachers and experts can moreover use Links to search for the information they need. An effort is made to update the links regularly and new links are added as the environment is further developed.

4. Implementation of previous teaching experiments and analysis of principle findings

Teaching experiments using the Russian on the Net learning environment have been carried out at the Teacher Training School of the University of Tampere and Yliäjärvi Upper Secondary School. The target group was teachers and students of Russian at these schools. During the experiment an average of two out of the five weekly hours of Russian was used for studying in the environment. Initial and final questionnaires were used to gather data from students and teachers and observations were made of the students' and teachers' work. In the questionnaires respondents were asked to describe their expectations of using the Russian on the Net learning environment and their conception of their roles as users and their experiences of the characteristics of the Russian on the Net environment.

The students' motivation for the computer-aided study of Russian was fair at the beginning of the experiment and remained fair after the experiment. The students expected the environment to provide variation, interest and versatility in the learning of Russian. The students' conception of studying Russian was grammar-based as they hoped that the tasks in the environment would include practice in grammar and sentence structure.

The students' expectations regarding the use of the Russian on the Net environment for language study were fulfilled. They felt that using the environment was useful and considered the teaching to be more meaningful and varied than conventional learning in the classroom. The students reported that the environment provided material at a suitable level, scope to progress individually and support and supervision in relation to prior studies.
The characteristics most highly rated by the students were the audio and video materials and the interesting and developing tasks. The students desired a list of contents to facilitate navigation in the environment, more exercises, games, crosswords and culture.

During the teaching experiment there was no time to try the link elements, the real-time chat tool in the Studio, the News-type discussion tool or the www editor. One might assume that it is the use of these tools and links which best facilitates encounter with the culture of the target country and native speakers of the target language.

The students felt that they needed more cultural information. Using the discussion tools teachers and students could exchange ideas and opinions, for example, with Russian students, teachers and experts. Expertise could be enhanced through the News-type discussion tool. The theme selected for discussion might be some specific subject to be commented on by students, teachers and experts from different cultures. This would yield topical information on matters of language and culture. Information in the net can be updated: for example, it is possible to disseminate information on new terms and usage over the net. The advantage of the net over textbooks is the option to update information quickly.

The results of the experiment permit the conclusion that the students did not benefit at all from the opportunity to use the options provided by the environment for project work. For example, the environment enables project work using the www editor for which information may be sought through Links. Such project work demands creative problem-solving skills such as objective setting, information seeking and analytical skills and a critical faculty in finding relevant material. The information available on the net is up-to-date and therefore interesting, but finding appropriate information from the vast amount is a challenge. More attention should be paid to information seeking skills.

When the teaching experiment began, the teachers assessed their motivation to teach Russian using hypermedia to be fair and this level was sustained after the experiment. The teachers expected that the experiment would provide them with variation and stimulation in the teaching of Russian, and that they would discover working methods to interest the students and learn something new. The teachers' expectations of the use of the Russian on the Net learning environment in teaching Russian were exceeded. They considered the best characteristics of the environment to be the option to progress individually, the various ways of working together with other students and the way in which the environment motivated different kinds of learners.

However, it was those characteristics enabling the use of co-operative methods and interaction between teacher and students and the tools for project work (including the www editor) which were least used in the teaching experiment. The teachers estimated that they needed technical support during the experiment, but did not feel that they needed pedagogical support. When the experiment the teachers' assessments were similar. One might assume that the teachers' estimation that there was little need for pedagogical support was due to their inadequate knowledge of the possibilities of net pedagogy. There has not yet been sufficient research on the use of net-based learning environments in foreign language teaching and especially of the possibilities of net pedagogy in language teaching.

5. Intercultural foreign language learning

Internationalisation and the increase in contact between cultures lends justification to the goal of intercultural learning in foreign language teaching. Modern ICTs make intercultural contacts easy and fast, and actually possible in real time. The development of the information society poses challenges to teaching and learning to which those developing modern hypermedia-based learning environments endeavour to respond.

The term intercultural, according to Kaikkonen (2000:50) refers to the dynamic process emanating from encounter and preparation for encounter. The point of departure in intercultural foreign language learning is to learn to cope optimally in varying situations in which cultures meet, in which both language and other culture-related behaviour such as tolerance, mutual understanding, interpretation and adequacy or target-oriented action are important. The objective in foreign language learning is to achieve competence in intercultural activity.

Lustig & Koster (1993; see also Kaikkonen 1996; 1997 and 1998) propose eight area of competence which promote intercultural ability. The following characteristics in the learner promote the development of competence in intercultural activity:

1. The ability to respect people who are culturally different and to be considerate and positive towards the other party.
2. The ability to react to the other party’s behaviour without emotions or condemnation.
3. The ability to comprehend concepts and the messages they convey in expressing thought.
4. The capacity for empathy and understanding of the other party’s conceptual world.
5. The ability to recognize the rules of cognitive role behaviour in shared problem-solving situations.
6. The ability to understand the role of social behaviour.
7. The ability for correct, interactive communication.
8. The ability to tolerate ambivalence.

A foreign language becomes real in intercultural situations, authentic encounter of languages and cultures. This encounter may be indirect through authentic textual material or then real-time communication in the classroom situation between teacher and students or increase of expertise over the net and by means of authentic texts.

According to Kaikkonen the encounter of cultures occurs most commonly through authentic textual material. Whether the students feel that the texts are authentic depends on how they are handled and how meaningfully. Contextuality is closely connected to authenticity. Different text

---

1) A page map has been included in the environment presenting the content of the environment by theme. This facilitates navigation for an ideal progress in the environment.

2) A culture component has been developed containing current information, for example, on Russian public holidays and the accompanying traditions and information on Russian people and their habitual modes of operation. Games, for example, memory and guessing games are planned to build vocabulary and practise structures.
types are felt to be authentic in different cultures. Van Lier (1996) places great emphasis on the importance of contextuality and the experiential in determining the authenticity of text. He suspects that not all the students in the class will feel the authenticity of language study in the same way as they feel differently about different matters. The same text says different things to different readers. Earlier experiences affect the orientation to learning something new. Learning is an active process in which the learner gradually builds on previous experiences creating new meanings and assimilating new meanings enhances the comprehension of the nature of language and culture.

Frequently the goal set for foreign language study is fluent communication, but in reality, study is guided by the study of grammar, for example on the basis of the passages of text in a textbook and exercise book. Kaikkonen (2000:57) states that the authenticity of language pursued does not always appear even in texts used to support study. The authentic and current material in hypermedia-based learning environments could provide various approaches to foreign language study with respect to pedagogical solutions.

6. Intercultural foreign language learning in the Russian on the Net learning environment - challenges and opportunities

The Russian on the Net learning environment contains many types of material for the implementation of intercultural foreign language learning. Kaikkonen (2000:50) describes authenticity and its components in foreign language learning. Authentic encounter creates a meaningful experience for the learner. Encounter may occur via text, in the form of a net contact or of encounter between teacher and student in the classroom situation.

The Russian on the Net learning environment contains authentic textual material, e.g. videos, links to collections of short stories, the pages of newspapers and periodicals and current informative www-pages on Russian culture and society. The choice of videos has endeavoured to include subjects which mean something to students, such as getting to know people, hobbies, travel and visiting restaurants. The choice of subjects has taken account of the typical nature of language use. In intercultural foreign language learning the emphasis is on preparing for linguistic encounter. By practising typical situations of language use an attempt is made to achieve communicative competence in different types of situation.

The dialogical presentation can be practised through interactive cartoons. In these the subjects occurring are very close to Russian culture and traditions, like making a visit in the Russian way. The learners may appear in the cartoons under Russian names and imagine that they are Russians. It would be desirable for learners identifying with Russians to compare, for example, the Finnish and Russian ways of acting in various situations. The assumption is that the knowledge that different cultures react differently in different situations will increase tolerance for different cultural habits and create a liberal attitude. The teacher and other experts, who are well acquainted with the target culture can direct the discussion and help students in situations where expertise is needed.

The Gallery is the space for intercultural encounter, because this is where teachers and students of different cultural backgrounds can locate their work. Looking at the works in the Gallery permits conclusions about what matters are considered important in the language teaching of different countries. The exhibition of examples of projects in the Gallery provides learners with new angles and ideas for individual practical assignments and more extensive projects and offers teachers new alternative methods in foreign language teaching. The communication tools enable discussion on the work displayed in the Gallery. Public expression of opinions and comments expands learners', teachers' and experts' conceptions and tolerance for seeing things differently. Analysis of the learning process on the net serves to develop skills in information seeking, processing and evaluation.

The Russian on the Net learning environment contains tasks which can be returned direct to the teacher at the Staff Room archive so that other learners cannot see each other's work. Teachers can also store their own work in the Staff Room archive or in the Gallery. Such work is visible to all teachers and experts. If all the teachers using the environment store their best work the environment could set up a material bank which would mean added value for teachers of Russian. At present all Russian teachers with a password and user ID have access to this material. For all the teachers using the material bank to produce material for the environment it would be necessary to add a capability to the environment to enable access to the bank only if the individual has produced, for example, two tasks. This carries implications for copyright.

Through net contacts it is possible to communicate with people from different cultural backgrounds. It is not necessary to have real contact in order to develop intercultural understanding. The Russian on the Net environment does not require any registration. Registration produces mixed feelings among learners, teachers and experts. On the one hand giving one's own personal information and getting to know other people's personal information would increase the feeling of belonging and commitment and provide an opportunity to meet users from different cultures, but on the other hand certain opinions and comments are easier to send anonymously. Anonymous comments can obtain no direct reply to the sender, thus, for example, timely supervision of a given learner is impossible.

Using the News-type discussion tool enables the enhancement of expertise. The theme selected for discussion may be one specific subject for comment by learners, teachers and experts from different cultures. This produces current information on matters pertaining to culture and language. Information on the net can be updated. For example, the net can be used to disseminate information on new words and usage in various situations. The advantage of the net compared to a textbook is the option to update information rapidly.

Although the teacher and learner come face to face in the classroom, an authentic, timely encounter may be problematic as there are numerous factors with bearing on teacher-student communication in the classroom. The learner may, for example, fear the reactions of others, and not attempt to solve the problem emerging in the learning situation. In my experience, Finnish students communicate less with other learners and the teacher than do students from many other countries. An expansion of intercultural communication through the discussion tools could lead to a change in Finnish students' attitudes and to a change in modes of action in the learning situation.¹ Both authentic encounter in the class and encounter on the net should be natural.

7. Discussion and conclusions

¹) On the international and multi-disciplinary teaching research and development project involving the University of Oulu, the University of Jyväskylä and in the USA the University of Indiana, called NINTER, an attempt has been made to create a net-based action model for community problem solving (Saarenkunne et al. 2000). This enables interaction between experts and novices. Net-mediated case discussion could also offer opportunities for language teaching. (Kuure et al. 2000)
This article described intercultural foreign language learning in the Russian on the Net learning environment. The first part of the article presented the learner-centred conception of learning underpinning the environment, the contents of the learning environment and its main characteristics and analysed the findings of earlier teaching experiments. The findings showed that the motivation of learners and teachers to use the computer in teaching and learning Russian is fair. However, the characteristics of the environment are not exploited in the best possible manner. Those characteristics enabling co-operative working methods in project work and interaction between teachers and students were used least in the teaching experiments. The teachers' inadequate command of net pedagogy may cause the environment to be used in the conventional way of learning material without taking advantage of the new working methods enabled by hypermedia-based learning materials.

The latter part of the article presented the intercultural foreign language learning perspective and considered how intercultural learning can be implemented in the Russian on the Net learning environment. Authentic encounter is closely connected to intercultural learning. Encounter may be interaction occurring through authentic text, communication occurring indirectly through discussion tools or directly through authentic encounter in the classroom. The tools developed for the Russian on the Net learning environment enable intercultural encounter on all these levels.

The intercultural approach to foreign language learning offers new pedagogical opportunities for users of the Russian on the Net learning environment. Foreign language learning occurring in open learning environments and the opportunities of net pedagogy in foreign language learning has so far been relatively little researched. The use of technology in teaching does not necessarily enhance the level of teaching if those concerned cannot use the equipment properly. There is a need for scientifically validated knowledge on the advantages of hypermedia-based foreign language learning environments over more conventional modes of study in which the main materials are books, cassettes and other non-computer-based materials. Once the advantages of open learning environments have been identified the way will be clear for the development of pedagogical support.

Abstract: The perceived effectiveness of traditional and computer-based educational resources, within the context of a single course in first year biology, was investigated within an action-research paradigm. The study examined the dynamic state of perceptions towards these resources by the major stakeholders involved (students, teaching staff and technical staff). A major focus of the research was the extent to which the computer-based resources were utilised, and the students' perceptions of the usefulness of these resources to their learning. The majority of students found the resources to be of use for their learning but some did not use them at all, even though they had access to the Internet, suggesting that the provision of on-line resources will not necessarily generate value-added learning.

Introduction

At The University of Sydney courses are still campus-based and students attend lectures and laboratory sessions in most weeks of the semester. In first year biology the development of educational multimedia to address the diversity of student characteristics, the ethnic/cultural sensitivities to animal dissections and specific learning difficulties has led to a focus on the use of computers in the learning process. This in turn has led to the development of an on-line virtual learning environment (http://fybio.bio.usyd.edu.au/vle/L1/) enabling the students to access our resources anywhere/any time. The development of this resource is discussed in Peat, (2000). The current study examined one of the first year courses, Human Biology, which integrates a range of computer-based learning modules, on-line materials and communications strategies with more traditional learning resources such as lectures and practical sessions, designed to cater for a variety of learning styles. The purpose of this study was to provide both a reflective and analytical assessment of a broad range of learning resources integrated through web-based technology and determine their impact on student learning. A major focus of the evaluation was the extent to which the computer-based resources (educational multimedia and information technologies) made available to the students were utilised and the students' perception of their usefulness to their learning. To achieve this, an action research model was implemented with all stakeholders contributing to the collection of data to enable assessment of the learning environment from all perspectives.

Methodology

The research model adopted the Eclectic-Mixed-Methods-Pragmatic Paradigm (Phillips, et al., 2000) considered more capable of handling the complexity of modern society and technology with a focus on practical problems rather than issues, whilst acknowledging the weakness of current evaluation tools. The overall study was based on the dynamic state of the perceptions of the major stakeholders involved in the course, whilst this paper focuses on the students' perceptions of their use of educational multimedia and communications technologies within an integrated curriculum. The stakeholders included students (n=up to 800), lecturers (n=5), laboratory teaching staff (n=20), technical staff (n=3), and courseware developers (n=2). The target population of students is typically recent high school leavers enrolled in science-based degree programs. The student body has become increasingly diverse over the years, with respect to culture, academic achievements, literacy and science backgrounds as well as extra-curricular activities such as paid employment. The overall data collections
involved all stakeholders and data were collected at four separate intervals, using surveys, interviews and/or focus groups. Data from the preceding survey were used to design the subsequent instruments.

Results and Discussion

The results to be described in the conference presentation will focus on the major factors emerging from the research process and examine each of the following aspects:

- student use and perceptions of the Internet, access to on-line materials and views of communications technologies;
- student perceptions about using on-line tutorials in general; and
- student use (specifically) of virtual dissections versus real dissections.

Nearly all students in this course (99.5%) have access to a computer, with 98.5% of all students indicating access to the Internet (84% access at home), however there appears to be competition within the home for access to the Internet line (36.5% of students indicating competition from siblings or parents). Whilst general access to computers and the Internet is good, there is some concern within the student body about access to the biology resources for this course on the Internet due to technological reasons. It appears we can provide the resources but we need to be careful that we match them with student technological abilities and experiences.

The data show that 20% (200 in the cohort) of the students are not using the Internet as a resource for this course but of those that do use it 55% indicate it is useful but not extremely useful. The overall student use of email was high, with 97% of all students surveyed indicating some use (mostly non-course related), however only 10% of the entire cohort found email useful in supporting student learning in this course. Only 75% of students made use of the computer-based tutorials provided to support their learning, but the majority (91%) of those students that did use the materials found them useful. This reinforces the idea that within the student cohort there is a variety of learning styles, which require the provision of a diverse range of learning resources, both on-line and off-line. Oliver & Omari (2001) reported a similar lack of uptake of web-based teaching with 20% of students not comfortable with using the web as their learning environment. The reason for this lack of uptake needs to be investigated before putting a large proportion of teaching and learning resources on the web. From a curriculum development viewpoint it was important to gain an understanding on the relative usefulness of animal dissections and virtual dissections to student learning outcomes which would help inform the debate about the replacement of animal cadavers in student laboratories. Many of the students remarked on the usefulness of both the cadaver and the virtual dissection, indicating that the former was probably more useful for understanding structure and the latter for function, illustrating how different media can be used for different inputs/outcomes. The data, however, indicate that there is little difference between the two types of instruction.

Initial data from this study indicate that there are students who embrace educational multimedia and information and communications technologies and who will find these learning experiences valuable. However, there remains the issue that some students do not find them useful and this reinforces the need to offer a variety of materials on offer. It reminds us that we cannot use on-line as a replacement but we can use it effectively in the teaching program. It is important to remember that the student body requires a variety of learning experiences that not only include the new technologies in teaching and learning but also the more traditional resources. The outcomes reinforce the need to offer a variety of learning experiences that target different learning styles and enable a mix of off-campus and on-campus opportunities.

Abstract: this paper reports on the development of CEDOT, a tool to support academics in the collaborative and iterative planning, development, creation and delivery of courses. It provides an environment for the conceptualisation and structuring of the different elements of the teaching and learning process situated in a supportive framework. CEDOT output is in XML, and includes both documentation and web-based courseware.

Introduction

"The really truly hard part to web-based course design is in content design. A reasonably competent computer professional can provide chat facilities, threaded discussion lists, web pages, on-line registration, etc. But the core of on-line course materials will have to be determined by experts in the field working with experts in distance education delivery." (Downs)

This paper will discuss the development and extension of an existing concept mapping tool (Webmapper) into a complete on-line course design support framework for academics – CEDOT, Course Elicitation, Development and Output Tool.

The tool provides a course design framework that faculty staff work through in an order of their choosing. It gives context specific help and advice that will enable them to complete all the required elements. But as well as taking them through the course design process and creating a document that adheres to a university-defined format, at its core is a concept mapping and navigation tool to plan and structure the relationship between the various course elements, processes and resources. The course design framework outlined here applies to web based courses and to courses designed to be delivered “conventionally” through face-to face teaching or through mixed modes of delivery.

A key feature of CEDOT is that at any time during the course development process the thinking and work carried out so far can be made available via the Web to other academics associated with the course. They can comment on the course structure so far developed and their input can be incorporated into revised versions.

CEDOT will output documentation associated with the course in various formats, exploiting the potential of XML according to the needs of identified groups. This includes information for course administrators and validation/approval committees and information for the student handbook and course guides.

The tool is more than a documentation framework, it also enables the publishing of the course resources onto the Web implementing the navigational structure as developed in the concept map element of the tool. This web structure may be in outline form, i.e. a navigational structure is in place with descriptors of the course content for further development or if appropriate, a fully functioning and complete version of the course resources may be output.

A key feature of CEDOT is its use of XML so that outputs can be customised according to the needs of different groups. CEDOT will also conform to emerging standards for learning architectures e.g. the IMS specifications.

The need for such a tool

The authors have been involved in a range of projects linked to the design, development and embedding of resource based learning, and in particular Web-based learning and teaching in UK universities. It is clear from this experience and our knowledge of the literature that faculty staff require help and support in the design of appropriate learning materials especially those that take full advantage offered by Web-based learning. While other tools have been successfully deployed that provide guidance and a framework for developing Web-based
courseware, we are not aware of any tool that also provides validated XML output, prototyping and development support in one package.

In a recent symposium of recognised experts in learning technology it was noted that:

"Frequently, one assumes that university faculty have an understanding of learning theory simply because they are teachers. In reality, many are exposed to these ideas for the first time during faculty development experiences. Through working in partnership with instructional designers, faculty can become knowledgeable about learning theory and its relationship to course design."6

It is a feature of our (and many other) institutions that this level of instructional design support is not routinely available. CEDOT is designed to go some way to address this situation by providing online context based help to guide and support to guide academics one through the course design process and then publish their outputs in appropriate formats.

An example of such a support framework is the Teaching for Understanding Framework 7. The Teaching for Understanding (TFU) framework helps educators to:

- formulate generative curriculum topics,
- define specific educational goals,
- design performances to help students develop and demonstrate understanding and,
- integrate ongoing assessment of student performances to monitor and promote learning.

A similar tool for supporting the process is that provided by MERLIN8, developed at the Northern Alberta Institute of Technology, Canada. This is a web-based curriculum development tool that adheres to NAIT's guidelines for its in-house Learning Outcome Guide for module development.

In developing CEDOT we wished to produce a framework that enabled staff to work through key elements of the instructional design process in a guided and supported manner while at the same time not being constrained to work through this process in a fixed given order. It is important to support the flexibility and range of modes of development that are typically found in the course planning process so that faculty staff can work in ways in which they are comfortable. Some academics for example adopt a strong top down approach, developing the overall structure, learning outcomes and pedagogical strategy before defining course content. In other cases academics have a model of the overall structure in their head and wish to flesh out elements of the content before finalising the overall structure.

CEDOT is designed to accommodate these approaches. It provides a graphical environment in which the course design process is modelled and from which output both in terms of course documentation and linked Web-based course resources are produced.

The course design model
The course design model on which it is based is represented in the work of Scott9. Figure 1 (below) represents the underlying conceptualisation of the course design process used in CEDOT.

Guidance to staff
Whilst working through CEDOT, onscreen context sensitive advice and guidance is available. This is in the form of brief notes linked to Acrobat PDF format documents that provide more detailed explanation and commentary. These are available for viewing onscreen but users are advised to refer to a referenced printed version while working through the software for ease of use.

The key elements of advice and support that exist in CEDOT are:
- guidance on identification of key characteristics of potential students,
- analysis of the relation of the proposed new course to existing courses both in terms of pre requisites and exit outcomes,
- guidance on the development of learning outcomes,
- knowledge and task analysis to elicit course content and structure,
- advice on the identification of student support needs and the student support strategy,
- advice on the identification and specification of assessment elements, identification of teaching strategies to be employed,
- advice on the methods and approaches to course evaluation,
- support in the planning and structuring of course resources and materials

Figure 1. The course design process
**Course development in practice**

Such models of course design may in practice be far removed from the way in which faculty staff do engage in the process of course creation. In reality course development is a much more fluid, "messy" process. An individual academic may, for example, having in general terms outlined the course structure, concentrate in some detail on one particular element. In another case it may be appropriate to incorporate materials and ideas that have already been developed elsewhere. Issues relating to the assessment system or the best way of providing targeted student support may be the most important concerns at a particular time. CEDOT can capture the ebb and flow of this creative process. It accommodates the building up and sequencing of different elements in a variety of ways so the user will not feel constrained to develop a course in a way that does not suit their own particular approach.

**Collaborative roles**

We have argued elsewhere\(^\text{10}\) that courseware is best developed in a team context, whereby individuals with a range of skills (subject experts, instructional designers, programmers) work together to agreed aims and objectives in the development of a project.

The development of powerful web authoring tools, and tools for the conversion of word processed documents into HTML format can tend to encourage the collapse of these various roles into one person - the universal courseware expert. When using such tools there is a tendency not to map out the courseware first, but in the act of marking up, to try to structure it at the same time. In effect, what happens is that the producer is both attempting to structure and plan the courseware and produce it simultaneously and in the process of so doing may lose sight of the main pedagogic structures and navigational routes.

CEDOT is designed to support interaction and collaboration. At any time the concept map and the associated documentation can be published so that other course team members can comment on it and their ideas be incorporated into the course design. The prototype facility allows a version of the course to the output on the Web and used so that other members of the team can comment on its navigational structure and other features.

**The development of CEDOT**

This has involved three, interconnected strands of activity.

First, it required work with academics to understand how they develop course materials and to identify particular issues and to specify a tool that addresses these issues.

The second element is to design an effective and transparent interface and navigation system which enables course designers to easily 'toggle' between the stages of the course design process, content development and navigational structures.

The third is to explore the capabilities of XML as a way of

- orchestrating data and its characteristics appropriate to this use so that written documentation appropriate to different groups may be produced and that this documentation when aggregated across a range of course can be further interrogated in order for example to produce summative reports.
- facilitating the creation of course resources from CEDOT either at the level of a prototype mode, a delivery mode or a simple documentation mode.

**An overview of the software**

**The technology**

The current development has two strands: a programmer is creating a Java-based implementation, and one of the authors (H Freeman) is creating a version in Revolution (a variant of MetaCard\(^\text{10}\)) that can be delivered as an executable on Macintosh, Windows and Unix platforms. Revolution is a graphical application development and multimedia authoring package for Windows 95/98/NT/2000, UNIX/X11 workstations, Linux and MacOS. The database behind both implementations is FileMaker Pro v5 (unlimited) running on a Macintosh G4 server although other databases could be used.

**CEDOT in action**

The Main Menu outlines the stages of course design at a general level as developed from figure 1. Selecting these menu items opens a further window with fields for text entry relating to sub topics.
A key feature of CEDOT is that it provides a visual environment in which the process of course development occurs. Building on the original Webmapper, a concept map of a course is created consisting of nodes that can be linked together and which in the final output represent sequences or clusters of Web pages.

Double-clicking a node opens a separate window that enables content to be described or created in the context of all of the headings in the main menu. Certain fields eg those relating to learning outcomes will be populated with text (if entered) from the main learning outcome menu.

At all stages textual entries are guided by on-line guidance and textual clues. In particular, the creation of learning outcomes is supported by lists of approved verb and compound verb lists obtained from the literature.

Figure 2. A browser view of the Java version of CEDOT in concept-mapping mode.

Selecting one of the items in the Main Menu allows a top-down approach to be taken to module development, whereas the concept-map approach enables a more granular, content-focused approach. Whilst it is possible to begin the design at the top level, the map must be used at some point. However, the reverse is not necessarily true, because groups of nodes may be allocated to a learning outcome, to an assessment instrument and to a resource requirement (such as a lecture room or a laboratory).

During development all changes are held within the server-based database. At any time during development a report can be generated that compares the structure of the working document against the University's module template DTD for compliance. Once this is satisfied an XML file is created for storage centrally. Further development to this software will focus on the integration of many module descriptions into a full course curriculum description.

Outputs from CEDOT
The outputs of the system include:
- documentation that describes the course and its various components,
- documentation that logs the process of course creation and development,
- a report on the degree of compliance between the current structure and the University's definition of a module template,
- a web deliverable that consists of a fully linked site but contains only node descriptions,
- a web deliverable that consists of a fully linked site and contains all content and linked graphics, applets etc
- The automatic generation of course guides, student handbooks and similar documentation that can be distributed to students.
- Version control throughout the development process and for the creation of new instances of the course design for future use.
These outputs are in XML or ASCII text, and we assume the development of both university wide systems that employ XML for data interchange and the existence of XML web browsers. The power of XML to enable the interchange, re-ordering and re-configuration of data will be of particular significance as substantial numbers of curriculum descriptions are generated.

CEDOT is addressing real academic needs in a way that will help faculty to design courses in a more collaborative, transparent and supported environment.

Evaluating the impact of multimedia learning environments: visit to a virtual primary school

Fiona French, Univ. of North London, UK; Ian Cumpson, Univ. of Greenwich, UK; Ruth Wood, Kingston Univ., UK

As recent advances in technology enable combinations of media to be delivered rapidly via networks, so more colleges are including online multimedia applications as part of their repertoire of learning resources. Some of these applications have an in-built feedback mechanism for the users, while others may demand a more interpretive approach. One focus of this session is on considering suitable methods for evaluating media-rich applications.

The session will showcase the recently developed prototype of a multimedia application used in teacher training, giving participants the opportunity to engage with the software and discuss the design issues. The application is a virtual primary school, intended as an interactive, immersive, learning environment for trainee ICT coordinators in the final year of an Initial Teacher training course. The prototype includes video interviews with members of staff, virtual classrooms to explore and relevant paper documentation.

This is an ongoing project that we hope will extend beyond the classroom, providing a computer-mediated support facility for professional ICT coordinators. Our initial evaluation is being carried out in April 2001. Results will be presented at this session, which we anticipate to be of interest to teachers, staff developers, researchers and multimedia designers.
Quality in Web-Supported Learning

Jill Fresen
Department of Telematic Learning and Education Innovation
University of Pretoria
Pretoria, 0002 South Africa
jfresen@postino.up.ac.za

Abstract: Are we meeting the needs of our learners? Are we fulfilling our vision of excellence in learning? How do we marry the theory of Quality Assurance with the service we offer, with particular reference to the Web-supported courses we design, develop and deliver? The Department of Telematic Learning and Education Innovation was established at the University of Pretoria in 1997. The Department is confident in the knowledge that it has the support of top management and from small beginnings is now becoming a showpiece of the University. Concomitant with such responsibility and visibility is the necessity to produce results, not just in the quantity of telematic courses developed and managed, but also in the quality thereof.

Introduction

Our Department embarked on a research project to explore and document the concept of Quality in telematic learning, with particular reference to web-supported learning. Without a Quality Plan in place, we found that different perceptions and expectations on the part of academic staff and students led to differing levels of satisfaction with our telematic learning offerings. Our approach is to begin with the immediate and real needs experienced within the University, but also to work towards accreditation with national and international standards bodies.

Evaluation of Courseware

Those of us who have been involved in the field of Instructional Systems Design (ISD) know that one of the vital steps in any Instructional Design model is Evaluation. Whether one follows a traditional linear Instructional Design model, or perhaps an R2D2 spiral model (Willis & Wright 2000), no one disputes the fact that an essential step somewhere along the line (or around the spiral) is Evaluation - formative evaluation, summative evaluation, ongoing review and maintenance of our courseware offerings. But what do we do with these findings? Do we plough them back into continuous improvement? Do we use them to eliminate faults, to streamline the instructional design process in future, to guarantee greater customer satisfaction and enhanced competitive advantage? What is the connection between the notions of Evaluation, Validation, Standards, Review, Quality and ultimately Return on Investment?

Quality Action Plan

Define Quality

In trade and industry, the notion of quality is relatively easy to grasp, in that one is dealing with products and services. In higher education however, it is not easy to discern well defined end products since it is a process which continues to make an impact on people’s lives long after the completion of a formal study program.
In order to come to grips with the elusive notion of Quality, we begin by considering Quality in general and discuss the following hierarchy of definitions: Quality; Quality Control; Quality Assurance and Total Quality Management. We explore the notions of Quality as exceptionally high standards, Quality as efficient production and Quality as transformation in the sense of adding value to the learning experiences of students, particularly those from intellectually impoverished backgrounds.

**Define our processes**

We discuss the definition of a process and the implementation of processes and procedures in our department. Our E-education Instructional Design Kit includes a Service Level Agreement signed by the Project Leader, Roles and Responsibilities, A Project Timeline, a Six Star Course rating system (adapted from Merrill 2001) and Minimum Requirements for Web-supported courses.

**Develop data collection tools and techniques**

It has been said that “Quality has no meaning, except as defined by the desires and needs of customers” (Gabor 1990). Our two customer populations are lecturers and students. The advent of web-supported learning necessitates changing roles for both lecturers and students. We describe the lecturer training program and student orientation sessions we offer. We have developed a lecturer questionnaire, as well as a pre-course quiz and a post-course survey to be completed online by students.

**Case Study**

We use as a case study the MBA (Master of Business Administration) Program at the University of Pretoria. This program is a high profile one, and it is critical that it be viewed as a highly effective combination of web-supported learning and contact sessions. The interesting opportunity that presented itself is that a colleague, who is a Professor of Computer-Integrated Education, is registered as a student on the MBA program. With his cooperation, we have the unique opportunity for peer review, expert review and student review all in the form of one individual.

**Conclusion**

Quality is an all-encompassing guiding light, which impacts on courseware development, staff development and training, student orientation and daily practices and procedures. We need to ensure that quality E-education programs result from our combined efforts, which impact positively on the global reputation of the University and on the ongoing lives of our students.

The Application for Hand-written Recognition in order to Search on Electric KANJI Dictionaries for Non-Japanese Learners

Shinichi FUJITA, Kazuto YAMADA, ChunChen Lin, Seinosuke NARITA
Waseda University
3-4-1, Okubo, Shinjuku-ku
Tokyo, Japan
fujita@narita.elec.waseda.ac.jp

1. Introduction
Due to increasing internationalization, more and more people are trying to learn Japanese. In spite of a lingering recession, Japan has a strong influence in economic and technology areas. Many students in the Asia region or other countries learn Japanese as a foreign language. Also in Japan, a considerable number of students from overseas have been studying Japanese.
For people speaking one of India-European language family, the Japanese language is one of the most difficult languages to master. Especially it is much harder for Japanese beginners to use a Kanji dictionary than for English beginners to look up a word on an English dictionary. An English word can be found through the knowledge of 26 letters of the English alphabet and its order however, to search for Kanji on a dictionary is not as simple. There are three keys for looking up a Kanji character. These are; "reading" or "number of strokes" or "root". They are all too hard for Japanese beginners to know.

Hand-written recognition systems used on PDA or others are designed for Japanese. Most of them attach importance to stroke order for the purpose of realization of better correctness and high-speed recognition. It is useful for native Japanese and middle or higher-level Japanese learners. However, for Japanese beginners, it is difficult to write unfamiliar Kanji characters in the right stroke order.

This paper provides a new method for looking up a Kanji on an electric dictionary by using handwriting recognition for Japanese beginners.

2. Our algorithm for a searching system
We tried to design a Kanji searching system for absolute Japanese beginners. Users input what she/he is looking for by dragging the mouse. It is easy even for a beginner to copy what he/she sees from a newspaper or textbook.
We gave priority to following points:
A) Fast response
B) Not depending on stroke order.
C) Not requiring too strict correctness because the system can also show 5 or more alternatives and users can select the correct Kanji character.
Details of the algorithm are followings.
2.1 Normalization
To obtain a more accurate recognition, input data is normalized before searching. The middle point is obtained from its height and width, and the input character is moved

![Fig.1 Example of inputted data](image-url)
parallel. Next, the character is stretched to 175 pixel * 175 pixel. "175" do not have special meaning here.

2.2 Data Format

175 pixel * 175 pixel square are divided by 7pixel * 7pixel of small squares into 25th*25th squares. If one or more black pixel is in the 7*7 square, it's data is "1" and if no black pixel inside, data '0' is stored (see Fig.3). Next, database has the place of value "1".

2.3 Matching

Inputted data is compared with example data preferred before and similarity "S" is calculated by the next expression.

\[ S = \frac{\text{the number of matching "1" between input and example}}{\text{the number of "1" in example data}} \]

The system shows 6 or fewer candidates in the order of descending similarity.

3. Examples

We made test version of this system and following is the result from test use.
This test system has 320 samples of Kanji. Test Machine's spec is as follows:
CPU: Celelon 433Mhz    Memory: 64Mbyte    OS: Microsoft Windows 98

3.1 Success Examples

Fig.2 is example of success. Searching time was about 9 or 10 seconds. It was much faster than using a paper dictionary.

3.2 Failed Examples

Fig.3 is failed examples because the input data was too small.

![Fig.2 Examples in success](image1)

![Fig.3 Examples in failed](image2)

4. Conclusion

Dictionaries are essential for language learning. However, Kanji dictionaries are too hard for Japanese beginners to look up using conventional methods.

In this paper, we showed a new method utilizing handwriting recognition to search for Kanji using online systems and developed a test system and could get a result that was effective.

We have already developed a Multimedia dictionary and we had a presentation on ED-MEDIA 2000 (see reference). Now we are joining this searching method to the Multimedia dictionary and will show them in the next time.

Learning Data Mining – A Tool for Understanding Knowledge Discovery and Qualitative Data Analysis

Satoru FUJITANI
Mejiro University College
4-31-1, Naka-ochiai,
Shinjuku, Tokyo 161-8539 Japan
E-mail: fujitani@mejiro.ac.jp

Abstract: This paper reports the development of a system for learning data mining and multivariate analysis methods. A work-in-progress developing tool deals with one procedure for qualitative data analysis such as Web access data or online discussion logs. Learners can experience data mining for hypotheses formulation which helps the understanding of variation from multivariate analysis. The support tool uses the natural language processing system for the analysis of on-line text data.

Introduction

Information interface is rapidly progressing even in our common computer environment. We can find answers to research and reference questions using several different types of information resources, e.g., subject guides, search engines, and specialized databases. Furthermore, we have focus on large-scale data not for understanding of millions of cases but for providing summaries and generating reports with the help of statistical techniques. This approach is known as knowledge discovery in databases (KDD) or data mining (Fayyad 1996a). The results of data mining acted as a sophisticated query for further data analysis such as multivariate analysis. Preceding research deals with the undergraduate data mining as information seeking skills can be found (Anthony 1998). The target of this work-in-progress study is to develop learning support tools for providing data mining experiences and to have practical opportunities for learning statistics. Learning the process of KDD gives an accessible approach to finding information on the World Wide Web and the Internet, and it helps students to try research issues. The support tool uses an existing technique, the natural language processing system (Kurohashi 1999) for the analysis of on-line text data. More detailed research is necessary, but the author outlines the study hereafter.

Knowledge discovery in databases and its method

Knowledge discovery in databases (KDD), or data mining, is a process for extracting useful knowledge from volumes of data. Meaningful knowledge is not derived from simple methods or techniques of KDD, but repeated inquisition procedures to find certain data patterns from less useful and condensed data. Some portion of its method is automated with the computer, but most of that is the so-called “trial and error” process.

The outline of the data mining method has the follow phases: 1) Statistical sampling for grasping a whole tendency, 2) Data inquisition for finding association or sequential pattern of whole data, and for directing the course of the analysis, 3) Data handling, e.g., summary data extraction, merging into a single database, or exclusion of erroneous data, 4) Model development for inference with a generalized linear model, regression model, neural network, or decision tree analysis, 5) Model assessment for inference model evaluation.

For example, a World Wide Web (web) server retrieves access log of the web site. The access log consists of the IP address of the accessed computer, access time, URL of watched web page, URL of referred web page, and so on. The active web site has an enormous log file. When the result of data mining detects that a certain two pages are being watched together by same person but they are not linked, the web site designer can continue to inquire the relationship of the two pages, and can link both two pages for their convenience. In this way, hypothesis formulations by data mining lead to the interface support for web design.

Data Mining Learning Tool

The author has developing a learning support tool for KDD and multivariate analysis methods. This PC-driven learning application software consists of: 1) a database development module, 2) a relation rule browsing module, 3) a statistics application learning module. The author will describe there in detail.
Database development module

This learning environment can handle both "Web site access logs" and "Mailing list messages" as sequenced text files into a database automatically. In case of Web site access logs that are recorded in the standard form of Apache HTTP Server (ASF 1996), they are converted to SQL-driven database tables with apportion between items. In the event of mailing list messages, firstly, the morpheme analysis system JUMAN (Kurohashi 1999) detects nouns in each message. Secondly, the nouns of each message are collected into SQL-driven database table. According to my previous investigations (Fujitani 2000a; Fujitani 2000b), the set of nouns in mailing list messages can adequately be used for summary sentences extraction of on-line discussions.

Relation rule browsing module

Learners use a web browser to observe correlation rules in database. When permutation and combination rules can be found at a fixed rate of data, the module detects them as "associations" and "sequential patterns". This module uses the index of the rule known as "support", "confidence", and "lift" (Fayyad 1996b). The module calculates the indexes and sorts the correlation rules in descending order. The learners are able to change the arrangement to which index they give more weight. Most data inquisition from databases is cut-and-try basis. Hence the proposing module can handle databases in various ways.

Statistics application learning module

With reference to the relation rule tables, the learners will approach a statistics application learning module. This module is used as on-line courseware for statistics application software. In the data mining sequences, the learners will develop mathematical models for inference. The module describes the characteristics of models such as regression models. The module calls the on-line help of statistics application software SPSS (SPSS Inc., 2000). In conformity to the important items on which the learners need to focus, the learners will choose the appropriate analysis methods by the courseware. To prevent overfitting and assessing statistical significance, part of data is retained for the cross-validation scoring phase.

Conclusions

The author has developed a learning support tool which deals with data mining and multivariate analysis methods. a problem yet to be solved in the future, we are interested in examining the effectiveness of the tool for practical use for freshman at college in the Department of Business Administration.

Abstract: Distance Training models, when integrated in a more complex framework, such as a Distance Consulting model, present specific features and impose a revision of the strategies commonly adopted in distance training experiences. In this paper we report on the distance training strategies adopted in an European funded project aimed at defining and developing Distance Consulting services for SME’s located in inland areas of Sicily. A distance consulting environment has been developed by integrating telematic tools which allow the consulting center and the enterprises to, respectively, develop and access both Synchronous and Asynchronous consulting and training activities.

Introduction

The continuous and rapid changes in the economical and technological factors behind the Information Society (development of the net-economy, the globalization of businesses, the macro changes in industrial and market structures, and so on) represent one of the most pressing challenges for Enterprises. Specifically, by looking at the New Economy sector, new terms appear everyday in order to describe how the traditional business activities are more and more moving towards ICT-based solution: eWork, eBusiness, eCommerce, Digital Economy, Global Market are only a few examples of this new emerging world. However enterprises, especially Small and Medium-Sized Enterprises (SMEs) in Europe, still need strong support in order to cope with the challenges raised by ICT and exploit the potentials offered by them. In particular, training and re-qualification is essential for enterprises for affording a constant adaptation and modification of their businesses and securing their competitive market position; therefore, training concepts should be part of the culture of any company. At the same time, accessing training modules is still considered by SMEs a costly and time-consuming process, which is very difficult to conciliate with production timetables; in addition, there is not a strong culture of retraining and lifelong learning amongst SMEs. Distance Training shows huge potential as an effective solution to the needs of training and re-qualification in SMEs, by overtaking many of the obstacles to the activation of training processes in a company.

Consulting centers are in the right position to promote both the use of ICT in production activities, and specially the culture of training amongst the SMEs. Support to training activities will become a more and more important role of the consulting centers. In addition, the consulting centers themselves can exploit the potentials offered by ICT, and offer Distance Consulting services.
At the Italian National Research Council, we have designed and led an experience of Distance Consulting, an ICT-based approach to consultancy, which systematically provides companies with information, communication and training services in an effective way. In this paper we analyze in depth the training model that has been adopted in a European funded project, called SOLARE (Support On-Line to Regional Enterprises), together with the technological solutions we have developed for the training activities. Because of the strong and systematic integration of the Distance Training model in a more general one (the Distance Consulting model), the training process has shown specific features which have in turn imposed a revision of the strategies commonly adopted in distance training experiences.

The SOLARE project

The SOLARE (Support On-Line to Regional Enterprises) project has been carried out in the framework of the European ADAPT initiative. The main objective of the SOLARE project is allowing a group of SME’s located in the inland areas of Sicily to benefit from consulting services through an innovative on-line cooperative environment that has been defined and developed at our Institute. Twenty enterprises have been connected, through telematic channels, to a consulting center, to a technological institute of the Italian National Research Council and to the Department of Economy of the University of Palermo. This network, named the SOLARE laboratory, has initially identified needs, constraints and objectives of the project, and then it has monitored the development of the activities of the project.

Starting from the specific needs of the involved enterprises, we have carried out consulting activities through a communication environment based on Information and Communication Technologies (ICT). There is not a generally accepted definition of Distance Consulting, and for our purposes we consider it as an ICT-based approach aimed at providing enterprises with information, communication and training services in a systematic way.

The methodology adopted for the SOLARE project starts from the use of a business check-up through which the consultant can understand the techniques of management of each enterprise, its culture, the followed politics, and so on. Actually, the check-up aims at analyzing the main activities of the enterprises: customer management, financial needs management, personnel management, investment decision, information system, and so forth. The analysis of the check-up results provides the consultant with the strengths and the weaknesses of each enterprise involved in the SOLARE project; according to this information, the consultant plans the activities to be carried out in order to support the enterprises in solving their weaknesses and improving their strengths. The intervention is based on a mix of traditional activities, strongly integrated with distance consulting activities which take place through the Net; traditional and distance activities are aimed at acting on the daily work of the entrepreneur. Examples of activities which have been carried out during the SOLARE experience are: seminars on specific topics, production of consulting materials, specific courses on the introduction of new technologies and new management techniques to increase business competitiveness, promotion of the use of multimedia and communication technologies for the acquisition of advanced services.

The distance consulting environment has been developed by integrating telematic tools which allow the consulting center and the enterprises to, respectively, develop and access both Synchronous and Asynchronous consulting activities.

The first form of activity is based on the use of real-time communication tools to make the different subjects communicate instantly: the consulting company and the entrepreneurs cooperate through a synchronous environment in which it is possible the activation of different work tools: Audio/video tool, Textual communication tool, Resource exchange tool, Whiteboards, Application sharing tool. This technological environment allows the creation of a direct channel of communication between the consulting company and the entrepreneur through which it is possible to co-operate without the need to move from a place to another one. This introduces a high degree of flexibility in the organization of the consulting activities as compared to traditional consulting processes; network-based meetings can be scheduled in order to discuss a specific topic or to arrange the documentation for a project, the complete a marketing plan marketing, and so forth. The software used for the synchronous consultancy activities is MS Net-meeting and its functions for the audio/video transmission, the textual communication, the exchange of resources; the remote control function has been used to guide the enterprises in carrying out specific activities and, more generally, for cooperative work activities.
The asynchronous consulting activities have been carried out by means of the *Asymmetrix Librarian* system. The system has allowed the organization of the documentation according to areas of interest and their association to group of enterprises with common training needs. The system has provided a high degree of flexibility in planning and organizing information: it has been structured through specific paths according to the SME's requests and the objectives of the consultancy. The client/server architecture of the system, based on the protocol HTTP and Java, has allowed an effective development of asynchronous consultancy by means of: the setting of enterprises groups; the setting of focus groups on specific topics; the production of consulting and training material and its organization in small modules; the association of the modules to the groups of enterprises; the production of reports on the access to information, for the evaluation of effectiveness of the whole process of consultancy. The enterprises get access to the material in a simple way: by means of a web browser they can go to the home page of the consultancy environment (specific to the group the enterprise belongs to); afterwards, they can: visualize and access the content (information on specific subjects, texts, lessons, seminars,..); stop and restore the lecture; share activities and communicate with other users. The consultancy material has been developed and organized according to the web hypertext model. Access to the material is password protected; we have assigned different work areas to each group of enterprises; in some work areas it is possible for the enterprises to put and share information of public interest. This sharing area and the news area have been very useful for the users, e.g. to exchange opinions about some practical aspects of the application and interpretation of laws in particular contexts, thus encouraging a peer-to-peer training strategy.

**The Distance Consulting model**

Our definition of *Distance Consulting* focuses on the systematic use of ICT-based solutions aimed at supporting enterprises; specifically, the systematic approach foresees the integration of ICT-based information, training and communication services which -in the whole- allow consulting companies to give a continuous support to their customers with cost-effective solutions, activating new kinds of consulting based on specific ICT features [Fig. 1]. Following, we analyze some of the most common ICT-based services that could be included in a Distance Consulting service.

**Information services**

One of the most impressive feature of the Information Society is the rapid growth of information made available through traditional and new communication technologies (cable TV, Satellite TV, Internet, and so on); this is particularly true in the new economy context, where the information is more and more global, it is highly volatile, it is produced 24 hours a day; in other words, the risk of information overwhelming is really serious. As a consequence, the Distance Consulting center can support customers through important added-value services concerning the information; amongst the others: brokering of information: search about specific requests in Internet or in traditional material; providing information structured according the enterprises needs: highlighting news, most important topics, deadlines, and so on; this means that the same information could be organized and shown in a personalized way, according to company typology, market sectors, and so on; publishing / broadcasting newsletters on specific economic topics; establishing Web portals.
Fig. 2: The Consultancy Center organizes training processes according to the specific needs of the SMEs.

Training services
Nowadays, it is extremely important to provide companies personnel with a continuous training (Lifelong Learning); it should be noted that sometimes it is not easy to distinguish between “traditional” consulting services and training services. On the other hand, ICT provide the Distance Consulting centers with important opportunities to activate training services for their own customers in an innovative way. Amongst the training services a distance consulting center can provide: organization of distance courses and seminars according to customers needs, by also asking enterprises for their specific needs; inviting experts from University, Research Institutes, other enterprises as “speakers” in seminars and courses; activation of “training on job” services, thus supporting enterprises in the application of contents of seminars and courses or supporting enterprises in the use of specific software.

Communication Services
New communication technologies can improve the communication between the subjects of the consulting process and, at the same time, widen the opportunities of relationships between them; as a consequence, the role of the consulting center changes, since it has the opportunity to improve communication with its own customers and, at the same time, it can provide them with the necessary ICT-based communication services. Amongst the services: activating effective electronic communication channels with its customers; widening the number of subjects connected through the network, such as enterprises, banks, universities and research centers, the distance consulting center itself, and so on; establishing communication channels among enterprises belonging to the same area of business and facing specific common problems. In such a way, entrepreneurs and managers have the possibility of discussing on common problems, according to a “peer consulting” model, and they can share experiences. Of course, this is quite possible for very general questions; on the contrary, very specific topics require the direct intervention of the consultant.

Distance Training as part of the Distance Consulting process
As told before, Distance Training in SOLARE is part of a more comprehensive model, the Distance Consulting one. As a consequence, the Distance Training process in SOLARE has very specific features:
- there is not always a clear distinction between the Training processes and the Consulting ones;
- as a generalization of the previous point, there are very weak borders between the three aspects of the Distance Consulting model: information services, communication services and training services. Getting access to information can be considered as a specific activity in a training process, and similarly communication services can be effectively used for training purposes;
- it is not a “general-purpose training”, as the one offered by many training centers, but it is a training strongly focusing on the specific needs of the beneficiaries;
- the consultant is also the promoter and the organizer of the training services: he knows very well the target of the training process, and can arrange the whole training process [Fig. 2];
- the consultant can analyze the training needs of several enterprises, so organizing courses involving employees and managers from different SMEs.

Some consequences of the features of the Distance Training model in SOLARE as stated before are here reported:
- the training process is strongly tailored to the needs of the beneficiaries, for two reasons: from one hand the consultant knows the company quite in depth; on the other hand the companies have the opportunity to, implicitly or explicitly, declare their own training needs;
- the companies play an active role in fixing the training modules, since the very initial phase of the whole establishment procedure; not only do the companies influence the decision on the content of the training, but also the same methodological and technological aspects of the distance training process: the distance training provider, in strict cooperation with the consultant, can take in account the technological infrastructure and skills of the beneficiary company, as well as the organization aspects in the company (e.g.: the number of people who will follow the distance training course, their position in the company, the time allowed to each person to participate in the training process, and so on), since the consultant knows the company very well, especially if they are very small companies, such as in the SOLARE project. This is very different from traditional training courses offered on the market, which are characterized by general technological and, sometimes, fixed time schedules, and it is up to the participant to the training course to make arrangements in order to be able to get access to the distance training module;
- the role of Training-on-job practices becomes more and more important (and more important than in traditional settings); actually, the training process, as part of the distance consulting approach, is to be brought inside the company, in order to better solve specific problems of the enterprise;
- through the Distance Consulting environment, SMEs get access to a continuous flow of updated and specific information offered by the Consulting center; in such a way, the management of the company receives continuous stimuli to re-qualification, thus undergoing a continuous training process (as far as the access to information is concerned). Generally speaking, Distance Training is a continuous process since it is integrated in a continuous Distance Consulting process;
- the Distance Training process can benefit from the communication services integrated into the Distance Consulting model, and enable company managers to discuss and cooperate on common problems straightforwardly. In such a way, peer-to-peer training strategies are encouraged;
- the evaluation process of the training plays a completely different role as compared to more traditional training contexts: firstly, the consultant has direct control of the training process, since s/he can verify if the training goals have been achieved during his normal professional activities (e.g. by meeting the entrepreneurs or the management of the companies). In addition, evaluation can be supported by the analysis of the communication flow through the discussion groups associated to the training topics (as it will be described in the following session).
- the costs of distance training courses can be optimized, by involving participants from different enterprises with the same needs;
- the consulting center can manage the search of training resources (teachers, on line courses, experts, and so on) starting from the needs of updating and re-qualification of a group of enterprises; the consultant and the teachers can organize new model of training, leading the enterprises towards an exchange of experiences. This aspect is particularly important in putting into practice new know-how acquired during the courses (for example in courses about the application of new laws, when enterprises in the same economic sector could face the same problem to apply the law in their context). In this case the exchange of experiences, with support from the expert, can be extremely effective;
- when the consulting center is also a support for the introduction and the development of ICT in the enterprise, it becomes the training center for ICT. In this case the courses are very specific and flexible at the same time, thus achieving high quality results.

Conclusions

In this paper, we have presented an experience of distance training as part of a Distance Consulting process. Distance Consulting is a new way of providing consulting services, as compared to more traditional approaches; a lot of consultancy services can use information technologies in order to improve their effectiveness; in addition, new
services based on technologies can be developed. In particular training processes, when analysed in the context of a Distance Consulting model, change their traditional role and can benefit from the use of ICT. One of the most significant benefits we have experienced in the SOLARE project has been the possibility of providing consulting and training services in a continuous way by means of: information areas, the exchange of experiences among enterprises facing the same problems, the training on job to put into practice the concepts acquired during the lessons. Moreover, the role of the Distance Consulting centre has become important also for the promotion, organization and delivery of distance training courses; in this way several enterprises with similar needs can share training materials and experts’ support, cutting down the costs.

Abstract: Courseware has to reflect the learning situation coined by contents, learning goals, characteristics of the learner, technical conditions etc. The efficient creation of appropriately designed courseware relies on flexible representations of reusable instructional material and learning circumstances. Contradictory approaches of different instructional design schools give little advice in case of design alternatives: The support gap for justified design decisions ranges from underlying instructional theory to ergonomic layout. Therefore, we separated factors influencing courseware design from design parameters and present the Instructional Material Description Language IMDL for their respective description. A simple rule language serves to express dependencies between influence factors and design parameters. Rule sets represent prescriptive design statements based on instructional design theory which are open for validation. A toolset enables efficient courseware production based on IMDL, e.g. an interpreter engine for rules produces complete courseware specifications and a generator outputs source code for specified courseware based on a framework of instructional Java-Beans™.

Introduction

The shift to the information or knowledge society is accompanied by the need for continuing education. The corresponding need for courseware grows with the gap between demand and otherwise deliverable supply of education. The efficient development of courseware is thus an important goal. Proprietary multimedia authoring tools like Authorware™ or Toolbook™ have been extended to meet the specific needs of courseware authors, but we don’t think that WYSIWYG-editors provide an appropriate methodological support for the systematic development of courseware. WBI (Web-based instruction) is taken for another remedy because it makes development faster for a wide area of applications. The simple and standards-based technology of the WWW has proven fruitful and is easily to learn and implement when persisting bandwidth limitations don’t obstruct its use. However, our point of view is that they may help non-programmers to build multimedia applications but tend to distract their attention from didactic and content related aspects. The first problem is thus lacking instructional design knowledge and tool support. Furthermore, attractive courseware that supports learning on demand has to be modular and designed to meet the targeted learners’ needs and thus requires even more complex engineering models or methodologies like the ones arising from the area of knowledge management.

Instructional System Development (ISD) is concerned with the former mentioned problems. We interpret the term “instructional system” as any system to foster learning, whereas our work is concerned with development of instructional software only. ISD consists of the phases planning, development and implementation (use and evaluation) where we focus on the development phase that in turn consists of design and production. A pragmatic definition of Instructional Design (ID) that we agree with is given by Lowyck & Elen (1993) who say that ID is a discipline that connects descriptive research findings with instructional practice by (1) identifying design parameters based on results of basic research from cognitive psychology; (2) instruments these as rules, procedures and methods and (3) provides prescriptions for the development of instruction to optimise teaching and learning. The most ambitious approach to put this definition to practice probably is the automation of ID that Tennyson & Baron (1995) or more recently Spector & Muraida (1997) give a survey of. Approaches from Software Engineering and Knowledge Management resulted in courseware standardization efforts like the Architecture and Reference Model by the Learning Technology Standards Committee of the...
IEEE [http://ltsc.ieee.org]. Its working group for Learning Objects Metadata develops a metadata standard to describe learning resources. A meta-modelling approach to the development and management of teachware based on re-use of contents and structure that uses metadata as a foundation of adaption is the Passau Knowledge Management System PaKMaS (see Brössler, Freitag & Siül, 1999). However, PaKMaS is not out to produce courseware but is a management system that transforms IM-models into hypertexts. On top of that, the modelling is done without didactical guidance or ID advice. Murray (1996) suggests “ontology objects, which allow for the creation of representational frameworks tailored to classes of domains or tasks (...)” for Intelligent Tutoring Systems (ITS).

We took up this approach and have built the Instructional Material Description Language (IMDL) based on XML. This multi-layer specification language consists of three parts to enable generic descriptions of courseware. IMDL-subsets serve to describe influence factors, design parameters and there dependencies. Base specifications of IMDL then simply describe actual material in terms of relevant influence factors (like content, structure, targeted learner and so on); complete courseware specifications become possible by the addition of a set of elements to describe design parameters. Elements of both subsets describe well-understood parts of the domain, whereas controversial aspects are ontologically separated; author-specific extensions. ProfiL, the "Produktionssystem für interaktive Lernsoftware" (German for "Production system for interactive courseware") first transforms base specifications into complete courseware specifications according to author-formulated dependencies (design rules) and finally generates according courseware based on a framework of instructional JavaBeans™.

In the following section aspects of courseware are analysed and summarized distinguishing between influence factors and design parameters before our approach to explicitly represent instructional design axioms is presented. Afterwards, the XML-based implementation of the approach as IMDL is roughly sketched. Another section addresses the architecture of ProfiL after clarifying the roles and relations of documents and document type definitions. The final section provides a brief summary, our conclusions and an outlook on future research and development.

Aspects of Courseware: An Analytical Approach

The description of courseware is not yet comprehensively possible due to its interdisciplinary and complex character. After all, various sets of metadata for learning resources can be found in the literature some of which (e.g. Learning Objects Metadata, IMS [http://www.imsproject.org] and ARIADNE [http://ariadne.unil.ch]) are standardized. None of these approaches provides vocabulary to describe didactical aspects, instead they are extensible for that purpose. We are convinced that this lack of common vocabulary indicates the general state of instructional design research, that is characterized by Seel and Dijkstra (1997): “An analysis of traditional ID demonstrates that it is not possible to map results of empirical research on learning onto instructional planning in a one-to-one manner, but rather the transformation of a descriptive knowledge base into a truly prescriptive instructional theory seems to be still in its infancy.” The situation is rather characterized by anecdotal results that are hard to compare or to integrate within a sound theory of ID as concluded in Kerres (1998), Mandl & Reinmann-Rothmeier (1997) or Schulmeister (1997).

For that purpose we tried to approach these problems in a bottom-up fashion: We first analysed the state of the art of ID and current trends of courseware engineering to identify influence factors and design parameters of courseware. The latter have then been considered as dependent variables with respect to the former. In the following, we want to distinguish instructional material (IM) from courseware: IM are self-contained units of learning content, that are also called knowledge objects (e.g. by Merrill, 1997) or conceptual units (Brössler, Freitag and Siül, 1999) in the literature. Absent contextual embedding and functionality make the distinction between the two. Based on this preliminary remark we can now take look at the influence factors of courseware design.

Influence Factors of Courseware Design

The inherently interdisciplinary development of courseware requires to take into account various different aspects. ID usually distinguishes between didactical assumptions (based on learning theory, media didactics, software ergonomics), contents and technical aspects. We pragmatically adapted this view by subsuming contents and learning objectives under instructional material. IM is thus particularly characterized by contents that we model as concepts, that are initially independent and that can be annotated with arbitrary learning objectives, e.g. according to Bloom, Ausubel or Gagné. Our focus is on cognitive and motivational affective objectives, since we don’t expect computers to be universally appropriate, e.g. for psychomotoric training.
Further aspects of IM are its mediality and granularity whereas its state (with respect to certainty or consensus about contents) and difficulty can be coded as metadata.

Structure of IM is another essential feature that we model as concept net. Link types can be added based on their graph-theoretical properties. The overall complexity can be expressed via metadata.

Learner properties are treated in such a heterogeneous way in the literature that an exclusive commitment would be pointless. We thus realized a common and flexible division into a (domain) knowledge model and a learner attribute model. The former is implemented as simple overlay model, whereas the attribute model is made up of descriptive primitives, among which appropriate subsets can be selected according to the learning situation. If patterns within the space of possible instantiations should be re-used this can be achieved via specific extensions. Overlay-learner-models can be re-used in the same way, e.g. by approximatively characterizing a pupil with respect to his previous knowledge by his grade. Further primitives are dedicated to media preferences (verbal - textual or auditive - or visual type), motivation (high, medium, low) computer literacy, availability (in terms of time to learn), environment, age, cultural predisposition (that sometimes insinuates analytical or synthetical learning preferences) and further learning styles, e.g. according to Kolb or Keirsey.

Another important component of most learning systems is assessment. Its application ranges from self control over feedback and adaption to certification. Authoring appropriate tests is a complex subject matter on its own that goes beyond the scope of this article. To automatically evaluate tests and integrate them into courseware, at least goals (e.g. as a threshold for variants mastery and normative) have to be specified as metadata.

The sketched selection of influence factors is not complete and doesn’t take into account important aspects like multilingualism, handicapped learners or psychomotoric learning objectives. The building of this ontology of influence factors certainly is a process that can hardly ever be considered to be completed.

Design Parameters of Courseware

This section presents design parameters of courseware that exist dependent on or independently of the above influence factors. Attention is also paid to possible ranges of values for these influence factors. We have derived an abstract generic model of courseware from a survey of available products and research prototypes. In addition, this model tries to integrate results of multimedia software engineering (see Gaede & Schneeberger, 1998) with the domain of Intelligent Tutoring Systems (ITS) and learning theory. Multimedia software should be built in a modular fashion that separates structure, contents, layout and functionality. ITS research contributes the separation of domain, learner and didactical module as well as user interface. Learning theory and media-didactics don’t actually propose a specific courseware architecture but the latter offers (partially general) rules to select, arrange and layout media. Learning theory with respect to instructional design is considered in the next section.

On the basis of this model we have localized possible differences and identified them as variables with exemplary values. These design parameters are related to all aspects of courseware again, which are: content, structure, learner, tests, and beyond this, to functionality. Additionally, metadata can be used according to specific requirements or established standards. The multi-layered specification design based on learning theory and media-didactics shall be outlined next.

From a didactical point of view, macro- and micro-strategies can be distinguished. Macro-strategies apply to sequencing of units and, in a more abstract way, to types of courseware (presentation, drill & practice, tutorial, and so on). Navigational options like a given degree of freedom or generally available access variants (sequential, hierarchical, guided tour or explorative) also belong to this sector. Micro-strategies relate to the selection of components (e.g. definition, explanation, summary, example, analogy, hint, feedback, question, answer, task) depending on their type and function. Selection of media and feedback variants plays another important role in this connection.

The design options with respect to contents are mainly made up of further selections. For example, the choice of IM can be done with respect to its difficulty or to previous knowledge of the learner.

The technical perspective is the easiest to handle though lots of factors play a role. Access (online/offline), if applicable bandwidth, target platform and many others fit in here. We tried to respond to related problems by choosing the largely platform-independent programming language Java and alternative generation of HTML code. However, the selection among different media representations can be made dependent on such aspects.

From Learning Theory and Didactics to Prescriptive Design Axioms

Now that we have presented primitives to describe influence factors as opposed to design parameters, it is quite straightforward to define design instructions in terms of relations between values of the former and the latter!
Nevertheless, it remains problematic to completely specify such dependencies, first, because of the obvious combinatorial explosion; and second, because of the mostly anecdotal research that can hardly be called empirical. The first can be tackled by abstraction, when describing primitives are hierarchically synthesized. The latter is a long-term goal of our approach, by making the usually implicit assumptions of ID explicit in terms of rules, that can be compared and evaluated.

Advocates of the three main trends in learning theory, behaviourism, cognitivism and constructivism, have different views of learning (processes) from which again different design instructions for courseware are derived, not to mention the varying terminology across and within the ID schools. The at present prevailing constructivist community remains (like its elder relatives) vague in its conclusions. So states Gruender (1996): "However, contrary to the claims of constructivism, nothing follows from this theory about what the best educational methods might be to help people to learn." The Profil-methodology thus enforces the formulation of detailed, specific design rules by courseware authors. Subsets of corpora of such rules can be pooled and arbitrarily named. In doing so, a number of rules that describe courseware design according to Ausubel (1960) could be organized as set of prescriptive axioms and be given a name like 'Ausubel_for_Hypertext'.

A Specification Language based on XML: IMDL

We have chosen the platform-independent meta document description language XML (Extensible Markup Language) for the implementation of the specification language because of the standardization efforts and the promising development of the WWW. It enables extensible language definitions using DTDs (Document Type Definitions, whereas XML-Schema definitions offer extended possibilities but still have the state W3C Working Draft) and thereby meets our requirements. The expressiveness of DTDs is similar to formalisms like EBNF although certain aspects are complicated to represent. The following three sections give an overview of IMDL, the Instructional Material Description Language, by sequentially presenting its subset to describe influence factors IMDL-I together with the subset for design parameters IMDL-D, their respective extensions IMDL-IE and IMDL-DE, and the IMDL-R to build rules based on the former subsets. The layered architecture of IMDL further distinguishes between layers for core-, strategy-, model-, component- and layout-specification but is suppressed here for clarity and brevity.

We present the higher levels of both descriptive languages. IMDL-I consists of five modular parts to describe learners, learning-objectives, domains, reusable media-units and reusable framework components. Details are hidden in the files for the different modules. IMDL-D contains elements and attributes to specify didactical objects and structures and is extended by elements to describe abstract software components and layout.

Whereas we tried to identify and name influence factors and design parameters at a fine-grained level, we have to provide the means to efficiently use them in an author-specific way. Authors aren't forced to explicitly use primitives but may use or add their own hierarchical language extensions for further use. One example is given to illustrate this for each, IMDL-IE and IMDL-DE: When previous math knowledge of a 7th class pupil is modelled once with IMDL-I, the extension '7th_class_pupil' could be added to IMDL-IE and then be used instead. If a design pattern of IMDL-D consists of information presentation, a test and depending on its result repeated presentation or presentation of another topic and the author wants to re-use this pattern he can introduce a language extension called 'Drill&Practice' and in future use that element of IMDL-DE instead.

These examples illustrate, that a set of best-practices of language extensions might be agreed upon by author communities and thereby result in a kind of standard representations of instructional patterns.

Figure 1: Relations of Document Type Definitions and Entities for Specifications and Rules
Language extensions are added in separate files and included into the common 'root file' via entities (see Figure 1). This has been necessary to avoid editing of the fixed language parts IMDL-I and IMDL-D. The root file isn’t edible either and contains only entities to include these constant parts and entities to include the variable parts edited by the author. All language extensions are done by the help of DTD-editors that will be extended by more specific tools to support this task. Authors can thus access and re-use all elements and attributes of included entity files.

Prescriptive Description of Design Rules: IMDL-R

Given the XML-based IMDL, the Extensible Stylesheet Language (XSL) and its part XSLT (Transformations) would be the obvious choice to describe design rules. XSLT is a language for transforming XML documents into other XML documents. It uses patterns and templates for conditions and actions respectively. However, the way rules are processed by so-called XSL-engines is deterministic whereby application of a set of rules to a specification (an IMDL-IE document) yields exactly one target (IMDL-DE) document. Since our goal is to generate alternative variants in case of under-specified influence factors, we defined the (trivial) rule language IMDL-R and implemented an according interpreter. The DTD for the rules allows for elements of IMDL-IE as pre- and elements of IMDL-DE as post-conditions.

Inclusion is done via entities again, because the XML standard and according tools don’t make it possible to include complete DTDs (i.e. with header). Therefore, the root-elements of IMDFL-IE and IMDL-DE are eliminated and the thus truncated rest is included unchanged.

We alternatively consider language elements as terms and work on a pre-processor that transforms specifications into first-order logic. Thereby, specifications of IM are to be seen as sets of facts whereas design rules become axioms. This enables the use of efficient theorem-provers instead of simple interpreter engines and lets sets of rules be checked for consistency and redundancy.

Architecture of ProfiL

We want to begin by illustrating (in Figure 2) the relations of the documents and document types described above before we sketch the architecture of the entire ProfiL-system. The DTDs IMDL-I and IMDL-D define how influence factors and design parameters are described at the lowest level respectively. They thus define the core language of ProfiL. Each of these two is included (1.) into the respective author specific DTD file IMDL-IE and IMDL-DE. IMDL-R lays down the syntax of rules to describe dependencies among them, what for essentially only variable symbols, quantifiers, sets and an implication symbol are introduced and the elements of IMDL-IE and IMDL-DE are assigned the role (2.) of pre- and post-conditions respectively. The IMDL-R.dtd is not editable but all elements an author added via extensions in IMDL-IE and IMDL-DE are available within rules.

![Diagram of Relations of Documents for Specifications and Design-Rules](image)

Figure 2: Relations of Documents for Specifications and Design-Rules
The document „Axioms.xml“ is written by an author or a group of authors. It lays down in the rule language IMDL-R specific design rules to be applied on specific conditions. The example document „IM.xml“ in turn describes actual IM with respect to contents and other influence factors. Both documents together are processed by the interpreter („Engine“) resulting in different variants of complete courseware specifications, here called „CS1.xml“ and following. To keep the illustration clear we have suppressed the multi-layer structure of the specification languages. Actually, language elements are distinguished as belonging to a core-, strategy-, model-, component- and layout-layer. Rules are accordingly applied in a multi-phase process.

We are now going to consider the roles of documents within the overall architecture of ProfiL as illustrated in Figure 3. A standard editor has been integrated to edit the extensible DTDs IMDL-IE and IMDL-DE; for clarity we labelled it „Structure Editor 1“ and „Structure Editor 2“ according to its use. The non-editable DTD IMDL-R parameterizes the „Ruleset Editor“ that serves to author instructional design rules. The same XML-Editor (now labeled „Courseware Specification Editor“) is used to author specifications of IM when parameterised with the DTD for IMDL-IE. The interpreter known from Figure 1 then generates several variants of courseware specifications („CS-1.xml“ and others) that can again be manually edited with the XML-Editor in the role of a „Courseware Specification Variant Editor“. This allows for review and selection of individually preferred variants and for individual design changes (exceptions) that shall not persistently influence the rules. Finally, the „ProfiL Generator“ is invoked with the selected specification(s) and produces Java source code („C-1.java“) that can be compiled into a executable application. The documents depicted below are called „LCS-i“ standing for „Lazy Courseware Specification“. The files contain either parts of the influence factor specification that haven’t been fixed at design time or dynamic parameters that are expected to change during courseware use. By analogy with partial evaluation, these parts aren’t evaluated immediately (during generation) but at runtime. An obvious example for this case is a learner’s domain knowledge model that of course has to adapt to the extended knowledge during learning. If this is impossible or not sensible, several alternative variants are generated.

Summary and Outlook

The separation of influence factors and design parameters and the explicit description of their dependencies is an essential prerequisite to consolidate instructional courseware design. The use of the ProfiL-toolset and the proposed methodology enforces courseware authors to make assumed dependencies explicit. This enables validation and comparison of didactical alternatives. The framework-based generation approach makes use of the extensible specification language IMDL. This results in modular and re-usable instructional material leading to more efficient courseware production. The final fully automatic generation of source code based on instructional Java-Beans in compliance with ergonomic and didactical aspects results in further savings. The implementation of the presented system is almost complete; all components have already proved to work as prototypes.

However, there remain problems: The use of our tools is not yet easy enough (e.g. compared to the tool described by Ainsworth & Grimshaw, 1999) and abstraction via extensions alone doesn’t seem to make
authoring easy enough either, though we expect improvements by collaborative ontology engineering as described by Staab (2000). Supposing that universally valid terminology is neither near nor realistic, partial domain- as well as pedagogical ontologies (see Mizoguchi Bourdeau, 1999) have already proven fruitful. The collaborative management and construction of ontologies by means of namespaces might thus help to ground courseware design in the spirit of Hannafin (1997). Another shortcoming of ProfiL is the renouncement of runnable domain models that make up the power of ITS but it is certainly possible to integrate such features after revising the framework that underlies the code generation. The actually implemented structural model already enables the automatic generation of simple tests. The lacking store of experience and the tedious initial specification of IM and design axioms are critical and at present prevent us from evaluating the authoring process let alone subsequent courseware use. It thus remains in question whether representing ID-knowledge as rules is acceptable to courseware authors. Early attempts towards programmed ID couldn’t prevail, but we attribute this to lacking increase in value (e.g. the advice system of Elen & Stevens, 1993) that multimedia courseware has overcome. Moreover, these approaches where often committed to a single instructional theory like Frank’s (1991) system ALSKINDI, that solely realized programmed instruction according to Skinner. The quality and efficiency of courseware development according to the ProfiL-methodology can be further increased by preceding measures related to the authoring of instructional content. Guidelines for the didactical text production can help domain experts with this task. Templates can result in better structured content and can easily be added to the IMDL. Very important is the improvement of the graphical editors that are refined at the same time the example specifications and axioms are further developed. We thereby try to directly take into account specific requirements. The integration of theorem provers is only loosely coupled with the rest of the ‘roadworks’ but we expect the additional generation of explanatory documentation of it: Tracked chains of applied design rules promise to provide justifications for produced courseware.

Abstract: In this paper we present an interdisciplinary research project which aims at developing an electronic vocabulary acquisition system for the German and the Italian language (ELDIT). The basic dictionary will be enlarged with text and exercise units in order to support a systematic approach for studying and practicing the vocabulary. To ensure maximum effectiveness of the learning process, modern psycholinguistic methods are applied alongside with new media and technologies including adaptive hypermedia. The system is implemented as an adaptive hyperbook and runs on the WWW.

1. Introduction

Recent research in the field of computer assisted language learning (CALL) shows that multimedia and hypermedia teachware seems to be effective and motivating for language learning (Egert 00). Such technologies open new doors for the presentation, maintenance, and dissemination of complex knowledge and information units. However, students who are less experienced in the use of information technologies may get into trouble and lose control over the system, especially if they are expected to work independently of a teacher or a tutor. Adaptive systems cope with this problem by maintaining a model of each individual user, which helps the system to prepare individually designed pages and to guide the users according to their personal learning goals.

Until now, such systems have mainly been developed for teaching natural science and computer science (Nejdl et al. 99, De Bra et al. 98). We are currently investigating the use of adaptive systems in the domain of foreign language learning. In the ongoing research project ELDIT we are developing an electronic vocabulary acquisition tool for the German and the Italian language. Modern linguistic and didactic issues are considered in the design of the system. It will further contain a model of each user, adapt the content to the individual needs and preferences of each user, and guide the user through a systematic but individually shaped vocabulary acquisition process.

The paper is structured as follows: In section 2 the concept of learners' dictionaries is introduced. In section 3 the ELDIT dictionary is described in detail. Section 4 provides an overview of how we intend to enlarge the basic dictionary to an adaptive vocabulary acquisition system. In section 5 we discuss related work.

2. Learners' Dictionaries

Vocabulary acquisition is an important part of foreign language learning. To support this difficult task, lexicographers designed a special kind of dictionary, so-called learners' dictionaries. A learners' dictionary serves both as a reference book to decode what the learner does not understand and as an instrument which supports text production (Aarts 99). Word definitions are simpler and might be supported by pictures. Carefully selected examples are very important for the illustration of the meaning of words, as well as typical lexico-grammatical patterns, etc.
Figure 1 shows the entry of the word „Fenster“ (English *window*) in Langenscheidt’s learners’ dictionary „Deutsch als Fremdsprache“. In a printed dictionary space is limited, information is structured in a linear manner, and a lot of abbreviations are used. Therefore it is difficult to get an overview of the provided information, to understand which information is provided in detail, and where particular information can be found. Moreover, it is impossible to directly access semantically related words, except derivatives which, according to their usual lexicographic order, are physically close to the word under consideration.

Modern hypermedia and multimedia technologies allow to address a lot of these problems by providing new ways for structuring and presenting complex information. An overview of English learners’ dictionaries available on CD-ROM is given in (Nesi 99). Cambridge Dictionaries Online provides web-access to a range of English learners’ dictionaries (Harley 00).

3. The ELDIT Dictionary

At the European Academy Bolzano we are currently developing an electronic learners’ dictionary called ELDIT (Elektronisches Lern(er)wörterbuch Deutsch ITalienisch). ELDIT can be used both as a monolingual and as a bilingual dictionary. Currently we are implementing ELDIT for the German and Italian languages, but the software could easily be adapted to different language pairs. The following sections describe the system in more detail by concentrating on different aspects of content and design.

3.1 A Sample Dictionary Entry

Figure 2 shows a screenshot of the dictionary entry for the German word “Haus” (English *house*). The information is presented in two different frames. The left-hand frame shows the lemma “Haus”, a loudspeaker-button which on activation plays a sound file with the pronunciation of the word, and different meanings of the word. The right-hand frame shows various pieces of information about the word, which are collected in different tabs. Some of these tabs can only be activated once a specific meaning of the word is selected. In figure 2 the first meaning of the word "Haus" is actually selected, and the right-hand frame shows the collocation tab, which contains a list of the most frequent collocations together with their translation and an illustrative example. ELDIT contains a large number of patterns for word usage (collocations, idiomatic expressions, constructions) in combination with a translation of the patterns as well as illustrative examples. These data are presented in the tabs „Verwendu

According to Aitchinson (Aitchinson 94), people not only remember words in a possible context, but group the words in their minds into multidimensional word nets. Several word nets are visualized in ELDIT, among them the semantic field which groups words by synonymy, hyperonymy, antonymy, etc. and can be accessed by activating the tab „Verwandte Wörter“.

Chapelle stresses the importance of drawing the users’ attention to linguistic characteristics of a specific language (Chapelle 98). ELDIT uses footnotes to inform learners about particular differences between the two languages. Clicking on a footnote opens a small window, where linguistic difficulties are explained (see figure 2). A
summary of all difficulties related to a specific word is shown in the „N.B.“ tab. For a more comprehensive description of these features in ELDIT see (Abel 00).

Figure 2: ELDIT screenshot for the German word “Haus”

3.2 Vocabulary Coverage

The ELDIT system should support learners of the German and the Italian language to prepare for the exam of bilingualism which is required for all employees at public institutions in South-Tyrol, a bilingual region in the North of Italy. For the selection of the vocabulary included in ELDIT the following considerations have been taken into account. The so-called basic vocabulary of a language consists of approximately 3,000 words and covers about 95% of the words in a normal text (Lewandowski 90). For both the Italian and the German languages an intersection of different basic vocabularies has been built. The two resulting vocabularies have been adjusted to each other in order to avoid big differences between the two languages. Finally, the two vocabularies have been enlarged by some frequently used words in South-Tyrol such as “farmer“, „wine“, etc. The resulting vocabularies cover standard German and Italian with focus on the language variants spoken in South-Tyrol.

3.3 Searching the Dictionary

One of the most obvious advantages of electronic media over print media is their possibility to provide fast and efficient search capabilities. In ELDIT, the user can search a lemma directly or by one of its declined or conjugated forms, e.g. „ging“ leads to the lemma „gehen“. The learner can also search more complex expressions such as collocations and idiomatic expressions, e.g. „aus dem Fenster schauen“, by simply typing the whole expression into the search field. Furthermore, the user is allowed to omit some problematic parts of an expression and to replace it by wildcards, e.g. „Geb*b*de e*ichten“ results in the collocation „ein Gebäude errichten“. Finally, ELDIT can detect spelling errors in the search expression and provide alternative propositions.

3.4 Data Model

Figure 3 shows a simplified version of our basic data model represented in an extended entity-relationship notation with generalisation/specialisation. The main objects in our domain are word entries, which are further classified into nouns, verbs, adjectives, and structure words (articles, prepositions, etc.). Every word entry is associated with various pieces of information. A distinction is made between information concerning the word itself (mainly lexical information) and information concerning a particular meaning of the word (mainly semantic information). The former class includes the lemma (e.g. "Haus"), morphological information (a word completed with article and plural form, e.g. "das Haus, die Häuser"), derivations (e.g. "das Häuschen" and "häuslich"),
idiomatic expressions (e.g. "jemandem ins Haus platzen"), and footnotes. The latter class concerns information about a specific word meaning and includes compound words (e.g. "Hausfrau"), collocations (e.g. "in einem Haus wohnen"), a list of adjectives which typically go with this noun (e.g. "baufällig", "renovierungsbedürftig"), constructions which describe the use of a verb together with a noun or a preposition, and a picture. Words will be grouped into associative and semantically related word fields. These fields will be visualized as interactive graphs, where nodes represent the words (word entries) and edges are annotated with information explaining the difference between related words.

Figure 3: Data Model

Most of the above mentioned pieces of information are complex units each of which might be composed of a definition, a pattern, a translation, examples, explanations, and comments. For instance, a collocation consists of a pattern, a translation, and an example (see figure 2).

The basic data model will be extended by several new classes of information units: extensive grammar units will provide grammatical background; exercises, tests, and text material will allow the learner to practice the acquired vocabulary and to train both reading and writing skills (gray part in figure 3).

4. Towards an Adaptive Vocabulary Acquisition System

In this section we discuss two extensions of the basic ELDIT system: adaptation to individual users and systematic vocabulary acquisition. We are currently implementing these features, an evaluation remains future work.

4.1 Adaptation of Information Presentation

A great advantage of hypermedia systems is their ability to be combined with adaptation techniques. This allows to adapt the system to individual users and to provide each user with the content which best fits his/her needs and wishes. Various user features have been identified to which the content presentation of the ELDIT dictionary should be adapted.

First of all, the user's language skills and knowledge should be considered. A novice should not be faced with too many different word meanings; collocations and difficulties concerning specific words are much more helpful. An advanced learner wishes a more comprehensive picture of the language and needs more word meanings as well as a precise definition thereof, free combinations, and lots of idiomatic expressions.

The second idea of adaptation concerns language for special purposes. The current version of ELDIT covers standard German and Italian, which is sufficient in many cases. However, people in South Tyrol are more and more required to use the second language at work, which means that professional terminology becomes increasingly important. Therefore, ELDIT should support the learning of languages for special purposes, e.g. by adapting the examples to the individual user's background, occupation, business, or interests.

There are several meaningful ways to adapt the presentation of the information to user preferences. Different users might focus on different pieces of information when they access a new word. ELDIT can record each user's actions. If certain preferences are observed, the system shows the preferred information immediately, e.g. if a user almost always listens to the pronunciation of a word, the sound-file can be activated automatically every time the user accesses a dictionary entry.

Another user feature for adaptation is the possibility to use the ELDIT system both as a monolingual and as a bilingual dictionary.
4.2 Systematic Vocabulary Acquisition

We will now describe our ideas concerning the extension of the basic dictionary to a tool for systematic vocabulary acquisition. In order to retain the acquired vocabulary, "the learner needs to have opportunities to produce target language output" (Chapelle 98). ELDIT will be enlarged with text units for studying and practicing the vocabulary. The words in the text units will be linked to the corresponding dictionary entry, and the vocabulary to be trained will be highlighted, as it was successfully done in Ridder's study about reading and incidental vocabulary acquisition (De Ridder 00). Each text contains a couple of questions. The learner has to answer these questions in his/her foreign language, which serves as an indication whether he/she has understood the text and whether he/she is able to use the vocabulary.

Furthermore, all word entries in ELDIT will be categorized in various groups. Such groups are, for example, the words belonging to a particular text or a specific domain, semantically related words, or the associative field. The ELDIT system will then support the following approaches:

- **Vocabulary acquisition by word groups**: The user can study a group of words and afterwards practice the acquired knowledge with a text.
- **Vocabulary acquisition by texts**: The user can choose a text, read it, check the meaning of unknown vocabulary in this particular context, try to answer the questions, and finally systematically explore and memorize the meanings, the usage, and the context of the unknown vocabulary.
- **Repetition of vocabulary**: The user can decide to repeat the formerly acquired vocabulary and practice it with a text.

In every situation the user can ask the system to choose an appropriate vocabulary group or a text that matches best. When choosing a text the system takes into account the frequency of known and unknown words within the chosen text as well as additional data stored in the user model.

5. Related Work

A large number of CD-ROMs and web-based tools for language learning are available, but very often these tools are just one-to-one copies of printed textbooks. Only a few systems exploit the potential of modern hypermedia technologies in a meaningful way (Gamper et al. 01). Closest to our work are the vocabulary acquisition system CAVOCA (Groot 00), the dictionary Alexia (Selva et al. 97), and the adaptive language learning program CASTLE (Murphy et al. 97).

ELDIT provides more possibilities to apply, practice, and repeat the acquired vocabulary than CAVOCA. With approximately 3000 words our system contains far more dictionary entries than the monolingual system Alexia, which contains about 200 word entries. Regarding the design, both Alexia and ELDIT visualize related words as interactive graphs. ELDIT is a bilingual system and covers two languages not yet covered by the other two systems. Furthermore, the inclusion of adaptive components is planned.

CASTLE (Murphy et al. 97) is one of the few adaptive language learning programs. The traditional grammatical approach is combined with a more functional communicative approach. ELDIT mainly differs from this system in its systematic approach to vocabulary acquisition, communicative components are provided as short dialogues which are included as illustrative examples.

6. Conclusion

In this paper we presented an ongoing research project concerning the development of an adaptive vocabulary acquisition system. The system consists of a learners' dictionary which contains about 3,000 word entries for the Italian and the German languages. The design of the dictionary is motivated by modern psycholinguistic theories - such as the mental lexicon – which help the learner to remember more easily the acquired information. The basic dictionary will be extended with texts and exercises, and a systematic vocabulary acquisition process based on individual user interests and guided by the system will be provided.

New media are explored in various ways in order to support information access and presentation. Hypertext and multimedia features allow new ways for structuring, linking and presenting complex knowledge and
information. Word entries as well as the various pieces of information composing a word entry can be organized, connected, and grouped in a non-linear way, which brings different views to the world of words in a dictionary. The presentation of the information can be tailored to the individual user needs. Visual and acoustic elements support knowledge transmission. Electronic search features provide a fast and efficient access to the information, which is a very important issue in dictionaries.

Future work includes the extension of the basic dictionary with text units and grammatical units as well as a systematic and comprehensive evaluation of the system.

Introduction:
With the Internet’s rapid growth, the web has become a powerful, global, interactive, dynamic 
and democratic medium of learning and teaching at a distance (Khan, 1997).
The significance of using the Internet for instructional purpose lies in its power to deliver large 
amounts of information, accessible to users worldwide in an open, non-linear way that provides 
alternative options during learning. The Internet’s capability for real-time interaction makes 
distributed and distance learning, more viable for fulfilling education needs. This paper reports 
the findings of an extensive evaluation of web course management tools. The purpose was to 
determine the best use of these tools to facilitate the creation and administration of online 
educational environments for higher education.

Background:
Higher education institutions are experiencing an increasing demand for technology-mediated 
learning. Reduced costs and increased functionality are allowing more and more academic 
decision makers to justify technology-mediated learning initiatives. One of the fastest growing 
areas in the technology-mediated educational arena is the use of the Internet by colleges and 
universities to enhance face-to-face courses with online components and to deliver some courses 
completely online.

The purpose of the evaluation was to help Syracuse University (SU) make informed decisions 
with regard to how best the university can support the development and deployment of web-based 
courses and support materials for courses. This research study helped to identify a robust set of 
features that support teaching and learning online. The Technical Issues Subcommittee of the 
Online and Distance Learning Study Committee at SU examined a number of web course 
management systems and tools (altogether 12 systems were demonstrated and considered). The 
committee then evaluated three leading Web Course Development Tools to determine the extent 
to which each one of the three packages provides the desired features.

Method:
Three vendors were invited back for more detailed development demonstrations and tryouts using 
a standard test course resource module. Vendors were given one week to develop a course 
prototype based on the test resource module. A representative student population evaluated 
materials developed by vendor representatives because we wanted to include student reactions 
and impressions as part of our evaluation. We were especially interested in faculty reactions and 
impressions because successful integration of such materials depends on faculty perceptions and 
support. For that reason, faculty were asked to develop a course framework and materials for the 
elaborated lesson in order to find out how well they think these tools might be used to support 
their teaching and how easy they were to use.

We selected a resource module that would be easy to understand, that could reasonably involve a 
variety of media and file formats, that would involve a variety of learner interactions, and that
would have no particular bias towards any school or department. A course entitled “Working at Syracuse University” became the test course with a lesson on “Parking at SU” as the elaborated lesson to be developed within that framework using the candidate tools. The Technical Issues Subcommittee developed the materials in the resource module.

A survey was developed and administered to gather reactions both from faculty and students. It included specific questions regarding the candidate tool in terms of:

- Planning and Design;
- Management;
- Customizing and revision;
- Levels and variety of interactivity;
- Administrative features;
- Student support tools;
- Multimedia support; and,
- Other related online course development and management issues.

The specific purpose was to exercise and evaluate the capabilities and features of an environment for hosting web-based course materials. We did not expect any single environment to provide all of the functionality required for all learning needs nor did we expect any single system to satisfy all the users in the institution. We proceeded on the assumption that many web-supported courses and lessons will involve many of the same characteristics introduced in this sample lesson. The point of this exercise was to evaluate a web course management tool - not to evaluate the content or pedagogy in the resource module. We were interested in faculty and student reactions to using the tools, especially with regard to those aspects and capabilities they found easy and worthwhile and those that caused difficulty and were not meaningful.

The innovative aspects of this evaluation schema relate to its user-centeredness. The criteria, nominations and the overall evaluation plan were solicited from the users. The evaluation was in depth and was designed to provide an outline of activities that exercise desirable features of an idealized product. The was achieved by:

1) a scripted demonstration of the courseware product presented by the product vendor;
2) A hands-on evaluation by faculty and staff members who also used the system to prepare and present a sample course with the assistance of experts from each vendor; and
3) A hands-on run through by students to simulate the actual presentation of the course as it might be presented over a term.

Conclusion:
This paper has reported an extensive evaluation of various web course management tools and technologies. The evaluation included structured tryouts with a representative faculty group as well as student evaluation of a number of different learning environments. While some tools were easy to use they were overly restrictive. Others were very flexible but more challenging for novice users. Paradoxically, the focus shifted from tool capability to a much wider context.

The university technical sub-committee recommended an integrated approach to developing a campus-wide learning environment for supporting and maintaining high quality online courses and course materials. The focus was not on a single web course management tool, although several are now centrally supported. Rather, the focus ended up being on flexible processes and procedures for designing effective online courses.

The on-line course will get better!
How to minimize critical success factors for on-line courses

Author: Marilene Garcia
Affiliation: Department of Post Graduate Studies in Communication and Education, Universidade Anhembi-Morumbi - São Paulo - Brazil
Email adress: lenagar@sti.com.br

Abstract
The results presented here are part of a larger study, organized in the Department of Post-Graduate Studies at the University Anhembi Morumbi, Brazil, that investigates and defines the borders, models and didactic strategies of a ciberpedagogy for on-line courses. I highlight cases of on-line student performance and the difficulties encountered being in large part due to individual profiles and the ability to adapt to the context of virtual learning. I propose a customized process for the development of online courses, trying to include individual elements to minimize critical success factors for distance learning.

Why do we have to think about this?
Sophisticated systems of interaction and of content development, games, colorful, attractive and fun interfaces have been coming onto the virtual learning scene more and more.
In our courses there is a difference in the way interfaces are treated and the attention given to teacher-student communication. Virtual learning environments, where on-line courses and educational virtual activities occur, must be different in a way that they are distinguished from simple pages or standing information pools, in order to yield a good pedagogical outcome.
This is accomplished primarily by the current Internet interactivity facilities. In order that interactive tools effectively implement communications and involvement with reflection and shared activities, some skills are required as related to the way subjects behave when facing such environments and interrelating peers and tutors.
The objective is not only to catch the students eye, but also to keep him going in the course after his initial desire to participate in an online course. We notice that such resources and visual stimuli make the job of teaching easier, but are not enough to make learning really effective. Therefore it would appear necessary to create a stricter relationship between the graphic interface and methodology of human communication of the course and the personality of the student. As well as these, other factors to be taken into consideration are the student’s notion of what it is to learn on-line, his ability to adapt to the virtual universe and his expectations regarding his personal performance in the course.
In a paper presented by Moore (2000), she writes about not so good results of on-line courses: “many major investments in technology-based learning have not been used as planned
- 25% of users abandoned training after registration
- 75% participated actively at the beginning
- 85% did not complete the course” (see Moore 2000)
So we can not stop thinking about this problem.

The argument
What could be proposed is the development of more specific and coherent teaching methodologies, which bring interactive and multimedia resources together with a sensitivity towards the student’s learning profile. In this sense we could be heading towards a future context of customized courses, where success would depend upon the harmony between the content and resources and the student’s psychological profile and his adaptation to the virtual surroundings. I base my suggestions in the observation of student performance in post-graduate courses in the
fashion department, throughout all of Brazil, which demonstrate particular needs regarding the attention given to students, needs beyond the mentor's performance.

**Students can be:**

- more proactive or more dependent on orientation;
- more interactive or less interactive;
- more cooperative or more individualistic;
- more apt to research on their own or to more stationary learning;
- more likely to take decisions or not;

**What should we do?**

The students would be put together in groups using different profiles, and from there the class activities would be based on these profile groups.

Activities can be structured to:

- use more problem solving ability or less problem solving ability;
- be more spontaneous and intuitive or more target-oriented
- be more communicative and collaboration-based, or more individual
- use more simulation devices or more research based activities
- develop more strategical thinking or to give directives;
- be more productive or observational;
- be visually more attractive or sparse use of graphics
- be based more in the exchange of ideas and debate or based more in individual capacity for production

**Last considerations**

Learning goals must be defined with human intervention. The role of mentor must mean a management attention like a value-adding activity. The mentor of online courses must domain interpersonal sensitivity, and teamwork organizational sensitivity. Thus through written communication the mentor can manager virtual group dynamics and build credibility for distance activities.

Therefore in the development of online courses what should prevail and help to minimize the critical success factors is the presentation of a variety of different activities which attend to the different needs of the students.

Abstract: The JOB project (JOB, 2000) was a European funded programme run between January 1998 to June 2000. This involved a consortium of partners in Birmingham, UK, and a network of transnational partners across Europe (GATE, 2000). The aim of the project was to develop remote vocation guidance to disabled people in their own home, fully utilising computer mediated communication. One of our concerns was about how to prepare tutors to work remotely, through Computer Mediated Communication (CMC) and as a result we developed our own Virtual Tutor training within JOB. This was accredited through the Open College Network of the West Midlands, and consisted of 5 units up to level 3.

Since 1998, over 120 Virtual Tutors have now been trained. Learners have been recruited from Higher Education, Further Education, Adult Education, health and social care and some unemployed people from disadvantaged groups. This programme is accredited and is delivered remotely using Computer Mediated Communication. Our evaluation indicates that this has been a positive experience for the learners even though, for some, it has been a steep learning curve particularly around mastering technology. In this paper the key issues for learners are described.

Introduction

The JOB project (JOB, 2000) was a European funded programme run between January 1998 to June 2000. This involved a consortium of partners in Birmingham, UK, and a network of transnational partners across Europe (GATE, 2000). The aim of the project was to develop remote vocation guidance to disabled people in their own home, fully utilising computer mediated communication. Partners in Italy also worked on developing tele-guidance, partners in Italy, Spain and Finland worked on aspects of tele-training and partners in Finland, Spain and Italy also focused on tele-work opportunities.

Across Europe we were bound together by our user group (people with disabilities) and our use of Information & Communication Technology to enable people to access services where and when they wanted to.

In the UK one of our concerns was about how to prepare tutors to work remotely, through Computer Mediated Communication (CMC). The steering group had all been previously involved in a CMC programme and had completed remote Computer Mediated Tutor training at a London University. This training was focused on the need of lecturers in Higher Education and it was felt that as we were working with a very different client group our needs, therefore, were significantly different. Thus we developed our own Virtual Tutor training within JOB. This was accredited through the Open College Network of the West Midlands, and consisted of 5 units up to level 3.

Since 1998, over 120 Virtual Tutors have now been trained. Learners have been recruited from Higher Education, Further Education, Adult Education, health and social care and some unemployed people from disadvantaged groups. This programme is accredited and is delivered remotely using Computer Mediated Communication.
We have feedback from 47 learners (37%), requested halfway through the programme and at the end. The evaluation documents have been reviewed and key features extracted from these. Additional material has been extracted from the archived on-line study rooms of each of the groups.

The Virtual Tutors programme:

‘CMC has a lot going for it as to when I work, reflection time on what I post, I can change my work as many times as I want, I don’t have to join in with everything that is going on. The atmosphere is relaxed, I don’t feel pressurised to compete.’

**Aim of the programme:**

To facilitate the transfer or adaptation of teaching and learning skills to a Computer Mediated Communication (CMC) environment and to enable the development of new skills required to work effectively within an electronic campus

**Objectives**

Include gaining experience as a learner within CMC: identifying benefits in education and training; exploration of teaching and learning styles and adaptation to a CMC environment; curricula development; explore confidentiality, student support, engagement, copyright: working without the benefit of non-verbal communication.

The Virtual Tutor programme runs over a 15-week period and learners are expected to study for 3 to 4 hours a week. This is a remote programme and tutors work in the same virtual college as the JOB students – their future potential clients. The Virtual College was designed to accommodate a Computer Mediated Communication (CMC) methodology and was built using Lotus Notes. The Virtual College consists of a study room per group, common room and library. Each of the learners have a copy of the Virtual College on his/her own desktop. The is a collaborative programme (each of the learners starting, and working through, the programme as part of a group), but this is set in an asynchronous medium thus giving people the opportunity to work when they want or were able to.

The Virtual College was designed to extend the learners possibility space. Possibility space is a space where all our ideas live before we bring them into being (Battram, 1996). When we explore ideas we explore possibility space, which is indeed in our mind. We do this using language because, according to Battram, the world we inhabit is constructed in language. Ones own possibility space is very small in the scale of things, but joined to other peoples possibility spaces we can create a massive expansion of views (and visions?). We have all experienced at some time the ‘buzz’ of exploring an idea with a group of enthusiastic people, and this idea turning into reality made possible by the joining together of different perspectives built on different experiences.

How do we join together our possibility spaces? For this we need a search space. This is an environment that allows people who would otherwise never meet to get together and discuss common issues. This can be in a face-to-face environment but applies favourably to the context of a CMC environment – our virtual college.

**Technology:**

Not all learners on this programme were introduced to the concept of CMC in the same way. The range of help in getting started ran from being sent an installation manual and a CD to attending a Induction session and being helped to load the technology. In addition, learners recruited to this programme were found to have a range of Information & Communication Technology (ICT) skills, knowledge and experience (from no experience to very experienced). The 2 extremes are demonstrated by the following quotes:

**A learner with no experience**

'We'll I have to say that I have amazed myself.... I have been such a technophobe.
prior experience:  for years and I have really enjoyed getting to grips with this machine!'.

'I started the course as a disgruntled sceptic – I thought the programme looked a bit tacky (I am one of those sad individuals who goes for flash over function) but as time progressed I grew to develop a mild fondness for the simplicity of the programme'.

Each of the extremes brought different issues to the delivery of the programme. For the learner new to ICT some of the introductory activities created difficulties in themselves. Changing symbols to text (in order to demonstrate that computers don’t always receive messages as we have sent them) is a good example of this. One learner wrote feel sufficiently frustrated to think about why I was doing all this; and then when others showed me the way through by their understanding or accidental discovery of the ‘answer’, I learnt something I won't forget! Others write about the positive aspects of the programme compensating for the steep learning curve required in mastering the technology.

The technical difficulties, writes one learner, appear to be at the beginning when people are stressed. Once that is over ‘the programme seems beautifully simple when used for discussion, and quite effective in learning ICT skills off other participants’. However, for some rising to the challenge of the technology in order to engage in study may not have been worth the perceived gains of succeeding in the programme of learning. This may be why we saw a relatively high dropout rate during the first 2 weeks of learning.

Can we apply theories of compliance to this problem? Compliance in medical terms is about patients following a prescribed treatment. ‘Compliance denies the right of a patient to be heard and freely decide that he would rather accept his disease than the tedium of taking his medication and suffering the side effects, which on occasions may restrict the patients life style more than the disease itself’ (Henry, 1985). This can equally be applied to learning. The challenge of becoming competent within a CMC environment may, for some people, be worse than not becoming knowledgeable about the subject area of the learning programme.

For those who were experts or skilled in the use of ICT, the tutor felt that the issues were to do with trying to get the learner to change the focus from the medium onto the curriculum. Many were able to do this but unfortunately a few were not. Of course other variables come into play here, not in the least the existence of any pre-course teacher training and subject specialism.

Getting Started:

As already discussed, learners had a varied introduction to the virtual college, CMC and the technology. The most a learner received in the way of induction was a 3-hour session where we discussed the principles of CMC, talked about the programme, guidelines for being an on-line learner and demonstrated the system. No learner was given ‘hands-on’ experience at this point. Some learners received nothing other than the handbook and software.

One of the big issues at this time is lack of prior knowledge or visualisation of what on-line learning means to the learner. It is difficult to imagine how ‘it’ works or what is required. Therefore the expectations of learners are not well formed and generally, in this programme, were about finding out what on-line learning was about and experiencing it. This led to the need to lead, advise, encourage learners through the programme until they were responding speedily to activities, and each other, and had picked up techniques for working effectively in this medium. For all groups progress into a ‘comfort’ zone was at different rates. Some groups ‘gelled’ early while others didn’t ‘gell’ at all. The factor that considerably affected this appeared to be the combination of personalities within the group.

Most learners in the review expressed the desirability of meeting face-to-face early on, even though some people had a really good experience and very much enjoyed the programme having never physically met the facilitator or the other learners within the group. However, many also identified the need for programmes to be delivered totally on-line, without dependency on initial meetings, for the sake of inclusion of the people from disadvantaged groups or who lived to far away.
Group size and other practicalities:

The group size: The majority of learners felt that a group of 10 was a desirable number to work with in CMC. This is small enough to keep up to date with all entries and get to know fellow learners. Smaller than this and learners commented on feeling exposed (as happened in peak holiday periods) and more than this and it would be difficult to get a feeling of group cohesion. In addition, nearly all recognised the pressure of work that bigger groups would create for a tutor/facilitator working in this methodology.

When learners engaged in the programme: The majority of the learners on this programme were working full time. Nearly all reported working late at night and for some this was really good in that they could settle down and relax while engaging in the programme. For others who worked up until 9 p.m. at night (for example those employed in Adult Education), sitting down to study when they came home was seen more as a chore and learners felt less able to give of their best. Replication data indeed shows that the most popular time for learners (and the tutor) is between 9 p.m. and 11 p.m. and daytime Sunday.

How long learners worked every week: Learners were asked to work for 3-hours a week over the 15-week period. The majority of learners reported working for up to 10 hours a week and reasons for this was the amount of reading and responses required, the time it took to formulate responses when keyboard skills were not well developed and, most importantly for some, the enjoyment factor.

Theories of flow may contribute to the time learners spent in study. According to Csikszentmihalyi, (in Jenson, 1995), optimal learning requires a state of consciousness known as flow. This is where one loses oneself in performance and where time passes very quickly because one is absorbed.

Group work and Collaboration:

Collaboration appears to be a double-edged sword! This programme was seen by the developer as one way of enabling busy people to access learning when able to. It is designed to fit around social, work and family life and accommodate fluctuations in health and availability etc. Indeed the majority agreed that this was one of the great advantages of CMC.

However, one learner writes: 'One problem is that the need for collaboration enforces the need for everyone to work at the same rate for the success of the learning to occur.' In addition, when learners were absent for any period of time through going on holiday, pressure of work or ill health, they often found the amount of discussion to catch up with was considerable. Even ignoring the unread documents in favour or joining the new activities made learners feel anxious as the unread entries constantly showed up in the system in another colour – a constant reminder of what had been missed.

In spite of this, the majority of learners were very positive about the group and collaborative nature of the medium. One learner writes 'I have found the collaboration/communication issues particularly challenging (and quite another 'Being put in such a diverse group has been a great experience, differing perspectives have broadened my considerations'.

Further advantages appeared to be seen as 'Loads of space for individuality and time to hide behind someone else sometimes while you think things through'. A great advantage!

What do learners need in order to be effective within a collaborative environment? Harri-Augustine & Weble (1995) believe that learning operates on the 'edge of chaos' which sits between 2 states known as order and chaos; two extremes of behaviour. In order we demonstrate predictability and don’t adapt to change. We use the same pattern of responses over and over again. We are complacent and unresponsive. The opposite of this is chaos, which is a system of disorder.
Between order and chaos we find complexity. This is a state now recognised as allowing information to organise and reorganise itself to increasing degrees of sophistication. This is the state that allows a person to construct new and more complex meanings.
